To some extent too, support for traditional justice has been pragmatic. The vast scale of atrocity crimes in places where transitional justice currently operates makes it very hard to hold every suspected perpetrator accountable. The *gacaca* system that emerged in Rwanda in 2001 to deal with the aftermath of the 1994 genocide was partly a national response to this kind of logistical dilemma. At least 800,000 people had been killed during the violence and the country's jails were reaching bursting point with 120,000 alleged perpetrators and only 15 judges able to oversee their trials. The United Nations Security Council had set up the International Criminal Tribunal for Rwanda (ICTR) in Arusha, Tanzania, in November 1994, but there was widespread frustration with the court: it was seen as too slow, too expensive, and too far removed from Rwanda. The Rwandan government's response was to adopt and adapt a traditional community conflict resolution system, the *gacaca*, and to train more than 250,000 community members to serve on panels in 11,000 jurisdictions (Clark 2010, p. 3). As Phil Clark explains, the Gacaca Law was enacted with the aim of expediting justice for genocide crimes by relieving the national courts and the ICTR of the vast numbers of low-level suspects and allowing them to focus on the more senior accused. The gacaca system was also intended to pursue the broader reparative goals of social healing and reconciliation (pp. 63–64).

The focus on traditional justice has certainly gained momentum since the Gacaca courts were set up and there are now numerous programs aimed at supporting it, but this has not resulted in a formalized typology in any international agreement. There is also diversity in state recognition of post-conflict traditional justice processes, ranging from de facto rejection to full incorporation. In Burundi, for example, the National Council of Bashingantahe was created by constitutional fiat to mediate disputes, including interethnic massacres and violence occurring since 1993. This occurred with foreign support in 2005, but the government has little enthusiasm for a revival of a precolonial decentralized system of adjudication that endowed the king and his chiefs with significant power at the local level (Uvin and Nee 2010). Meanwhile, in Mozambique, the government has been quietly tolerant of traditional accountability and reconciliation rituals. Ordinary people have been conducting *magamba* spirit ceremonies to create a socio-cultural environment conducive to engagement with the past and communal repair (Igreja and Dias-Lambranca 2008). However, there has been no formal engagement or endorsement of these practices, and the official line, premised on the allocation of impunity to known perpetrators of terrible acts, is to try to forget what happened.

In contrast, in some other post-conflict places, such as Sierra Leone and East Timor, traditional justice has been officially recognized and sanctioned. The 2000 Sierra Leone Truth and Reconciliation Act authorized the Truth and Reconciliation Commission (TRC) to "seek assistance for traditional and religious leaders to facilitate its public sessions and in resolving local conflicts arising from past violations of abuses in support of healing and reconciliation" (TRC Act Part 3(2)). Incorporation of traditional justice into the workings of the TRC was, however, rather weak (Huyse and Salter 2008). In East Timor, the government incorporated a more extensive range of customary law into their Reception and Reconciliation Commission (CAVR) community hearings. Three quarters of the reconciliation hearings involved a local dispute resolution practice named *nahe biti boot* (Drexler 2009; Stanley 2009). The hearings also incorporated long-established processes of *adat* or *lisan* to build local participation. In both Sierra Leone and East Timor, then – albeit to varying degrees – traditional justice has been used to supplement and legitimize more "formal" transitional justice processes. However, Rwanda is the only country where an adapted traditional accountability mechanism has been made wholly part of the official post-conflict justice policy and granted a central role as part of the formal state system (Wojkowska 2006).

Key Issues/Controversies

As noted in the introduction, literature promoting traditional justice as an aspect of transitional justice tends not to be focused on measuring the effectiveness of such processes or on understanding how such processes are experienced on the ground (Weinstein 2011). The result is a knowledge gap which has "produced decision making based on weak data, ex-ante evaluation and speculation" (Huyse and Salter 2008, p. 6). However, while the literature remains small and partial, it is becoming gradually more nuanced. In the following subsections, we comment on some of the key debates that have emerged.

Does State Capture Matter?

The term traditional justice usually ends up referring to a range of qualities found in local procedures which are in some way similar to those associated with conventional judicial processes, or established notions of transitional justice, or with generalized ideas about forgiveness. However, this kind of perception may mean that other qualities of local procedures may be entirely overlooked. Kimberly Theidon, for example, has warned of "the facile embrace of the local or community" as the "the realm of solution" (Theidon 2009, p. 296). Just because a process or an institution is nominally traditional does not insulate it from interference from various kinds of public authority, including the state. Furthermore, as anthropologists have shown, local customs relating to accountability can be highly dynamic and remarkably adaptable; they are rarely static and timeless. This is partly because they are mostly not written down but are endlessly negotiated. To codify or regulate them changes them.

These are issues that have been raised about the *gacaca* courts in Rwanda. International NGOs such as Amnesty International and Human Rights Watch, as well as non-Rwandan scholars have argued that the modern *gacaca* courts are controlled by the Rwandan government and have been used by an increasingly oppressive and authoritarian state to regulate reconciliation and justice processes in the peripheries (Ingelaere 2008). The argument follows that the state has interfered in the hearings in order to collectivize the guilt of all Hutu and, in doing so, has coerced Rwandans into publicly sharing the details of the genocide, thus violating a cultural and pragmatic inclination towards silence. Thus, legislation has transformed the original *gacaca* institution into something qualitatively different: legalistic procedures, state control, and forced participation for the population mean that the current process bears only partial resemblance to that which it was originally modeled on.

Other analysts have taken a more complex position, accepting that there has been a good deal of state capture, but noting that the *gacaca* system is not homogenous, and that the government's controlling role is not as pervasive as has been suggested. The *gacaca* system they maintain has a degree of autonomy and continues to resonate with local custom, even if the local courts are not quite what they were before. Phil Clark in particular has highlighted the elasticity and dynamism of the *gacaca* courts in his important finding that *gacaca* in one village could differ significantly from *gacaca* in another just a short distance away in terms of conduct, vibrancy of debate, and "societal impact" of hearings (Clark 2010). In his analysis, arguments about the government's role in *gacaca* tend to neglect the "importance of individual and communal agency in *gacaca* and the vital role of the general population in running and shaping the institution, often with highly unpredictable results" (87).

These autonomous and varied aspects of *gacaca* must be accepted. It is still, however, the case that the Rwandan government effectively used the system to institutionalize the allocation of blame. Where the state can, perhaps, most effectively "capture" traditional justice or at least most successfully manipulate it is not in the battle for direct control of these processes but rather in the battle of perceptions of wrongdoing. This has been a fundamental problem with the focus on the ritual of *mato oput* in Uganda. The focus on a custom associated with just one group, the Acholi, implies that the Lord's Resistance Army insurgency was a local affair, when in fact it was a conflict underpinned by national and international dimensions (Allen 2006, 2010). Elizabeth Drexler comes to a similar conclusion in East Timor, where she observes that the "excessive localization" of transitional justice processes risks "horizontalizing conflicts," positing them as "conflicts between different groups in society, rather than between a state and its citizens" (Drexler 2009, p. 50). In both these cases, a preoccupation with local justice (unintentionally or otherwise) protects crimes allegedly perpetrated by government officials and soldiers from scrutiny and accountability. It actually makes national political justice more elusive (Branch 2011).

Is Traditional Justice Restorative?

Related to the above discussion is the long-standing question as to whether justice should be restorative or retributive. As has already been indicated, some enthusiasts of traditional approaches assert that they are essentially restorative and reparative. Although the evidence base for this is open to question, it does seems that communal reconciliation and social repair are the apparent goals of reintegration rituals in many situations. This has been described for lower level ex-soldiers and perpetrators in countries such as East Timor and Sierra Leone (Shaw et al. 2010).

However, too much has been made of the almost intangible innateness of non-Western impulses towards forgiveness and restoration of social harmony. Such arguments reached their rhetorical height at the time of the South African Truth and Reconciliation Commission. As Pierre Hazan notes, Archbishop Desmond Tutu successfully "constructed a spiritual dimension to the process, linking Christian forgiveness and African mysticism to the goal of reconciliation" (Hazan 2010, p. 36). The resulting narrative was the notion that the "third way" (amnesty without oblivion) was somehow the African way. Invoking the concept of *ubuntu* which is largely a romantic expression of the "rural African community," Tutu said in one interview, "Ubuntu says I am human only because you are human… you must do what you can to maintain this great harmony which is perpetually undermined by resentment, anger, desire for vengeance. That is why African jurisprudence is restorative rather than retributive" (cf. Wilson 2001, p. 9). But this is misleading. We only need to look at the legacy of the South African TRC to understand that a single prescription of how to deal with South Africa's past was oppressive, and dissenting voices, although present at the time, were largely drowned out. Studies reflecting on the success of the TRC have found that earlier support for amnesty was "a reluctant, contingent concession that coexisted with a basic interest in seeing at least a degree of accountability," and that victims involved in hearings stressed that the desire for acknowledgement of wrongdoing and learning new information was the priority: it was truth, not reconciliation or forgiveness, that was paramount (Backer 2010, p. 453).

Despite the emphasis on a restoration of social harmony, there is a clear accountability component to most of the documented reconciliation rites (Huyse and Salter 2008). Reconciliation ceremonies in Uganda, Mozambique, Rwanda, Sierra Leone, and Burundi that have been adopted by activists tend to contain the requirement that the offender must acknowledge his or her guilt in order to be redeemed. In northern Uganda, for example, it is obvious to anyone who had read historical studies and early sources on the region that claims about the Acholi people forgiving offenders and accepting compensation were overblown. Punitive measures were common. It depended on the crime, who had committed it, and who was arbitrating (Allen 2006, 2010). In situations in which a crime is locally understood to be heinous, such as certain kinds of witchcraft, punishment could be very severe. In many places that remains the case, and violent responses to alleged witches and sorcerers, have been reported from numerous parts of Africa. In several countries, including South Africa, there have also been concerted efforts to incorporate trials for what might be called traditional or customary crimes into the formal system and to ensure custodial sentences for those found guilty. In Central African Republic, a UN prison study found that more than half of those being held had been accused of witchcraft.

In East Timor meanwhile, it is true that the Community Reconciliation Hearings were successful in reintegrating low-level combatants. The Commission for Reception, Truth, and Reconciliation in East Timor is said to have gained more than just legitimacy by promoting the hearings among traditional leaders. It secured widespread participation (Stanley 2009). The CAVR undertook 216 community reconciliation hearings for 1,379 perpetrators and it is also estimated that up to 40,000 people attended (CAVR 2005; Ch. 1.5:126). Such achievements are impressive, but it is important not to conflate the characteristics of a process with its outcomes. Widespread frustration has been reported among participants, who lamented their inability to challenge Indonesian impunity (Stanley 2009; Drexler 2009).

The reality is that Western justice systems and indigenous dispute resolution systems pursue the similar objectives to different degrees and the restorative/retributive dichotomy is exaggerated and essentializing. Usually the biggest difference between formal and informal approaches is the actual procedures employed to reach the various objectives (PRI 2002). Although there are exceptions, informal systems tend to draw more on ritual elements and emphasize the community dimension of criminal behavior over individual accountability (Huyse and Salter 2008). This is where local processes have very clear benefits. In complicated situations, the “guilty,” “not guilty,” “victim,” and “perpetrator” dichotomies can be misleading and even harmful. Violent conflicts characterized by moral “grey zones” in which different forms of guilt and innocence are mixed are complicated territory for criminal law and render the delivery of clear verdicts a difficult exercise (Shaw et al. 2010; Hinton 2011). These are situations in which people inhabit shifting “perpetrator-victim” identities: the child soldier, abducted from its family and forced to commit brutal crimes in the course of conflicts in Sierra Leone and Uganda, provides a case in point (Baines 2010). Courtrooms are not usually capable of dealing with the subtlety needed to address such complexities, and moreover, the shaping of these complexities into simple legal categories risks misrepresenting the situation and can make post-conflict reconciliation ever harder (Shaw et al. 2010; Hinton 2011). As one scholar notes “a combination of palavers, the African way of prolonging discussions, and ritual events create in principle, more opportunities for exploring issues of accountability, innocence and guilt that are integral to the legacy of violent conflict” (Huyse and Salter 2008, p.15).

Does It Matter That Traditional Justice Can Be Discriminatory?

From Afghanistan to Sierra Leone, studies have highlighted the persistent ethnic, religious, generational, and gender hierarchies and divisions that complicate and limit the effectiveness of traditional practice from a transitional justice perspective. This is a point implicitly recognized in Kofi Annan’s observation to the UN Security Council that the rule of law and transitional justice must be “in conformity with both international standards and local tradition” (UNSC 2004, p. 12).

In African contexts, for example, social accountability is closely connected with hierarchies, ones which may systematically subordinate and repress particular groups, notably women. Probably the most frequently mentioned cause of concern is that tradition-based systems of dispute resolution are likely to be dominated by men. As Huyse and Salter find in their edited collection on post-conflict traditional justice, in Mozambique, only the spirits of men killed during the civil war are allowed to return to the realm of the living to claim justice; in Burundi, women are not allowed to become members of the Ubushinganthe; they can only participate in the proceedings as the wife of the widow of a member, and the traditional justice system in Sierra Leone exhibits a clear prejudice towards married women, although some provision is made for female representation (Huyse and Salter 2008). It has been documented that in Somalia, a woman who is raped is often forced to marry her attacker, while customary practices of wife inheritance as an aspect of ritual cleansing continue in parts of Kenya (Wojkowska 2006). In Afghanistan, women can be exchanged in compensation for criminal offences. This is regarded as preferable to the alternative: a blood feud that might escalate into full-blown tribal conflict (Schmeidl 2011). A Commission on Conflict Mediation set up in Khost Province in 2007 attempted to integrate formal and informal justice processes, and while it has been regarded as relatively successful, the Commission still follows the practice of only allowing men to litigate traditional justice (Schmeidl 2011, p. 162). In East Timor, women were sidelined in the community reconciliation hearings because their participation faced resistance from male family members and also because they were constrained in their ability to attend due to family and home duties. In a study by Elizabeth Stanley, CAVR staff commented that this was probably to be expected: "We are living in a patriarchal society so patriarchy is bound to be reflected in the collation of testimonies" (Stanley 2009, p. 117). Despite efforts by regional workers to access women's stories she finds that the CAVR "framed women out of stories" (Stanley 2009, p. 117).

The male dominance of local justice mechanisms can also be compounded by overtly patriarchal characteristics too. Rituals may be co-opted by male elders to further their own interests. In Sierra Leone, for example, customary law is the domain of senior men and this creates concern among younger men that their land and other possessions may be removed from them through "notoriously arbitrary and excessive fines" (Shaw et al. 2010, p. 16). It has been observed that although the TRC reconciliation rituals may have been effective in helping to reintegrate high-ranking ex-combatants, they also "retrenched young men's subordination to 'big men', a situation that had watered the roots of Sierra Leone's armed conflict in the first place" (Shaw et al. 2010, p. 17). It has also been noted that elders in northern Uganda have deployed traditional justice techniques as a way of disciplining returning LRA combatants, particularly young men and women (Branch 2011). Sometimes traditional justice seems to be focused on the *re*constitution of *pre*-conflict structures. The kind of senior male authority that is legitimated in customary law is largely upended during conflict and war. Family dislocation, mass displacement into refugee camps, and mass migration (particularly of youth) into the cities have disrupted the "natural biotope" of traditional practice and undermined the status enjoyed by customary leaders (Huyse and Salter 2008, pp. 185–186). But is it socially progressive to reinstate the social order? If that social order was linked to the outbreak of violent conflict, it is not at all clear that such an agenda is appropriate. Also many will resist it if they can, especially women and young people who have found new opportunities during times of upheaval (Branch 2011). Sometimes, it is in such circumstances that accusations of witchcraft proliferate, with arbitration procedures being co-opted by senior men to assert authority, and vulnerable women often ending up being targeted.

There are, however, some interesting ways in which traditional mechanisms are being used to challenge traditional values and social orders. In Afghanistan, the *jirga*, traditionally an ad hoc forum for Pashtun elders to assemble and discuss a particular issue of concern, has been redesignated to describe any gathering aimed at consultation with the general population. In 2010, Afghan Civil Society groups established the *Victims Jirga for Justice* in response to the flawed, non-inclusive government run *Peace Jirga*. The *Victims Jirga* included over 100 victims from all over Afghanistan and provided the first truly national articulation of a transitional justice agenda, including demands for prosecutions, truth-seeking, and reparations (Kouvo and Mazoori 2011). By loosely adopting the traditional *jirga* framework for discussion, the meetings provided a familiar and supportive space to recount the abuses that had been endured and to formulate policy proposals to the government (Kouvo and Mazoori 2011). Similar "curative" spaces have been created by Women's Courts in Guatemala and Columbia. In Columbia, women have been holding regional tribunals in preparation for the launch of the permanent Columbian Women's Court Against Forgetting and Re-existence (Quest 2008). A hybrid of legal and nonlegal procedures, the tribunals include rituals of apology and judgment by a panel of "wise women." In the case of the Victims Jirga and women's courts, traditional processes are being used by excluded populations to facilitate testimony and to formulate recommendations based on these testimonies to the government. Nevertheless, while promising, these kinds of measures are far from widespread, and the underlying problem remains. In practice, customary justice can elevate the goal of community harmony above individual rights and freedoms in worrying ways.

Is Traditional Justice Appropriate to Deal with Mass Crimes?

Probably the important outstanding question in any given instance where traditional processes are a focus of post-conflict policies is whether the measures being promoted are really capable of dealing with large-scale war crimes, genocide, and crimes against humanity, sometimes committed over long-time periods and often involving the destruction of the very social and material systems upon which indigenous processes depend. As has already been alluded to, it is unclear whether community-based processes can resolve intercommunal problems as their scope and legitimacy tends to be limited. A big concern among international lawyers and human rights NGOs is that customary tools do not respect the duty under international law to prosecute mass atrocities. Large NGOs such as Human Rights Watch and Amnesty International are outspoken defenders of this position and accept no curtailment of the international obligation to prosecute. Legalist critics apply strict criteria in their assessment of community-based justice processes, and as such, institutions like the *gacaca* have come under widespread criticism for an apparent failure to ensure due process, including professional representation and rules of evidence.

Analysts with a less narrowly legalistic approach are more open to the possibilities of informal procedures. Indeed, among such commentators, there is a tendency to begin with a kind of ideal model of transitional justice in which traditional processes are complementary to more formal post-conflict justice processes. Although findings remain rather vague, inconclusive, and anecdotal, studies of places as varied as Peru, Burundi, and Afghanistan tend to suggest that traditional processes are "partially effective" and "partially legitimate" in addressing post-conflict justice issues (Huyse and Salter 2008, pp. 188–190) and that they could effectively combine with other strategies for dealing with accountability and reconciliation. However, even where this is being attempted, we do not have a clear enough understanding about how different processes actually function together in practice and with what outcomes. In so far as there is evidence, it would appear the relationship is characterized by suspicion, friction, and sometimes incompetence rather than productive cooperation.

Competition of this kind is evident in Rwanda, where international, national, and localized courts comprise judges and lawyers with "divergent interpretations of the role and objectives of transitional justice" resulting in a "stratified and at times competitive set of criminal courts" (Palmer 2012, p. 3). In Sierra Leone, the TRC and the SCSL worked in parallel for 18 months, and the precise nature of their relationship was never clarified. The two bodies ended their period of parallel operation with tension over testimony of indicted prisoners, but it is still up for debate whether the court and the TRC, generally, coexisted happily (Schabas 2004). Certainly the lack of clarity between the two institutions confused Sierra Leoneans, and one widespread theory was that there was an underground tunnel linking the two, through which information given to the TRC was immediately leaked to the SCSL (Nkansah 2011). Meanwhile, in East Timor, the failure of collaboration between the CAVR process and the Special Crimes Unit has been commented on by victims who suggest that "good" progress in the former was "downgraded" by the failure of the latter to bring cases to court and that there remains "a considerable amount of unfinished business – a significant caseload that falls in between the two procedures" (Stanley 2009, p. 122). Finally, Tim Kelsall (2009) has shown how the kinds of "supernatural evidence" common to ritual and informal processes fared during the hearings of the Special Court for Sierra Leone. He finds that rather than clash directly, international legal and local norms appeared to simply elude one another. He argues that the court's decision to sidestep the issue of magic and the occult during the trial was an ethnocentric mistake which made little sense to local populations.

Does It Matter That Traditional Justice Is Sometimes Largely Invented?

As elsewhere in Africa, research in northern Uganda has shown how rituals and ceremonies are used to interpret the spirit world and the experience of misfortune and to reestablish or make manifest social relations. Ceremonies and rituals that become important at any particular time are by no means always old ones that are taken "off the peg," but rather ideas about old models are used to help shape new ones. Despite this, attempts *have* been made to try and codify rituals into an ostensibly coherent form of traditional justice. During the time of the Ugandan Protectorate, the British administrators incorporated selected tribal customs into the indirect system of government through chiefs and other local agents. More recently in northern Uganda, in the context of efforts to establish peace and reconciliation during the 20-year conflict between the Government of Uganda and the Lord's Resistance Army (LRA), there have been moves to codify community-based rituals, particularly those that draw on traditional Acholi values and institutions. For the powerful coalition of sympathetic international agencies, activists, traditional leaders, and religious leaders advocating this, the reasons were twofold: firstly, the war had led to a breakdown in traditional social values that needed to be restored and secondly, decisions about peace, justice, and reconciliation should be made by the victims and not by the Ugandan government or a foreign institution, such as the ICC (Allen 2006, 2010).

This approach was subsequently articulated vigorously in the peace negotiations between the Ugandan government and the LRA in Juba and ended up being formalized in the 2007 Agreement on Accountability and Reconciliation signed between the Government of Uganda and the Lord's Resistance Army, which listed both Acholi and non-Acholi rituals as part of the broader transitional justice effort in Uganda, alongside a new War Crimes Division in the High Court and a possible truth commission. During these developments, the local justice mechanisms were promoted without much understanding of local circumstances. Indeed serious concerns had emerged about the chieftaincy system's capacity to implement the agenda that was being proposed. Critical examinations concluded that traditional structures were weak and fragmented, that many of the elders were themselves not sure how to carry out traditional rituals, and that there was widespread disagreement about who the *real* traditional leaders were (Bradbury 1999). It was also noted that there were tensions between elders over the possible financial benefits and that there were concerns that the external support for traditional chiefs was just another way of trying to bring the region under closer government control without contributing to improved education and economic development (Bradbury 1999). Other research in the region undertaken in 2004 and 2005 found that northern Ugandan populations were critical and circumspect about the value and potential of traditional justice solutions and that few people considered the traditional structures a key priority (Allen 2006).

Does this matter if the newly codified practices prove to be helpful? Probably it does. The problem with codifying selected local practice, as noted above, is that it takes them out of the contexts in which they have been used and adapted flexibly to specific circumstances, and it reifies them. If they are categorized and institutionalized into semiformal judicial systems, they will inevitably be very different to what they were to start with. They will lose their flexibility and will no longer have all the many resonances and associations of lived ritual actions.

But crucially, they will have a status that is at least partly based on their externally supported authority. They will become privileged rites and most likely the preserve of certain figures of male authority recognized by the international community or the government. Interestingly, one supportive NGO report conceded that elders will need to be trained on traditional practices and the younger generation "do not even know how to be Acholi" (Liu Institute 2000, p. 22). It is revealing that on one occasion, the USAID funded Northern Ugandan Peace Initiative (NUPI) organized for elders to explain Acholi forgiveness rituals to representatives of "the youth." At the time, the paramount chief admitted that he did not know how to perform the traditional *mato oput* ceremony (Allen 2010). It seems odd that it is now up to non-Acholi experts and outsiders to help revive those traditions among the Acholi.

This was most likely not the intention of many of the advocates of traditional justice, but it is certainly symptomatic of what Adam Branch has described as the "ethnojustice" agenda (Branch 2011). This approach mistakenly views traditional systems of justice as a "single, coherent and positive system... universally, consensually and spontaneously adhered to by all members of that culture" (Branch 2011, p. 163). It goes without saying that the reality is more nuanced than this. In a study of the Kpaa Mende, southern and eastern Sierra Leone, Joe Alie found that certain Mende customary practices are only applicable to and resonant with certain elements of the community and, since there has been a great deal of intermarriage with other ethnic groups over the years, these practices may not be suitable for settling disputes between Mende and non-Mende people within the community (Alie 2008). In northern Uganda, the Acholi *Mato Oput* receives the most attention, but the Langi, Teso, and Madi, also affected by the 20-year conflict, have their own rituals. An even more neglected fact, even though it may sound like a truism, is that attitudes towards traditional approaches vary *within* ethnic groups too. There is no integrated system of traditional justice among the Acholi, for example. Traditional approaches are less relevant and less acceptable to some – this is especially true for young people who have grown up during a time of war with restricted opportunities to experience or participate in such practices. As Branch points out, and it is surely a point that is applicable across contexts: rather than Acholi traditional justice, we should talk about Acholi *traditions* of justice (Branch 2011, p. 177).

Conclusion

It is difficult to conclude with a general statement about traditional justice, because it is not clear exactly what is being discussed. Measures associated with social accountability vary widely within population groups as well as between them, and the kinds of mechanisms selected to be called traditional justice by advocates are rarely more than a selection of activities that conform with normative ideals, usually linked to the notion that they ought to be restorative. As we have indicated here, research reveals that local judicial measures may be linked to state interests or may have qualities that are highly problematic from an international perspective. However, problems of legitimacy, exclusion, gender bias, and politicization are also manifestly evident in formal national justice systems dealing with post-conflict accountability, and these problems also emerge in various ways at the level of international tribunals and courts. So the turn to the local and traditional for a better approach is likely to persist, whatever the controversies involved.

There is to date little detailed knowledge of the effects of projects and programs that have sought to promote putatively traditional systems. The findings of research that has been carried out suggest that they may be helpful in some instances, but overall results are mixed. In some instances, counter-productive consequences have been noted. Much more adequate assessment is required and much better monitoring. There is no doubt that local rituals and customs are important for populations caught up in violent conflict and dealing with its aftermath. However, there is also no doubt too that those local rituals and customs do not form a coherent alternative to formal national and international processes. Traditional justice cannot be harnessed to the transitional justice agenda in a straightforward way. The situation will vary radically from place to place, and where it occurs, the local mechanisms will take on hybrid qualities. Indeed to call them traditional will almost inevitably become a misnomer. They will change, and how they change needs to be closely observed to ensure positive outcomes.

Postmodern Criminology

Bruce A. Arrigo and Heather Y. Bersot
Department of Criminal Justice and Criminology, University of North Carolina at Charlotte, Charlotte, NC, USA

Overview

Postmodern criminology is a critically-animated theoretical framework that humanistically accounts for the problems of crime and the possibilities of justice at the self/society divide. Mindful of the development of postmodernist-inspired criminology, this entry succinctly reviews four issues. First, it describes the philosophical evolution of the theory, emphasizing its negative and fatalistic; affirmative, constitutive, and integrative; and ultramodern strains of heterodoxy. Second, it presents several key concepts refined throughout postmodern criminology's historical development. These pivotal concepts include the following: (1) discourse; (2) meaning; (3) knowledge; (4) power; and (5) subjectivity/agency. Third, it delineates at some greater length postmodern criminology's "state-of-the art" philosophy. This delineation includes attention to current (and novel) directions in theory, method, and praxis. The entry concludes by specifying a number of conceptual controversies that warrant further philosophical elaboration. These controversies are characterized as "open questions" that await postmodern criminology's consideration.

Origins of Postmodern Criminology

Throughout history, people have sought ways to make sense of human behavior and social phenomena. During the Middle Ages, theologically-based concepts were employed to explain human nature and the seemingly ongoing battle between good and evil. When such accounts were deemed inadequate, people endeavored to better understand themselves and the world in which they lived through more scientific methods. This modern age, also known as the Enlightenment period, ushered in a new philosophical approach to examining peoples' thoughts and actions. Humans were now perceived as logical beings capable of exercising deductive reasoning, employing free will, and choosing their own desires (Best and Kellner 1991). In this way, absolute truths purportedly were made discernable. This modern age "held the extravagant expectation that the arts and sciences would further not only the control of the forces of nature but also the understanding of self and world, moral progress, justice in social institutions, and even human happiness." (Habermas 1980, pp. 162–163.)

The phrase, *Cogito, ergo sum – I think, therefore I am*, is often utilized to describe the modernist's logical and fully autonomous subject. Since the Enlightenment period, this belief in a reasoning agent has endured. As such, the concept of the rational individual has provided the foundation for numerous criminological theories employed by researchers to study and explain wayward behavior. For example, rational choice theory rests on the notion of a self-made person who purposefully chooses his or her actions. The theory asserts that a criminal makes use of deductive reasoning while weighing the benefits and costs of committing an offense. If the perceived benefits of committing the crime (e.g., money) outweigh the perceived costs (e.g., incarceration), the criminal will engage in the unlawful act. Thus, these and other modernist-inspired theories support a number of deterrence and retributive-based responses to crime and delinquency.

While modernism seemingly promises systematic and robust ways to explain and predict human behavior, some question its ability to adequately address problems that plague contemporary society (Best and Kellner 1991). The philosophy of postmodernism emerged in response to the modernist contentions regarding human behavior and social phenomena. Its proponents charge that science fails to sufficiently account for the human experience. In other words, while empirical methods may explain the biology of human beings, they cannot fully explicate the anomalies of being human differently. After all, contradictions and inconsistencies, spontaneities and absurdities are also a part of our humanities.

Further, while supporters of the modernist agenda argue that truth is absolute and knowledge is certain, postmodern thinkers assert that commitments to totalizing truths or universalizing epistemologies are the fictions of the Enlightenment era (Arrigo et al. 2005). As Foucault (1977) insightfully proclaimed, knowledge consists of only "claims to truth." A number of postmodern commentators contend that such claims have contributed to the establishment of harmful movements that egregiously advance the ideological interests of imperialism, sexism, racism, and class oppression (Henry and Milovanovic 1999). Thus, as one of the foremost postmodernists, Jean-Francois Lyotard (1984) declared, "Let us wage a war on totality; let us be witnesses to the unpresentable; let us activate the differences and save the honor of the name" (p. 82). The "honor" to which he alludes, is our own dignity lived differently and celebrated dynamically.

Negative and Fatalistic

Some of the earliest postmodern thinkers consisted of Jacques Lacan, Roland Barthes, Gilles Deleuze and Felix Guattari, Jean Baudrillard, Jacques Derrida, and Julia Kristeva (Arrigo et al. 2005). Although he did not formally promote a postmodern perspective, French philosopher Michel Foucault is traditionally hailed as one of the leading exponents of this approach. The intellectual stance that these post-Enlightenment luminaries maintained with respect to truth and knowledge has led some to describe them as negative and fatalistic in philosophical orientation (e.g., Schwartz and Friedrichs 1994). Indeed, according to "first wave" postmodern scholars, total objectivity cannot be established, final truths neither exist nor are they fully discoverable, and the foundations of any proposed structure (whether in art, reason, science, and/or their cultural artifacts) can be disassembled and reassembled in countless ways. Thus, negative and fatalistic postmodernists seek to challenge all claims to certainty, exactitude, and completeness. In doing so, they endeavor to expose underlying assumptions in text-making that seemingly support such finite declarations.

To debunk absolute claims to truth, postmodern commentators engage in critique. This approach to uncovering fragments, fictions, and falsehoods in knowledge production is not simply rooted in criticism but also is sourced in *deconstruction*. As method, deconstruction systematically examines that which appears to be true and reveals contradictions, inconsistencies, oppositions, and interdependencies lodged within presumably neutral and impartial texts (Derrida 1970, 1981). As such, those who endorse this method of inquiry do not insist on the existence of alternative truths. This reasoning would undo the logic of deconstruction. Indeed, from the negative and fatalistic perspective of postmodernism, to insist on an epistemological standpoint entails that one make a categorical truth claim. Assertions such as these represent a landscape of inexhaustible deconstructive inquiry. This is why the early postmodernists have been classified as skeptics, nihilists, and anti-foundationalists (Henry and Milovanovic 1996, 1999). Under these de-stabilizing conditions, what purpose could the making of meaning serve?

Affirmative, Constitutive, and Integrative

Where the negative and fatalistic approach to postmodernism seeks to make explicit the "undecidable" nature of texts, the affirmative, constitutive, and integrative perspective (*for applications see*, Arrigo and Milovanovic 2010) also endeavors to *reconstruct* them. This reconstruction entails claims to conditional, positional, and relational truth and knowledge (Arrigo 1995). As an intellectual transition in theory development, attention is directed toward understanding how an "edifice [a text or system of thought] is built, and how it stands, in spite of opposition [but also] how it can be rebuilt or built differently" (Einstadter and Henry 1995, pp. 280–281). These replacement constructions acknowledge that humans co-produce and reify the structures, organizations, and institutions of which they are a part, while, simultaneously and interdependently, these material forces contribute to defining the subject's very own possibilities. This is the meaning of the constitutive enterprise (e.g., Henry and Milovanovic 1996).

While negative and fatalistic postmodernists contend that humans are susceptible to the limit-setting influences of these structural intensities (e.g., the "death" of the subject), second wave proponents of postmodernism demonstrate how people can nevertheless create new social worlds and emergent social selves (Henry and Milovanovic 1999). Along these lines, criminologists in support of actualizing these potentialities have called for greater interdisciplinary academic border-crossing. This would entail synthesizing insights derived from such disparate fields as chaos theory, psychoanalytic semiotics, literary criticism, cultural studies, existential phenomenology, and critical dialogical pedagogy (Arrigo and Milovanovic 2010).

Ultramodern

Recently, a third transition within the philosophy of postmodernism has developed. This new wave of thinking is known as the ultramodern. Consistent with constitutive theory, this perspective asserts that the self/society mutuality is co-produced by the human agent and the structural/organizational intensities that influence/shape the subject. To this notion, ultra-modernists contribute the view that four mutually supporting spheres of interdependent influence exist. These influencing flows include circumscribed images (Symbolic realm), privileged texts (Linguistic realm), embodied inscriptions (Material realm), and their replications and disseminations (Cultural realm) (Arrigo et al. 2011; Arrigo and Milovanovic 2009; Milovanovic 2011). The relationship between the four spheres and the twin dynamics (i.e., self/society mutuality) is one in which each force contributes to the maintenance of the others. Ultramodern commentators charge that these spheres of influence currently perpetuate and sustain harms of reduction (limits to being) and harms of repression (denials of becoming). This harm, both material and existential in composition, extends its captivity beyond offenders (the kept) to include their keepers, regulators and watchers. In the ultramodern age, this captivity is criminal.

The ultramodern version of postmodernism seeks to specify how the ubiquity of this captivity renders human/social progress no more than a *shadow* of what it could be or could become for one and about all. To transcend harms of reduction/repression, ultra-modernists employ both deconstructive and reconstructive techniques. The most promising reconstructive technique emerges from within a virtue ethic that celebrates human/social flourishing and the different and transformative possibilities that pursuing this ethic implies. Through ongoing engagement of this sort, ultra-modernists maintain that a new type of citizenship (i.e., personal well-being; individual excellence) and a new quality of justice (i.e., for one, about all, and collectivist) can be seeded and nurtured in provisional, positional, and relational contexts (Arrigo et al. 2011).

Background on Postmodern Criminology Concepts

Postmodern criminology is an ever-evolving philosophy. Indeed, there are numerous contributors to its theoretical development and research trajectory (Arrigo and Milovanovic 2010). Notwithstanding this rich intellectual history, several shared notions have been pivotal to its evolution. These notions include: discourse, meaning, knowledge, power, and subjectivity/agency. In what follows, each of these concepts is briefly described.

Discourse

From the modernist perspective, discourse is neutral. That is, the act of speech and the act of writing are instruments by which individuals communicate rationally formulated expressions. However, postmodernists regard discourse as a powerful vehicle through which humans construct identity (e.g., self, others, situations). Drawing primarily upon Lacan's (1977) groundbreaking work on discourse construction and analysis, postmodernists view human subjects as "formed by and through their use of language and by the inherent meaning that language use creates and invokes" (Henry and Milovanovic 1996, p. 8).

Lacan's schematizations on discourse are featured prominently in the theory and method of deconstructionism (Arrigo et al. 2005). This latter concept is something of a fulcrum for a number of ideas on which postmodernism rests. Indeed, postmodern thinkers "consider all narrative accounts to be texts, including books, stories, descriptions, reports, accounts, even non-verbal communication such as demeanor and gestures. Thus, all discourse of any kind is a text, as are all phenomena and events" (Henry and Milovanovic 1996, p. 5; *see also* Rosenau 1992). And, as previously explained, the undecidable nature of all texts (i.e., that they are filled with multiple readings), means that truth, even when specified as such, can never fully or exhaustively be discerned. For example, juridical language is a text through which judges convey their opinions on legal matters. However, court declarations are only one rendition of a given reality. The text of "legalese" produces meaning that is consistent with black letter law; however, lived experience is purified by way of legal language. Thus, "court talk" cannot fully communicate or embrace the non-sanitized experiences of those to whom or about whom it is directed. This "cleansing" process is what makes juridical discourse totalizing in its stigmatization.

In the illustration above, we see how human interactions and social phenomena are connected through language, including the system of language (i.e., the text) that is the law. But, given the postmodernist perspective on discourse, any text can be disassembled to make more explicit how it (unwittingly) gives preference to majority "voices" (e.g., those of status and standing) over minority "voices" (e.g., those lacking social, economic, political capital). This is why "[d]econstruction tears a text apart [and] reveals its contradictions and assumptions" (Rosenau 1992, p. xi). Legal and criminological postmodernists, particularly those who endorse the affirmative and ultramodern perspectives, contend that these texts can then be reassembled so that they more completely affirm the voices (the identities) of the excluded and powerless (e.g., Arrigo and Milovanovic 2009, 2010).

Meaning

People construct their identities, their realities, through communication (the written or spoken word), and by assigning meaning to the language they utilize. Postmodernists frequently employ phrases such as “language games,” “regimes of signs,” “discursive formations,” “rhetorics,” and “linguistic coordinate systems” when referencing the specialized meaning situated within a given text (Henry and Milovanovic 1996, p. 8). In the lexicon of postmodernism, words are often referred to as signifiers. That is, words are unstable, value-laden, and freighted with meaning. To illustrate, consider Henry and Milovanovic’s (1996) assessment of the language employed in the Fourteenth Amendment’s provision that “no person. . .shall be deprived of life, liberty, or property without due process of the law” (p. 9). As they contend, terms such as “person,” “life,” “liberty,” and “law” are signifiers. These signifiers have a specific meaning within the realm of jurisprudence. The process of meaning-making by way of signifiers, then, is a critical component to how the subject constructs identity, including their social worlds and social selves (Lacan 1977, *see also* Arrigo et al. 2005).

Knowledge

From the modernist perspective, truth can only be retrieved by relying on robust, scientifically-sourced methods. In doing so, “Absolute Postulates” emerge in which “all other ‘facts’ can be explained [utilizing] linear, deductive logic” (Milovanovic 1997, p. 14). With such truth claims, a preferred system of knowledge is established. It is a system of thought, of knowing, that demands compliance if conventional meaning is to be assured. Stated differently, this system of knowing is one that demands that others think, communicate, and live similarly rather than differently.

In contrast, postmodern adherents argue that since texts are poly-vocal, knowledge about such renditions of reality and identity are, at best, communicated in fragments and through impressions. This is why there is “no independent reality other than in the minds and practices of those who create them and recreate them” (Henry and Milovanovic, 1999, p. 5). Indeed, truth and the knowledge claims about its legitimacy are social constructions or fictions that temporarily anchor our existences in circumscribed and incomplete ways (Arrigo and Williams, 2006; Best and Kellner 1991). In other words, specialized types of knowledge exist for individuals and/or groups but they can only ever be historically contingent, awaiting careful textual exegeses. Thus, while extant systems of modernist knowledge contend that empirical inquiry provides the most exacting path by which to explain and predict human behavior, postmodernists point out that science’s mantle of privilege and respectability often discounts, ignores, or dismisses other worthwhile avenues for knowing and communicating the difference that is the human/social experience. After all, “science,” too, is a social construction, a way of rendering reality.

Power

Featured prominently in postmodern thinking is the role of power. According to two of its leading exponents, Deleuze (1988) and Foucault (1977), the concept of power is present in all relations. A number of postmodernists posit that crime is the power to harm and deny others their humanity (Arrigo et al., 2011; Arrigo and Milovanovic 2009; Henry and Milovanovic 1996). In other words, crime is “an expression of energy to make a difference over others, to the exclusion of those others who, in the instant, are rendered powerless to make [and be] their own difference” (Henry and Milovanovic 1996, p. x). This power is legitimized through systems of thought within such “disciplines” as education, medicine, law, and penology. This disciplining is then institutionalized by way of indoctrinated agents (the keepers and regulators of the kept) (Arrigo and Milovanovic 2009; Arrigo et al. 2011). From the postmodernist perspective, however, such systems of knowing “advance only specialized truths that serve to establish or maintain oppressive power relations" (Arrigo and Williams 2006, p. 13).

The effects of such disciplining by way of privileging some texts (i.e., slavishly obeying circumscribed ways of knowing, of making meaning, and of constructing identity) is the power to harm. As captivity, this harm extends to all (the kept, and their keepers, managers, and watchers). Indeed, this is the *maddening* power to harm by way of total confinement, experienced both existentially and materially to, from, and about us all (Arrigo 2012). These harms, as crimes, involve denials of being (i.e., the subject who seeks recovery) and limits on becoming (i.e., the subject who seeks transformation) (Arrigo and Milovanovic 2009).

Harms of reduction occur when an individual's ability *to make a difference productively* is hindered through the actions of some system's agent or representative. For example, a recovering addict may be prevented from pursuing palliative health-enhancing activities because of the ex-user's history of relapse addiction. The person is rendered less than what he or she could be (i.e., as in further restored, recovered, or healed). Harms of repression occur when an individual's ability *to be different dynamically* is hindered by the actions of some system's agent or representative. Here, the subject's transformative possibilities are limited because of one's status as a recovering addict (i.e., rendered finite given one's already marginalized standing) or are circumscribed (i.e., defined by the terms and conditions of others given that one's consequent life already has been decided and determined). This is the powerful realm of harm in which one's societally-enforced and/or self-inscribed text disciplines subjectivity (the individual is forever branded as deviant, diseased, dangerous, or other). Moreover, both forms of harm extend to the manifold incarnations of subjectivity. Indeed, the keepers, managers, and watchers (i.e., the anesthetized general public) also are texts that write their own captivity as subjects, especially when they teach, proscribe, govern, enforce, and/or inter-relate by way of harms of reduction and repression.

Subjectivity/Agency

As noted previously, the modernist perspective asserts that humans are rational. Following this episteme, people are "conscious, whole, self-directing, reflective, unitary, and transparent" subjects (Milovanovic 1997, p. 9). They are purposeful as in criminology's rational choice theory, and centered (i.e., in control, stable) as in law's juridic subject developed in the "reasonable woman or man" standard (Arrigo et al. 2005).

The postmodernist perspective argues that the subject, the acting agent, is de-centered. This is an individual who is open to transitions; fluid and in-process; and whose humanity is more fully expressed and embodied through the chaotic (i.e., orderly disordered) forces of contradiction, inconsistency, spontaneity, and even absurdity. For postmodernists, these aspects of our existences must be extolled rather than confined. In other words, unlike the predictable, linear, and static subject of modernity, post-modernity maintains that our identities are not so easily reducible to finite categorizations or cause-effect rationales. This is how captivity in texts and in systems of thought prevails. To illustrate, when we define individuals through an "either/or" logic and view them as "deviants or conformists; law violators or law abiders; villains or heroes" (Arrigo 1995, p. 454), we fail to comprehend that their (our) more complete subjectivity is located in the *mutuality* that these binaries signify. Restoring this agency (i.e., the recovering subject) and revolutionizing it (i.e., the transforming subject) is the ultramodern journey that awaits all subjects (e.g., Lecercle 1985; Milovanovic 2011).

State of the Art Postmodern Criminology

Drawing upon the concepts established in the first two transitions of postmodern thinking, ultramodern commentators have developed an innovative model for assessing the madness (the captivity) manufactured, reified, and legitimized by way of the criminal justice apparatus.

This is a reference to institutional decision making that dangerously and fearfully supports the technologies of risk/threat avoidance, hypervigilance, and panoptic surveillance, notwithstanding considerable evidence to the contrary on their capacity to grow citizenship and advance justice. Among other examples, three specific institutional practices have been examined in the recent literature and are worth noting: (1) cognitively impaired juveniles waived to the adult system, (2) psychiatrically disordered inmates placed in long-term disciplinary solitary confinement, and (3) formerly incarcerated sexually violent predators placed in civil detention followed by multiple forms of community inspection and reentry monitoring (Arrigo et al. 2011).

In each instance, the precedent-setting and/or prevailing case law was identified and reviewed. These three systems of thought (i.e., texts of mental health law), were then deconstructed at the level of judicial temperament (i.e., attitudes and perceptions) and jurisprudential ethic (i.e., moral philosophy informing juridical disposition). At issue were the ways in which jurists talk about and render decisions affecting troubled, vulnerable, and distressed offenders; those victimized by their actions whether in free society or behind prison walls; and the communities that bind all of these constituencies together. In this qualitative study, the investigators demonstrated how a careful re-reading (i.e., deconstruction) of these mental health law texts could further explain how state-regulated institutions, by way of their respective agents, operate as “totalizing apparatuses” that sustain harms of reduction and repression (Arrigo 2004, p. vii; see also Arrigo et al. 2011). Stated differently, virtue ethics and its promise of excellence for one and about all were not a part of these systems of thought; character did not write these texts. Thus, decision making that spoke of courage, compassion, generosity, mercifulness, etc., for one and about all was altogether lacking in and throughout the case law narratives. However, these virtues, when written about and lived, are the habits of character that help to seed and grow excellence in human/social flourishing (Aristotle 2000; Levinas 2004). The madness of *total* captivity sustains itself when identities are constructed, meaning is made, and subjectivity is categorized in the absence of such mutating self/society excellence (Arrigo 2012). In what follows, the relevance of these observations will be tentatively explored in relation to further developing ultramodern theory, method, and praxis. These comments provide some grounding for conceiving of ultramodern philosophy as an emerging and postmodernist-informed human/social science of criminology.

Developments in Theory

How does the power exercised through harms of reduction and repression operate? In other words, how do these limits and denials unconsciously emerge, take up residence in texts, materially and existentially discipline self/social identities, and guarantee the culturalized replication of each whose co-productive effects reify the normalization of violence? As described previously, four interactive and mutually supporting spheres of influence co-shape the self/society binary. These flows, with their corresponding frequencies and fluctuating intensities, include the symbolic, linguistic, material, and cultural realms. Presently, the interdependent and constitutive effects of these forces resonate as domains of captivity, as conditions of control.

The self/society mutuality consists of the human agent and the structural and/or organizational intensities to which the person is directed and captured and from which the subject co-shapes these flows. The relationship among the four spheres and the twin dynamics (i.e., self/society) is porous in nature. In other words, each force is dependent on and contributes to the composition of the other spheres. Because harms of reduction and repression are existentially and materially ubiquitous, ultramodern theorists argue that their power must be de-stabilized by way of deconstruction. To accomplish this, some further commentary is needed on how these dynamically supporting spheres interact with the twin dynamics such that these flows function as conditions of control reifying and legitimizing captivity for one and all.

The Symbolic sphere involves the consumption of prevailing, incomplete, and circumscribed images (i.e., pictures or scenes in our minds). These images symbolize an aesthetic about and for crime and those who commit acts of violence and victimization. But this inadequate symbolization extends to others as well. Indeed, an aesthetic sensibility also is conjured about victims and how their injury is managed and/or corrected by way of social institutions and their agents. Thus, the space that the symbolic spheres inhabits, is one that commits or assigns us to "the consumption of a particular and dominant aesthetic regarding vulnerable, troubled, and distressed individuals; those professionals whose expertise includes treatment, corrections, and societal reentry; and the interventions exercised to ameliorate offenders and the offended" (Arrigo et al. 2011, p. 164).

Once they are spoken, the shadows that these images cast about the self/society mutuality become an oral history. Eventually, these spoken images become a written text. This is the realm that represents the influencing force of the linguistic sphere on the twin dynamics. Because the image-crafting at the symbolic level lacks an aesthetic that more completely signifies our dynamic and transformative humanity, the story that it tells (for example, about offenders) while one that communicates a type of narrative coherence, can only read as a summary representation (Cicourel 1981; Knorr-Cetina 1981) of, for, and about the incarcerate. As such, the knowledge that is constructed by way of these representations constitutes a false epistemology; it tells a fictional story through its incompleteness. Indeed, these texts are fashioned by way of partial truths about those who injure wrongly, those who are victimized painfully, those who keep and manage both purposefully, and those who watch on hypnotically and docilely (i.e., uncritically). The currency in identity construction and in meaning making regarding these truths is sourced in politics – the politics of rendering silent the texts and images of social selves and social relations that could be dynamically restorative and vibrantly transformative for one and about all. Nurturing and sustaining this lack of experimentation and innovation in storytelling, is how harms of reduction and repression become reified texts.

When the fictional story that is told about crime and criminals becomes a lived narrative, then it is materially embodied as virtuous. This is the influencing force of the material sphere that produces bodies of knowledge or systems of thought whose fluctuating intensities discipline the self/society mutuality. This disciplining extends to the use of productive technologies of control that ensure compliance – whether, for example, in education, medicine, law, or economics. These technologies (e.g., threat/risk assessment protocol, actuarial penology, and "evidence-based" science) endorse renditions of reality, of self/society identities, whose deployment often demands total and slavish-like obedience to these regimes of captivating truth and normalizing regimens of human/social existence. These regimes and regimens dangerously "inscribe the twin dynamics and problematically render. . .silent manifestations of dissent" (Arrigo et al. 2011, p. 165). Here, too, this captivity and normalization extend to and from the kept, as well as their keepers, managers, and watchers.

The fluctuating intensities of the symbolic, linguistic, and material spheres are culturalized by way of their continuously replicated multimedia-based derivatives. The immediacy and reproduction of iterative information, of manufactured reality, by way of the Internet's global village, 24/7 news cycles, Hollywood dramatizations and re-enactments, and even the sites and sounds of Las Vegas' "other worldly" spectacles or Disney World's animatronic simulations, makes identities instantly, although incompletely, accessible. This is because these identities about the self, others, and of situations are nothing more than illusions. These copies of reality, as fictions, are problematic in that they can be interpreted as more authentic and true than the reality from which they are derived (Baudrillard 1983a, b). This *cosmopolitan* influence is the force of the cultural sphere. It imitatively perpetuates and sustains the status quo in image-crafting, text-making, and material disciplining. The cultural sphere is both the source and product of violence normalized, of harms experienced reductively and repressively, and of humanity rendered an ontological shadow of what it could be or could become.

Developments in Method

As method, the ultramodern builds on the deconstructive approach. The postmodernist critique that ensues emphasizes a re-consideration of the text in question. This questioning consists of a re-examination of the reality rendered to which the self/society is directed and from which this mutuality co-produces that reality. This rendering of reality is informed by its constituent conditions of control with their interdependent flows, intensities, fluctuations, and effects. These conditions, as spheres of influence, are prisms through which the disassembling critique is filtered in historically contingent although manifest form. The manifestations of reality, then, are the images, texts, embodiments, and cultural reproductions of each that exercise power existentially and materially. This is the power to set limits on being and impose denials of becoming for one and about all. This harm, as the crime of captivity, is what ultra-modernity seeks to specify and renounce. The criminal justice apparatus is replete with texts whose rendering of reality is both totalizing and maddening. These renditions await ultramodern critique (e.g., Arrigo et al. 2011).

Overcoming the madness reified and legitimized by the systems of thought that are criminal justice entails yet another methodological journey. This excursion rebuilds or builds differently the text in question. This is the activity of reconstruction. At issue are the assemblages of images, texts, embodiments, and cultural reproductions of each that celebrate, both virtuously and excellently, how one can make a difference productively (the recovering subject) and how one can be different dynamically (the transformative subject). Undertaking this reconstructive journey is how the shadows of our selves can be quieted and the captivity of all subjectivities can be quelled. Methodologically, ultramodernists have not yet sufficiently charted the constituents of this passage. To be clear, what is envisioned here is a revolution in, a re-writing and re-reading of, the scientific method. This observation notwithstanding, the criminal justice apparatus is replete with texts awaiting alternative renderings of its realities (e.g., Arrigo et al. 2011; Arrigo 2012). These renditions would be provisional, positional, and relational; otherwise, they, too, would become totalities and this condition is anathema to the evolution in ultramodern philosophy and postmodernist-informed criminological science.

Developments in Praxis

The deconstructive/reconstructive ultramodern method is also relevant at the level of engaged praxis. This is the realm of thinking about and doing habits of character so that the possibilities of vibrantly living virtuously become more realizable for one and about all. In other words, in an era of captivity that engenders harms of totalizing madness, "ideas like "dignity," "the therapeutic," "restorative," "fair-mindedness," "injury," "community," "health," "self," "society," and the like are all filtered through the intemperance that this captivity most assuredly guarantees" (Arrigo et al. 2011, p. 169). The presence of this captivity is how a dynamic praxis is both deferred and denied. However, this far-from-equilibrium activity is the condition that grows a transformative citizenship informed by emergent visions of justice. This is why the symbolic, linguistic, material, and cultural meanings that attach to the *practices* of this self/society mutuality must be dis- and reengaged. This is how ultra-modernity's conception of deconstruction and reconstruction operates at the realm of lived praxis.

To illustrate this perspective, let us consider the following. What images do we conjure (the symbolic realm), what texts do we write (linguistic realm), what oral histories do we live and embody (the material realm), and what imitations of each do we reproduce (cultural realm) when we honor an offender's dignity, heal a victim's injury, and restore a community's conscience in the wake of violence and victimization? Mindful of ultramodern praxis, constructs such as dignity, health, restoration, and community must be critiqued in order to discern the potentially concealed aesthetical, epistemological, ethical, and ontological preferences that reductively and repressively co-produce harm. In essence, then, the ultramodern reminds us that thinking about and doing virtue as dynamic and transformative praxis is an embodied ethic that questions the rendition of reality, of justice, from which such possibilities are advanced and to which they are directed. Indeed, for whom and under what conditions is justice served by any particularized rendering?

Controversies in Postmodern Literature

The proposed developments in ultramodern theory, method, and praxis as constituents of a postmodernist-informed science are controversial in their originality and experimentation. Undertaking this journey – of developing and growing this uncultivated criminology – is an exercise in renovation and innovation for a people yet to come (Deleuze and Guattari 1984, 1987). But transcending the society of captives and overcoming the shadows of our selves is a *strange* expedition. It is an awaiting revolution (Arrigo and Milovanovic 2009). This revolution begins as critique – from the symbolic to the linguistic, from the material to the cultural, and unfolds in historically contingent although manifest form. This critique seeks to restore and transform all those who experience harms of reduction and repression as crime and violence normalized so that they (and all of us) can make a difference productively and become a difference dynamically. This is the critical pedagogy by which captivity, in all of its manifestations, is studied and revolutionized. Each of the above notions – especially in their relationships to ultramodern philosophy – contributes to the contentious postmodern landscape.

Open Questions

What is the nature of authentic human/social interconnectedness in the age of the ultramodern?

This is a quality of citizenship and of social justice whose mutuality remains problematically under-developed. To illustrate, the global village of the Internet and its hyper-real progeny normalize violence (re-imagine, re-tell, and re-inscribe) through limit-setting and denial-imposing meaning-making. This is identity construction that re-conceives such human/social phenomena as "intimacy," "courage," and even "friendship." In the digital age, identity that celebrates the virtual rather than the visceral, the imitative rather than the authenticated, is privileged. Text-messaging, myspacing, facebooking, and skyping are proliferating forms of social networking. But how are these forms of relatedness renditions of reality that replicate human/social citizenship excellently? In other words, what does the ubiquity of this immediately accessible interconnectivity teach us about intimacy, courage, and friendship? If it is found by way of the previously and provisionally enumerated methodology that these digitized encounters are lacking in a mutating authenticity, then overcoming the harms that they seed and nurture (i.e., excessive investments in liquid identities and virtual realities that reduce/repress humanity) is a revolutionary journey that must be deconstructively and reconstructively pursued.

If liquid identities and virtual realities are artifacts of the ultramodern, how do we overcome the death of experience that similarly disappears along with them?

The conditions of a society at its center, tell us a great deal about the nature of behavior at its fringes. The fringe behavior at issue here is the breadth and depth of experience that the power to harm reifies and captures by way of its systems of thought. The tendencies of such captivity are to discipline and to normalize. The maintenance of these sanitizing tendencies or central conditions is the power to harm teleologically. The death of experience alluded to here encompasses the pseudo-realities individuals both construct and encounter, and they consist of their replicas and façades that function to supplant matter and materiality (Arrigo 2012). Overcoming such finalizing of experience requires that we shatter and increase our language so that we can shatter and increase our realities. These activities return us to the excavation work of the unconscious and the images that await symbolization and activation for a people yet to come. Specifying the constituents of this mobilization, of this awaiting revolution, is a strange and uncharted journey of becoming other (Levinas 2004). The activity of becoming other – of being present to and for another always already more courageously, generously, compassionately, mercifully, etc., – is the promise of character. Living this promise excellently is captivity's release. This release is how the retrieval and transformation of experience appears in consciousness, travels through texts, inhabits histories, and culturally manufactures the constitutive reproductions of each.

How do the death of experience and the inauthenticities to and from which liquid identities and virtual realities sustain their mutuality, make possible an experiential conversion (an overcoming) in images, texts, embodiments, and replications?

The possibilities for an experiential conversion that renovates and innovates the human agency – social structure mutuality, are located in the vast reservoir that is the unconscious. The co-productive flows, intensities, frequencies, and fluctuations that shape and are shaped by extant identities and realities, currently write the subject, the social, and their constitutive interdependencies as a text of totalizing confinement. This is a systemic madness because the recursive effects of such captivity impede citizenship's potential (i.e., in its images, texts, and embodied practices). These harm-generating impediments thwart the possibility of conceiving of citizenship as dynamic difference lived ever more virtuously and humanly. Additionally, the effects of this systemic pathology produce circumscribed visions of justice for one and about all whose consequent limits and denials derivatively manufacture mere shadows of justice. However, when we inhabit the space of otherness – dwell joyfully, lovingly, virtuously, and excellently within this strange, uncertain basin – this act of will mobilized to power helps to spark the awaiting revolution for a people yet to come. Occupying this space is much like becoming a jazz player. The cascading conditions, fluctuating intensities, and corresponding frequencies that extol such otherness, such difference, remain a source of future postmodernist-inspired ultramodern inquiry.

Conclusion

The problem of explicating human behavior and social phenomena in ways that respectively grow citizenship and advance justice undoubtedly will persist. One facet of this persistence is in recognizing how the power that harm exercises, reifies crimes of reduction and repression. The modernist approach employs quantitatively-sourced and empirically tested scientific methods to explain and predict criminal and delinquent behavior. According to postmodernists, this criminological approach is less than sufficient and, at worst, inflicts existential and material harms on all those within its fearfully hypervigilant and dangerously panoptic ambit. This captivity is totalizing. It is a madness that limits being and denies becoming for the kept, and their keepers, regulators, and watchers. Sustaining the influencing shadows of this captivity is how the normalization of violence, of crime, prevails. Its co-productive effects extend from the aesthetical to the epistemological, from the ethical to the ontological. A postmodern criminology informed by ultramodern philosophy seeks to overcome the reductive and repressive power to harm by way of restorative and transformative flows, frequencies, fluctuations, and intensities. These influencing forces celebrate spheres of human/social flourishing. Cultivating this ethic is an invitation to further develop theory, method, and praxis. This is the ultramodern challenge of igniting a revolutionary science of criminology.

Poverty, Inequality, and Area Differences in Crime

Travis C. Pratt and Bryan D. Eisentraut
School of Criminology and Criminal Justice,
Arizona State University, Phoenix, AZ, USA

Overview

American criminological research and theory has predominantly focused on individual offenders. Following the growth and refinement of survey research methods in the 1960s, which had a strict focus on the individual as the unit of analysis, a resurgence of macro-level criminological research has taken place in recent decades. Two of the most commonly assessed ecological correlates of crime rates include poverty (absolute deprivation) and inequality (relative deprivation). This entry takes stock of this body of literature that has examined the effects of poverty and inequality to explain area differences in crime rates.

Introduction

Since its inception, American criminological research and theory has predominantly focused on individual offenders. Criminology grew largely out of the classical school and positivist notions of human behavior in the early 1900s. Both of these perspectives focused on the individual correlates of crime and deviance. While the classical school emphasized the rational decision-making processes of individuals, the positivist school looked for physical and/or psychological explanations of criminal behavior. Despite the different assumptions underlying the classical and positivist schools of criminology, it was their shared focus on the individual that guided much of the subsequent theoretical development in criminology. As such, most of the major criminological theories covered in books, edited volumes, and introductory level textbooks are individual-level theories. The majority of empirical research in criminology also treats the individual as the unit of analysis. Consider, for example, the ubiquity of research employing individuals' responses to self-report scales in academic journals.

In part as a response to criminology's emphasis on the individual, Shaw and McKay's work and the anomie tradition began by Merton directed attention toward macro-level factors in the mid-twentieth century. This is not, of course, to say that the approaches taken by Shaw and McKay and by Merton were merely reactions to the previously articulated individualistic theories of crime. Rather, their work started from a different premise altogether: that human behavior was guided primarily by social conditions and/or structural constraints, as opposed to inherent biological drives and inhibitions. These formulations outlined aggregate-level conditions of geographic regions (e.g., urban characteristics) and sociocultural characteristics (e.g., a society's collective emphasis on material success) that may lead to increased *rates* of crime. But as Bursik and Grasmick (1993, p. ix) note, "with the refinement of survey approaches to data collection and the increased interest in social-psychological theories of control, deterrence, learning, and labeling, the focus of the discipline significantly began to shift from group dynamics to individual processes during the 1960s and 1970s." Even so, beginning in the late 1970s and early 1980s, macro-level (or "ecological") theory and research reemerged and has since earned sustained criminological attention. Indeed, Bursik and Grasmick (1993, p. ix) argue that "the pendulum has begun to swing in the other direction, and there has been a relatively recent acceleration in the number of studies that have been conducted with an explicit focus on [macro-level] dynamics."

At least in part, this resurgence of interest in macro-level approaches has been encouraged by Cohen and Felson's (1979) development of routine activity theory, the seminal work of Blau and Blau (1982) on inequality and violent crime, the rediscovery in the 1980s of Shaw and McKay's social disorganization theory by scholars such as Bursik (1988) and Sampson and Groves (1989), and the renewed interest in deterrence-rational choice theory as well as the rise of conflict theory at the macro level during the 1970s and 1980s (see, Pratt and Cullen 2005).

Two of the most commonly assessed macro-level correlates of crime include poverty (or absolute deprivation) and inequality (or relative deprivation). Numerous tests of theoretical propositions surrounding poverty and inequality have been conducted in the sociological and criminological literature (see Pratt and Cullen 2005) over the last 50 years. The purpose here is to take stock of this body of literature. In particular, this entry begins with a review of the spectrum of theoretical perspectives that have specified the importance of either poverty or inequality in both defining and explaining crime. The discussion then turns to an assessment of the empirical evidence concerning the effects of both poverty and inequality on macro-level crime rates. The entry concludes with an overview of the new directions that have been taken in the poverty-inequality criminological literature.

Poverty and Crime

Poverty and the Definition of Crime

Both social disorganization and anomie/strain theories, for example, point to the structural characteristics that may allow criminal activity to flourish. While these theories differ in their propositions regarding how certain social conditions may produce high crime rates, they are in tacit agreement that "crime," as a social phenomenon, is an objective social reality. In other words, these theories – and most others – implicitly assume that a rough consensus exists within societies about what types of behaviors should, and should not, be considered "criminal."

Thus, neither perspective devotes much attention to how certain behaviors come to be labeled by society as "criminal." Indeed, although the bulk of the theories that are typically covered in criminology textbooks share the contention that groups of individuals are mired in a system of social stratification, they overlook the degree to which power differentials between the relatively powerful and powerless groups in society may shape not only individuals' behaviors, but also the social perceptions of those behaviors. Discussions of the relationship between poverty and crime, which are often guided by conflict theory, attempt to fill this theoretical void.

At its most basic level, conflict theory draws on the Marxian tradition and is most concerned with "[focusing] attention on struggles between individuals and/or groups in terms of power differentials" (Lilly et al. 1995, pp. 132–133). In essence, conflict theory sees crime as a socially constructed label that powerful groups are able to place on the behaviors of groups or individuals who hold, in comparison, less social power and/or political authority. Crime, therefore, is viewed through the lens of conflict theory as being morally relativistic. Since, although both members of the upper and lower social classes may engage in morally questionable behaviors, the legal system – which is assumed by conflict theorists to be a tool wielded only by the upper classes – tends to punish only the deviant activities of the lower classes, particularly those seen as threatening the privileged position of the powerful (Bonger 1916[1969]).

Variations and Critiques of Conflict Theory's Views on Poverty

It is important to note that conflict theory places its iron in multiple fires. Some versions of conflict theory are concerned only with the dynamics of conflict between social groups. For example, early work by Vold (1958) focused on how social groups in conflict tended to maintain an equilibrium that eventually led to social stability and order. Other versions of conflict theory attempt to specify methods for which conflict may be eliminated – such as through trading in the evils of capitalism for the bliss of communism (Marx and Engels 1848[1992]).

The plurality of approaches falling under the heading of conflict theory has, to a certain extent, contributed to its somewhat shaky empirical foundation and to its theoretical murkiness. In particular, many conflict theorists have focused explicitly on "political" crimes (e.g., protest movements, conflicts between labor and management) as indicators of how powerful groups may shape and define substantive law (Vold 1958). Other conflict theorists attempt to marshal in their defense laws against "victimless" crimes, such as "vagrancy," as evidence that the "normal" everyday activities of politically disenfranchised groups of individuals are routinely demonized by the rule-making upper classes (Chambliss 1964). Granted, each of these approaches may be useful for illustrating how "law" may be used as a method of social control. The central problem facing conflict theorists, however, in one of attempting to convince the criminological community that certain violent offenses, such as rape or murder, are socially constructed labels placed on the preferred behaviors of the lower classes (Akers 1997). Certain conflict theorists, however (see, e.g., Reiman 1995), argue that even with regard to violent crimes, members of the upper classes are typically viewed as less responsible for their actions, and tend to receive relatively favorable treatment from the criminal justice system. For example, negligent business practices that result in multiple employee deaths (e.g., mining accidents) are often couched in the language of "liability" instead of "homicide." Reiman (1995) goes on to note how this may be treated as de facto evidence that the wealthy are able to "get away with murder."

The debates surrounding these elements of conflict theory are unlikely to be resolved any time soon. There are, however, other versions of conflict theory that are relatively unconcerned with the more postmodern endeavor of delineating the "definitions" of criminal and noncriminal behavior. Indeed, certain versions of conflict theory attempt to provide an explanation, setting aside "value judgments" regarding the "definition" of crime, as to the causal mechanisms by which social conflict leads to high rates of crime (Bonger 1916[1969]). It is this final variant of conflict theory – which overlaps substantially in its intellectual focus with a host of other ecological perspectives on crime causation (e.g., strain/anomie and social disorganization theories) – that is the focus of the remainder of this section since its primary concern is the *explanation* (and therefore prediction) of how poverty influences crime rates.

Conflict Theory and Crime Causation

In its simplest terms, conflict theory views the "causes" of crime in the following manner. First, a capitalist economic structure is likely to produce a condition of widespread poverty, where large groups of people will experience significant "resource deprivations" in terms of money and property. This absolute deprivation, in turn, heightens and reinforces the animosity harbored by the groups living in conditions of poverty toward those in the leisure class (see, e.g., Veblen 1889[1934]). Finally, the condition of poverty may be criminogenic, by itself, in two ways.

First, poverty may *directly* cause crime among the "subordinate classes" as members of such groups seek daily survival. In other words, certain criminal offenses (e.g., theft) may be necessary for some individuals to simply "get by" (see, e.g., the discussion by Bonger 1916[1969]; see also Lilly et al. 1995). This position is similar to Merton's (1938) notion of deviant/criminal adaptations to strain, where such instrumental offenses would simply be the result of creative ways of engaging in an economy to which those in the lower classes are disenfranchised. Second, poverty may lead to crime *indirectly* as members of the poverty-stricken groups may eventually come to question the validity of the social arrangement they have been handed. Feeling as though they have been given a "raw deal," these groups "would then be more likely to organize and to bring the conflict out in the open, after which there would be polarization and violence" (Lilly et al. 1995, p. 134). A somewhat more nuanced take on this process comes from Shaw and McKay's social disorganization perspective, which holds that conditions of economic deprivation (poverty) provide the context for a conflict of values to take place. In economically-deprived communities, some groups will harbor values in opposition to the law, which may challenge traditional middle-class values and, in turn, may influence the next generation of would-be delinquents through the transmission of such values. Thus, regardless of the theoretical tradition one is drawing upon (e.g., conflict, strain/anomie, social disorganization), they all share the common proposition that impoverishment itself is criminogenic, and that there should be an empirical link between variables which proxy economic conditions, such as poverty rates, and crime rates.

Inequality and Crime

Along with discussions of the criminogenic effects of absolute deprivation, criminologists have also focused on the importance of understanding the consequences of relative deprivation, or inequality. Dating all the way back to

Merton (1938) and continuing up to the present day, inequality has long held the interests of scholars in the field. And in one of the more important works in this tradition, in their landmark study of metropolitan structure and violent crime, Blau and Blau (1982) set forth an explanation as to the "cause" of violent crime that differed from the absolute deprivation/conflict theory model. In short, Blau and Blau (1982, p. 116) noted that the "poverty" model of crime argues that urban slums tend to create a particular subculture where youths value "toughness, smartness, excitement, and fatalism" which, in turn, "bring young persons into contact with the law." Thus, the macro-level perspective on absolute deprivation/conflict theory "interprets delinquency not in terms of individual poverty but in terms of the shared cultural values that tend to develop in the impoverished conditions of urban slums" (Blau and Blau 1982, p. 116). This position is similar to the urban subcultural perspective developed by Fischer (1975), who argued that the population density associated with rapid urbanization increased the likelihood that individuals with values in opposition to the law will run into each other and form their own deviant groups.

Blau and Blau (1982), however, viewed this position as problematic. Specifically, based on Blau's (1977) previously articulated general macrosocial theory, Blau and Blau (1982) held that a number of Marxian perspectives and theories of opportunity are at least implicitly concerned with the effects of economic inequality, or "relative deprivation," on crime rates. For example, early works by Bonger (1916[1969]) and the more contemporary writings of Quinney (1974) both focus on the exploitation of the poor by the rich in terms of property relations and living conditions and on the inevitability of crime as a result of such inequalities. Blau and Blau even noted that Merton highlighted how inequalities – particularly those based on ascribed characteristics (e.g., race/ethnicity) – tend to breed high levels of resentment and anger. Even more explicit is the statement by McDonald (1976, p. 22) that "Inequalities in power, economic or political, were ultimately responsible for the nature of the criminal law established, its enforcement, and the pattern of criminal behavior appearing."

As a first step toward differentiating the effects of inequality on crime rates relative to the effects of poverty, Blau and Blau (1982) analyzed the violent crime rates from a sample of 125 of the largest American SMSAs. Using measures of socioeconomic inequality between racial groups and economic inequality in general, the results suggested considerable support for the inequality/relative deprivation hypothesis. In particular, after controlling for the effects of inequality, poverty – the key variable for absolute deprivation/conflict theory – was not significantly related to total violent crime rates or to disaggregated rates of murder, rape, or assault. While poverty was significantly related to rates of robbery, the magnitude of its effect was substantially weaker than the effects of inequality (the beta weight values for inequality and poverty were .49 and − .30, respectively). Thus, the main theoretical proposition being made by Blau and Blau (1982, p. 126) is that "aggressive acts of violence seem to result not so much from lack of advantages as from being taken advantage of, not from absolute but from relative deprivation."

Theoretically, then, there is a plurality of reasons that have been set forth as to why poverty and/or inequality should be related to crime rates at the macro level. While some perspectives focus explicitly on either poverty or inequality, the majority of these theories appear to recognize the importance of both absolute and relative levels of economic deprivation when it comes to explaining crime. And though there is wide variation in the issue of why either poverty or inequality should "matter," nearly all of the criminological theories addressing these issues highlight how such ecological conditions provide fertile ground for anger and frustration on the part of the citizens. And when citizens are angry and frustrated, bad things tend to happen, including crime (Agnew 1999).

The Empirical Evidence

Poverty and the Definition of Crime/Enforcement of the Criminal Law

Although purely economic variables tend to be the preferred vehicles of poverty-related research, other relationships have been specified by within this tradition. For example, much of this work does not treat "crime rates" as the dependent variable. Rather, a number of studies grounded in the poverty-crime literature have examined the "threat hypothesis" of crime control (Liska et al. 1981). In this body of work, researchers have drawn on the proposition that impoverished members of racial and economic minority groups are viewed as a threat by the dominant groups in a social system. A corollary assumption is that the "powerful groups and strata are able to translate their perceptions of threat into public policy and thereby affect the size and administration of crime control apparatuses" (Chamlin 1989, p. 355). Typically, these studies examine the effect of the relative size of a social aggregate's poor racial minority population on its capacity to provide crime control – often through police expenditures (see, Pratt and Cullen 2005).

Chamlin (1989) took this perspective a step further and examined the relationship between "threat hypothesis" variables and a particular type of crime – rates of police killings. Using state-level data, four measures were constructed to measure the presence of threatening groups: the percentage of families below the poverty level, income inequality (measured as the Gini index of income concentration), the percentage of blacks, and the percentage of individuals with Spanish surnames. After controlling for arrest rates (for index offenses), total index crime rates, police size, and the divorce rate, the threat hypothesis variables were consistently related to rates of police killings. Further, it was not uncommon for the threat hypothesis variables to be the strongest predictors of police killings in the regression models.

Poverty as a Cause of Crime

Aside from this work on the racial threat hypothesis, most of the empirical studies within this tradition have examined the effects of absolute economic deprivation variables, such as "poverty rates," on crime rates. The measures of "poverty rates" across studies are fairly consistent: The percent below the poverty threshold as defined by the Social Security Administration – which has been adopted by the US Census Bureau – is typically used. Other approaches have, however, been taken. For example, Loftin and Hill (1974) used a "structural poverty index" (SPI) that is based on aggregate indicators such as the percentage of children living with one parent, and the percentage of the population failing the Armed Forces Mental Test. Also, Messner and South (1986) used an annual household income of $4,000 as a cutoff point for "absolute poverty." This estimate closely resembled the official poverty level for a family of four ($3,698) during the time of their data collection. Other methodological characteristics, however, exhibit considerable variation across studies. For example, studies of poverty and crime have been conducted at the neighborhood level, at the city level, on standard metropolitan statistical areas (SMSAs), and on countries (Pratt and Cullen 2005).

Studies also differ in terms of the types of offenses comprising the dependent variable. Studies of poverty and crime have attempted to predict general rates of violent crime, homicide rates alone, or multiple rates of different types of violent and/or property crime rates. Overall, Pratt and Cullen's (2005) meta-analysis of the macro-level criminological literature indicated that the effect of poverty on crime has been well tested, with over 200 studies examining the effect of poverty on crime. The aggregated mean "effect size" (or predictive capacity) of poverty variables on crime is both strong and robust across a number of different methodological specifications.

Inequality and Crime

Similar to the body of empirical work on the relationship between poverty and crime, studies of the relationship between absolute deprivation/ inequality variables and crime rates differ considerably in terms of the methodological approaches taken since the study conducted by Blau and Blau (1982). In particular, researchers have employed a number of different measures of the central concept of "inequality." General inequality is typically measured by the Gini coefficient for family income. This measure is generally computed for heads of households that are families and is based on the combined income of all family members (see Blau and Blau 1982). The Gini index includes wages or salary, income from self-employment, social security, public assistance funds, retirement benefits/pensions, and all other types of income (e.g., stock dividends, interest).

Even so, studies vary as to whether racially homogeneous or heterogeneous measures of inequality are investigated. This may pose a potential problem, some argue, since racial inequality, as opposed to inequality in general, may be the chief predictor of rates of urban violence (see, e.g., the discussions by Blau and Blau 1982; Sampson and Wilson 1995). Accordingly, researchers have also argued that racially disaggregated crime rates should be used in studies of inequality and crime, since the social and economic histories of different racial groups (e.g., blacks and whites) may have conditioned the relationship between inequality and crime (Messner 1983; Messner and Golden 1992).

Studies of the inequality-crime relationship have also focused on different levels of aggregation. Analyses have been conducted at the neighborhood level, at the city level, using SMSAs as the unit of analysis, at the state level, and at the national level. Studies of inequality and crime also vary in terms of what types of crime rates are being predicted. For example, some studies of the inequality-crime link focus on rates of violent crime in general, homicide rates, or rates of individual types of violent and/or property crime rates. In assessing all of this literature, Pratt and Cullen's (2005) analysis revealed that, similar to its absolute deprivation cousin, the relationship between relative deprivation/inequality and crime has also been well tested empirically. The overall mean effect size estimate for inequality is also quite strong, which places it in the top tier of predictive strength among all macro-level predictors of crime.

Conclusions

It is clear that both poverty and inequality are strong predictors of crime rates across units of analysis. Of course, some scholars contend that separating poverty and inequality amounts to creating a false dichotomy (Land et al. 1990), since both constructs tap into the broader issue of resource deprivation. The bulk of the empirical evidence, however, reveals that across units of analysis (from neighborhoods to nations) and across different indicators of crime rates (from various violent to property offenses), poverty and inequality seem to exert independent effects on crime (see Pratt and Cullen 2005). It is equally possible, however, that poverty and inequality operate in an interactive way. For example, it could be the case that, when it comes to predicting crime, inequality matters more when conditions of poverty are also present – that is, perhaps inequality is not so criminogenic if those on the bottom are doing alright in an absolute sense. Either way, it remains to be seen how future empirical work addresses this question across various units of analysis and across various crime measures – something that has yet to be addressed meaningfully in the criminological literature.

Even so, macro-level concepts such as poverty and inequality are now being extended into new areas of criminological research. In particular, studies of offender recidivism are now being couched in the both the language and theory of poverty and inequality (Reisig et al. 2007), as is work regarding the "institutional efficacy" of correctional treatment programs (Wright et al. 2012). These are good starts, but there are other directions for future work in this tradition that are equally important and have thus far been all but ignored by criminologists. For example, it would be incredibly useful theoretically for future empirical work to address the intervening mechanisms that operate between poverty, inequality, and crime. Indeed, studies that have included direct measures of these intervening processes in macro-level research are extremely rare in the literature (see Sampson and Groves 1989; see also Lowenkamp et al. 2003), and if work in this vein were to continue, many of the debates concerning *why* poverty and/or inequality should or should not matter could be resolved. In addition, future work should focus on how other institutional arrangements – such as state welfare programs, reentry services for released prison inmates, and investments in public education – may ameliorate the potentially harmful social consequences of poverty and inequality. All in all, poverty and inequality have a strong presence in the criminological literature that shows no signs of slowing down.

Overview

Predicting crime is a necessary condition for its prevention, and crime is most predictable along those dimensions in which it is concentrated. The most established forms of crime's tendency to concentrate or cluster are repeat offending, repeat victimization, and geographical hot spots, with complementary concepts including supertargets, hot products, hot places, hot targets, risky facilities, risky routes, and crime sprees and spates. This entry charts the relationship between such clusters, observing how a broad conception of "near repeats," incorporating crimes with similar situations and characteristics, is a useful unifying concept. Metrics of nearness, or conversely the difference between crime events, may inform efforts to understand and disperse crime clusters. The theories of repeat victimization and hot spots are shown to be overlapping and compatible and suggest a unified theory of clusters should result from greater conceptual integration in this field. The overall aim of such integration should be to inform cluster-busting crime prevention efforts.

Definitions and Concepts

In what follows the term "crime clusters" is used to refer to crime's tendency to concentrate in time, space, and other dimensions along which it is measured. A range of related concepts and terms has emerged. *Repeat victimization* can be thought of as crime against the same target, however defined. That can be the same person, household, business, vehicle, place, or other target. Crime follows crime such that a small proportion of targets and places experience a vastly disproportionate amount. One study found that 1 % of people experience 59 % of personal crime including violence and that 2 % of households experience 41 % of property crime (Pease 1998). This is largely responsible for spatial clustering wherein a small percentage of *hot spot* locations accounted for a significant proportion of all calls for police service (Sherman et al. 1989; Andresen and Malleson 2011). The most chronically victimized targets are termed *supertargets*, with many studies finding two or so percent of potential targets and locations accounting for around half or more of crime. Hot spots may or may not be synonymous with *high-crime areas*, depending on geographical scales, which are also disproportionately composed of repeats.

A common feature of retail crime and personal theft is the *hot product*. These are typically high-value portable electronic goods including – at the time of writing – smartphones, laptops, and SatNav-GPS systems, or low-value items easy to dispose of to unscrupulous retail outlets, such as razor blades or cosmetics. Locations which host crimes of the same type – for example, if pharmacies suffer more robberies than other stores – have been termed *hot targets* (Velasco and Boba 2000), and those hosting multiple crimes of the same and different types have been explored as *hot places* (Block and Block 1994), *crime generators* and *crime attractors* (Brantingham and Brantingham 1995), and *risky facilities* (Eck et al. 2007). This can include bars, retail establishments, and land use of different types. Banks are risky facilities with, crucially for the present discussion, some chains and some branches experiencing many repeat robberies, and a few schools are victimized far more than others (Lindstrom 1997).

Crime is common for passengers on some bus routes (Tompson et al. 2009). The term "hot routes" is used in the urban planning literature to refer to roads with high traffic flow (Li et al. 2007), so perhaps *risky routes* distinguishes those with disproportionate crime. The *risky professions* tend to be those that provide care or services to the public such as nurses, customer services staff, and emergency services staff. Some taxi drivers are unusually likely to be robbed (Smith 2005), while firefighters, police, and paramedics often find themselves in the firing line. Within those professions, crime is concentrated on a small percentage of oft victimized staff who experience a lot of the crime. One study of police officers found that around half were assaulted but 3.5 % experienced a quarter of all assaults – likely a conservative estimate. But such statements can be frustratingly unnuanced, in that one needs to know, within the general observation, the times, circumstances, and personalities around which events cluster.

Evolving from work on repeat victimization, the term *near repeats* (Morgan 2001) is used to refer to similar crimes occurring a short time and distance from an earlier crime. The phrase near repeats has mostly been used as synonymous with spatiotemporal proximity. Neighboring and nearby households are more likely to be victimized after a break-in (Townsley et al. 2003; Johnson et al. 2007a, b). Ratcliffe and Rengert (2008) found repeat shootings in Philadelphia were more likely within a city block and two weeks. To return to an earlier issue, repeats and near repeats suggest why crime clusters spatially. Levy and Tartaro note:

> In 1996, repeat locations became known as hot dots (Pease & Laycock, 1996; Townsley, Homel, & Chaseling, 2000). "Hot dots" are locations within a hot spot that are known to have a high incidence of victimization – a repeat victimization location. (Levy and Tartaro 2010, p. 300)

Studying car theft, Levy and Tartaro use the concept of repeat victimization locations as a useful way of examining a combination of repeats and near repeats, hot dots and hot spots:

> Repeat victimization locations are defined as any street segment on which more than one auto theft occurred during the study period. In Atlantic City the average length of a city block is approximately 150 ft. (Levy and Tartaro 2010, pp. 304–305)

The same offenders are more likely to be those committing repeats, and such returners are more likely to be prolific (Everson 2003). This implies that a crime *spree* (from the offender's perspective) or crime *spate* (from the victim's perspective), typically defined as more than two similar crimes in a short time period, is usually composed of quick and near repeats. The conceptualization of near repeats is developed further later in this entry.

Most of the clustering concepts referred to so far relate to crime recurring over relatively short periods of time. Yet crime is also common against certain targets over a longer period. Averdijk (2010) explored the area of victimization over the life course, or "victim careers," identifying a clear need for further research. Similar terminology had previously been developed in relation to the criminal careers of places (see chapters in Eck and Weisburd 1995). In a similar vein, the onset, frequency, duration, and decline in the criminal careers of stolen products have been explored (Mailley et al. 2008). The trajectory of a product theft career depends on the extent to which it is *craved*, that is, the extent to which it is concealable, removable, available, valuable, enjoyable, and disposable (Clarke 1999; Wellsmith and Burrell 2005). Heavy valueless items have little if any theft career.

Hence, the study of crime clusters, concentration, or repeats has evolved on a piecemeal basis.

One result is the diverse lexicon of sometimes overlapping terms and concepts described so far. Naming specific clusters is useful because it provides the handles with which to grasp how crime against certain targets, times, and places can be predicted and thereby prevented. Yet it is clear that there are many common threads emerging that are naturally leading the field toward increased conceptual and theoretical integration, and the bulk of the remainder of this entry outlines how this is occurring.

Near Repeats as a Broad Inclusive Concept

The concept of near repeats has been discussed so far as referring primarily to *spatial* and *temporal* proximity. However, the concept of nearness can be applied more widely. Spatial proximity is perhaps the easiest form of nearness of which to conceive, but a crime may also be a near repeat in terms of any quantifiable characteristic or combination of quantifiable characteristics. Quantification here includes classification. For example, hot product theft is a form of near repeat along the dimension of product similarity. Drive offs from service stations may reveal a form of near repeat in terms of forecourt layout or oil company concerns. A few professions are disproportionately targeted, and within those a few individuals with common characteristics (such as the particular population or area they serve) may be disproportionately victimized. Linking profession and time of victimization yields, for example, insights about the victimization of emergency room nurses in the late evening. Near repeats may be inferred from similarities between types of recreational establishment or location, staffing levels, and client surveillability. Route characteristics in public transport will reveal forms of near repeat either directly or in interaction with time of day and day of week.

Two further points about the near repeats terminology are warranted. First, near repeat provides a useful and distinct term because it embodies the *mechanism* by which crime is patterned, namely, their nearness along at least one dimension. Nearness may vary, and there are degrees of nearness because some crimes are more similar than others, an issue returned to later. However, a broad concept of near repeats includes a range of types of crime cluster where similarity between event, participants, and contexts is key. Second, it could be suggested that terms such as “hot” or “risky” are equally good as near repeats. They are catchy terms and this can be a surprisingly important component of academic concepts and theories – think of Buckyballs or of chaos theory, the latter of which was frequently contested (because the name inaccurately represents the field) until its popularity brought credibility. However, unlike the term near repeats, they do not embody the notion of why repetition occurs. Near repeats seems a preferable general term because it embodies the notion of similarity and difference between crimes across any dimension or combination of dimensions. This is critical because it is similarity that defines all forms of crime cluster. Defining how concentration is distinguished from a non-concentration of crime is avoided here, but a simple definition as a rule of thumb would be two standard deviations from the mean.

One way of thinking about the distinctiveness of near repeats is to consider it as a reflection of offender targeting practices, summed across offenders. Target selection will, in the aggregate, be represented in the pattern of near repeats. Locally, departures from the aggregate pattern will reflect the signature of prolific individuals.

Mapping the Relationships

This section describes the matrix of crime clusters shown as Table 1 which builds on Farrell (2005) and Farrell and Pease (2008). Following routine activity theory, the columns relate to targets, locations, or offenders. The rows denote four dimensions along which individual crimes cluster, described further below: spatial unit, time, crime type, and modus operandi. The matrix is a heuristic device that allows different types of crime cluster to be viewed simultaneously in terms of their key characteristics,

Prediction and Crime Clusters, Table 1 Matrix of crime clusters

	Target	Location	Offender
Spatial repeat	Same target in same or nearby place. *Hot dots*	Near repeat at same/nearby place (not necessarily same offender or crime type). Includes *repeat victimization locations*, *attractors*, *generators*, *hot smudges and hot spots*, *risky facilities*, *risky routes*	Same offender reoffending at same/similar place (not necessarily same crime type). Linked to *repeat offending*
Temporal repeat	Quick repeat against same target, e.g., much domestic violence; *risky professions*. Longer term: *victim careers*	Quick repeat at same or nearby place (not necessarily same offender), e.g., looting of a prone store. Longer term: *criminal careers of places*	Quick repeat by same offender (not necessarily same crime type or place) – a *spree* or *spate*. Longer term: *criminal careers*
Crime-type repeat	Same crime type against same targets, e.g., robbery in same location	The same crime type in the same or similar place, e.g., continued drug dealing in local area	Same offender commits same crime type, e.g., identity theft from different persons. Linked to *serial offending* and *offence specialization*
Tactical repeat	*Virtual repeat* using same tactic (modus operandi) leads to *hot products*	Same tactic facilitated by same place, e.g., theft and pickpocket at a street market	Repeat offending using same *modus operandi*; linked to *offence specialization*

though of course it is a simplification of reality because in practice many of the cells overlap and some of the possible characterizations of near repeat clusters are excluded.

The first column of Table 1 identifies crime against the same or similar (including perceived similar) targets. Such crime may be in the same or a nearby place, but not all repeat targets are spatially alike: Consider a victim who is robbed, harassed, and assaulted at different places, perhaps on the basis of ethnicity, sexual orientation, ostentatious wealth, or perceived vulnerability. The cell in the second row of the first column identifies the role of time. Many repeats and near repeats occur quickly, particularly when committed by the same offenders. Continuing down the first column, many repeats are of the same crime type. The row for tactic or modus operandi identifies the fact that crime is often repeated using the same method, particular quick repeats of the same crime type by the same offender, as when a burglar reenters a home through the same rear patio door.

In practice, crime is usually common along many dimensions. The limiting case here is crime against the same target in the same place shortly after the previous crime and committed by the same offender using the same tools and tactics. In many instances, however, nearness is greater in some dimensions than others. Crimes concentrated upon the same victims and product types but not necessarily temporally concentrated have been noted already in the context of the criminal careers of places, victims, and products.

Just as the definition of target was broad, the second column of Table 1 defines repeats at the same location, one nearby or with similar characteristics. The term location or place is scalable. It could cover a region, a country, city, neighborhood, building, apartment, street corner or intersection, or other precise geographical or virtual coordinate. Consequently, the intersection with spatial repeats (the top cell in the second column) reflects the importance of possible variation in spatial unit. A street or neighborhood which hosts a cluster of burglaries, or a shopping mall suffering a cluster of robberies, may be the same location for many crime reduction purposes.

Within those locations, however, there are specific targets where crime is repeated – particular houses, retail outlets, street corners, or alleyways. Levy and Tartaro are worth quoting at length in relation to unit of analysis:

> Other aspects of the event should be studied to better understand the repeat victimization phenomenon. One such concept is the "unit of analysis" for the initial criminal event. As the unit of analysis changes, the way in which police and researchers view the crime may also change. Using auto theft as an example, if the unit of analysis is the car, and the car is stolen and dismantled, there is no chance of that car being stolen again. However, if the unit of analysis is the location from which the car is stolen, the fate of the first car has little to do with whether another car could be stolen from that lot. In this situation, there is a chance for repeat victimization, another car could be stolen from that lot and the lot would then be victimized twice. Similarly, the location may be repeatedly victimized, but the owner may not be. If the location is a parking lot, many cars can be stolen from the lot, but they may not belong to the same owner. An owner can be yet another type of repeat victim. The owner could have a different car stolen at different points in time, from the same or different locations. Though the same car has not been victimized again, the owner has still been victimized repeatedly. (Levy and Tartaro 2010, p. 301)

It may be necessary to consider other unit types for analysis. The recommended practice for police seeking to prevent repeat victimization has long been to use that unit of analysis which worked best to facilitate prevention, although that may be easier with hindsight.

It is also necessary to consider the composition and nature of exact and near repeats, as these may inform how crime prevention resources are best allocated. Hence, Table 1 includes concepts relating to attractors and generators, hot spots, and risky facilities. Spatially defined repeats may also vary in the time to repetition, in the type of crime and the modus operandi, or some combination of these relating to the criminal career of the place.

Column three of Table 1 refers to repeats by the same offenders. Progressing down the column, these may be at the same or a similar location, may recur quickly, and may be the same type of offence committed by the same tactic. The same offender committing further crimes shortly afterward could result in a *spree* or *spate*, usually defined as more than two crimes in quick succession, and which may or may not involve the same crime types and tactics. However, crimes of the same type may be indicative of offence specialization. It should be noted that using offender characteristics to identify commonality is only possible after detection. The more usual causal direction involves taking event characteristics to suggest likely offenders.

The matrix provides an overview of a few of the key dimensions of the various clusters and helps clarify their relationships. Since patterning is a necessary condition of nonrandom prediction, the matrix may well provide information and insight that assists in the development of cluster-busting preventive responses.

Measuring the Relationships

In offender profiling, behavioral linkage analysis (BHA) seeks to determine whether, in the absence of physical evidence, unsolved crimes were committed by the same serial offender. For example, with a burglary where there is no DNA or other evidence, the behavioral characteristics of the crime (e.g., type of property targeted, means of access and egress, type of items stolen, the presence of gratuitous mess) are used to develop a behavioral profile. The characteristics of different crimes can then be compared to determine, within parameters, whether they may plausibly have been committed by the same offender. There are multiple comparison techniques which use metrics of the goodness of a match between case characteristics. Some crimes are more similar than others. Two of the more prominent measures are Jaccard's similarity coefficient and the taxonomic similarity index. Thus, behavioral linkage analysis has been used to determine whether, in the absence of physical evidence, unsolved crimes were committed by the same offender, based on across-crime similarity coefficients (Melnyk et al. 2010).

BHA is predicated on two assumptions (Canter 2004). The first is behavioral stability – the assumption that offenders are reasonably consistent in their offending so that a series of their crimes has common characteristics. The second is behavioral distinctiveness – the notion that each offender's crime series embodies particular characteristics that effectively serve as their behavioral signature.

The application of linkage analysis and similarity coefficients to a crime *event* profiling, rather than *offender* profiling, sits well with evolving approaches to crime cluster analysis. Crime clusters can be linked by factors other than the offender. They have other similar characteristics and similar underlying causal mechanisms relating to the opportunity structure (e.g., the characteristics of frequently stolen products). Crime event linkage analysis is thus predicated on the supposition that similarity across crimes is a key factor underpinning clusters of crime irrespective of the dimensions across which common features are held. The orientation of such analysis should be to inform crime understanding and consequent prevention efforts. That could involve the detection of serial offenders but seems more likely to involve designing out crime.

Most concepts relating to crime clusters hinge on the similarity between criminal events. This can be gauged via an index of similarity. Consider how crimes differ. One crime is only perfectly identical to itself. Thus, "identical" is the theoretic maximum level of commonality. Two entirely unrelated crimes of, say, different types in different countries and eras are in effect completely dissimilar (other than that they both involve human behavior and breach of a criminal code). This theoretically maximum difference defines the theoretically minimum level of similarity. All other criminal events lie on a spectrum somewhere in-between.

Quick repeat burglaries by the same offender against the same household are very similar crimes, as is repeated domestic violence involving the same partners, household, and situation. They are sufficiently similar to have been termed "exact" repeats (Summers 2010), differing primarily in time of occurrence. Likewise, simultaneous attacks on two computer networks by the same hacker using the same modus operandi differ primarily in the geographical location of the target. Hence, they are also exact repeats insofar as they differ primarily in one dimension (of course, the violence may result in different injuries, and different goods may be stolen in repeat burglaries, but they are assumed similar for present purposes).

One step further away is a spatially near repeat burglary of a neighboring household shortly after a burglary. This differs in two elements – time and target – from the prior burglary, although only by a relatively small amount in each case. Other forms of crime commonality are typically very similar or "near" in relation to other characteristics. Frequently stolen hot products such as some types of smartphones, laptops, and GPS-SatNavs may be stolen by the same offenders using the same modus operandi (such as sneak theft) but differ in terms of time and place. Racist attacks against members of the same ethnic group by the same perpetrator have different specific targets. However such targets are similar in key characteristics whether that is portability and high resale value or perceived ethnicity. For present purposes, the target is the same and they are forms of near repeat victimization. Whereas the near repeat burglary was defined by spatial proximity, the near repeat theft or assault is defined by the nearness of interchangeability of the target. That is, as noted earlier, the concept of "nearness" is not confined to the spatial and temporal variables. Here the broad inclusive definition of near repeats is important because it demonstrates that it is the degree of similarity between crimes that is the key to crime clusters. For present purposes, spatially near repeat burglaries might be considered equally similar as the targeting of hot products which are near repeat thefts. A hot spot has crimes that are similar in spatial terms but perhaps in little else. This means a hot spot warrants closer scrutiny to determine if it is composed of repeat victimization of the same target or victimization of different targets and crime types. The important point, however, is the following: Similarity is the key to prediction and informed crime prevention. The greater the commonality across crimes, the potentially more informed the response and the greater the preventive scope. The predictability of a repeat crime depends on the type of crime and the context. Hence, quick repeats of the same crime type against the same target, by the same offenders using the same tactic, present the greatest potential for crime prevention. Such precise repeats should be easiest to prevent because the maximum amount of information is available. Other forms of crime commonality are derivatives with less similarity or, conversely, a higher index of dissimilarity.

The appropriate terminology is likely to be that of *difference* rather than similarity. Difference might be preferred when metrics are developed because it allows lower values to refer to more similar crimes – that is, it is more appropriate to refer to a *low* difference score. Similar indices exist in various fields including the Hamming distance, and the Sorensen Index and various metrics for DNA fingerprint matches. Critical elements of crime event similarity are the *target*, the *location*, the *time*, the crime *type*, the *modus operandi*, and the *offender*. Measures of the extent of difference *within* each variable require more sophisticated indices. However, there is a likely benefit to simplicity in a crime event difference index as it would be useful primarily to the extent it served as a heuristic device for crime prevention.

Toward a Crime Cluster Theory

Theories of repeat victimization and hot spots emerged around the same time and from a similar epidemiological tradition. As key areas of crime commonality where theory is established, if they prove compatible, then this may provide a platform for further integration of both theory and crime control practice. Hence, while recognizing the need for a wider repertoire of variables to be considered in understanding crime patterns, this section of the entry reverts to the more familiar ones because they are the most established and readily comprehended.

Cohen and Felson, in the landmark study that developed routine activity theory, anticipated more recent theories of crime clustering when they noted

> [T]he effects of the convergence in time and space of these elements [suitable targets, likely offenders, and the absence of capable guardianship] may be multiplicative rather than additive. That is, their convergence by a fixed percentage may produce increases in crime rates far greater than that fixed percentage. (Cohen and Felson 1979, p. 604)

There are two main theories of hot spots. These are embodied in the concepts of crime attractors and generators. Generators are places with high flows of people which yield spatial concentrations of crime, even though one crime may be no more related to another than elsewhere. Attractors are places that gain a reputation for crime and thereby attract likely offenders. The same place can be a generator and an attractor, because a generator is likely to attract would-be offenders due to the rich supply of possible targets. Brantingham and Brantingham (1995, pp. 7–8) observe that

> Crime generators are particular areas to which large numbers of people are attracted for reasons unrelated to any particular level of criminal motivation they might have or to any particular crime they might end up committing. Typical examples might include shopping precincts; entertainment districts; office concentrations; or sports stadiums. . . . Crime generators produce crime by creating particular times and places that provide appropriate concentrations of people and other targets (Angel, 1968) in settings that are conducive to particular types of criminal acts. Mixed into the people gathered at generator locations are some potential offenders with sufficient general levels of criminal motivation that although they did not come to the area with the explicit intent of doing a crime, they notice and exploit criminal opportunities as presented (either immediately or on a subsequent occasion).

There is much in common here with Cohen and Felson's notion of multiplicative interaction effects. Further, the Brantinghams state that

> Crime attractors are particular places, areas, neighbourhoods, districts which create well-known criminal opportunities to which strongly motivated, intending criminal offenders are attracted because of the known opportunities for particular types of crime. Examples might include bar districts; prostitution areas; drug markets; large shopping malls, particularly those near major public transit exchanges; large, insecure parking lots in business or commercial areas. The intending offender goes to rough bars looking for fights or other kinds of 'action.'

These definitions are consistent with those in the more recent work of Kinney et al. (2008). With respect to repeat victimization, Farrell and Pease (1993, p. 13) offered three theories. The first is that

> It is possible that a first victimisation does not increase the probability of repeat victimisation, but merely flags the high prior probability of victimisation, which is attested again by its suffering a repeat burglary.

which has become known as the risk heterogeneity or flag theory. The second is that

> The same offenders may return to take things they had forgotten the first time, or for which they now have fencing opportunities. Since they know house layout and exit points, problems are less numerous than for the first offence.

which has become known as the event dependency or boost theory. A successful crime boosts the chances of repetition, so that, for example, bank robbers who escape with a good haul are more likely to return to the same bank branch. The third theory is that

> The offenders on the first occasion may tell others of the remaining goods, and those whom they tell return to commit offences.

which could be termed the buddy theory. Drawing upon this work, a theory of the relationship between repeat victimization and high-crime areas was proposed independently to the work on attractors and generators but which also drew on Cohen and Felson's (1979) notion of multiplicative interactions. The theoretical model draws on routine activity and has three principal steps. The first observes that linear increases in interactions between suitable targets, potential offenders, and conducive environments (the absence of guardianship) produce nonlinear increases in crime, the effect on repeat victimization depending upon the specifics of the respective changes. Thus, this interactor is similar to a crime generator. The second step adds a contagion or boost component wherein victimized targets have a heightened risk of experiencing further crime. Such risk is known to increase with each victimization so that a small proportion of targets progress to become chronically victimized supertargets. This explains why repeat victimization accounts disproportionately for crime in high-crime areas as found elsewhere (Johnson et al. 1997). The interactor-contagion model was developed in Farrell et al. (1994, 2005).

The interactor-contagion model offers a stepping-stone from repeat victimization to hot spots. Some hot spots are defined solely in terms of repeat victimization. Others include multiple targets that may or may not be repeatedly victimized. The mechanism that underlies generators is common to these theoretical perspectives. The interactor-contagion model incorporates increases in targets and suitable environments plus the same offenders returning, in addition to the increase in likely offenders that is the characteristic of attractors.

This brief review suggests theories of repeat victimization, and hot spots are compatible and to a large extent already integrated, at least implicitly, though differences in terminology and emphasis mean this not always obvious. Interactor-generator notions are common to both. Statistically, these result in a random chance or Poisson distribution of victimization across targets in the absence of a boost or attractor effect, and this has been a mainstay of research on repeat victimization since Sparks et al. (1977). Boosts, buddies, and attractors offer similar but distinct explanatory mechanisms. Boost denotes increased likelihood of *the same* offenders returning, buddies denotes increased likelihood of criminal *associates* returning, while attractors denote increased likelihood of *other* offenders returning.

The links between the theories bodes well for integration of theory and concepts relating to crime clusters. It seems that perhaps crime concentration of all types take place by the same basic mechanisms. Hence, a unified theory of crime clusters would include flags, interactor-generators, boosters, buddies, and attractors. Such a theory appears to account for changes in the number and interactions of suitable targets, suitable environments, and likely offenders, and thereby for variation in both individual and area-level risk. It might be applied more universally across clusters so that, for example, hot products flag their attractiveness and are found more frequently at interactor-generators, with their theft producing boost, buddy, and attractor effects.

Conclusion

Crime clusters are central to prediction, and absent prediction there is no prevention. The term clusters was used as a shorthand for, or stepping-stone to, a broad definition of near repeats incorporating the various dimensions and types of crime commonality and concentration.

A diverse set of crime clusters and commonality was reviewed, and crime event difference indices may assist in the exploration of how similarity, or nearness, is key to crime's clustering in all its forms. A comparison of the theories of key crime clusters showed them to be overlapping and compatible and suggests that the unification of theory in this area may promote cluster-busting crime prevention practice.

Forecasting crime or crime forecasting

Overview

Predictive policing is a new concept for law enforcement in the twenty-first century. While still in its infancy and relatively untested, predictive policing has the potential to change the way in which law enforcement deals with crime and victims. This entry describes predictive policing in terms of its definition and roots, the theories and models that have been developed, applications in law enforcement, and the issues that surround it.

Conceptually, predictive policing involves the use of data and predictive analytics to predict or forecast where and when the next crime or series of crimes will take place. The concept has engendered new terminology in law enforcement. “Predictive analytics,” “data mining,” “nonobvious relationships,” and “predictive spatial analysis” are among the new phrases used by chief executives, policy makers, and researchers to describe aspects of predictive policing. These and other phrases will be described and discussed.

Definition

Bill Bratton et al. (2009) initially defined predictive policing as “any policing strategy or tactic that develops and uses information and advanced analysis to inform forward-thinking crime prevention.” The Los Angeles Police Department and Uchida (2009) refined the definition and said, predictive policing is a “multi-disciplinary, law enforcement-based strategy that brings together advanced technologies, criminological theory, predictive analysis, and tactical operations that ultimately lead to results and outcomes – crime reduction, management efficiency, and safer communities.” Other definitions have emerged as well. Pearsall (2009) sees predictive policing as a “generic term for any crime fighting approach that includes a reliance on information technology (usually crime mapping data and analysis), criminology theory, predictive algorithms, and the use of data to improve crime suppression on the streets.” The National

Institute of Justice's Geospatial Technical Working Group (Wilson et al. 2009) broadly discussed predictive policing as including risk-based assessments, problem solving, crime prevention, and "as a strategy by which uncertainties are minimized and expectations are maximized."

Fundamentals

Using the LAPD/Uchida definition (Uchida 2009), predictive policing is built on multiple pillars including advanced technologies and analytics from the business world, statistical forecasting, criminological theory, and tactics and operations that are based on problem-oriented, intelligence-led, and hot spot policing. Understanding each of these components and how they converge into predictive policing is the central focus of this entry.

Advanced Technologies and Analytics: Business Intelligence

Predictive policing is based in part on business intelligence models and data analysis tools used by retailers like Wal-Mart and Amazon, insurance companies, or credit card companies like American Express. Netflix uses predictive analytics and data mining as the basis for its business model. They establish their regional centers, manage their inventory, and market their services based on the predicted behaviors of its customers.

In sports, baseball statisticians developed models and use analytics to predict performance. The Society for American Baseball Research (SABR) founded by Bill James in 1977 includes members who use different statistical models to predict or forecast the performance of individual ballplayers and teams. Though largely ignored by Major League Baseball executives for almost 25 years, sabermetricians became popular when Oakland A's general manager Billy Beane successfully showed the value of data and analytics to propel the A's to division championships in 2002 and 2003. Beane's story was chronicled in *Moneyball* (Lewis 2004). As a result of Beane's success, every baseball team now uses some form of statistical analysis to measure performance.

Other sports-related enterprises have followed this trend in using statistics and predictive algorithms. The New England Patriots of the National Football League was one of the first football teams to use analytics to evaluate college players and the Leicester Tigers in the United Kingdom, a two-time European champion in rugby, uses predictive tools to reduce injuries.

The commonalities of these diverse businesses are their use of data mining and predictive analytics. Data mining entails the analysis of data to identify trends, patterns, or relationships among the data. Basically, data mining is about "practical application – application of the algorithms developed by researchers in artificial intelligence, machine learning, computer science, and statistics" (Williams 2011).

Data mining includes the development of a predictive model. For example, Wal-Mart relied upon data from its supply chain to predict future demand. Analysts mined data seeking relationships between weather patterns and customer needs. They found that in anticipation of a large weather event like a hurricane or tropical storm, products like duct tape, bottled water, plywood, and Pop-Tarts are sent to an affected area. While water, tape, and plywood are typical necessities, Pop-Tarts (specifically strawberry ones) were discovered through data mining techniques and serve as an example of a "non-obvious relationship" (Beck and McCue 2009).

Predictive analytics is a fairly broad phrase that describes a variety of statistical and analytical techniques used to develop models for prediction. The form of these predictive models varies, depending on the behavior or event that is being predicted. Most predictive models generate a score, with a higher score indicating a higher likelihood of the given event occurring. Predictive analytics rely on increasingly sophisticated statistical methods, including multivariate analyses like time series and advanced regression models. These techniques enable the analyst to determine trends and relationships that may not be readily apparent or are "nonobvious" relationships.

Criminological Research and Theory

Criminologists have applied forecasting and predictive methods for nearly a hundred years. Berk (2008) notes that research on crime trends in the nineteenth century paved the way for explicit forecasts on both aggregate patterns of crime and on the behavior of individuals. As data and statistical tools have improved over time, a wide variety of work on forecasting and prediction have occurred. He cites 18 examples of forecasting studies between 1928 and 2007 (Berk 2008: 221), many of which forecast behavior of offenders after they have been released from prison and those that forecast prison populations. He cautions that many of the studies were not successful in accurately predicting behavior or crime and that the forecasts have not been properly evaluated.

In addition to Berk's examination of forecasts, the subtext for predictive policing lies within a number of macro-level, quantitative criminological research studies, including those that use repeat victimization, social disorganization, collective efficacy, strain, economic deprivation, routine activity, deterrence or rational choice, social support, and subcultural theories. These theories use "predictor variables" to forecast and predict crime locations and victims.

The theory of repeat victimization posits that for every type of crime studied (with the exception of homicide), the risk of victimization increases following an initial event, that a small proportion of victims accounts for a large proportion of crime, and where repeat victimizations occur, they usually do so within a brief period of time, allowing for a small window of opportunity for intervention (Johnson et al. 2009).

Theories of social disorganization and collective efficacy are also relevant in identifying and predicting where crime may flourish or not. Sociological literature over the last 30 years establishes the relationship between community characteristics and problem behavior. Areas characterized by high levels of economic disadvantage have long been associated with crime and other forms of disorder. Bursik and Grasmick (1993) argued that concentrated disadvantage and other neighborhood-level indicators of social disorganization create conditions that hamper the development of meaningful pro-social institutions to flourish. Institutions such as schools, churches, formal/informal community groups play an important role in regulating behavior among its residents. Sampson and Groves (1989) found that disorganized neighborhoods were also characterized by low organizational participation, sparse friendship networks, and large numbers of unsupervised youth. Neighborhoods with the most extreme forms of social disorganization also tended to experience greatly reduced levels of collective efficacy. Collective efficacy, which relates to the capacity of residents and other groups to exert levels of social control, has important implications for how neighborhoods are informally managed by residents. Research shows that neighborhoods with higher levels of collective efficacy generally experience lower levels of violence. With poor community organization, the capacity of the communities to develop formal and informal mechanisms of legal social control was diminished. From these findings, one can predict that violent crime may be higher in areas of low collective efficacy and lower in areas of high collective efficacy.

Other criminological theories can be applied to predictive policing models. Environmental criminology, which includes routine activity, rational choice, and situational crime prevention, is the broad, general approach that is most germane. Routine activity theory explains the components of a criminal incident by breaking it down to three basic elements: (1) a likely offender, (2) a suitable target, and (3) the absence of a capable guardian. It is only when these three elements converge in time and space that a crime occurs (Cohen and Felson 1979). This perspective established the spatial and temporal context of criminal events as an important focus of study.

Situational crime prevention involves crime prevention strategies that are aimed at reducing the criminal opportunities that arise from the routines of everyday life. Situational crime prevention assumes that crime is a rational choice by offenders and that crime can be prevented by hardening targets to increase the risks and reduce the rewards. British scholars, led by Ronald Clarke, explored the practical application of this theory in the United Kingdom. They saw that "opportunity" was at the core of crime, and rather than trying to reform offenders, they sought to reduce the criminal opportunities available to the criminal. Thus, they sought to change the environment through target hardening, improving surveillance of areas that might attract crime, and deflecting potential offenders from settings in which crimes might occur.

Criminological theory is important in predictive policing – because it assists in determining the appropriate unit of analysis for prediction, guides the specification of the predictive algorithms, and determines the measures of an intervention or tactic employed by the police.

Problem-Oriented, Intelligence-Led, and Hotspot Policing

Predictive policing is tied directly to principles, research findings, and tactics and operations established in problem-oriented, intelligence-led, and hot spot policing. Central to the notion of problem-oriented policing is the idea that police agencies need to become proactive rather than reactive, moving away from simply reacting to citizen calls-for-service, and moving toward identifying and solving the problems that generate excessive calls (Goldstein 1990). For example, research in Minneapolis showed that only 3.3 % of addresses and intersections were responsible for 50.4 % of all calls for which a police car was dispatched (Sherman et al. 1989). Solving the chronic, recurring problems underlying these "hot spots" might reduce crime, fear of crime, and calls-for-service, and improve police-community relations. While spatial proximity is one of the ways that individual incidents or calls to the police can be grouped into larger problem types, there are many others. For instance, police might group individual incidents together into larger problem types based on similarities in victim characteristics, offender characteristics, modus operandi, or temporal patterns.

Likewise, hot spot policing implicitly and directly includes predictive components. Weisburd's notion of "the law of crime concentrations at places" refers to research that shows "irrespective … of the city, or even country examined, … 20 to 25 % of crime is found at only 1 % of the places in a city" (Weisburd 2012). By extension and implication, these are "predictable" locations.

Intelligence-led policing is also closely associated with predictive and problem-oriented policing because they all fit into the community-oriented policing paradigm. Ratcliffe defines intelligence-led policing as "a business model and managerial philosophy where data analysis and crime intelligence are pivotal to an objective, decision-making framework that facilitates crime and problem reduction, disruption and prevention through both strategic management and effective enforcement strategies that target prolific and serious offenders" (Radcliffe 2008).

Predictive Models

A number of models currently exist for predicting crime within the geography of crime literature (Groff and La Vigne 2002) and in texts and articles on statistical and mathematical methods (Berk 2008, 2009; Williams 2011). Prediction models may use a variety of regression models, including linear regression (OLS), partial and stepwise regression, logit or probit regressions, and regression splines. Regression models describe the relationship between the dependent variable (in predictive situations, the variable to be predicted) and independent, explanatory variables. Regression implies some causation and then tests how well the regression model fits the specified relationship. However, the statistical techniques used in predictive analytics are largely untested and have not been rigorously evaluated.

Geography of Crime

Geographic information systems (GISs) have been used to develop models for forecasting and predicting crime. Over the past decade, these models vary from simple to complex. The simplest forecasting method is common to Compstat, where the hot spots of last week or last month are the hot spots of next week or next month. Crime analysts prepare maps of crime that have already occurred and those maps are used to determine where to deploy officers and where to intervene. Other methods include the use of raster GIS, a method included in ArcView's Spatial Analyst that interpolates a surface of crime and looks similar to a weather map.

Risk Terrain Modeling (Caplan et al. 2011) uses multiple layers of raster maps relying on the "dynamic interaction between social, physical and behavioral factors that occurs at places." Risk Terrain Modeling (RTM) will identify particular risk factors for crime. The model will assign a value to every place within a specific geographic area and will signify the presence, absence, or intensity of each risk factor. When multiple layers are combined into a risk terrain map, it provides a composite risk value to particular places. The higher the risk value, the greater the likelihood of a crime occurring at that location. RTM has been applied to shootings, violent crimes, and burglaries in Newark and Philadelphia (Caplan et al. 2011).

Another example of predictive mapping is ProMap, a prospective mathematical model that predicts where burglaries would next occur. Using repeat victimization theory, Johnson et al. (2009) determined that specific grid locations were predicted to have the greatest imminent risk where the greatest number of burglaries clustered in time and space both recently and nearby. The researchers theorized that risk of burglaries diminished over time and used a short time period of 1 week for their temporal interval. They compared the predictive ability of ProMap to two methods – Kernel Density Estimation (KDE) and to maps generated by analysts using police beat geography and data from Merseyside, UK. The ProMap model consistently performed better than the KDE method in identifying 10 %, 25 %, 50 %, and 75 % of burglaries. The mapping approach used by analysts was worse than the KDE method as it "failed to exceed chance for almost very trial" (Johnson et al. 2009).

Swatt (2003) attempted forecasts of burglary and robbery in Omaha on a monthly basis for Census blocks using a Hierarchical Linear Model framework. He found that overdispersed models were overwhelmed by the large number of zero event counts and thus could not accurately forecast either crime. Gorr and Olligschlaeger (2002) compared simple univariate, OLS regression, and neural networks strategies for forecasting calls-for-service in Pittsburgh. Their results did not convincingly demonstrate an advantage for the neural network method. Brown and Kerchner (2000) developed a methodology for forecasting criminal events based on the "feature space" of offender site selection, a set of spatial, temporal, and site characteristics that influence an offender's decision to engage in crime. This strategy, as well as the strategy outlined by Liu and Brown (2000), outperformed a simple model for predicting breaking and entering, with only limited improvement for auto theft. Recently, Fox and colleagues (2012) have extended this model by incorporating it within a Hierarchical Bayesian Model to introduce spatial and temporal effects. Their results suggest that although the extended model outperforms the original Brown and Kercher (2000) strategy for predicting short-term variation in assaults at the Census block group level, the added computation time limits the applicability of this strategy.

Statistical Learning Models

"Statistical learning" includes methods that experiment with many different models for data. Statistical learning has a strong focus on data mining and machine learning traditions of data analysis. In describing the use of statistical learning, Berk (2008) begins with regression splines and moves to other models, particularly those that make use of decision trees or classification and regression trees (CARTs). Decision trees or CARTs are the building blocks of data mining. Statisticians have found that using one decision tree model is overly simplistic, so combining multiple models into a single ensemble of models – a forest of trees – works better in prediction (Williams 2011). "Bagging," "boosting," and "random forests" are among the algorithms used within statistical learning methods that have been developed for predicting and forecasting.

The random forest algorithm holds substantial promise as a method of forecasting crime using statistical learning. The random forest algorithm is an extension of the decision tree or CART method. The random forest algorithm (see Berk 2008 and Williams 2011) grows a large number of decision trees using samples (500 or more, Berk 2008) from a database. At each stage in CART, a random sample of predictors is used (this is referred to as "bagging," as a random sample of observations is placed in a "bag"). After the trees are formed, classifications are found by majority vote across trees where the case in question was in the bagged data. In other words, in CART, each tree will develop its own predictive value. When there are 500 trees in a random forest, the majority of trees will determine the prediction. If 300 of 500 trees predict that a crime will occur at a location tomorrow, then it is expected that there is a high likelihood (60 %) that the crime will occur at the location.

The random forest algorithm appears to offer a number of advantages over other methods. First, data do not need to be preprocessed or normalized for use. For example, outliers (defined as extreme deviations in the data) do not need to be expunged or normalized. Second, if there are many input variables, specific selection of those variables does not need to take place because the random forest model targets the most useful variables. Third, "overfitting" of data (when a statistical model describes random error or noise instead of the underlying relationship) is less of a problem because classifications are averaged across a large number of trees (Berk 2008). The random forest model is yet to be tested with police data, so it is not yet known whether and how it can be used for predictive policing. Berk (2011), however, demonstrates its use and value in forecasting parole or probation failures.

Applications

One of the first applications of predictive policing methods occurred in the Richmond (VA) Police Department (RPD) in 2003. With the assistance of vendors, RPD developed a system that included a combination of predictive crime analysis, data mining, geographic information system (GIS) capabilities, and reporting to RPD officers. Data from the RPD records management system were integrated and analyzed using SPSS's predictive analytic.

Richmond analysts created a model that automatically improved itself and avoided the manual refreshing of variables. Time, day, holidays, weather, moon phases, city events, paydays, and crime records were among the data that were analyzed. RPD developed a custom solution using several different technologies. Information Builders' WebFocus software included business intelligence capabilities that display criminal activity every 4 hours. Officers received the information at police stations and in squad cars, and real-time alerts were sent by email and text messages. GIS mapping from ESRI and aerial photography from Pictometry provided maps and pictures of the reported incident locations and the surrounding neighborhoods. RPD used SPSS's Clementine and Predictive Enterprise Services products for data mining capabilities that examine how current crime reports relate to data on past, present, and projected actions (Harris 2008).

Data mining tools and predictive analytics were the key elements in the Richmond effort. Using data mining techniques, which basically churned through data, analysts found "hidden patterns and relationships" (McCue and Parker 2003). According to McCue, hypotheses were created, models were developed, and "what if" questions were posed. The data mining tools allowed RPD to conduct a multitude of activities focusing on crime fighting and efficient use of manpower. The developers of these tools asserted that they added value to (1) deployment, (2) tactical crime analysis, (3) behavioral analysis of violent crime, and (4) officer safety.

In using this approach, the Richmond police deployed officers at different hours of the day, during different seasons, and for varying types of offenses. The tools provided them with unanticipated factors that they would not ordinarily find without data mining. While initially this approach showed promise in Richmond, a new police administration has opted to move away from it and return to more traditional strategies.

LAPD and Santa Cruz Applications

In 2011, the Los Angeles Police Department (LAPD) and the Santa Cruz Police Department (SCPD) made news headlines for their use of predictive analytics developed by mathematicians at UCLA and Santa Clara University. Using methods from seismology, Dr. George Mohler and Dr. Martin Short developed math algorithms that have the potential to predict crime across time and space (Mohler et al. 2011). The algorithms were initially tested using core data from the LAPD. The math model is based on "self-exciting point processes" and repeat victimization theory. That is, crime tends to display similar statistical patterns whereby an initial crime event is followed close in time and close in space by additional crimes. In the case of property crimes, offenders tend to return to the same, or a nearby location to commit more crime in a short period of time to replicate the successes of the prior offense (Townsley et al. 2003). In the case of many violent crimes, repeat offenses occur in short successions in the same places as part of cycles of reprisals and counter-reprisals.

The self-exciting point process model describes the rate at which crime occurs at a given spatial location (e.g., street address) and does so in terms of a background rate and a self-exciting component. The background rate is connected to general features of the local environment, which are thought to be constant relative to the time scales at which criminals make decisions. For example, houses targeted by burglars generally do not change fast enough in their characteristics to deter a burglar who has recently committed a crime there. By contrast, the self-exciting component takes into account the notion that recent crimes at a given location or neighboring locations tend to increase the rate at which crime occurs there. Burglars often learn of goods that they could steal during the process of breaking into and burglarizing a home. They act on this information by returning to victimize that home again a few days later.

In Los Angeles and in Santa Cruz, the math algorithm is tested on burglaries and burglaries from motor vehicles on 3 years of data. The expectation is that there is a background component to burglary rates as well as a strong self-exciting component. Locations targeted for burglary from motor vehicles typically offer both a large numbers of targets (e.g., parking lots, high-density street parking), with high variance in target types (e.g., car types) and goods to steal (e.g., laptops, cell phones, GPS units). Offenders specializing in burglary from motor vehicles will tend to return to the same or nearby locations to replicate previous successes and they will do so over short time intervals, consistent with a self-exciting process. The researchers quantified these background and self-exciting components for burglary from motor vehicles and developed forecasts based on these quantitative models. Forecasts take the form of probabilistic assessment of the likelihood that different locations will experience burglaries. The volume of burglary from motor vehicle crimes and the greater stationarity of the target base suggest that forecasts may be possible at the scale of days and perhaps even finer temporal scales.

The self-exciting point process is being tested in the field in five divisions in Los Angeles. The algorithm identifies 500 by 500 ft areas of probable criminal activity. Each week, 60 areas are designated as predictive policing areas. Using an experimental design, the police captain within each division directs officers to 30 randomly assigned areas to prevent the crimes from occurring and leaves 30 areas as control areas where routine patrol activities take place. Measures include the time spent in each predictive area by "extra patrol" and by regular patrol. Crimes are also measured to determine how many have been prevented. Preliminary findings show that nonviolent crime has dropped in the areas.

A number other agencies are in the process of using predictive analytics to predict crime and locations. These include: Cambridge (MA), Charlotte-Mecklenburg (NC), Charleston, SC. Chicago, Indio (CA), Lincoln (NE), Memphis, Miami-Dade, New York City, Redlands (CA), Salt Lake City, and Shreveport (LA).

Key Issues/Controversies

This section examines three major issues: questions about "Minority Report," civil liberties, and intelligence gathering; importance of data; and untested predictive analytic methods.

"Minority Report," Civil Liberties, and Intelligence Gathering

The Steven Spielberg production of "Minority Report" starring Tom Cruise was released in 2002 and tells the story of a futuristic "Department of Pre-Crime" that works out of the US Department of Justice. The film depicts the use of "pre-cogs" who predict crimes as they float in an indoor swimming pool and send telepathic messages that name potential victims and suspects to Justice Department police. Using advanced technology and having access to untold databases, the police investigate the crime before it happens. The police seemingly ignore the 4th Amendment by entering houses without warrants, use biometrics to confirm identities, surveil and enter apartments using spider-like devices that "read" corneas for identification, and when they apprehend a suspect before the crime takes place they arrest him for a "pre-crime."

The actions in the film led many policymakers, researchers, and law enforcement to ask: "Is predictive policing similar to Minority Report? Are we headed in that direction?" The questions raise a number of issues related to civil liberties, the 4th Amendment's right to be free from unreasonable searches and seizures, and a concern for the type of information that is or could be collected by law enforcement.

Police departments and executives are keenly aware of the negative implications raised by the film and its application to predictive policing. In Los Angeles, the chief responds publicly and privately that "you can't break the law to enforce the law" (OurWeekly 2010) and that the police "practice Constitutional policing." More importantly, the concern for civil liberties has led to discussions with the American Civil Liberties Union (ACLU), the development of policies and procedures, and acknowledgement of the need for training on all facets of predictive policing. As a result of these discussions, the focus of the LAPD effort is centered on preventing specific types of crime and reducing crime in specific locations rather than predicting offender behavior.

Data

As with all uses of analytics, data are among the most critical aspects of predictive policing. The validity and legitimacy of any predictive model depends on the quality and quantity of data available. In law enforcement, data are usually in abundance – calls-for-service, incident reports, arrest reports, field interviews, and other data are collected routinely by most large- and medium-size departments across the country. But these data vary by police agency in terms of consistency and uniformity, and while they are abundant, their quality is unknown. Data need to be cleaned and validated to ensure that the results from predictive analytics are accurate.

While the amount of data may be sufficient for use in a predictive model, the information is often stored on legacy systems that may not be compatible with systems running predictive analytics software. Converting data on these legacy systems to a useable format is a challenge.

Untested Methods

The statistical techniques used in predictive analytics are largely untested and have not been rigorously evaluated. Risk Terrain Modeling, ProMap, neural networks, feature space, statistical learning models, the self-exciting point process, and predictive analytics developed by private vendors (IBM SPSS, SAS, IBI, and others) are yet to be fully tested in the field by independent evaluators.

Conclusion

Though predictive policing remains an untested concept, many police departments have adopted ways to begin to predict crime using mapping, business, and statistical analytic methods. The reasons behind the use of predictive analytics are many, including the need to increase efficiency and maximize police resources. In cities like Los Angeles, where resources are limited because of the downturn in the economy, cost-effective information technology solutions are an essential management tool. Increasing the ability of police agencies to effectively analyze existing and new data may provide broader crime reduction opportunities. This in turn will lead to new deployment strategies, different methods for measuring prevention, and ultimately, safer communities.

Overview

Prediction research in criminology has, by and large, focused on characteristics of offenders: various facts about criminals are recorded – their age, previous arrests and convictions, social history, and so forth. It is then statistically determined which of these factors are most strongly associated with subsequent offending (see Gottfredson 1967). The result is a "selective" prediction strategy: among those convicted of a given category of offense, some will be identified as bad risks and others will not. Under an incapacitative strategy, those convicted offenders who constitute bad risks would be imprisoned or imprisoned for longer periods.

Traditional Prediction Methods

Traditional statistical prediction techniques pursued this selective approach. Generally, they found that certain facts about an offender (principally, his previous criminal history, drug habits, and history of unemployment) were to a modest extent indicative of increased likelihood of recidivism on his part (Gottfredson 1967).

These techniques did not, however, distinguish between serious and lesser forms of reoffending. Both the offender who subsequently committed a single minor offense and the individual who committed many serious new crimes would be lumped together as potential recidivists. Moreover, the technique offered no promise of generating reduced net crime rates, as they did not attempt to estimate such incapacitative strategies' aggregate crime-preventive effects. Locking up the potential recidivist thus assured only that he or she would be restrained; since other criminals remained at large, it did not necessarily diminish the overall risk of victimization. These limitations eventually reduced penologists' interest in traditional prediction techniques.

"Selective Incapacitation"

Surveys of imprisoned offenders conducted in the USA in the early 1980s found that a small number of active offenders admitted responsibility for a disproportionate number of serious offenses. If that minority of dangerous offenders could be identified and segregated, perhaps this could reduce crime rates after all. These surveys thus generated a renewed interest in prediction research.

The most notable product was a 1982 RAND Corporation study by Peter W. Greenwood (1982). He named his prediction strategy "selective incapacitation." His idea was to target high-rate, serious offenders – namely, those offenders likely to commit frequent further acts of robbery or other violent crimes in the future. For that purpose, he took a group of incarcerated robbers, asked them how frequently they had committed such crimes, and then identified the characteristics of those reporting the highest robbery rates. From this, he fashioned a predictive index, which identified potential high-rate offenders on the basis of their criminal records and histories of drug use and unemployment. Greenwood's predictive factors were (i) prior convictions of instant offense type, (ii) incarceration for more than half the preceding 2 years, (iii) conviction before age 16, (iv) time served in a state juvenile facility, (v) drug use during the preceding 2 years, (vi) juvenile druguse, and (vii) employment for less than 50 % of the preceding 2 years. He defined "high-risk" offenders as those for whom at least four of these seven factors were present (Greenwood 1982).

Greenwood also devised a novel method of projecting the aggregate crime reduction impact of this prediction technique. On the basis of offender self-reports, he estimated the average annual rate of offending of those robbers who were identified as high risks by his prediction index. He then calculated the number of robberies that would be prevented by incarcerating such individuals for given periods. By increasing the prison terms for the high-risk robbers while reducing the terms for the others, he concluded it would become possible to reduce the robbery rate by as much as 15–20 % – without causing prison population to rise (Greenwood 1982).

Queries About Effectiveness

While Greenwood's study initially attracted much interest, certain difficulties became apparent. One difficulty was making the predictions hold up when official data of the kind that sentencing courts have available are relied upon. The objective of selective incapacitation is to target the potential high-rate serious offenders and to distinguish them from recidivists who reoffend less frequently or gravely. To make this distinction, the RAND studies, including Greenwood's, relied upon offender self-reports. A sentencing court, however, is seldom in the position to rely upon defendants' willingness to supply the necessary information about their criminal histories. The court will need to rely instead on officially recorded information about offenders' adult and juvenile records, and such documentation is too meager to make the distinction adequately. When Greenwood's data were reanalyzed to see how well the potential high-risk serious offenders could be identified from the information available in court records, the results were disappointing. The officially recorded facts –arrests, convictions, and information about offenders' personal histories – did not permit the potential high-rate robbers to be distinguished from (say) the potential car thieves. The factors in the self-report study that had proved the most useful – such as early and extensive youthful violence and multiple drug use – were not reflected in court records (Chaiken and Chaiken 1984). To make the predictions work, the courts would need to obtain and rely on information in school and social-service file – with all the problems of practicability and due process that would involve.

Questions became apparent, also, in the projections of preventive impact. Greenwood based his crime reduction estimates on the self-reported activities only of incarcerated robbers and then extrapolated those estimates to robbers generally. Incarcerated robbers, however, are scarcely a representative group: they tend to offend more frequently than robbers generally in the community. (It is like trying to learn about the smoking habits of smokers generally by studying the self-reported smoking activities of patients in a lung cancer ward.) When this kind of extrapolation is eliminated, the projected crime reduction impact is reduced by about half (see von Hirsch 1985, Chap. 10).

Other problems with the projections also became apparent. Greenwood assumed, for example, that his high-rate robbers would continue offending for a long time. When shorter (and perhaps more realistic) residual criminal careers are assumed instead, the estimated preventive effect shrinks dramatically. The accuracy of the forecasts was also disappointing: comparing predicted with actual offending rates, Greenwood's analysis showed that only about half of the respondents were categorized accurately the by predictive scale.

These doubts were confirmed by a report of a National Academy of Sciences' Panel on criminal careers that appeared 4 years after the Greenwood study (for text of the Panel's report, see Blumstein et al. 1986). The Panel included several noted advocates of predictively based sentencing – and the report endorsed the idea of predictive strategies (within certain limits) so long as these could be shown to be effective. Nevertheless, the Panel's conclusions regarding the crime-preventive effects of selective incapacitation were quite skeptical. After recalculating Greenwood's results and thus scaling its initial preventive estimates down considerably, the Panel noted that even those revised estimates would shrink further were the scale drawn from a broader and potentially more heterogeneous population than persons in confinement andwere to utilize officially recorded rather than self-reported information. Even those reduced projected effects would largely disappear, moreover, if the estimated length of the residual criminal career were scaled down (see von Hirsch 1988).

Prospects for Improving Predictive Techniques

Could these difficulties be overcome? Greenwood's research has been only a beginning, and future selective incapacitation research may eventually produce more convincing results. The obstacles are considerable, however. If the aim is to distinguish potential high-rate, serious offenders from lesser potential criminals, this task remains difficult to achieve using the scant official records courts have at their disposal. Records of early offending might become somewhat more accessible with a change in the law concerning the confidentiality of juvenile records – but such records notoriously suffer from incompleteness and inaccuracy. Social histories, such as drug use and unemployment, will be even more difficult to ascertain accurately.

Estimation of the impact of selective incapacitation on crime rates also involves difficult problems of sampling. Analyses of convicted or incarcerated offenders' criminal activities suffer from the difficulty mentioned already: it is not clear to what extent these person's activities are representative of the activity of offenders in the community. Samples drawn from the general population are free from such bias but may contain too small a number of active offenders.

The most troublesome issue, however, remains that of estimating the length of offenders' residual criminal careers. The serious offenders who are the targets of selective incapacitation policies ordinarily would be imprisoned in any event; the most salient policy issue is that of the length of their confinement. The strategy is to impose longer terms on the supposed high-risk offenders, but that assumes they will continue their criminal activities for a protracted period. Little prevention is achieved if the bad risks who are confined are those whose active careers will terminate fairly soon. This means that selective incapacitation, to succeed, needs not merely to pick out high-risk offenders during their initial periods of high-rate offending, but rather those who are likely to go offending for substantial time. But how much do we know about forecasting residual careers?

A number of recent criminal-career studies have attempted to make estimates of the duration and intensity of offenders' residual criminal careers (see, e.g., Kazemian and Farrington 2006). These studies confirm that residual career length and frequency of offending decline significantly with age. Moreover, offenders' scores on risk-assessment indices – when based mainly on information included in official records – were significantly but only modestly associated with the extent of their remaining criminal careers. These findings also suggest that incapacitative benefits will decline significantly during the remainder of a predictively based sentence – thus limiting the crime-preventive payoff of selective incapacitation strategies.

Even with improved predictive efficacy, there would be no assurance as to how much confining the higher-risk offenders will prevent offenses from taking place. With group crimes and network offenses, for example, the offender may be replaced easily by other criminal participants. Moreover, it also needs to be born in mind that individuals who are admitted into prisons must eventually be released. Sampson and Laub's (1997) theory of cumulative disadvantage, for example, emphasizes the "*indirect* role of incarceration in generating future crime," which may occur through severance of bonds to conventional social institutions.

Proportionality Problems

Selective prediction strategies – whether the traditional sort or more sophisticated methods such as Greenwood's – must confront also an important ethical question: their apparent conflict with the requirements of proportionality. The conflict stems from the character of the factors relied upon to predict. Those predictive factors tend to have little relation to degree of reprehensibleness of the offender's criminal choices (which is the basis of proportionality judgements – see more fully von Hirsch and Ashworth 2005, Chap. 9).

Proportionality requires that penalties be based chiefly on the seriousness of the crime for which the offender currently stands convicted. The offender's previous criminal record, if considered at all, should have a secondary role and the offender's social status is largely immaterial to the penalty he or she deserves. With selective prediction, the emphasis necessarily shifts away from the seriousness of the current offense. In fact, Kazemian and Farrington found that offense type was not a significant predictor of residual career length or residual number of offenses. Since the aim is to select the higher-risk individuals from among those convicted of a given category of crime, the character of the current offense cannot have much weight.

Traditional prediction indices largely ignored the gravity of the current offense and concentrated on the offender's earlier criminal and social histories. Selective incapacitation techniques have similar emphasis: of Greenwood's predictive factors, three do not measure criminal activity of a significant nature at all but, instead, measure the offender's personal drug consumption and lack of stable employment. Of the four other factors, only two reflect the offender's recent criminal record, and none measures the heinousness (e.g., the degree of violence) of the offender's current offense (see discussion above).

When aggregate preventive effects are taken into account, the proportionality problems become more worrisome still. Selective incapacitation techniques, by their own proponent's reckoning, could promise significant crime reduction effects only by infringing proportionality requirements to a very substantial degree. Greenwood's projection of a significant reduction on the robbery rate was made on the assumption that robbers who score badly on his prediction index would receive about 8 years imprisonment, whereas better-scoring robbers would receive only 1 year in jail (Greenwood 1982). This means a great difference in severity – in Greenwood's study, about 800 % – in the punishment of offenders convicted of the same type of offense, and one that can scarcely begin to be accounted for by distinctions in the seriousness of the offender's criminal conduct. When this punishment differential is narrowed – when high-risk robbers receive only modestly longer terms than robbers deemed lower risks – the crime reduction payoff (even by Greenwood's methodology) shrinks to slender proportions.

Conclusion

Where does this leave us? A limited capacity to forecast risk has long existed: persons with criminal records, drug habits, and no jobs tend to recidivate at a higher rate than other offenders, as researchers have known for decades. However, the limitations in that forecasting capacity must be recognized – for selective incapacitation as well as more traditional forecasting techniques. Identifying high-risk, serious offenders will be impeded by the quality of information available (or likely to become available) to sentencing courts. The potential impact of selective incapacitation on crime rates is far below proponents' initial estimates and is likely to be modest. Considerations of proportionality limit the inequalities in sentence that may fairly be visited for the sake of restraining high-risk offenders, and limiting these permissible inequalities will, in turn, further restrict the technique's impact on crime. In order for this sentencing model to be effective, some important empirical and ethical caveats associated with selective incapacitation policies must be addressed.

Predictors of Successful Investigations

Robert T. Meesig
Melbourne, FL, USA

Overview

The continuing tension in our society between community and individual interests has shaped police investigation styles since the 1840s. In the context of this tension, the relative ineffectiveness of the current traditional, reactive, and case-oriented investigation style is examined in terms of four predictors that affect whether or not the investigation of a crime may be successful. Recent developments in community policing and terrorism matters indicate how to increase investigative successes, but they can also alter the balance between community and individual interests in ways that may not have yet been fully resolved.

Introduction

When a crime is committed in the United States, what is the likelihood that it will be investigated successfully? Apparently, based on the available information, it does not appear to be very likely indeed. In this entry, four major predictors of police criminal investigation successes are examined in separate sections. They are as follows:

- Does the crime become known to the police?
- Does the crime survive the case screening process of the police?
- What factors affect the police investigation?
- What is a successful investigation?

For each predictor, the entry describes significant influences on investigative outcomes and identifies some of the major issues involved. It concludes with a look at what the future may hold for police investigations.

Does the Crime Become Known to the Police?

In the United States, one of the more common ways to categorize various types of crimes is as follows (Cole and Smith 2008):

- Visible crimes – including murder, rape, robbery, assault, burglary, larceny, motor vehicle theft, and arson and lesser disorders such as vagrancy, shoplifting, vandalism, and violations of local ordinances and codes
- Victimless crimes – crimes such as drug offenses, prostitution, and gambling that involve illegal exchanges of goods or services
- Organized crimes – crimes committed by social frameworks organized to commit crimes
- Occupational crimes – crimes committed within a legal business or profession
- Political crimes – crimes such as terrorism, treason, sedition, and espionage

It is only in the Visible Crime Category that we have national crime statistics programs that annually document the number of crimes committed in the United States, and there are two such programs. The National Crime Victimization Survey (NCVS) is one program and is discussed below. The Uniform Crime Report (UCR) is the other and is addressed in the next section.

The NCVS is a national survey effort in which about 60,000 people aged 12 and over are interviewed twice during a year's period to learn about crime and victims of crime. It generates estimates of victimization rates for the violent crimes of rape or sexual assault, robbery, and aggravated and simple assault and the property crimes of burglary, motor vehicle theft, and household theft. It is sponsored by the United States Department of Justice Bureau of Justice Statistics (BJS) (BJS 2010b).

One might think that when a crime is committed, it is only natural to report it to the police. However, upon examination, it becomes obvious that this is not the case. In fact, it seems there are often more reasons for not reporting crimes than for reporting them. The NCVS is the only major national program that gives a clear indicator from the victim's perspective as to whether or not crimes are reported to police, and it shows that fewer than half of the visible crimes that it tracks are actually reported. When the self-identified victims of those crimes were asked why they did not report to the police crimes that were committed against them, their reasons included the crime being a personal or private matter, the severity of the offense, fear of reprisal, and to protect the offender (Hart and Rennison 2003).

For the remaining four major crime categories (victimless, organized, occupational, and political), it is much more difficult to determine the number of crimes committed, as there are no national crime statistics programs that document them, and there are reasons for this. With regard to victimless crimes, for example, many of the people involved are willing participants (e.g., drug dealers and users) who are typically strongly motivated to not report their crimes to the police or anyone else for fear of incriminating themselves. Often, in organized crimes involving gangs, (city gangs, the Mafia, etc.), even when there are clear victims, such as in extortion cases, the victims may not report crimes because of the very real threats of reprisal made by the gangs. Occupational crimes committed in corporations (cybercrime, industrial espionage, internal fraud, tax evasion, etc.) may not be reported for fear of damaging corporate reputations and the potential harm that such exposure to the public could have on their business and financial status. Political crimes involving terrorists and spies (treason, espionage, etc.) are often not reported openly to the public for security reasons and also for many of the same reasons that crimes in the other categories may not be reported, including guilty involvement, fear of reprisal, and national reputations (Cole and Smith 2008).

Issues

It is clear that most crimes committed in the United States never become known to the police and are never subjected to police investigations. Therefore, one of the primary predictors of the successful investigation of a crime is that it first becomes known to the police.

It seems that the decision of individuals to report crime is often based on whether or not they adjudge it to be in their best self-interest to do so. If they, as victims or community members, are motivated to seek justice, or to maintain or regain freedom from crime, they will likely report crime to the police to achieve those ends. However, if they view reporting crime as a threat to their personal interests or status, then they will likely not seek recourse or justice through the criminal justice system (May et al. 2008).

This theme of how community vs. individual interests influences the reporting of crime information to the police is mirrored in how information is processed through the criminal justice system. Two models have been used to describe the process – crime control and due process. While both models emphasize personal freedom, crime control applies an assembly line approach to repress crime by subjecting criminal matters to a routine, informal administrative and discretionary process in order to maximize disposition. This includes filtering out cases that do not contain sufficient information to act upon. This model essentially represents the community interest in maintaining freedom by dealing with as many crime problems as possible in a practical and efficient way. Due process, on the other hand, emphasizes individual interests and liberty. It advocates an obstacle course approach that relies on legal and procedural restraints to test the reliability of evidence regarding criminal matters in a formalized adversarial process. Its aim is to protect the innocent from undue persecution, even at the expense of allowing the guilty to not be held to account (Cole and Smith 2008). As will be seen in the following sections, the American criminal justice system appears to operate generally along the lines of the crime control model, but with increasingly more due process constraints built into it as an accused person is processed through it.

Does the Crime Survive the Case Screening Process of the Police?

If most crimes are not reported to the police, then how effectively do the police deal with the ones that are in fact reported to them? In addressing this question, the UCR, mentioned previously, provides some answers. It should be noted here that the terms “agency” and “agencies” are used in this entry to refer to governmental law enforcement organizations in the United States in general, and the term “police” includes state, county, and municipal law enforcement agencies.

The UCR is a compilation of data reported by more than 18,000 police agencies regarding the types and numbers of crimes reported to them. Police document in the UCR 28 categories of crimes reported to them. However, they report the crimes that they subsequently resolve, or clear, for only eight categories. A “cleared” crime, or “clearance,” generally means that an offender has been arrested, charged with the commission of an offense, and turned over to the courts for prosecution. The eight crimes for which police report clearance rates are the violent crimes of murder, forcible rape, robbery, and aggravated assault and the property crimes of burglary, larceny, motor vehicle theft, and arson. These eight crimes are known as the UCR Index crimes, and they overlap to some extent with the six crimes tracked by the NCVS. However, whereas the NCVS counts crimes that victims say were committed against them, the UCR reflects only the crimes that police say are reported to them, and the UCR Index crimes reflect the numbers of those reported crimes that the police say they cleared. The UCR is published annually by the Federal Bureau of Investigation (FBI) (FBI 2010).

The UCR data help to understand the police case screening process. When a crime is reported to the police, a police patrol officer usually responds to the complainant or crime scene and conducts a preliminary investigation. The term "patrol officer" is used generically here and includes law enforcement officers (police officers, sheriff deputies, state troopers, etc.) whose primary duties are related to patrol. Based on the preliminary investigation, the reported crime is documented in the agency UCR crime report.

If the crime is a non-Index crime, its further disposition is not documented in the UCR. If the crime is an Index crime and the patrol officer's preliminary investigation clears it, then it is counted in the UCR as a cleared crime. If sufficient information is not developed during the preliminary investigation to clear a crime, it will usually be referred to investigators to determine whether a follow-up investigation is warranted. Detectives in about 60 % of agencies use written criteria called case solvability factors as guides to determine this. (The terms "investigator" and "detective" are used interchangeably.) If the case is "screened" out (not further pursued) or if it is pursued in a follow-up investigation but not resolved, the likelihood of it ever being solved is minimal. If the case is pursued and subsequently cleared, it is documented as such in the UCR. According to the UCR, the police investigation and case screening process result in clearing only about 20 % of all the reported Index crimes (BJS 1988; Eck 1983; Greenwood et al. 1977; Maguire and Pastore 2001).

The seminal study on the police criminal investigation process, called the Rand Report, was conducted during the 1970s (Greenwood et al. 1977). Although it surveyed only about 300 large municipal and sheriff agencies, it found that investigators comprised an average of 17 % of an agency's sworn officers and that they generally investigated only the more serious crimes. It also found that the primary investigative task of investigators was talking to people and that they actually spent less than one-third of their time investigating unsolved cases. They spent the remainder of their time on non-case (45 %) and post-arrest activities (26 %).

During the 1970s and 1980s, a number of other research studies were conducted in an effort to improve agency investigative performance. The following points represent the general consensus regarding what they found:

- The public is by far the largest source of crime information for the police.
- The police detect by themselves only about 5 % of the Index crimes they deal with.
- The patrol officer plays a critical role in the investigation process, in that the preliminary investigation either clears the case or determines whether the crime will be screened out or further investigated.
- More than 80 % of the cases cleared by the police are the result of the identification of perpetrators when a crime is initially reported, on-scene arrests made by patrol officers, other patrol officer investigative activity, or information provided spontaneously by the public.
- Detectives play a critical role in conducting follow-up investigations and post-arrest activities, and many of their duties require highly specialized skills.
- The amount of information available to police about reported crimes is mainly a function of the type of crime and the circumstances in which they occur.
- For most reported crimes (i.e., burglaries, larcenies), the amount of information that can be provided by the public to responding patrol officers is very low, and therefore, the capacity of the police to solve crime based on the reported circumstances is generally quite limited.
- Physical evidence is collected in less than 10 % of police investigations, and much of the collected evidence is never submitted for analysis. Thus, in the great majority of cases, physical evidence plays a relatively minor role.
- A number of investigative reforms to improve agency clearance rates were tested in field studies since the 1970s, but they showed at best only a marginal effect, as investigators had only a relatively minor impact on agency arrest and clearance rates.
- Case resolution rates are much more heavily influenced by cooperation between citizens and the police and patrol officer activities.

The research essentially agreed on the relative ineffectiveness of what has become known as the traditional, reactive, and case-oriented style of police investigation (respond to reports of crime, conduct preliminary investigation, screen out cases with insufficient information, conduct follow-up investigation as appropriate, and either clear or cease further investigation – hereinafter referred to as the "traditional" investigation style) (Eck 1983; Greenwood et al. 1977; Horvath and Meesig 1996; Skogan and Antunes 1979).

Over the past four decades, the average UCR Index crime rates have fluctuated only about 2 % (from lows of just under 4,000 crimes per 100,000 inhabitants in the 1970s to highs of over 5,900 per 100,000 in the 1990s) and, in recent years, have hovered below the 1970s crime rates. Additionally, average clearance rates have consistently ranged about 2.6 % around a 20 % average, despite changes in the nature of crime, the police, and our society (FBI 2010; Maguire and Pastore 2001). This suggests that successful (defined here as cleared) investigations may be influenced at least as much by the traditional investigation style itself as other factors. This lends support to the Rand Report and other research that the amount of information available regarding reported crimes is normally very low and that the constrained traditional investigation style produces consistent case outcomes over time.

Issues

If the first major predictor of a successful investigation is a crime becoming known to the police, then clearly the second major predictor is for the crime to survive the police case screening process. Together they exclude from consideration by the rest of the criminal justice system (prosecution, courts, corrections) the great bulk of the visible crimes committed in our society. This is in addition to the unknown amounts of victimless, organizational, occupational, and political crimes that are eliminated because they are never reported to, investigated, or cleared by the police.

The police case screening process illustrates to some degree how the community and crime control interests vs. the individual due process interests are applied in the criminal justice system, and how they influence investigative outcomes. Cases and offenders are subjected to a winnowing screening process that supports community interests in repressing crime by routinely producing cleared cases that will best support a prosecution. While these cleared cases may be considered successful investigations, the system at the same time protects individuals by screening out most of the cases due to the lack of sufficient evidence. While these might in turn be considered unsuccessful investigations, they do provide for an orderly way to safeguard individual rights. To better understand how this has impacted the police, it is worth taking a brief look at how and why the police investigation process has evolved in the United States.

What Factors Affect the Police Investigation?

In the early nineteenth century, the powerful forces unleashed by the Industrial Revolution brought with them burgeoning problems of social disorder in the dynamic and expanding cities of the United States. Based on the general model of local government police organizations that were formed in England to deal with similar problems in the 1830 s, new public city police forces began to appear in American cities in the 1840s. The focus of detectives in these agencies was essentially offender-oriented, in that their job was mainly to associate with the criminal underworld, either covertly or openly, in order to obtain information about criminal activities.

Described as Secretive Rogues, they often worked proactively with minimal central control or supervision. Corruption, abuse of authority, privacy issues, and political influence were common problems in police agencies, including among the Secretive Rogue detectives. This has been described as the "Political Era" of policing (Kuykendall 1986; Langworthy and Travis 1999).

In the early twentieth century, the increasing public outcry against widespread government corruption and abuse eventually brought about broad societal change, including the reorganization and centralization of the police. The resulting new "Reform Era" of policing "professionalized" the police by reducing political influence, corruption, and abuse and by increasing police accountability (Trojanowicz and Carter 1988).

Detectives also experienced changes regarding how they performed their duties during this era. Initially, the Secretive Rogue proactive offender-oriented style was restructured into an Inquisitor style of reactive case-oriented investigations. Detective autonomy and access to the underworld was constrained by closer supervisory controls and, rather than working to detect crime, they were assigned to investigate criminal cases that had already been committed and reported to the police. In order to compensate for the loss of their own direct contacts with criminals in the underworld, detectives often resorted to the inquisitorial tactics of coercion to develop clandestine informers to collect information for them, and they focused on strong interrogation methods utilizing physical brutality and psychological pressure to elicit confessions from identified suspects (Kuykendall 1986).

By the 1940s, however, the Inquisitor investigator style began to evolve into an administration-oriented Bureaucrat who practiced an even more confined style of investigation. The increasing police controls over investigators and the burgeoning caseloads forced agencies to emphasize stronger and more organized case management in order to permit prosecutors and courts to deal with cases more efficiently. The goal of investigators changed from solving crime by any means to a more bureaucratic, legally guided, and orderly management of information designed primarily to process and dispose of cases, whether they were solved or not (Kuykendall 1986).

In the 1960s, again amid widespread civil unrest and rising crime rates in urban areas, the police once again became the target of strong public disapproval. The police were often viewed as both hostile and repressive, and the professional policing style came under heavy criticism for having isolated the police from the social environment in which they operated. In response to this, the federal government funded a series of research programs to better understand and deal with this issue. This marked the first time that any significant empirical research (including the Rand Report and other studies reviewed above) was conducted in this area (Kuykendall 1986; President's Commission on Law Enforcement and Administration of Justice 1968; Langworthy and Travis 1999).

The "Era of Community Policing" essentially evolved out of much of the research regarding the police/public relationship in the 1970s and 1980s. Community policing has been described as a fundamental shift away from traditional policing and toward a broader, more comprehensive philosophy of crime prevention. It is arguably the dominant model of policing in the United States today, in that at least two-thirds of all local agencies practice some form of community policing. In general terms, it promotes the "Broken Windows" approach by using patrol officers as Community Policing Officers to build close working relationships with the community and to use problem-solving methodologies with community partners to prevent crime. However, the effect of community policing on the traditional investigation style of the Bureaucrat investigator was not clear (BJS 2010a; Trojanowicz and Carter 1988; Wilson and Kelling 1982).

In 2001, the first-ever nationally representative survey of police agencies regarding the police criminal investigation process was conducted to update and expand the Rand Report (Horvath et al. 2001). A total of 3,123 agencies of all sizes were surveyed, and 1,746 (56 %) responded. The respondents employed more than half of the full-time sworn officers (over 350,000) in the country, about 16 % (50,000) of which were investigators. Overall, the survey findings revealed that the police investigation process seemed to have been relatively uninfluenced by changes in policing over the prior 30 years. Although there were some promising developments, the traditional Bureaucrat style of investigations remained predominant. Beyond unique case-specific problems, the overwhelming majority (90 %) of agencies did not identify any legal issues as important problems affecting investigations. This included the use of operational techniques such as searches, informants, undercover activities, sting operations, surveillance, covert listening devices, interviews and interrogations, coercion, and arrests. Further, they did not identify any significant problems regarding their relationships with prosecutors. They reported that the top three factors that would improve their investigation clearance rates were more personnel, technology, and training. They indicated no significant plans to change the investigation process in the future, and they did not project any clear vision of how their role in community policing related to their investigative function.

In 2004, an analysis of the data in the 2001 survey was conducted to determine specifically whether community policing had affected police practices in investigating and solving crime (Meesig 2004). The study found that general community policing practices in agencies have a significant positive effect on murder and robbery, and provided clear support for the effective integration of community policing and investigations to improve police clearance rates. However, as in the 2001 survey, no significant evidence was found of any substantive internal agency management efforts among most agencies to do so.

In addition to community policing, a more recent factor has affected the police investigations process – terrorism. After the destruction of the twin towers of the World Trade Center in New York City, and the attack on the Pentagon in the Washington, D.C. area, by terrorists on September 11, 2001, this has become a national priority. While the act of a terrorist incident itself is designed to take place in a public venue, the planning and preparation for such an attack often occurs in the homes and neighborhoods of our communities. And while federal and military agencies (more than 65 agencies, 85,000 sworn officers) may have primary jurisdiction over many such attacks, it is the people who live in our communities who stand to bear the brunt of most of the attacks, and it is the much larger force of municipal and sheriff agencies (more than 15,000 agencies and 600,000 sworn officers) that are already situated in the communities that have the greatest access to potentially terrorist-related information over the longest periods of time (Meesig et al. 2002). Also, as the primary goal of terrorism investigations is to prevent the terrorist act from occurring, they frequently require intrusive offender-oriented investigative tactics and extensive information collection and collaboration between federal and local agencies (Horvath et al. 2001; Meesig 2004).

To facilitate the investigation of terrorism, various laws have expanded the legal and organizational authorities of agencies to collect and use information to prevent terrorism (Bulzomi 2003). Additionally, federal and local investigators have out of necessity resorted to many of the methods employed in the past by the Secretive Rogue and Inquisitor detectives (covert/undercover activities, the use of clandestine sources, etc.) to neutralize terrorist plots before they can be carried out. This has apparently been done to good effect to date, as at least 40 significant terrorist plots against the United States have reportedly been thwarted since 2001 (Carafano and Zuckerman 2011).

Issues

As can be seen from a historical perspective, a third predictor of successful investigations is an investigation style that is acceptable to both community and individual interests. The various aspects, or factors, of investigation styles that have created controversy in the past have included the corruption, abuse, privacy issues, and political influence that were prevalent in the Secretive Rogue style and the coercion and brutality factors in the Inquisitor style. It appears that by minimizing these factors, in conjunction with implementing less aggressive case-oriented and screening factors, the current traditional Bureaucratic style has become more accepted by community and individual interests.

While community policing and terrorism investigations have demonstrated positive results and support community crime control interests in preventing and repressing crime, they employ more intrusive and offender-oriented methods than the traditional investigation style, and they clearly raise issues regarding the protection of individual rights and due process. One need only recall the NCVS survey findings regarding victims' stated reasons for not reporting crimes (privacy matters, severity of offense, fear of reprisal, offender relationships, etc.) to wonder how long the public will continue to tolerate these offender-oriented investigations in the future, even though they are legally sanctioned.

What Is a Successful Investigation?

How one describes a successful investigation can depend on one's view. In this section, several different perspectives of success are examined.

An unfounded crime is essentially a report to the police that a crime occurred, but subsequent investigation determines that the crime actually did not occur. The investigation is successful in that it resolved the false crime report. However, it is generally not counted as a success because it is not counted in the UCR (FBI 2010).

Whereas the term unfounded focuses on the status of a crime, the term cleared focuses more broadly on the status of a person. As previously mentioned, a reported crime is documented as cleared in the UCR if at least one person has been arrested, charged with the crime, and turned over to the court for prosecution (FBI 2010). Cleared crimes are commonly considered to be successful investigations, but there are some definitional issues:

- The UCR only counts the number of crimes that are cleared, not the number of persons arrested.
- In some cases, an offender may have been identified and located and sufficient evidence gathered to support an arrest, but circumstances beyond an agency's control precluded the agency from making the actual arrest (offender's death, extradition issues, etc). In such cases, the crime is considered cleared by exception in UCR reporting, even though no one has been arrested or prosecuted.
- In matters involving a juvenile offender, a case may be considered cleared if the juvenile is cited to appear before juvenile authorities, even though no arrest was made.

So using the UCR definition of a cleared crime as a criterion of a successful investigation, one or more persons may be arrested or not arrested (exceptional and juvenile clearance) and then turned over or not turned over (again exceptional and juvenile clearance) to the courts. That statement may seem a bit confusing, but it illustrates the nuances involved in using clearance rates to identify successful investigations.

Aside from the definitional issues regarding unfounded crimes and clearance rates, there are a number of other issues, three of which are mentioned here:

- Some agencies do not report crimes to the UCR, and others may either accidentally or knowingly report erroneous data (BJS 1999).
- Sometimes key information regarding an offender's identification or arrest warrants is not entered in a timely and reasonable manner into state-wide and national databases that make such information available to law enforcement agencies throughout the country (BJS 1999).
- Technical advances, such as the Automated Fingerprint Identification System (AFIS) and deoxyribonucleic acid (DNA) analysis, which become available after a case is closed without being cleared, may help to identify suspects from evidence previously collected. They may also help to clear people convicted of crimes they did not commit and to identify the actual offenders (Cromett and Thurston-Myster 2005; DNA Institute 2010; Moses et al. 2010).

These reporting- and technology-related issues are often beyond the purview of individual investigators to directly influence, but they can affect whether or not an investigation is considered successfully cleared because they may provide key pieces of information impacting on investigation outcomes.

It can be argued that an investigation should not be considered successful unless it leads to the prosecution of an offender. However, determinations to prosecute can also depend upon circumstances beyond police control. In about one-third of the cleared police investigations, the offenders are juveniles and are referred to juvenile authorities and often not prosecuted.

In the remaining two-thirds of cleared cases, the adult offenders are referred to a prosecutor, but only about 55 % of them are actually accepted for prosecution. The remaining 45 % are not prosecuted for a variety of reasons. For example, the police tend to use what has been described as a "probable cause" standard to refer cases for prosecution. In essence, once they make the determination that there is probable cause (e.g., sufficient information has been developed) to indicate that a specific person is likely to be guilty of a crime, they make the referral. However, a prosecutor is required to prove the guilt of a person "beyond a reasonable doubt" in court and may decide that insufficient evidence existed to meet that higher standard. This is reported to be the situation for about 50 % of referred-but-not-prosecuted cases. Other reasons for non-prosecution may include witness issues (about 20 % of cases) or other factors (BJS 1988; Cole and Smith 2008; Forst 1995).

It can also be argued that the clearance and prosecution of a case are still insufficient to be considered a successful investigation. Rather, success should depend on whether or not an offender is actually convicted of a crime. The majority of cases brought into court by prosecutors result in guilty pleas. However, guilty pleas are often offered based on negotiations to reduce the nature of the charges brought against an offender or for consideration of lighter sentencing decisions, rather than solely on the strength of the investigation. In those very few cases that actually go to a jury or bench trial, most result in convictions. But even they can be appealed and reversed on grounds which may be beyond the control of the investigation process (May et al. 2008; National Center for State Courts 2003).

From a broader perspective, the various filters and outcomes regarding the police investigation process have been described in terms of a criminal justice funnel, as follows (Cole and Smith 2008; May et al. 2008):

- Out of 1,000 serious crimes, only about 500 are reported to the police, and about 100 result in arrests.
- Roughly 35 of the 100 arrests involve juvenile offenders, who are referred to juvenile authorities for disposition.
- About 65 of the 100 arrests are adults that the police refer to prosecutors, and only about 35 are accepted for prosecution.
- Five of the 35 accepted cases are not prosecuted for reasons beyond the control of the prosecutor, and the remaining 30 go to trial.
- Twenty-three of the 30 plead guilty, four are convicted during trial, and three are acquitted.
- Of the 27 convicted offenders, a few may subsequently have their convictions reversed on appeal for legal, technical, or other reasons.

Issues

A fourth predictor of successful investigations is how success is defined. UCR definitions, reporting and technical issues, and prosecution and conviction rates all judge success somewhat differently, and they all include at least some factors that are beyond the ability of investigators to influence. Further, proactive investigations that prevent crimes (e.g., neutralizing serial offenders, drug interdiction, and terrorist activities) are often not included in conventional descriptions of success.

From a community crime control perspective, the criminal justice funnel figures – only 27 convictions (less than 3 %) out of 1,000 crimes committed – may be sobering. However, from the perspective of individuals, the funnel serves as a series of important due process safeguards against the wrongful investigation and conviction of innocent people.

The Future

In sum, four major predictors have been identified as influencing successful police investigations. First, a crime must become known to police, and second, it must not be screened out by them. Third, the investigation style factors used by the police must be legal and accepted by the public. And finally, the different criteria used for evaluating investigative outcomes can alter the definition of investigative success considerably.

The tension between community and individual interests in American society is reflected in the crime control vs. due process description of the criminal justice system and affects the manner in which police investigate crime. The research, clearance rates, and the criminal justice funnel all indicate that the current traditional investigation style is a relatively ineffective approach toward addressing most crimes in the nation, yet the police report no significant problems regarding that style. This suggests a relative balance between community and individual interests regarding the manner in which police deal with crime.

Recent developments regarding community policing and terrorism show that changes to the traditional investigation style can lead to improved Index crime clearance rates and prevent some types of crime. Although the police have used these developments effectively in some areas, they have not fully integrated them into their overall investigative function, and there may be several reasons for this. The changes focus more on the offender-oriented methods that were in the past associated with factors that engendered public acrimony regarding their effects on community and individual interests. Additionally, the downward trend in Index crime rates and the absence of any significant terrorist attacks on American soil during the past few years may tend to minimize the perceived fear of crime by the public over time and heighten public sensitivity to further infringements on personal liberties.

In the past, nationally publicized incidents reflecting negatively on the police have driven public demands to constrain police activities, and it is quite possible that this could occur again in the future (Lasley 1994; Lynch 2001). But, conversely, another catastrophic event like the terrorist attacks of September 11, 2001, could once again suddenly increase demand for even greater community security. In such a situation, it is not hard to imagine an evolution from the Bureaucrat investigator to a more modernized "Community Policing" investigator. This new approach could conceivably expand the traditional investigation style from merely reacting to reported crime to combine a community policing crime prevention approach with more offender-oriented investigation methods. However, while such an approach might improve the overall success of the police criminal investigations process, it would necessarily have to be done in a legally sanctioned and publicly accepted way.

In conclusion, the balance between community and individual interests will probably continue to shape the police criminal investigation process in the future in much the same manner as it has historically. At this point in time, the absence of any significant problems or demand for change indicates that the traditional investigation style will continue as the predominant investigation model. The concept of the Community Policing investigator that was described above will likely remain for the most part relegated to the paperbound confines of research studies, and not become a greater reality on the street until there is a stronger public mandate for it. If and when this should happen, hopefully the guiding research for the development and implementation of more successful investigation strategies will be as prescient going forward as it has been in the past.

Prenatal and Postnatal Preventive Interventions Based on Risk Factors

Lynette Feder[1] and Marianne Junger[2]

Prenatal intervention; Prevention

Overview

Research from a wide array of disciplines indicates that specific factors in a child's life are associated with an increased likelihood of delinquency and other poor outcomes. These correlates, collectively known as risk factors, operate in the multiple domains in which the child interacts including his family, schools, peers, and community. These factors have been found to operate not simply in an additive manner but instead cumulatively and interactively, thereby producing higher likelihood, severity, and frequency of negative life outcomes with the increasing numbers of risk factors the child faces. Additionally, research finds that the children from these disadvantaged households demonstrate a high and stable trajectory of disruptive and disturbing behaviors that continue and even escalate into adolescence. As many of these risk factors can be identified prenatally or early in the child's first few years of life, there is the opportunity to intervene preventively. Prevention programs seek to compensate or correct for factors placing the child's developmental course at risk by targeting the child, their caregivers, and/or their communities. This entry provides an overview of three preventive programs implemented during pregnancy, infancy, or early childhood that have been rigorously tested and found effective in lessening the likelihood of these poor outcomes for children deemed to be at high risk. Included are home visitation programs, parent training programs, and early enriched educational programs.

Research from a wide array of disciplines shows surprising similarity in their findings regarding childhood variables associated with a higher likelihood of negative life outcomes. These variables are collectively known as risk factors and have been found to exist in the multiple domains in which a child interacts including his family, peers, school, and community.

Current research has found that many different disorders share the same risk factors. That is, predictors of any one specific negative outcome, such as delinquency, are associated with a wide array of problematic outcomes such as disruptive and defiant behavior, poor school adjustment, academic failure, drug use and alcohol abuse, mental illness, risky sexual behaviors, and suicide, among others. Importantly, these risk factors appear to operate similarly across different racial and cultural groups. Therefore, carefully and well-designed preventive programs have the potential to affect multiple health and behavioral problems simultaneously thereby proving highly cost-effective.

Many of these risk factors can be identified prenatally or early in the child's first few years of life. Longitudinal research has found several factors associated with maternal characteristics and behavior during pregnancy that are related to an increased likelihood of early childhood disruptive behaviors. These include mother's socioeconomic status, young age at first birth, low educational status, and smoking while pregnant. In the months and years following the child's birth, the parent's inability to effectively socialize has been found to be a powerful predictor of a child's long-term poor outcomes.

While research indicates that all young children engage in disruptive and physically aggressive behaviors, most children learn to control these impulses by the time they enter school. However, studies have found that a small percentage continue to demonstrate a high and stable trajectory of disruptive and disturbing behaviors that continue well into adolescence. Data from a large longitudinal study conducted in America (Campbell et al. 2006) found that a problematic trajectory is associated with high risk for poor academic and social functioning. These results have been confirmed by data from six sites in three countries finding that disruptive behaviors in children entering school are one of the best predictors of adolescent and adult criminality, including nonviolent and violent offending (Broidy et al. 2003).

In fact, children coming from households where they have been ineffectively parented are likely to arrive at school with multiple deficits, chief among them an inability to control their behavior as indicated by impulsive, oppositional, and/or aggressive behaviors. These children will then be at high risk for poor classroom outcomes thereby increasing the likelihood that they will experience negative teacher-child interactions. Additionally, their bad behavior will alienate their peers leading to rejection by their classmates. This exclusion from normative peers will serve as another risk factor by further feeding their anger while curtailing opportunities to learn pro-social behaviors.

The escalating spiral of aggressive and aversive interactions with teachers and peers, along with the additional learning difficulties accrued as these children fall further behind, increases the likelihood that they will engage in even more disruptive and inattentive behaviors. This, in turn, makes it more likely that the child will fail at school and either drop out or be expelled. Research has found that failing to graduate exposes the child to a new array of risks outside of the school setting including unemployment, teen parenthood, low income, delinquency, drug use, and alcohol abuse. As such, a troubling school performance is both highly related to conduct problems at school entry and strongly predictive of later and more serious problematic behaviors within as well as outside of the school setting.

This "chain of cumulative continuity" (Moffitt 1993) captures the idea that with each stage the individual diminishes his probabilities of enjoying future legitimate prospects. This relationship between early disruptive behavior and a winnowing of conventional life opportunities has been found in studies using large samples in other countries. Simply put, the child's inability to behave pro-socially provokes dysfunctional transactions with parents, peers, and teachers which then set him upon a path of decreasing opportunities to learn to behave pro-socially. This may largely explain why studies find that correcting bad behaviors is so much more challenging than preventing them.

An understanding of risk factors has obvious implications for criminology. If an individual's antisocial behavior is stable from preschool to adulthood, then there is the ability to look for its roots early in life and based on factors that are present before or soon after birth. In fact, this is the focus of developmental criminology – to study retrospectively and prospectively the earliest factors associated with a high risk for delinquent behavior and its continuation into adulthood. From this perspective, randomized controlled trials with long-term follow-ups embedded in evidence-based preventive interventions occurring prenatally and postnatally are the necessary next step.

As these preventive interventions are based on a risk factor approach, a description of these factors and the developmental sequence associated with these problems is provided first. General categories of preventive interventions that have been implemented prenatally and in the first few years of an individual's life and found effective in changing these negative trajectories are then discussed followed by a brief overview of some of the most widely respected programs that serve as models in each of these categories.

Background Description

Though longitudinal studies from infancy to adolescence are rare, they demonstrate that there is a constellation of correlates associated with a child's long-term unfavorable developmental trajectory. These include mother's antisocial behaviors as indicated by such things as having children at a young age, achieving low educational status, and smoking while pregnant. While disruptive and aggressive behaviors are widespread in the first few years of life, by age three or four, children are learning to regulate their behavior. For those who do not learn, their problematic behaviors serve as a risk marker for later poor outcomes.

The term prevention is used broadly to refer to a wide range of programs provided during pregnancy, infancy, and/or early childhood. Prevention programs typically seek to compensate or correct for factors placing the child at risk for any number of bad outcomes. Alternately, prevention can seek to enhance protective factors already in existence. Either way, these programs target the child, their caregivers, and/or their communities.

Prevention programs have now been implemented in countries around the world and have demonstrated both short- and long-term success in changing the developmental trajectories of those born into high-risk disadvantaged households. Unfortunately, most programs to prevent delinquency intervene only once the disruptive and physically aggressive behaviors and responses to them from parents, schools, and their communities have become entrenched making it less likely for them to succeed.

Many researchers are now finding that risk factors impacted early are more likely to be successfully modified. Recently, researchers have combined developmental studies and experimental interventions with economic modeling to analyze skill formation in young children and its relationship to life outcomes. Results indicate that achievement is determined by cognitive abilities, as well as noncognitive skills like motivation, self-control, and perseverance. These skills influence positive outcomes, such as steady employment and high income, as well as deviant behavior like delinquency, teenage pregnancies, and drug use. Researchers have further found evidence that well-designed preventive interventions can positively impact these adult outcomes thereby proving more cost effective (Cunha and Heckman 2009). These findings have led James Heckman, a Nobel laureate economist, to conclude, “In an era of tight government budgets, it is impractical to consider active investment programs for all persons. The real question is how to use the available funds wisely. The best evidence supports the policy prescription: invest in the very young and improve basic learning and socialization skills” (Heckman 2000, 8).

The categories of the various promising single-component early prevention strategies for reducing risks and/or increasing protective factors, along with a brief description of its intervention, intended outcomes, and effectiveness, are discussed below. This includes (a) home visitation, (b) parent training, and (c) enriched early education. The next section will then provide a state-of-the-art example falling under each category.

Home Visitation. Home visitation programs typically target mothers-to-be and new mothers. They are growing in popularity and presently number in the thousands across the United States. These programs are built upon research indicating that parents play a significant role in their child’s development, most especially prenatally and postnatally. Additionally, home visitation programs have found that the best way to reach disadvantaged new mothers is to bring services to them and their newborns rather than expecting that they will consistently keep office appointments.

While home visitation programs are popular, they do not represent one specific intervention. Instead, they are a strategy for providing services to mothers of young children with the home visitor fulfilling any number of roles including case manager, parent trainer, and/or family consultant. Typically their goal is to improve the child’s well-being by positively affecting pregnancy outcomes and/or the mother’s ability to properly parent her child. Home visitation programs vary in the staff that is used to fulfill this function. Some programs use paid volunteers, others use paraprofessionals, and a few use community health nurses.

Even as home visitation programs are growing in numbers across the world, the research on their effectiveness is inconsistent. One review of six rigorously evaluated home visitation programs found these programs to have some positive impact on the mothers (better parenting practices and improved attitudes and knowledge), but the benefits to children (in terms of their health, development, and rates of abuse and neglect) were elusive (Gomby et al. 1999). Another review of 20 home visitation programs exclusively using nurse visitors revealed significant and positive outcomes in terms of both the child (as measured by mental development, mental health, and physical growth) and mother (as indicated by depressive symptoms, employment, education, and nutrition) (Ciliska et al. 2001). But a systematic review and meta-analysis conducted for the Cochrane Collaboration identifying 11 distinct experimental studies found no significant overall differences in terms of maternal (as indicated by depression, anxiety, stress, parenting skills, or child abuse risk) or child (as measured by preventive health-care visits, psychosocial health, language development, behavior problems, or number of accidental injuries) outcomes (Bennett et al. 2007).

It may be that who delivers the intervention or, alternately, the rigor of the methodology used to evaluate these preventive interventions, which accounts for the differences observed in the effectiveness of home visitation programs.

Parent Training. Those interventions aimed at teaching caregivers to more properly parent are generally referred to as parent training. The rationale underlying these programs is based on research indicating that antisocial youth have parents who engage in negative practices that promote children's bad behavior. Parent training assumes that if poor parenting practices have created antisocial behavior, one only needs to change the parenting style – teach the parent how to correctly supervise, monitor, reward, and non-punitively correct misbehaviors – to accomplish positive behavior changes in the child. These training programs have been applied to infants and toddlers, as well as young children and adolescents.

There are a wide array of different parent training programs though most share the following common characteristics: (a) minimal or no contact between the therapist and the child; (b) didactic instruction in social learning principles; (c) training parents to identify, define, and observe problem behaviors in their children; (d) training parents to effectively respond to their child's problematic behaviors; and (e) providing parents with the opportunities to see and practice these parenting techniques.

Parent training is one of the most thoroughly evaluated interventions for the treatment of antisocial behavior in children and adolescents. Several of these studies have used experimental and quasi-experimental methods in their evaluations of these programs' effectiveness. In three meta-analyses of various parent training programs (Durlak and Wells 1997; Barlow 2000; Serketich and Dumas 1996) and three systematic reviews (Berkowitz and Graziano 1972; Farrington and Welsh 2003; Weisz and Simpson Gray 2008), all but one (Durlak and Wells 1997) indicated positive effects for the children of parents who received parent training versus those in the control condition who did not receive this program. Furthermore, these studies have found treatment effectiveness maintained up to 4.5 years post-intervention.

Finally, evaluation of different treatment characteristics and delivery approaches used in parent training has found that the program typically works better with parents of younger rather than older children and that therapist training and skill, as well as duration of treatment (with shorter interventions less effective), may affect treatment outcomes. There are inconsistent findings as to whether parent training works better in individual versus group sessions, with some arguing that group sessions provide the additional opportunity of receiving support from other parents.

Early Enriched Education. One of the most widely used prevention programs in the United States today is a structured and enriched educational day care or preschool for at-risk children. As has already been discussed, quite a lot is known about children at risk. Many are from families that are themselves at risk. The stressors these families face, due to social and economic disadvantage, may lead to problems in their parenting behavior. This then increases the likelihood that the child will enter school demonstrating disruptive and highly problematic behavior. A person who has not learned to control his behavior will have difficulties in the classroom setting, including problematic relations with teachers and peers. His disruptive and inattentive behavior, along with his growing aversion for school, increases the likelihood of learning difficulties.

Additionally, because of limited interactions with the parent, the child may not have received sufficient cognitive stimulation in the early years leading to his entering school with significant deficiencies. Researchers are increasingly recognizing how critical the first few years of life are for a child's attainment of developmental milestones. So, for instance, entering school with a language deficiency leads to a greater likelihood that the child will fail in school, again placing him at greater risk for a negative school experience and, with that, yet another path towards a problematic life outcome. Given the strong relationship between cognitive and academic impairments and conduct disorder, these deficiencies become a natural target for prevention.

As with the other preventive programs already discussed, these enriched early education programs do not represent one single entity but rather should be viewed as a vehicle for delivering services to children who are at risk of arriving at school with deficits that will interrupt the learning sequence. They are typically delivered in the preschool years though there is great variety in the rigor of the program as well as its duration. Some programs are center based, others are provided out of the home, and some use a combination of the two. Similarly, many of these programs serve the child directly, while others seek to accomplish their goals by targeting the child's caregivers, and still others use both modalities. All, though, are based on research indicating that conception through the first few years of life provides the foundation for long-term physical, mental, and cognitive development. Therefore, they seek to build a strong base starting very young so as to increase the likelihood that the child will not follow a negative developmental trajectory inside as well as outside of the school setting.

Data from a number of earlier studies on enriched preschool programs found that while IQ scores and academic performance might initially increase, this was not maintained over time. However, there were significant and positive long-term social and academic benefits to children attending these programs. And a systematic review and meta-analysis reported by the Cochrane Collaboration found that out-of-home day care for preschool children (note that this did not necessarily include an intensive educational component), singularly or in combination with an additional preventive component, had significant beneficial effects in terms of the child's IQ, school performance, and behavior (Zoritch et al. 2009). Additionally, these beneficial social and cognitive effects were more pronounced for children from high-risk families (Anderson et al. 2003).

The Abecedarian Project specifically evaluated the long-term effects of preschool education for at-risk children. In that evaluation, infants from high-risk families were randomly assigned into an intensive preschool intervention (vs. control condition) and then randomly assigned again into a school-age intervention (or control condition), thereby creating four cohorts who were followed until age 21. Findings indicated that while the school-age intervention only had weak long-term effects, the preschool treatment led to significant and long-lasting differences academically and socially for study children. Specifically, those receiving the intensive early education program had higher cognitive test scores as well as achieving higher reading and math scores in comparison to their control counterparts. Those in the early experimental intervention also attained more education, were more likely to attend a 4-year college or university, and were less likely to become teen parents (Campbell et al. 2002). Finally, while there were no significant differences in rates of employment, experimental children were more likely to be in a skilled job than those in the control condition (Clarke and Campbell 1998).

The policy implications from this review are clear and are very much in line with Heckman's recommendations. That is, we need to invest in the young with well-designed and rigorously evaluated preventive interventions that improve children's basic skills and socialization.

State of the Art

As space is limited, examples of successful programs from each of the three categories are presented below. This is followed by an example of a hybrid program combining these separate preventive intervention components. Each of the programs highlighted has been rigorously tested and found effective when delivered to high-risk young children and/or their families.

Home Visitation. David Olds' Nurse-Family Partnership (NFP) (see also http://www.nursefamilypartnership.org/) provides one of the most highly regarded and rigorously evaluated home visitation programs. This preventive program targets high-risk first-time mothers-to-be from the time they are in their second trimester through the child's second birthday using nurse visitors who provide frequent and regular (weekly and then biweekly) contact with the woman. NFP focuses on maximizing (1) healthy behaviors in mothers-to-be during pregnancy to increase the likelihood of a positive birth outcome, (2) sensitive and caring parenting to increase the mother-child bond and decrease the likelihood of neglect and abuse, and (3) positive life course for the mother to increase her long-term outcomes.

Olds originally tested the NFP program in Elmira, New York, using a randomized controlled trial (RCT) with a large sample of women. Results 4 years post-program completion indicated positive and significant effects for the mothers and their children. More home-visited mothers returned to and graduated from high school, demonstrated higher employment rates, had lower rates of subsequent pregnancies, were more involved with their children, and displayed improved coping around their parenting in comparison to the control women who received treatment as usual. Children from nurse-visited homes demonstrated fewer behavioral problems, lived in homes with fewer hazards, and made fewer emergency room visits in comparison to controls. Unfortunately, no significant differences emerged in terms of rates of child abuse or neglect or child's intellectual functioning (Olds et al. 1988).

Whereas the RCT in Elmira included predominantly white high-risk women living in a rural area, NFP was next tested with a largely African-American high-risk urban population in Memphis, Tennessee. As with Elmira, Olds and his colleagues found some success. Specifically, women visited by nurses had lower pregnancy-induced hypertension, fewer health-care encounters for their children due to injuries or ingestion, and a lower rate of second pregnancies. However, home-visited mothers and their children did not differ significantly from their non-visited counterparts in terms of the children's birth weight, rates of immunization, mental development, and behavioral problems or the mother's education and employment (KItzman et al. 1997).

In their latest trial conducted in Colorado, Olds tested nurse- versus paraprofessional-delivered home visitation, and both were then compared to a no-treatment control group to see if program effects would maintain when NFP was delivered by well-trained non-nurses to a disproportionately Hispanic sample. Whereas effects for women and their children who were visited by paraprofessionals were small and typically not significantly different than those for control women, those visited by nurses continued to show important differences on both maternal (fewer subsequent pregnancies, higher employment rates, and higher rates of interaction with their infants) and child (improved language and emotional development) outcomes. However, there were limitations with what NFP was able to achieve. Nurse-home-visited women and their children did not differ with controls on the mother's educational achievement and use of welfare or the children's temperament and behavioral problems (Olds et al. 2002).

Though the results across these three sites were mixed in terms of outcomes, a 15-year follow-up of the original Elmira sample showed that the children of mothers served in NFP also benefited from this program over time. Specifically, the children of women enrolled in NFP demonstrated significantly lowered rates of running away, cigarette and alcohol use, and arrests and reported having fewer lifetime sexual partners (Olds et al. 1998).

Olds' Nurse-Family Partnership (NFP) is now implemented in more than 100 sites in 31 states in the United States in addition to half a dozen sites worldwide. Today, a national NFP office handles information dissemination and ensures that there is high fidelity to the model. The largest concern with NFP to date continues to be that its effectiveness has yet to be independently evaluated against a no-treatment control group by researchers who are not connected to the program. However, an independent Dutch replication study using an experimental design is currently underway and initial results seem promising (http://www.voorzorg.info/voorzorg/download/20120324_Factsheet_VoorZorg_mrt_2012_final[1].pdf).

Parent Training. Parent-child Interaction Therapy (PCIT) (see also http://pcit.phhp.ufl.edu/Literature.htm) provides an excellent example of a widely used and rigorously evaluated parent training program. Developed by Sheila Eyberg, PCIT has been recommended as a best practice by several state and federal agencies and has now been implemented worldwide. PCIT was initially developed for children between the ages of 2 and 7, but recent evidence has demonstrated its efficacy with children as young as 18 months (Bagner et al. 2010). PCIT has been found to improve the quality of the parent-child relationship, aid parents in developing appropriate child management skills, and significantly decrease parenting stress (Zisser and Eyberg 2010). PCIT is comprised of two distinct phases.

In the Child-Directed Interaction (CDI) phase, the program focuses on establishing a warm relationship between the parent and child by teaching parents to follow the child's lead which helps them become more responsive to their children. It is thought that this will establish a more secure and nurturing relationship from which to move to the second phase of PCIT, the Parent-Directed Interaction (PDI). The goal of PDI is to teach the parent how to set limits, clearly communicate these limits to the child, and then consistently and firmly use discipline when the child does not comply. In both phases of PCIT, the mother is actively involved in the learning process by being coached and provided with moment-to-moment feedback by the psychologist as she plays with her child.

Based on several randomized controlled trials, PCIT has been shown to be an effective intervention with children demonstrating disruptive behavioral problems, children with developmental disabilities, and families from racially and ethnically diverse backgrounds, among others. PCIT has also been shown to be effective in a group format provided in a primary care setting and is currently being tested with infants. A meta-analysis based on nine PCIT experimental and quasi-experimental evaluations (Thomas and Zimmer-Gembeck 2007) reported a moderate to large effect size ($d = 1.21 - 1.57$) leading to the conclusion that PCIT met criteria for a well-established intervention. Importantly, PCIT's effects have been found to maintain up to 6 years post-intervention (Hood and Eyberg 2003). Just as critically, PCIT has been evaluated not only by Eyberg and her colleagues but additionally by others who are not connected to the program's development.

Enriched Early Education. The Early Training Program (ETP) provides one of the first examples of this type of intervention. Begun in 1962 by Susan Gray in a rural town in Tennessee, this preventive intervention was highly influential in gaining support for programs like Head Start. In the summer of 1962, 65 disadvantaged black children (ages 3–4) were enrolled in this study and randomly assigned to either the experimental intervention – a three-summer or two-summer intensive enrichment program combined with weekly visits by a preschool teacher to the child's home to meet the parents in educating her child – or control (treatment as usual) conditions. Their results demonstrated an increase in performance scores initially with most of these differences dissipating by the time the child reached the fourth grade (Gray and Klaus 1970).

As the sample size for this and similar research on early enriched educational programs was small, and the results somewhat confusing, the data from the ETP plus ten other well-known studies were pooled to form the Consortium on Longitudinal Studies. With a fairly low attrition rate (20 %), the Consortium followed these individuals in 1975 (with ETP individuals now between 16 and 17 years of age). Results from the Consortium indicated that IQ scores increased for approximately 3–4 years after the study ended but were not maintained. However, they discovered that these programs had a significant and positive long-term impact. Specifically, the children who received the preventive intervention demonstrated reductions in both special education placement and grade retention, and they demonstrated more positive attitudes towards achievement when compared to their control counterparts (Lazar et al. 1982).

With research surfacing showing a gender gap in benefits accruing to children receiving these early enriched educational programs, the Consortium data was disaggregated to separately study program effects for males and females. Analyses revealed that while cognitive benefits faded over time, there was a clear pattern of treatment effects by gender. Specifically, girls who were exposed to the ETP showed improved rates in high school graduation, college attendance, marital rates, and overall economic well-being. These women also demonstrated lower rates of criminal behavior and drug use. There was limited evidence for positive treatment effects for the men who received this program (Anderson 2008).

Hybrid Preventive Interventions. While there are many hybrid interventions combining two or more of the previously mentioned three program types, like single-component preventive interventions, most have not been rigorously evaluated with follow-up of subjects over a lengthy period of time to validly investigate its effects. However, there are a few notable and noteworthy exceptions.

An excellent example is the Perry Preschool Project (PPP) which randomly assigned 123 disadvantaged African-American preschoolers (3–4 years of age) in Ypsilanti, Michigan, either to the control condition (treatment as usual) or to a high-quality early education program that emphasized the child’s intellectual and social development. In addition to the education component, the Perry Preschool Project also provided home visitation where teachers met weekly with parents to work with them on parenting skills. (Though the Early Training Program had a home visitation component, the preschool teachers did not work on parent training but rather attempted to get parents allied with their teaching goals.) In fact, this combination of an enriched early education for the child combined with a parent training component for the caregivers has been found to be one of the most successful models for preventive interventions.

By age 19, researchers were finding significant benefits for the Perry Preschool Project in terms of both academic and social outcomes. As with the Early Training Project, children in the experimental group originally demonstrated higher IQ scores that diminished with the ending of the program. But other results maintained and even increased over time. Children receiving the preventive intervention had fewer special education placements and improved attitudes towards schooling, better grades, increased rates of high school graduation, and more postsecondary education. Socially, these children had higher rates of employment and self-sufficiency and lower rates of welfare, self-reported misconducts, and arrests (Weikart and Schweinhart 1992).

A follow-up conducted when these individuals were 40 years of age revealed that the social benefits continued to accumulate for those attending this hybrid preventive program. Specifically, these individuals had fewer arrests (including arrests for violent crimes) and were less likely to have a history that included a jail or prison sentence. They were also more likely to have a savings account. As with the ETP, researchers noted that the Perry Preschool Project benefited girls academically and socially more so than boys and that this held true for both short- and long-term results (Schweinhart 2005).

Possible Controversies in the Literature

Most criminologists focus on adolescents or adults who are getting in trouble with the law. This seems logical as these are the individuals who, when disruptive, are perceived as a danger to the public. But prevention scientists instead attend to infants, toddlers, and young children who, though not currently violating legal standards, are at high risk for poor outcomes. As these young children are not currently a threat to the public, given their limited physical abilities to harm others through their disruptive behaviors, some think it foolish to focus interventions on this population. But as we have seen, one of the best predictors of antisocial behavior in adolescents is a child's chronic physical aggression during the preschool years. Adding to this, evaluations of interventions implemented once bad behaviors have begun have shown limited effectiveness. In the end, therefore, criminology may find it fruitful to take a lesson from public health. They have found prevention to be more successful and cost effective than treatment.

Individuals might also be worried that prevention programs, by targeting high-risk youngsters, will negatively label these individuals early on, thereby causing the bad behaviors that it was intended to prevent. However, if these programs are offered as a way to assist parents in parenting, help build strong bonds in families, or ready a child for entrance to school, then individuals are not being labeled as predelinquents. While each of these programs has one or the other aims, we have seen through research how strengthening parenting practices or building a stronger foundation for educational success also significantly lowers the likelihood of a delinquent outcome.

Two current controversies in the criminological literature deal with the methodology that is implemented in prevention science. The first is the use of longitudinal versus cross-sectional data for testing causal hypotheses, and the second is the utilization of randomized controlled trials. Each is discussed in more detail below.

There are some who argue that longitudinal data is unnecessary, as it serves no purpose that cannot be obtained by cross-sectional data. Prevention scientists, on the other hand, argue that longitudinal studies are necessary (though not sufficient) as it allows the study of an individual's development over time. Criminologists have recently recognized the need to go beyond studying the causes of crime exclusively. Instead, they are finding that it is more informative to study the correlates associated with onset, continuation, and desistance of crime. To do this, longitudinal data is necessary as factors associated with onset may not be the same as those correlated with continuation or desistance.

However, while it is understood that longitudinal studies can reveal correlates associated with delinquency's onset, persistence, or desistance, they cannot determine if these correlates are causative. Therefore, prevention scientists also advocate for these interventions to be embedded in randomized controlled trials and for individuals to then be followed over lengthy periods of time. This design would not only demonstrate the intervention's effect on the child's short- and long-term behavior in comparison to the control group; it also allows the testing of causal hypotheses.

The use of randomized controlled trials in criminology has also led to some suggestions that it is unethical to use human subjects to test interventions. But the fact is that these interventions are being implemented all the time – it is just that they are usually being implemented without any control and therefore their true effects cannot be determined. Others argue that it is unethical to deny individuals an intervention based on what amounts to a flip of a coin. However, this misses the point of conducting randomized controlled trials. If the full effects of the intervention were known, then there would be no need to rigorously test it. Those in prevention science note that even well-intended programs can have harmful effects, and therefore not to test these programs using the most rigorous methods possible is truly what should be thought unethical.

Conclusion

While the majority of violence "prevention" programs target adolescent youth, many of these are really corrective interventions. However, we now have a number of longitudinal studies from early childhood to adolescence that clearly point to specific risk factors associated with poor outcomes such as delinquency and crime. These include coming from a background of disadvantage as indicated by having low socioeconomic status and a young and undereducated mother who proves to be deficient in her parenting skills. As many of these variables can be easily measured at the child's birth or shortly after, this provides the opportunity to intervene preventively in the early years. If that chance is missed, these children can be easily screened upon entrance to preschool or kindergarten as they are most likely to display highly impulsive, disruptive, and/or aggressive behaviors. A great deal of research indicates that failure to do so increases the likelihood that the individual will experience deeply troubled and troubling lives once they leave school.

Though the field is undoubtedly in its infancy, there are now specific preventive interventions that have been rigorously tested and replicated and found effective in significantly changing this negative trajectory. In this review of prenatal and postnatal single- and multiple-component preventive interventions representing a wide range of program strategies, better interventions started early in a child's life, used a risk factor approach that intervened in multiple domains of high-risk families, and then rigorously evaluated the program's effectiveness using long follow-up periods so as to assess the full range of effects. There is a need, however, for an additional suggestion. As human behavior is influenced by a multitude of factors (biology, family, school, peer, community, etc.), using a collaborative interdisciplinary approach when addressing prevention is deemed necessary to achieve diversity in expertise and breadth of knowledge. Taken together, these recommendations would go far in building the knowledge base for better addressing the social ills that our society currently faces.

Preventing of Terror at Shopping Malls

Robert C. Davis
RAND Corporation, Arlington, VA, USA

Synonyms

Emergency response; Malls; Private security; Risk assessment; Terrorism

Overview

For the most part, malls and other soft targets that are part of US homeland security concerns are protected, not by public police but by private security. The events of 9/11 thrust private security officers into a new and important role. This entry examines issues involved in providing security in shopping malls against terrorist attack. It begins by examining the threat environment. It then describes some of the unique problems involved in trying to protect against terrorist attack in a "mass private space" that is open to public access. It discusses two major studies that have examined the preparedness of shopping malls both to prevent and to respond to a terrorist attack. Lastly, it examines how Israel – where the threat of terrorism is far more pervasive than in the USA – has approached the issue of mall security. The entry concludes that malls are better prepared today than prior to 2001 to prevent and respond to terrorist attack. It also argues that, while terrorist attack against a mall is unlikely in the current threat environment, some of the same measures that would be effective against terrorism – risk assessments, drills with emergency responders, counterterrorism training for security staff, and enhanced partnerships with the private sector – would also be effective against random violence, natural disaster, and other emergencies that malls are more likely to face.

Introduction

Since the events of September 11, 2001, security concerns have figured prominently in the national agenda. Government officials and the public now recognize a wider array of potential terrorist targets extending beyond military installations. These "soft targets," or areas with public access, include transit hubs, schools, and mass private spaces like amusement parks and sports arenas.

One type of soft target that has received too little attention is the retail mall. With all the other soft targets that exist (e.g., transit systems, schools, hospitals), why should citizens be concerned about attacks against shopping malls? One reason is that the nature of malls makes them very vulnerable: there are multiple entrances and exits, and they are open to the public. Large numbers of people come and go, making it easy for potential terrorists to blend in unnoticed. Many of the visitors carry large parcels that could hide a bomb or other weapon. There are multiple ways to attack a mall, ranging from automatic weapons to car bombs to bombs placed inside the mall, even to an attack using a biological or chemical agent.

Moreover, the consequences of an attack could be quite serious. In the case of an attack using a biological or chemical agent, or a bomb blast resulting in structural collapse, the casualties could be very high. An attack could also produce insurance and job losses. A coordinated series of attacks against malls would almost certainly result in long-term lost business and serious regional or national economic consequences, as we saw in the airline industry following 9/11.

In fact, malls and the retail sector in general have been attacked in various parts of the world for the past several decades. Israel has experienced or thwarted attacks against malls on ten occasions since the start of the Intifada in the West Bank in the mid-1990s. Countries as disparate as Turkey and Finland have had attacks against malls in recent years. England suffered attacks against retail stores by the Irish Republican Army as far back as the 1970s (Bilefsky and Zimmerman 2002). A RAND

Corporation study identified 62 terrorist attacks against shopping malls between 1998 and 2005 (LaTourette et al. 2006).

In the United States, several terrorist plots against malls have been uncovered by law enforcement:

- In 2003, the FBI arrested a man on charges that he intended to blow up a Columbus, Ohio, shopping center. The man, a Somali immigrant who allegedly traveled to Ethiopia to obtain terrorist training, was a friend of a man convicted of conspiring to blow up the Brooklyn Bridge. The Columbus suspect was sentenced to 10 years in prison (CBS News 2009).
- In 2007, the FBI warned, based on information from a source considered reliable, of a plot by al Qaeda to disrupt the US economy through a series of holiday attacks against shopping malls in Los Angeles and Chicago (Esposito and Walter 2007).
- In 2009, Federal prosecutors charged a 27-year-old Muslim convert in Boston with plotting to kill politicians and wage violent jihad by randomly shooting people at shopping malls (Bryan 2009).

The Challenge of Securing Shopping Malls

Like gated communities and sports arenas, shopping malls are an example of what Stenning and Shearing termed “mass private property” (Stenning and Shearing 1980). These are large tracts of public-access, privately owned space which have traditionally fallen outside of the domain of public police. In these mass private spaces, the line between what is public and private property – and who is responsible for policing public and private space – is fuzzy. Private mall security officers are the first line of defense against criminal behavior and other threats to the public in shopping malls. But, in cases of serious criminal behavior or other serious threats to the public, public police and other first responders have authority once they arrive on the scene so that public police and private security agencies must develop cooperative relationships and emergency plans. Moreover, mall security officers are typically responsible for what goes on in the mall’s common spaces, while individual stores may have their own security personnel and systems in place. The shared responsibility for security means that coordination between the different entities is essential for an effective response to emergencies.

Shopping malls are also a challenge to secure against terrorist attacks because they have multiple entrances and exits. Typically, there are a number of main entry ways plus entry through large anchor department stores. It would be difficult to screen persons coming and going through so many portals. Moreover, to do so would risk turning customers off and nullifying the efforts of mall owners to create an environment that represents a safe and secure getaway from people’s day-to-day worries and problems.

Finally, mall security is challenging because security staff are not well paid and turnover is rampant. There are exceptions, to be sure, but typically mall security officer positions require little education or experience and salaries reflect that. High turnover rates discourage mall owners from investing in extensive training programs for their officers.

Research on Mall Preparedness for Terrorist Attacks

There have been two major empirical studies on the preparedness of shopping malls to prevent and respond to terrorist attack. Washington, D.C.’s Police Foundation conducted an assessment of the level of security in large enclosed shopping malls as well as the associated issues of training and legislation of private security forces (Davis et al. 2006). The core issue addressed in the Police Foundation report was the degree to which malls had become better prepared to respond to terrorist attacks in the aftermath of 9/11. The investigation included surveys with

33 state homeland security advisors to get their views on mall preparedness as well as surveys with 120 security directors of the nation's largest indoor retail malls. The researchers conducted site visits to eight US malls and two Israeli malls to gain greater insight into how they are dealing with security preparedness and response to disasters. They also conducted a state-by-state analysis of legislation regulating the hiring and training of private security.

The report painted a picture of what malls were doing in the areas of risk assessments, preventive measures, emergency preparedness plans, training, and coordination with state and local government. The comprehensive picture that emerged of the state of security in large retail malls suggested that (a) there were significant gaps in preparedness, (b) there were relatively inexpensive steps that could be taken to fill those gaps, and (c) state homeland security officials and local police as well as mall owners have a role to play in filling those gaps.

The Police Foundation assessment found that malls have taken some steps to improve security. Most security personnel now get several hours of antiterrorism training. Still, half of the mall security directors answering the survey nonetheless felt that their staff could use more training. The report noted as well that a large majority of mall security directors said they have emergency management plans to define actions that security staff should take in the event of a disaster.

However, the surveys and site visits found that, outside of areas receiving specific Department of Homeland Security grants, very little money is being spent to upgrade security. Only a few states had changed their statutes to require background checks, minimum hiring standards or training, and few malls had upgraded hiring standards of their own accord. Risk assessments were rare and, when they were performed, were instigated by the Department of Homeland Security programs and state homeland security officials. Emergency management plans were too often developed without the participation of local first responders or mall store owners and their security staff. Drills to test the security staff's knowledge of what to do in emergencies – when done at all – were seldom rigorous, seldom done with first responders, and were usually done without clear standards to measure their success. Many malls did not even have plans to limit access to sensitive areas in times of heightened alert. Many state homeland security offices had not taken an active interest in working with large malls to enhance security.

The Police Foundation report made four recommendations, including the following:

- Conduct formal risk assessments and take steps to mitigate known risks on a cost-benefit basis.
- Develop and rehearse detailed and coordinated emergency response plans and involve stakeholders.
- Standardize antiterrorism training courses.
- Enhance partnerships with the public sector.

The RAND study examined physical security approaches to reducing the risk of terrorist attack at commercial shopping centers (LaTourette et al. 2006). Unlike the Police Foundation study that examined both reducing risk of an attack and responding effectively in the aftermath of an attack, the RAND study focused solely on reducing the risk of an attack. It used a modeling approach developed on the basis of information obtained from three shopping centers to identify and prioritize the effectiveness of various security options at increasing the odds of thwarting different types of terrorist attacks. The study was intended to help guide shopping centers in designing and implementing strategies aimed at reducing risk.

The RAND analysis included 17 types of terrorist attacks, ranging from sniper attacks to hostage taking to bombs to biological or chemical attacks. The different types of attacks were rated according to their likelihood and according to the extent of damage they were likely to effect, both based on historical data. The responses examined included implementation of 32 different security measures ranging from installation of bollards to searches of people and vehicles to arming security staff to chemical and biological weapon detectors. Responses were rated in terms of their cost and likely effectiveness in thwarting various types of attacks.

The study found that implementing traditional security approaches such as installation of bollards, searching bags, encouraging reporting of suspicious packages, and searching vehicles were likely to be the most effective ways to reduce the risk and cost of an attack. The report also noted that some of these responses might have the effect of driving some customers away.

How Israeli Malls Handle the Terrorism Threat

In Israel, where the threat of terrorist attack is high, malls have been far more stringent in their approach to terrorism than US malls. The Israeli approach to mall security is based on the concept of concentric circles. At the outermost circle, there are roving patrols of one or two security officers and vehicle inspection points. Bollards and retractable barriers are utilized to restrict the possibility of vehicles being driven through the checkpoints. All vehicles entering mall parking areas and pedestrians are subjected to search by officers equipped with explosive detection technology (Story 2011). In addition, visitors are assertively questioned by security officers in an effort to determine whether they pose a possible security threat.

The Police Foundation study reported that approximately 40 % of the operational budget of Israeli malls was devoted to security, compared to 3–5 % in the USA. The high cost of security was driven, in large part, by government standards regarding numbers of security guards, vehicle checkpoints, and barricades, all of which must be met in order for malls to keep their operating licenses.

In Israel, mall security represents a close partnership of private and public sectors. The district police license all armed and unarmed security candidates. They conduct frequent on-site inspections and observe many of the drills being conducted by the mall security staff. Joint exercises team mall security in drills with the district fire brigade, ambulance system, and the entire police district. In addition, there is a system of transparency and open intelligence sharing between mall security and local law enforcement. Finally, mall security and local law enforcement share interoperable communication systems allowing communication over a shared radio band.

Israeli malls are required under governmental regulation structures to conduct periodic risk assessments, using independent contractors. The experts produce a comprehensive security plan for each mall. Once the plan is completed, it is handed over to the district police for approval.

Israeli malls have comprehensive emergency response plans for various contingencies, also required by the government. Each security officer is given a duty under the plan including a subset of officers assigned to an emergency response team. Plans include preventing outsiders from gaining access to the mall as well as possible evacuation – a decision that is entirely up to the security director. An immediate reaction squad meets in a special control room to monitor and direct security actions until the police arrive.

Malls provide monthly training for all officers, almost entirely focused on recognizing and responding to terror threats. Training is highly repetitive, both to engrain the procedures in the minds of the officers and to counteract the effects of high security staff turnover, a problem as acute in Israel as it is in the USA. One advantage that Israel has is that, while turnover is high, many security officers come to the job with recent military training as a result of the country's policy of compulsory military service.

According to the Police Foundation study, Israeli malls usually conduct about 50 drills per month. The drills range from minor procedural drills to covert drills during which false bombs are planted and attempts are made to bring them into the mall.

For a further comparison of antiterrorist efforts in Israel and the USA, see Hasisi, Alpert, and Flynn (2009).

Conclusion

The level of security in Israeli malls is striking and, in fact, even during the last Intifada, not in any ten bomb attempts did the attacker actually penetrate a shopping mall. Israeli malls clearly have done an excellent job of creating as secure an environment as possible under very difficult circumstances.

There are those who would argue that US malls should take a lesson from Israel and do much more to secure themselves against a terrorist attack. A 2010 article on malls predicted that

> . . .the mall in many ways symbolizes the United States to people across the world, acting as a kind of American Horn of Plenty. . .attacks will come and they will be ugly. (Dunn 2010)

The author's recommended solution to the problem he foresaw was to set up armed patrols of ex-soldiers and police officers or to organize mall workers who own guns to bring their firearms to work.

This seems like a serious over-reaction. A recent industry survey found that just 13 % of shoppers thought that malls were unsafe (Smith 2011). Moreover, a recent National Public Radio story examined the practice of "security interviews" conducted by mall staff of people deemed to be suspicious. The story documented instances where shoppers were visibly upset by the questioning and questioned the practice of sharing this information with local and federal law enforcement agencies (Schulz et al. 2011).

No reasonable person would suggest importing the level of security used in Israeli malls to the USA in the present security environment. Additional terrorist attacks feared after 9/11 have not materialized. People would not stand for queuing to go through metal detectors, and there is no reason to ask them to do so. As a society, we have a strong predisposition against the kind of ethnic profiling that is standard practice in Israeli malls. There is no justification for malls to spend nearly half of their operating budgets on security.

However, while there is no reason to take the extreme security measures that have been adopted in Israeli malls, the level of preparedness in a post-9/11 environment ought to be substantially higher than previously. New programs have been put in place by mall owners since the publication of the 2006 Police Foundation study, including bollards placed at strategic points, expanded use of security cameras, more extensive counterterrorism training of security staff, and emergency preparedness drills conducted with local first responders (Smith 2011).

Even if the possibility of an attack by ideologically inspired terrorists is discounted, the same kinds of actions that would help secure malls against that kind of threat also would largely serve to protect against other disasters as well. Risk assessments, emergency management plans, and drills with local first responders can help mitigate the impact of the sort of random acts of violence by individuals that have occasionally occurred in shopping malls (Heffter et al. 2005), as well as the effects of fires and other natural disasters.

Moreover, as Hasisi et al. (2009) have pointed out, the best plans and strategies will only be effective if they are carried out in active partnership with the community. Here, the USA can take a lesson from Israel, where the police have educated the public in identifying suspicious persons, vehicles, and objects. Public education efforts have also focused on how to behave in case of emergency so they reduce the likelihood of harm to themselves and provide help to the police rather than hindering investigations.

Preventive Order: Civil Law

Daniel Ohana
The Hebrew University, Jerusalem, Israel
Tel Aviv University, Tel Aviv, Israel

Overview

What legal mechanisms are available to control an individual whose behavior reveals a propensity for harm? For the greater part of the twentieth century, with the exception of civilly committing the mentally ill, the state acted through the criminal sanctioning process to counter actors who presented a risk of criminal conduct. Law enforcement authorities could thus immediately perform an arrest and initiate a prosecution; if a conviction followed, the court could impose sanctions to protect the public, including measures to rehabilitate or incapacitate the offender. Recent decades, however, have been marked by the growing use in Anglo-American jurisdictions of preventive mechanisms beyond the criminal law to cope with the likelihood that an actor will commit a crime. Significantly, these preventive orders are deemed civil rather than criminal in nature and may be granted in respect of an individual who has not actually perpetrated an offence. Furthermore, the state need not meet all of the heightened procedural and evidentiary barriers which apply in a criminal trial. Since the trend of using preventive orders has been especially pronounced in the United Kingdom, the following discussion largely focuses on the developments that have marked the English landscape of criminal justice.

Historical Background

For the greater part of the twentieth century, legislative practice in Anglo-American jurisdictions proceeded on the assumption that, in coping with the risk posed by an individual whose behavior suggests a propensity for harm, preventive measures, such as arrest and detention or the seizure of tools intended to be used for criminal purposes, could only be taken if the actor actually engaged in conduct which has been criminalized. However, the past three decades have been characterized by a growing trend which involves the use of preventive orders in lieu of, or in conjunction with, the machinery of the criminal law, which do not necessarily require the performance of conduct which amounts to a criminal offence. These preventive orders subject individuals who present a risk of harm to judicial control. The court may impose restrictions on movement, contacts with specified individuals, and access to designated materials or tools. These judicial powers are not without antecedents (Ramsay 2012). Common-law courts have historically had the power to "bind over" an individual likely to breach the peace and enjoin her to enter into a recognizance to keep the peace and specify reasonable conditions to secure her good conduct (Williams 1953). Similarly, the traditional civil injunction process granted courts the power to impose preventive measures by requiring individuals who pose a risk of harm to refrain from performing certain actions. So-called "status" offences criminalizing such activities as begging and vagrancy also commonly served as a vehicle to subject to public control individuals whose behavior was believed to evince a criminal proclivity (Williams 1955). Inchoate offences that criminalize preparatory actions and other remote risks of harm now serve a similar preventive function (Dubber 2002), although it should be noted that, in some cases, the criminalization of conduct performed with the intention of laying the groundwork for the commission of a substantive offence may be justified based on retributive principles of justice (Ohana 2007). Modern forerunners of the preventive order can also be traced back to the *ante delictum* security measures which emerged in a number of European countries in the early and middle twentieth century. These measures were championed by members of the "Social defense" movement who were opposed to the classical model of criminal law and punishment guided by the purposes of deterrence and retribution (Digneffe 2008). Viewing crime primarily as a symptom of an "*état dangereux*" (a dangerous condition), they argued that conviction of a criminal offence should not necessarily be required in order to authorize preventive and rehabilitative action by the criminal justice system and that once satisfactory indications were forthcoming that an individual is in a state of dangerousness, steps should be taken to avoid further deterioration in her condition (Ancel 1987). *Ante delictum* security measures failed to fulfill the expectations of their supporters, inter alia, because the measures were exploited by authoritarian regimes to exclude social deviants and repress political opponents (Pradel 2002). A vestige of the *ante delictum* preventive measures can still be found in the Italian system of *misure di prevenzione*, which is now used to control individuals associated with Mafia organizations and terrorist groups (Molinari and Papadia 2002).

In American jurisdictions, the civil injunction has most notably been used in recent decades to protect against spousal abuse (Finn and O'Brien Hylton 1994) and gang-related criminal activity (O'Deane 2012). This legislative practice forms part of a larger trend, whereby a variety of civil remedies, such as civil monetary penalties and civil forfeiture, are pressed into service to address criminal behavior (Cheh 1991). This trend has given rise to the formation of a "middleground jurisprudence" (Mann 1992) between the criminal law and the civil law. In Canadian law, preventive measures, which are not predicated on the commission of a criminal offence, have been statutorily framed as an exercise of the Common-law judicial power to "bind over" an individual likely to breach the peace (Criminal Code of Canada, R.S.C., 1985, c. C-46, sections 810–810.2; R. v. Budreo, 104 C.C.C. (3d) 245). These measures may be imposed on an individual who is likely to engage in spousal or child abuse, a criminal organization or terrorism offence, sexual misconduct towards a minor, or a serious personal injury offence.

Although preventive instruments allowing for the imposition of protective measures in respect of an individual who presents a risk of harm can be found in the legislation of a variety of

Common-law countries, the tendency of using preventive orders in lieu of, or in conjunction with, the machinery of the criminal law has been especially pronounced in the United Kingdom. The preventive order first rose to prominence with the enactment of the Crime and Disorder Act 1998, which empowered courts to extensively restrict the movement of individuals found to have acted in an antisocial manner by subjecting them to an "Anti-Social Behaviour Order." The Prevention of Terrorism Act 2005 provided another impetus for the entrenchment of the preventive order within the English landscape of criminal justice. The Act empowered the Secretary of State for the Home Department to impose a "Control Order" significantly curtailing the activities of individuals suspected of involvement in terrorism-related activity. Both of these preventive orders proved to be controversial. As explained below, these preventive orders have lately been the subject of reform initiatives by lawmaking authorities. In this context, the Prevention of Terrorism Act 2005 (and, with it, the Control Order) was abolished and replaced by the Terrorism Prevention and Investigation Measures Act 2011, which introduced a new preventive mechanism, namely, the Terrorism Prevention and Investigation Measure. Moreover, a program for comprehensive reform of the Anti-Social Behaviour Order was recently announced.

Even with these efforts to reform the preventive orders available to protect against antisocial behavior and terrorism-related activity, legislative schemes authorizing the imposition of a preventive order on an individual due to the likelihood of criminal conduct on her part have become commonplace in the British statute books. Indeed, the scope of the preventive order has greatly expanded as of late. Most tellingly, the Serious Crime Act 2007 significantly widened the range of criminal activities in respect to which a preventive order may be sought. The Act provides that a Serious Crime Prevention Order may be issued to prevent drug trafficking, human trafficking, prostitution, armed robbery, money laundering, fraud, tax evasion, corruption and bribery, blackmail, intellectual property offences, and environmental crimes (Serious Crime Act 2007, Schedule 1). Furthermore, a Serious Crime Prevention Order may also be made to prevent any offence which "in the particular circumstances of the case, the court considers to be sufficiently serious to be treated for the purposes of the application or matter as if it were so specified" (Serious Crime Act 2007, section 2(2)(b)).

Characteristics and Functions of the Preventive Order

According to Andrew Ashworth and Lucia Zedner, "the essence of [preventive] measures is that they involve (i) restrictions on individual liberty of action; (ii) in order to prevent harm or risk of harm and (iii) are backed by threats of coercive sanctions" (Ashworth and Zedner 2010, p. 61). There is a major structural difference between the preventive order and the machinery of the criminal law. The preventive order is explicitly intended to be preventive, not punitive. Although conviction of a criminal offence may constitute a prerequisite for the making of a preventive order, it is fundamentally oriented towards the future. The actor's prior conduct is only taken into consideration to assess the likelihood that she will engage in the commission of a crime. Setting in motion the criminal sanctioning process, on the other hand, hinges on the past conduct of the offender, rather than on her personal dangerousness. Whereas punishment of offenders may fulfill an important function in protecting the public, the fact that the machinery of the criminal law can only be triggered by the commission of an offence endows it with an essentially backward-looking dimension, which does not exist in the preventive order.

A typical legislative scheme which allows for the issuance of a preventive order contains rules pertaining to most or all of the following: the specific harm to be averted, the preventive restrictions available, the conduct prerequisites, the principles of procedure and evidence applicable, the penal consequences of a breach of the order, the competent authority, the parties qualified to file an application, the possibility of obtaining an interim order pending decision on the merits, and the duration, variation, and discharge of the order. There is considerable diversity across statutory arrangements in the specifics of each of these components.

A standard preventive order places a number of obligations on the targeted person, and the violation of these obligations may constitute a criminal offence subject to a maximum penalty of 5 years of imprisonment. Hence, the preventive order has been dubbed a "two-step prohibition" (Simester and Von Hirsch 2006, p. 174). As onerous as some of the obligations may be, they involve restrictions on, rather than deprivations of, liberty (Ashworth and Zedner 2010). The conditions attached to a preventive order typically enjoin the actor to refrain from engaging in specified forms of activity, such as accessing certain areas, coming into contact with potential accomplices or victims, and possessing designated instruments. For instance, the Sexual Offences Act 2003 empowers a court to grant a Sexual Offences Prohibition Order that might prohibit having unsupervised contact with anyone under the age of 18, being present in certain places such as schools or playgrounds or accessing the Internet. Significantly, the court must be satisfied that "it is *necessary* to make an order for the purpose of protecting the public or any particular members of the public from serious sexual harm from the defendant" (Sexual Offences Act 2003, section 104, emphasis added). Some statutes set a lower threshold: Under the Serious Crime Act 2007, a Serious Crime Prevention Order may be issued restricting the person's place of residence, working arrangements, business dealings, access to specified premises, travel, and means of communication and association with others (Serious Crime Act 2007, section 5) provided that the court has "*reasonable grounds to believe* that the order *would* protect the public by preventing, restricting or disrupting involvement by the person in serious crime" (Serious Crime Act 2007, section 1(1)(a)) (emphasis added).

Since the issuance of a preventive order may result in stringent restrictions of liberty, the function of adjudicating the application process is confined in principle to the judiciary. Some legislative schemes, however, provide for special arrangements. The Terrorism Prevention and Investigation Measures Act 2011 gives the Secretary of State the power to *decide* to impose a Terrorism Prevention and Investigation Measure (hereinafter, TPIM) on an individual who is involved in terrorism-related activity. Before imposing the measure, the Secretary of State must obtain the permission of the court, except in cases of urgency, where the measure must be immediately referred to the court for confirmation. The court may refuse permission if the Secretary of State's decision is "obviously flawed" (section 6(3)(a)). In practice, the courts subject the decision of the Secretary of State to a relatively high level of scrutiny both with respect to the finding that the individual concerned is involved in terrorism-related activity and with respect to the necessity for each of the restrictions imposed to prevent further such activity (Walker and Horne 2012).

Under nearly all legislative schemes governing the making of a preventive order, it is required that the applicant prove that the person concerned engaged in a course of conduct defined in the statute. There are some preventive orders, such as the Sexual Offences Prohibition Order under the Sexual Offences Act 2003, that may almost only be imposed if the actor was convicted of a designated offence (Sexual Offences Act 2003, section 104). Under a number of statutes, inappropriate conduct that does not necessarily amount to a criminal offence may provide grounds for the issuance of a preventive order. Under the Sexual Offences Act 2003, a Risk of Sexual Harm Order can be made against an individual who has, on at least two occasions, engaged in such conduct as sexual activity involving a child or in the presence of a child; causing or inciting a child to watch a person engaging in sexual activity or to look at a moving or still image that is sexual; giving a child anything that relates to sexual activity or contains a reference to such activity; and communicating with a child, where any part of the communication is sexual (Sexual Offences Act 2003, section 123(3)).

Since the application proceeding for a preventive order is classified as civil, the hearsay rule does not apply as a rule. Indeed, the fact that hearsay evidence may be used in application proceedings for an Anti-Social Behaviour Order is viewed as representing a significant advantage for public authorities, since it enables them to overcome the problem of witness intimidation. That the preventive order is viewed as a civil mechanism also entails that the criminal ("beyond a reasonable doubt") standard of proof does not need to be met. The Terrorism Prevention and Investigation Measures Act 2011 provides for a relatively low evidentiary threshold: It is sufficient that the Secretary of State "reasonably believes" that the individual concerned is involved in terrorism-related activity (Terrorism Prevention and Investigation Measures Act 2011, section 3) (Walker and Horne 2012). The vast majority of preventive measures rest on a civil proof standard ("balance of probabilities"). The House of Lords, however, ruled in *R* (*McCann and Others*) v *Manchester Crown Court* [2002] 4 All E.R. 593 that, although the application proceeding for an Anti-Social Behaviour Order should be classified as civil, it must be proven beyond a reasonable doubt that the individual acted in an antisocial manner.

To conclude, it is not always the case that the application process for the issuance of a preventive order may only be initiated by the police or the prosecution authorities. Some legislative schemes allow other state and non-state actors to set the process in motion. This is not surprising, perhaps, given that the protective measures involved are deemed civil rather than criminal in nature. For instance, the Crime and Disorder Act 1998, which lays down the legislative framework for the imposition of an "Anti-Social Behaviour Order" on an individual who acts in an antisocial manner, specifies that this preventive order may be sought by the council for a local government area as well as by a person who by statute provides or manages any houses or hostels in a local government area (Crime and Disorder Act 1998, section 1A). Under some statutes, a private individual may seek a preventive order. Thus, the Family Law Act 1996 states that any person may apply for a non-molestation order prohibiting another person previously associated with her in marriage, civil partnership, cohabitation, or an intimate physical relationship of significant duration from harassing the applicant or a relevant child (Family Law Act 1996, section 42).

Current Issues and Controversies

The preventive order has proven to be a controversial mechanism of legal control amongst criminal law theorists and criminologists. Although commentators generally agree that the state has the obligation to take steps to protect citizens from an individual who poses a risk of harm, they argue that when the state resorts to the preventive order, rather than the criminal law, to achieve security, it does not give sufficient weight to the autonomy and liberty of the individual concerned and to her expectations of legal certainty. It is also argued that the preventive order does not provide for enough procedural safeguards and that it undermines the principle of proportionality in punishment and the separation of powers doctrine. As explained below, various aspects of this preventive instrument have provoked concerns and trenchant criticisms, based on considerations of both principle and policy.

First, it has been argued that the preventive order is inconsistent with the principle that the state should treat its citizens as responsible agents, because it allows for restrictions to be set on an individual based on a prediction about her future conduct, thereby violating her freedom to autonomously decide whether to abstain or not from breaking the law. A similar claim has been made from a communitarian standpoint, namely, that the preventive order runs counter to a mode of governance which befits dealings between fellow members of the polity, because it unjustifiably singles out a given actor as an untrustworthy citizen, whose commitment to the values underpinning the norms of the criminal law is put in doubt (Duff and Marshall 2006; Simester and Von Hirsch 2006).

Second, the hybrid character of the preventive order has been attacked for failing to concur with a liberal paradigm of criminal justice, in which respect for the rights of suspects and defendants constitutes a central value. Since it is categorized as a measure that is civil rather than penal in nature, the preventive order enables the state to impose intrusive restrictions while circumventing principles of due process that apply as a rule in a criminal trial. Indeed, "[t]he principal reason why some governments have been devising forms of civil proceedings. . .is that the criminal justice system is thought to present too many barriers to swift and effective outcomes" (Ashworth 2004, p. 273). It has been argued that an application for a preventive order should not be classified as a civil proceeding simply because the order is made with preventive rather than punitive objectives. Rather, attention should also focus on the impact and potentially detrimental consequences of the prohibitions attached to an order for the dignity and freedom of movement of the individual concerned (Ashworth 2004). The boundaries between the civil and the criminal law are not only blurred by the fact that the restrictions which attach to a preventive order may be onerous but also by the fact that a breach of the order may constitute a criminal offence (Simester and Von Hirsch 2006). Given the stringent character of some of the restrictions which may be imposed on an individual targeted by a preventive order, some commentators have argued that the core procedural protections guaranteed to defendants in a criminal trial should also apply in a proceeding leading to the making of such an order, even if the proceeding is formally categorized as civil (Ashworth and Zedner 2010).

Third, the preventive order has been criticized for not according with a desert-centered conception of criminal liability and punishment. Specifically, critics note that a violation of the terms of a preventive order without reasonable excuse suffices to establish liability for a breach and that no evidence need be adduced to prove the mental state of the defendant (Simester and Von Hirsch 2006). It is also argued that the issuance of a preventive order can generate outcomes which are at odds with the principle of proportionality in punishment, since restrictions may be imposed on an offender even after completion of sentence if these are deemed necessary to protect the public (Ohana 2010). The fact that, as noted below, in practice courts sometimes impose disproportionately harsh sanctions (including imprisonment) in response to a breach strengthens this objection.

Fourth, it has been argued that unduly harsh criminal sanctions are imposed for a violation of the terms of a preventive order. Significantly, the breach of a preventive order is often threatened with a maximum penalty of 5 years imprisonment. The preventive order has been likened to a Trojan horse, with the civil law serving as a vehicle for setting in motion the machinery of the criminal law once a breach has taken place (Simester and Von Hirsch 2006). Given that the prohibitions can be wide-ranging and poorly targeted, and that little rehabilitative assistance is provided to the individual concerned, it has been argued that the preventive order involves significant potential for "net-widening" – that is, it risks entangling actors who would not otherwise have been prosecuted for dangerous or harmful conduct constitutive of a criminal offence (Crawford 2009). This criticism has been raised most forcefully in respect of the Anti-Social Behaviour Order. Research has found that the prohibitions contained in Anti-Social Behaviour Orders made by magistrates are often loosely defined, and thus not only often entirely bar the person concerned from a wide range of public areas, such as parks and shopping malls, but also heighten the risk of a breach later on (Von Hirsch and Shearing 2000; Hoffman and Macdonald 2010). More importantly, approximately half of all Anti-Social Behaviour Orders are breached, and approximately half of those convicted receive a custodial sanction (Home Office 2010). These findings reveal that the Anti-Social Behaviour Order is not entirely successful in its preventative function. More generally, these findings reveal how the preventive order can blur the boundaries between the civil and criminal law and detract from the potency of the condemnatory message and sanctions of the criminal law and from its standing as a distinct moral voice within the community.

Fifth, critics have taken issue with the imprecision which often characterizes the conduct prerequisite in some of the statutes authorizing the imposition of a preventive order (Ashworth 2004). Specifically, it is argued that there are often vague statutory formulations, which run afoul of the principle of legal certainty, failing to provide citizens the guidance needed to steer themselves in such a way as to remain free of state intervention. For instance, the Crime and Disorder Act 1998 defines antisocial behavior for the purpose of obtaining an Anti-Social Behaviour Order as acting in "a manner which causes or is likely to cause harassment, alarm or distress to one or more persons not of the same household" as the actor concerned (Crime and Disorder Act 1998, section 1(1)(a)). The Serious Crime Prevention Order provides another example of the ways in which, as Lucia Zedner has observed, "uncertainty now provides the grounds for action against individuals who are believed, but not known, to be involved in harmful behaviours[.]" (Zedner 2009, p. 51) It may be made against an individual who has been involved in serious crime, which is defined as including cases where the individual has conducted herself in such a way *that was likely to* facilitate the commission by herself or another person of a serious offence. In assessing whether the conduct prerequisite is established, the court is to disregard the intentions of the actor at the time of the act in question, as well as acts which are shown to have been reasonable under the circumstances (Serious Crime Act 2007, sections 4(2)-(3)).

Sixth, it has been argued that the proliferation of preventive orders within the English landscape of criminal justice is problematic because unelected judges are given the power to proclaim which norms of conduct must be complied with, on pain of criminal sanction for failure to do so, in the absence of detailed legislative guidance (Ashworth and Zedner 2010). This arguably runs counter to the fundamental principle of democratic governance, according to which the power to prohibit conduct by means of the criminal law should reside in the legislature, which is composed of the elected representatives of the citizenry and which offers a forum for public debate (Simester and Von Hirsch 2006).

Reforms and Proposals

Following this review of the objections leveled at the preventive order, it should be noted that although academic experts in the criminal justice field have faulted the preventive order on many grounds, it has not encountered significant hostility amongst actors within the criminal justice system, such as policymakers, judges, law enforcement officials, and local governmental offices (Ramsay 2009). Moreover, as mentioned previously, in recent years, steps have been taken towards reforming some varieties of the preventive order while taking into account a number of relevant criticisms. The Terrorism Prevention and Investigation Measures Act 2011 abolished the controversial "Control Order" which had been introduced under the Prevention of Terrorism Act 2005 and replaced it with a new system of TPIMs. This new system arguably represents an attempt to strike a more measured balance between counterterrorism security measures and individual liberties by tightening the normative framework for imposing preventive restrictions on persons suspected of involvement in terrorism (Walker and Horne 2012). The new Act requires that the Secretary of State have a reasonable *belief* that the individual is or has been involved in terrorism-related activity, whereas earlier, only a reasonable *suspicion* was needed to make a Control Order. And whereas Control Orders could previously remain in force for 12 months and be renewed an indefinite number of times, TPIMs are now subject to a 2-year time limit, unless there is new evidence of further involvement in terrorism-related activity. The Terrorism Prevention and Investigation Measures Act 2011 is similarly distinguished from its predecessor by exhaustively listing the prohibitions, restrictions, and requirements which may attach to a TPIM. In some respects, the measures have been made less onerous. Most notably, 16-h curfews have been replaced with overnight residence requirements.

There has also been a recent governmental proposal to reform the Anti-Social Behaviour Order. A White Paper published by the Home Secretary in May 2012 aims to enhance the effectiveness of the legal powers available to respond to antisocial behavior. The most far-reaching proposal is to abolish the criminal sanction for a breach and relabel the Anti-Social Behaviour Order as a “Crime Prevention Injunction” (Home Office 2012). This proposal differs importantly from current law in that positive requirements as well as prohibitions could be attached to the order. Specifically, positive obligations could require the offender to participate in rehabilitative programs to address underlying causes of antisocial behavior, such as drug dependency. In addition, only a civil, rather than criminal, standard of proof would have to be met within application proceedings. This change in the law would have the effect of offsetting the previously mentioned ruling of the House of Lords in the *McCann* case that, although application proceedings for an Anti-Social Behaviour Order are civil in nature, it must be established beyond a reasonable doubt that the individual engaged in antisocial behavior. A breach of the Crime Prevention Injunction would be subject to civil sanctions by triggering liability for civil contempt. Lastly, the Crime Prevention Injunction would exist alongside a “Criminal Behaviour Order,” the breach of which would be subject to criminal sanctions. This preventive order would be reserved for actors convicted of an offence and would be imposed at sentencing.

Although some criminal law theorists have called for the outright abolition of the Anti-Social Behaviour Order (Ramsay 2010), suggestions for reform have been advanced in the academic literature. Andrew Cornford has proposed that the Anti-Social Behaviour Order be reformed by narrowing the remit of the definition of antisocial behavior. In his view, the Anti-Social Behaviour Order should only be available in respect of individuals whose conduct causes others to experience justifiable anxiety about the safety of their local community (Cornford 2011). As regards more generally the appropriate uses which may be made of the preventive order as a mechanism of legal control in lieu of the criminal sanctioning process, Daniel Ohana has examined the possibilities of revamping the preventive order in order to allow for moderate preventive intervention vis-à-vis an actor who has taken concrete steps with the intention to commit a crime (Ohana 2006). He has suggested that the preventive order could serve to avoid the criminalization of minor preparatory offences which are not sufficiently blameworthy to justify the invocation of criminal sanctions, without neglecting public protection concerns. Ohana has argued that the infringement on liberty imposed by a preventive order can be mitigated by following a similar approach to that used by situational crime prevention practitioners, who draw upon empirical “script” (Cornish 1994) analyses of crime-commission processes to provide tailor-made solutions to particular crime problems. More specifically, Ohana has articulated how script studies can be used to pinpoint the restrictions imposed by a preventive order and thus ensure that the hardship suffered by the individual concerned is not disproportionate to the relatively low level of seriousness of the preparatory actions performed and that their ability to lead a reasonably normal life is not unduly hampered.

The Rise of the Preventive Order and the Sociopolitical Context of Late Modernity

Many commentators have inquired why it is that particularly in recent decades the preventive order has attained such a high level of prominence in the English landscape of criminal justice. Examining the wider historical, political, and socioeconomic context of the late twentieth century and early twenty-first century, they have explored and drawn out the various ways in which the preventive order is related to ideas and practices of governance that have gained currency in the present era. Given that the preventive order allows for state intervention to avert harmful behavior well beyond the traditional boundaries of the criminal law, Ashworth and Zedner have identified its ascent as emblematic of the rise of the "preventive state" (Ashworth and Zedner 2008, p. 40; Steiker 1998). This institutional "ideal type" is characterized by a temporal shift in the focus of governance, whereby the state is preoccupied with preventing future harm no less than with punishing past crimes. Preventive orders are infused by the logic of precaution and arguably represent an extension of the so-called precautionary principle (Ewald 2002) which was first developed in the field of environmental protection to address the risk of serious, irreversible damage to natural resources (Crawford 2009; Zedner 2009). According to the precautionary principle, it is incumbent upon public authorities confronted with a possible threat of harm to take action immediately – even where uncertainty prevails as to the nature, intensity, and scope of the risk at hand. In this context, uncertainty concerning whether a source of potential danger will actually prove harmful is no excuse for adopting a posture of nonintervention. On the contrary, active, widespread anticipatory actions are required, so as to ensure safety and avert harm. From this perspective, the rapid growth and entrenchment of the preventive order as a tool of crime control dovetails with the emergence of the "risk society" (Beck 1992) in which institutional goals and strategies are focused on identifying, ordering, and responding to risks and assuaging fear and anxiety by providing assurances that various risks are under control (Ashworth 2004).

Peter Ramsay has argued that the preventive order has found favor with English lawmakers over the past two decades because it serves as a tool for the protection of what he calls "vulnerable autonomy" (Ramsay 2008). More specifically, the preventive order enforces a demand that members of the polity not "fail to reassure" others. Ramsay locates the source of this normative demand to respect vulnerability in political theories which have gained preponderant influence in the United Kingdom, namely, the Third Way, communitarianism, and neoliberalism. Moreover, Ramsay observes that this depiction of citizens as vulnerable "views the law generally and the criminal law in particular, as having failed in relation to anti-social behaviour and fear of crime." Ramsay's thesis echoes Lord Steyn's comments in the *McCann* case, which concerned the Anti-Social Behaviour Order:

> It is well known that. . .young persons, and groups of young persons, cause fear, distress and insecurity to law-abiding and innocent people by outrageous anti-social behaviour. . ..Sometimes the conduct falls short of cognisable criminal offences. . .In recent years this phenomenon became a serious problem. There appeared to be a gap in the law. The criminal law offered insufficient protection to communities. Public confidence in the rule of law was undermined by a not unreasonable view in some communities that the law failed them.

The Anti-Social Behaviour Order, from this viewpoint, forms part of a "political strategy self-consciously aimed at restoring "public confidence" in the exercise of state power" (Ramsay 2009, p. 175). Indeed, several commentators have noted that, beyond its instrumental capacity to provide security, the preventive order acts to assuage the anxiety of a public bewildered by the erosion of the state's power to prevent crime. Specifically, it has been said that the preventive order reassures the public by manifesting the readiness of law enforcement authorities to act decisively and by conveying that, as Adam Crawford as has put it, "problems have reached such a point as to require drastic and exceptional action" (Crawford 2008, p. 774). Ohana has also emphasized the function fulfilled by the preventive order in restoring the trust of the public in the authority of the criminal law while attempting to bring to light the various ways in which the public's trust rests on its belief in the readiness of citizens to abide by the norms of the criminal law (Ohana 2010). Specifically, Ohana has scrutinized the conduct prerequisites of the preventive order and has argued that it bolsters confidence in the criminal justice system by verifying the law-abidingness of citizens. By initially eliciting awareness of suspicious behavior that tarnishes the perceived authority of the criminal law by upsetting social expectations of responsible behavior, the preventive order sets in motion an inquiry in which the competent authority tries to ascertain whether this behavior is actually symptomatic of a lack of law-abidingness. In this manner, the practices and procedures involved in the making of a preventive order constitute a ritual of verification which reassures the public that, aside from those untrustworthy actors who have actually been made subject to a preventive order, the criminal law largely continues to hold sway within society.

General patrol; Patrol; Routine patrol

Overview

Preventive patrol is the most basic and oldest function of the police and historically has been the primary method that the police seek to prevent crime, maintain peace, and provide general policing services. However, strong evidence suggests that traditional preventive patrol has very limited crime prevention benefit, so over time the police have supplemented this function with other refined interventions that are more strategic, and proactive in nature, including foot patrol, directed patrol, crackdowns, and hot spot policing. These approaches vary considerably across three dimensions, including dosage, geographic and crime/problem focus, and type of intervention.

Patrol is an indispensable service that plays a leading role in the accomplishment of the police purpose. It is the only form of police service that directly attempts to eliminate opportunity for misconduct; it also checks the development of desire for misconduct by destroying unwholesome stimuli, by actively creating wholesome ones, and by favorably influencing individual and group attitudes in its routine daily association with the public.

Insofar as patrol fails to eliminate desire and belief in opportunity, misconduct results. Patrol is then immediately available to investigate offenses, apprehend offenders, and recover stolen property. Constant availability is important because time is of the essence in most police work (Wilson and McClaren 1963, 320).

Patrol has been referred to as the backbone of policing because the majority of sworn officers in most departments engage in this activity (Bayley 1994). Preventive patrol is perhaps among the oldest forms of police technology, dating back to the Bow Street Runners and early formulation of the Metropolitan Police Force in London, but could in fact be traced to thirteenth-century Hangchow, China (Kelling et al. 1974). Preventive patrol relies on the assumption that the omnipresence of the police will deter criminal activity and availability of officers will promote rapid response to crime emergencies, and as such, it continues to be the primary vehicle for the delivery of police services. It is the most basic of police activities. More sworn officers are assigned to patrol than other functions within the department (Bayley 1994), and a significant amount of personnel and capital resources are dedicated to preventive patrol. Typically preventive patrol is the first assignment for rookie officers, where cultural values and production norms are learned and where officers demonstrate their police competency. Patrol affords officers ample opportunity to interact with the public and make high-discretion decisions. As gatekeepers of the criminal justice system, patrol officers can initiate the criminal justice process. However, patrol is no longer the “only form of police service that directly attempts to eliminate” criminal opportunity, and while all police departments continue to engage in preventive patrol, there are many strategies that the police have developed over time to effectively and efficiently realize their public safety goals. Many of these contemporary strategies have evolved from the traditional patrol function.

Patrol seeks to accomplish a variety of goals. Chief among these goals is public safety; however, it is not clear whether this goal is consistently achieved. Other important but secondary goals may include crime prevention, preserving the peace/order maintenance, deterrence, being available to respond to crimes or other emergencies, apprehending suspects, increasing citizens' perceptions of safety, improving citizens' attitudes toward the police, traffic enforcement, ensuring roadway safety, identifying and responding to community problems, or responding to any number of service requests from the public. However, preventive patrol – i.e., nondirected, random patrolling by officers when not handling citizen requests or other emergencies – continues to occupy a considerable amount of the typical officer's time (Famega et al. 2005).

Crime prevention interventions can extend beyond uniformed officers randomly driving around geographic areas waiting to react to citizens' requests via 911 calls for service. Patrol functions can also include high levels of crime, problem or geographic focus, as well as a variety of interventions from law enforcement to problem solving. This essay examines traditional preventive patrol and its adaptations and will critically examine the impact of patrol through the lens of effectiveness and efficiency. A variety of methods of patrol will be introduced, including random preventive patrol, foot patrol, directed patrol, crackdowns, and hot spot policing. This essay will demonstrate that the best practices for public safety have evolved from the standard, traditional, reactive, passive model of patrol to a more flexible, data-driven, intelligence-led, proactive approach.

Random Preventive Patrol

Typically police jurisdictions are geographically divided into patrol beats or zones, and officers are assigned to these beats in order to conduct patrol activities. Beats deliberately vary in size based on a variety of factors, including residential population, commercial business density, number of calls for service, and crime rates in order to equalize officer workload. The result is some beats are very large (many square miles) while some are very small. These factors, when taken together, have an impact on officer workload and activities (Herbert 1997).

The most influential early study on the impact of preventive patrol was conducted in Kansas City (MO) in the early 1970s. This large-scale experiment involved manipulating the level of patrol allocation (or patrol dosage) across 15 beats in the South Patrol Division of the KCPD for an entire year, with the goal of determining what effect patrol has across a variety of outcomes. Each of the beats was assigned among three treatment conditions: proactive beats were assigned 2 to 3 additional patrol units, reactive beats were assigned no patrol units, and control beats were assigned the normal dosage levels. These beats were matched across a variety of crime and social characteristics permitting meaningful comparisons. Results indicated that assignment to one of the treatment conditions had little significant, or inconsistent, impact on a variety of suspected outcomes. Specifically, victimization surveys indicated no differences across residential and nonresidential burglaries, auto thefts (or thefts from autos), robberies, or vandalism; rates in which crimes were reported to the police did not vary; citizens' attitudes toward the police, satisfaction with police encounters, and fear of crime did not vary; citizens' protective measures (e.g., target hardening) did not vary; business owners had similar attitudes toward the police; response times were not faster in proactive beats; and the rate of traffic accidents did not vary (Kelling et al. 1974). Additionally, the project observed that officers had a significant level of uncommitted time; in fact, less than 20 % of an officer's time was dedicated to crime-related activities, whereas up to 80 % was spent on various service and peacekeeping activities. About 60 % of officers' total time was "uncommitted." These conclusions suggest that traditional preventive patrol may not be very effective at achieving objectively measured performance measures (e.g., crime suppression) or subjectively measured performance measures (e.g., citizens' perceptions).

The Kansas City Preventive Patrol Experiment (KCPPE) remains among the most influential and important examinations of the police function in America. The size and scope of this project was remarkable, and at its time, it was truly unique and, in fact, has not been fully replicated. Yet it is challenging to draw firm conclusions about the impact of the project. The research endeavor was truly path marking; however, methodological and theoretical limitations cast doubt on its findings (see Bayley 1994; Sherman and Weisburd 1995; Weisburd and Eck 2004). Nevertheless, minor adjustments to normal patrol allocations across beats probably do not increase a potential offender's perception of being caught. Beats in urban environments are often many square miles, so doubling police presence within those areas is likely undetectable. Also, the deterrence model assumes a rational offender is able to calculate the certainty of being caught, where in reality many crimes are the function of impulse, passion, or opportunity, which would break down any inherent value of police presence. Many crimes are not suppressible by patrol, including crimes committed indoors and outside the observation of the police (or offender). Finally, traditional preventive patrol may be too passive and reactive. Assuming that crime is prevented when randomly driving within large patrol beats and waiting for calls for service places the police at a crime prevention disadvantage, as little of these resources are dedicated to anticipating or preventing criminal events (Bayley 1994). Recognizing that officers have significant levels of uncommitted time presents an opportunity to guide proactive activities of officers strategically to increase the deterrent value of routine police activities. As Sherman and Eck (2002, 307) note, "there is little evidence that changing the number of officers patrolling beats has a consistent and measurable impact on crime." However, although these limitations may undermine the effects of patrol generally, the more focused and strategic uses of patrol may increase the likelihood that patrol officers are in the right places at the right times to deter or interrupt crimes (even those involving impulse or passion) and that their regular presence in hot spots will tend to drive would-be offenders away from areas that provide the greatest opportunities. Also, greater familiarity between police and citizens in high-risk locations may encourage cooperation and trust between these groups and facilitate higher clearances for crimes that do occur.

Another assumption of traditional preventive patrol is that officers will be out in the community and available to respond to citizens' requests for emergency assistance, and this activity will enhance public safety. While this may be an important service the police provide to the public, rapid response to emergencies has not been closely tied to crime prevention or public safety. The idea is that quick response by officers increases the likelihood of apprehending criminals, and this process provides a general crime deterrence (National Research Council 2004). However, empirical examinations note a weak relationship between rapid response and public safety (Spelman and Brown 1981) mostly because typical calls for service involve discovery crimes, where citizens "discover" the crime long after the offender has fled the scene or that citizens delay in contacting the police even after crimes involving contact with an offender(s). It is unlikely that rapid response will reduce crime (Sherman and Eck 2002), but because it is symbolically important to citizens, many police departments continue to monitor and track response times as an indication of effectiveness.

Why, despite the evidence and conventional wisdom that indicates preventive patrol is not as effective as intended, do police departments continue to utilize it as a core function? Perhaps one reason is citizen demand. Patrol can be viewed as an institutionalized component that is so engrained in American policing that the police may feel they have to minimally conform to citizens' desires, regardless of whether it is effective. Citizens expect to see uniformed officers patrolling streets in marked vehicles, and police risk criticism if they fail to comply with these traditions. Preventive patrol is a fixture within the institutional environment of policing. Crank and Langworthy (1992, p346) noted that “even though the rituals of 911 systems and random preventive patrol may be neither effective nor efficient as law enforcement or crime prevention strategies, they provide ceremonial evidence that a police department behaves as it should. . .Failure to sustain these important rituals may result in the de-legitimation of a police department.” Therefore, it really does not matter whether patrol “works” (in terms of crime control); the police must do it anyway. Furthermore, preventive patrol and rapid response provides ample opportunity for the police to interact with the public. These encounters are important components of the police–public relationship as it provides opportunities for the police to deliver important service (which is often unrelated to crime). Another reason may simply be habit or organizational inertia. Police organizations continue to assign vast personnel and capital resources to preventive patrol simply because they always have. It is a paradox that citizens may demand the police engage in a particular technology while also holding them accountable for public safety. Tying these concepts together, Mastrofski and Willis (2010) note that traditional preventive patrol is the “main course” that citizens crave – the standard or traditional model of policing provides citizens an opportunity to request police services and summon officers to them for a face-to-face encounter. Perhaps there is nothing more democratic than the ability of citizens to call the police (as agents of government) and know that they will respond, and in fact, citizens are more likely to have an encounter with a police officer than any other governmental representative (Langan et al. 2001). Preventive patrol and rapid response, even if it is ineffective and/or inefficient as crime control, provide other material and symbolic value to both the police and citizens.

But opportunity emerges from this reality. Recognizing the limits of preventive patrol along with the fact that officers often have large amounts of uncommitted time (Kelling, et al. 1974), the police have complemented this strategy with other tactics. Preventive patrol is viewed as the standard model (Weisburd and Eck 2004; National Research Council 2004) of policing, and while preventive patrol may not ever be completely eliminated or replaced, increasingly resources that could be used on patrol are being siphoned away toward strategies that have higher levels of focus and greater diversity in approaches. Supplemental patrol approaches, such as foot patrol, directed patrol, crackdowns, and hot spot policing, seek to focus resources in smaller geographic areas or on specific types of problems, sometimes using real-time, locally relevant crime information. These approaches are presented here within the context of patrol because they do not necessarily indicate a paradigm shift in the philosophy of policing, as problem-oriented policing or community policing may.

Beyond preventive patrol, crime prevention approaches may be characterized across at least three different dimensions. These dimensions borrow heavily from existing conceptualizations of police crime prevention strategies (see Weisburd and Eck 2004; Lum et al. 2011). The first dimension is officer *dosage* or overall allocation of personnel resources. Officer staffing levels may remain the same, and existing personnel can be reallocated in a more strategic manner with no additional resources. Shifting existing personnel from patrol to other, more focused strategies represents greater efficiency than adding additional personnel beyond current staffing levels (e.g., hiring more officers or more likely paying officers overtime to conduct special projects like crackdowns). Second is *focus*, including geographic and problem/crime focus. Using data, intelligence, and local knowledge, geographic areas may be identified that have specific types of crime problems, including guns and drugs. Police focus their attention in smaller geographic areas to address these specific types of problems. Third is the type of *intervention* or the activities that officers emphasize. Officers may be engaged in proactive, zero-tolerance style of law enforcement, or problem-solving approaches, or offender-focused approaches, or other activities that seek to address the problem identified earlier (e.g., trying to remove guns from the street to reduce gun-related crimes). Because crime prevention strategies tend to vary considerably across these and other dimensions, it can be challenging to draw broad conclusions on the best practices, and likewise, it is challenging to label specific activities as being a crackdown rather than directed patrol. What is clearer is that these progeny represent alternatives or supplements to traditional preventive patrol and with that in mind will be discussed collectively.

Foot Patrol

Even since the advent of motorized patrol, assigning officers to foot patrol has remained widely popular for decades. In fact, it is estimated that 55 % of all police departments regularly schedule officers to foot patrol, and utilization is most frequent in larger jurisdictions (Reaves 2010). Because motorized officers spend more time isolated in their vehicles, automobile patrol separates and creates a barrier between the police and the public, but foot patrol or bicycle patrol is positioned to encourage nonconfrontational interactions between officers and citizens, which in part can improve communication and relationships, as well as aid in peacekeeping and service delivery. But despite the widespread adoption of this strategy (which involves significant expenditure of personnel resources), the actual effectiveness of foot patrol is less clear. Evaluations have generally found citizens' satisfaction with the police and perceived safety increase, but there is a lack of consensus whether foot patrol influences actual crime rates (particularly violent crime rates). Two comprehensive evaluations of foot patrol revealed that although foot patrol may result in a slight reduction in crime, it primarily reduces citizens' fear of crime and changes the nature of police–citizen interactions toward more positive and non-adversarial exchanges. The major studies were the Newark Foot Patrol Experiment, which included data on foot patrol in Newark and 28 additional cities (Police Foundation 1981), and the Neighborhood Foot Patrol Program, which was conducted in 14 neighborhoods of Flint (MI) (Trojanowicz 1982). Later reports on the Flint study discovered an increased positive acceptance of the program and confidence in police services (Trojanowicz and Banas 1985). The size of a foot patrol beat should be small enough that it can be covered at least once or twice per shift to improve police–community interactions and reduce fear of crime (Payne and Trojanowicz 1985). At best, evaluations elsewhere demonstrated little-to-modest crime prevention benefit, which may have relegated foot patrol (as a strategy) as an add-on or supplement to real public safety interventions or conceptualized it as a public-relations tool.

Examinations of foot patrol may have been biased toward null results for several reasons. First, patrol areas for which officers were responsible may have been too large, creating dosage problems or diluting any possible benefit. This is analogous to the observations of early patrol experiments (Sherman and Weisburd 1995), and crime prevention and problem solving is more effective when it focuses on geographically small micro-places (Sherman and Weisburd 1995; Weisburd and Eck 2004). Second, the content of what officers actually do also matters. Increases in the mere presence of officers may yield modest crime prevention benefits; however, there is evidence that when coupled with specific problem-solving tactics, the impact may increase (Braga et al. 1999; Weisburd and Eck 2004). Early examinations of the effectiveness of foot patrol did not use rigorous research methodologies, and stronger research strategies are necessary to inform best practices in police crime prevention strategies.

Recent research conducted within the Philadelphia Police Department (PPD) paints a different picture of the effectiveness of foot patrol. The PPD identified micro-places within the city which could be considered hot spots for violent crime (particularly homicide, aggravated assaults, and outdoor robberies). These foot beats were small high-crime areas that averaged about 14.7 intersections and 1.3 miles of surface streets. The intervention involved areas that were amenable to foot patrol, without diluting dosage to the community level. A quasi-experimental design was employed to assign half to a treatment condition (foot patrol) with the other half serving as a control or comparison area. Violent crime in foot patrol areas declined significantly, while no measurable impact was observed in control areas, even after taking possible geographic displacement into account. The greatest crime prevention benefit was observed in the most crime-prone foot beats – those beats above the 60th percentile in their violent crime rate experienced less violent crime than their comparable control areas (Ratcliffe et al. 2011). This proactive, focused, micro-place strategy resulted in a successful outcome, which is consistent with results from evidence-based policing (EBP) studies, in that "police strategies are more effective when they are place-based, proactive and focused" (Lum et al. 2011, p. 5). Foot patrol can be implemented using existing resources, as evidenced in Philadelphia. However, because they can be so labor-intensive, if implemented over a large number of areas, then staffing and personnel increases may be necessary.

Directed Patrol and Crackdowns

Directed patrol represents a more strategic approach to use of patrol resources. While officers may in fact have considerable amount of discretionary time during preventive patrol, this uncommitted time can be interrupted by a call for service at inopportune times, making it challenging for officers to engage in meaningful, strategic crime prevention. Additionally, randomly patrolling throughout assigned beats in order to provide general deterrence may not be an efficient or effective use of resources. Directed patrol seeks to mitigate this by relieving some officers from responding to calls for service in order to provide them with uninterrupted time and further focuses their presence in smaller areas that have higher incidents of crime problems. This can also provide officers an opportunity to tailor interventions to particular areas. For example, an early application of directed patrol occurred in Pontiac (MI), where officers performed aggressive activities at strategic locations during uncommitted time. In analyzing the relationship between directed patrol activities and target crime specifically robberies, burglaries, auto thefts, and larcenies from automobiles, the number of arrests during program periods increased significantly. Results suggested that intervention while on directed patrol had more of an effect on crime than simply how many police were on patrol or how much time was devoted to directed patrol. Proactive patrol activities, such as arrests, vehicle stops, and field interrogations, decreased "at least some categories of reported crime" (Cordner 1981, 52), and Sherman and Eck (2002, 310) explain, "while there is very little empirical support for the effectiveness of adding more police across the board, there is a consistent body of strong scientific support for concentrating police patrols at places and times where crime is the most likely to occur. Patrolling low crime areas is unlikely to improve safety, but more patrolling in high crime places can be effective."

Intensive, sudden, short-term increases in officers' presence and proactive arrests for specific or all offenses in particular areas are known as crackdowns. Police crackdowns have been used to focus the attention of officers in particular areas for a variety of place-specific problems and as such may be considered a more intense form of directed patrol. This approach assumes that crackdowns increase the perceived risk of apprehension while simultaneously focusing on high-risk offenders within targeted areas, achieving crime prevention through deterrence and short-term incapacitation. Evidence indicates that crackdowns can achieve initial deterrence for some offenses as well as crime reduction after the crackdown has ended (e.g., residual deterrence). Crackdowns tend to have positive results – in a comprehensive review of 43 evaluations of crackdowns, Scott (2004) identified 24 that reported effectiveness, while 5 others reported mixed results. Case studies indicated that short-term crackdowns incur less deterrence decay after the conclusion of the strategy than long-term crackdowns, which suggests that personnel resources can be saturated in areas for relatively short periods of time, withdrawn, and crime prevention will linger for periods following the withdraw. This can be an effective and efficient practice, if strategically undertaken. For example, an examination of a 30-day crackdown in Richmond (VA) revealed a 92 % reduction in reported crime, relative to a comparison area. The crackdown produced some residual deterrence over the subsequent 6-month period; however, shortly thereafter some crime had returned to pre-project levels in some parts of the targeted zone (Smith 2001). An intensive crackdown for gun-related offense demonstrated similar benefits. Officers saturated a specific patrol beat in Kansas City (MO) for 29 weeks, during which time they proactively concentrated on removing guns from the street. Gun seizures increased by 65 %, while gun-related crime decreased by 49 %. There was no indication of crime displacement to adjacent areas (Sherman et al. 1995). The effect is likely because the intervention was geographically focused to address a specific crime, rather than offering a mere general deterrent effect of increased presence. A similar initiative in Indianapolis that involved directed police patrol in high-crime areas yielded results when employing a targeted offender/specific deterrence strategy on suspicious people and problem places within beats to reducing violence (McGarrell et al. 2001).

There are limitations with crackdowns that are worth noting. First, crackdowns typically are expensive and labor-intensive, which compromises its efficiency as a crime prevention strategy. It is promising that short-term crackdowns yield the greatest residual deterrence; however, intense saturation of patrol in small areas may be cost prohibitive as a general public safety model. This is particularly true if crackdowns are implemented as a special project where officers are paid overtime for participation in the crackdown. In the crackdowns described above, Smith (2001) indicated that 4,812 additional man-hours were realized to implement the crackdown; the Kansas City Gun Experiment was executed with an additional 4,512 officer hours (Sherman et al. 1995); the Indianapolis directed patrol intervention involved 2,905 additional officer hours (McGarrell et al. 2001). Crackdowns, unlike other strategies like the intervention describe above in Pontiac and hot spots policing (to be discussed later) may not be easily implemented with existing resources. Second, crackdowns can compromise police–public relationships. Proactive, zero-tolerance arrests within areas increase the possibility of negative, confrontational police–public contacts that can interrupt the ability of these parties to engage in meaningful coproductive partnerships. Crackdowns that focus on street-level activity in socially disorganized areas disproportionately impact poor citizens, which could not only exacerbate police–public relationships but also heighten fear among residents. It is wise to consult with citizens in advance of implementing crackdowns to determine appropriate and ethical target selection and officer behavior (Sherman, et al. 1995; McGarrell, et al. 2001). Related, because crackdowns involve aggressive law enforcement efforts, there is an increased potential for abuse of citizens' rights by the police, which further underscores the importance of careful planning and constant monitoring of activities by administration. Crackdowns may be best suited as short-term, quick fixes to emerging problems implemented in consultation with residents rather than a long-term strategic public safety solution, particularly since crackdowns rarely address the underlying causes of crime (Scott 2004).

Hot Spots of Crime and Disorder

Within patrol beats there may be micro-places that account for a disproportionate amount of police activities. Calls for service, crimes, or disorder tend to be concentrated spatially among a few parcel addresses, street corners, or city blocks and further may be concentrated temporally. An analysis of calls for service in Minneapolis revealed that very few places accounted for a disproportionate amount of recurring problems requiring police attention. In fact, over the course of a year, most places in the city produced one call for service or less, whereas 3.3 % of all places accounted for over 50 % of all calls for service. This was also true for predatory crimes, such as robbery, rape/sexual conduct, and auto theft (Sherman et al. 1989). Places with the highest rate of crime and calls for service which required police attention are referred to as "hot spots" of crime. This has direct implications for patrol allocation in that local information can be used to identify places within the city where crime and calls for service are so frequent that they almost become predictable, and this is further concentrated among certain "hot times" during the day or week. Recognizing that random preventive patrol has limited effectiveness to begin with, and coupled with the reality that much of a patrol officer's day includes uncommitted time, it becomes possible to strategically allocate officers to hot spots during hot times to effectively impact crime and disorder without significant alterations to personnel resources. Hot spot policing differs from directed patrol or crackdowns primarily in that its geographic focus is much smaller.

There is compelling evidence that hot spot policing can be an effective and efficient strategy to impact crime. Geographically focused policing strategies such as this have been identified as a promising strategy for increasing the effectiveness of the police (National Research Council 2004). Braga (2007) systematically examined existing published empirical examinations and concluded that 7 of the 9 studies reported significant reductions in crime and disorder and therefore will be explored more fully in another entry of the current work (see Telep and Weisburd *citation here*). The Minneapolis Hot Spots Patrol Experiment was an early examination of the efficacy of this spatially focused approach and was designed to examine the crime prevention effects of patrol officer presence at hot spots during hot times. Police and researchers identified 110 hot spot places and randomly assigned half of these places to a treatment condition. Officers were instructed to be present at one of the targeted hot spots during uncommitted time; thus, this examination was not so much concerned about specific officers' activities as it was focused on additional officer presence to deter criminal activity. Results indicated that increased police presence in hot spots yielded significant reductions in calls for crime. Calls for service regarding disorder experienced the largest decline, and researchers conducting systematic social observations of hot spots observed less disorder in target hot spots relative to their counterparts. The deterrent effect of hot spot policing may be different from what was observed in the KCPPE because police focused on place-specific "micro-deterrence" (Sherman and Weisburd 1995, 646), thus strategically focusing officers on identifiable, small problem places so as to not dilute their deterrent effect across large beats. Subsequent analyses revealed that the amount of time officers are at a hot spot does not need to be too long to experience measurable reductions in disorder. Officers need to minimally be at a hot spot for 10 min to yield beneficial results, with the optimal time being 14 to 15 min for each hot spot per hot spot. Time spent at a hot spot beyond 15 min begins to yield diminishing returns which compromise the efficiency of personnel resources (Koper 1995).

Lessons from the Minneapolis examination continue to have relevance for everyday patrol work. These results demonstrate that police departments can use timely, locally relevant data to focus patrol activities in very specific locations. Famega et al. (2005) noted that typically 75 % of officers assigned to preventive patrol have uncommitted or highly discretionary time but further note that very little of that unassigned time is spent on proactive strategies such as problem solving. Rather, they note that officer typically engage in routine patrol, back up other officers, or wait to be dispatched. Opportunity arises from this in that patrol officers can target hot spots as part of their normal routine. Internal crime analysts can utilize local crime data, as done in Minneapolis, to continually redefine hot spots, examine the persistence of crime in these micro-places, and reassign officers to emerging hot spots as necessary. This reality, perhaps more than others, has the greatest potential to improve police effectiveness while utilizing existing organizational resources.

Hot spot policing strategies can have notable shortcomings. First, the overall utility of hot spots policing would be mitigated if crime and disorder were merely pushed around the corner – displacing crime and disorder from a hot spot to another location yields a zero-sum gain for public safety, and there exists a serious risk of creating new hot spots in locations that were previously crime-free. Recognizing this risk it is important to monitor areas contiguous to hot spots (i.e., catchment areas). Measuring and monitoring displacement can be complicated, as crime can be displaced territorially (from one location to another), temporally (from one time of the day to another), tactically (changing the method of crime, e.g., auto theft decline but carjacking increase), by target (different victims in the same area), functionally (offenders commit different offenses because the risk of committing the original is too high), or by perpetrator (some offenders are deterred, but new offenders emerge to replace them) (Lab 2010). Previous studies tend to demonstrate minimal territorial displacement to surrounding catchment areas, and in some cases, crime in surrounding areas actually decreases. A diffusion of benefits occurs when areas not targeted for police intervention nevertheless experience residual benefit and crime decreases (see Weisburd and Green 1995). The weight of the evidence on various hot spot policing interventions suggests that the police can impact crime, calls for service, and disorder within localities without significant risk for crime displacement. Second, like crackdowns, hot spot policing may demonstrate short-term impacts with little long-term benefits unless the strategy is coupled with meaning problem solving aimed at addressing the underlying social problems that permitted crime to flourish in the first place (i.e., what made this spot "hot" to begin with?). Third, this approach also runs the serious potential for alienating citizens. If citizens view hot spot policing as police officers saturating the area with aggressive enforcement activities, then the police may inadvertently compromise police–public relations. This can result in labeling or stigmatizing areas (and the people in those areas) as undesirable. To avoid these and other unanticipated consequences, Rosenbaum (2006) encourages comprehensive analyses using a variety of different information sources to identify hot spots; employ a variety of alternatives in the areas to facilitate short- and long-term success; build meaningful partnerships between the police and other governmental, private, and citizens groups who are hidden allies in facilitating public safety; and pay attention to preventing crime across individual, family, and community levels (and not just the micro-spatial level).

Summary

Preventive patrol remains a dominant activity function of the police; however, the evidence suggests that it has limited effectiveness and efficiency in promoting public safety. Over time a number of approaches have developed to counterbalance this reality, and while it remains challenging to suggest that a single evolving approach is superior to another, it is safe to say that they represent a dramatic improvement to and hold more crime prevention promise than preventive patrol.

The evolving nature of street-level activities of police officers to achieve effective and efficient crime prevention comes with it a number of challenges and considerations for policy makers. These considerations are directly related to the dimensions previously developed. First is a strategic allocation of resources. Effective and efficient crime prevention often must be accomplished within fiscal realities; thus, it is important to determine whether officers traditionally assigned to preventive patrol duties can be engaged to participate in the supplements such as foot patrol, directed patrol, crackdowns, or hot spot policing. Will officers be tasked with performing activities during periods of uncommitted time, or will they be untethered from responding to calls for service in order to engage in strategic problem solving? Hot spot policing or some version of directed patrol may be suitable for generalist officers who are still responsible for calls for service, whereas foot patrol and crackdowns may be most easily implemented by either assigning officers to blocks of time where they are not responding to calls to implement this strategy. Interventions that are executed through the use of overtime assignments may be doomed to be inefficient and too episodic in nature to have a lasting public safety benefit, and thus may be reserved for unusual, exigent circumstances rather than business as usual.

Second, identification and focus become paramount importance. Rather than conceptualizing geographic areas as large beats, neighborhoods, or some other arbitrary quasi-permanent boundary, focus would have to be defined as smaller areas within patrol beats. Related, the type of crime, problem, or disorder occurring within the jurisdiction may also vary from place to place. Some areas may be prone to gun-related violence, whereas others are plagued by drugs. Some areas may be hot spots of disorder and public nuisances, whereas others may be prone to violence. Even after disaggregation by these means, further analysis and local knowledge may be necessary. Regardless, greater geographic and crime/problem specificity is necessary to more fully identify locations in need of supplemental police attention and intervention and must be monitored on a regular basis in order to determine whether problems emerge in new areas (territorial displacement) at different times (temporal displacement) or whether old problems are replaced with new problems (tactical displacement).

Third, interventions will vary and will need to be place and crime specific. Mere presence for general deterrence, problem solving, focused activities, and aggressive law enforcement all can have public safety benefits; however, they must be suited to the geographic and crime/problem focus of different places. Strategic, data-driven, intelligent policing coupled with monitoring of objective and subjective outcomes holds public safety promise beyond the traditional preventive patrol approach.

Fourth, preventive patrol and other interventions will need to make an effort to continually engage the public in a collaborative manner. An unanticipated consequence of random motor patrol is that it separated the police from the public, created a barrier for nonconfrontational interactions, and created social distance between the police and citizens. A conscientious approach to facilitating a partnership between these groups will avoid misconceptions, help the police to strategically identify places of greatest concern and the underlying problems associated with these places, and facilitate effective order maintenance and delivery of police services.

Overview

While many studies examine factors relating to job satisfaction and job stress of correctional officers and correctional treatment staff, the scholarly literature on job satisfaction and job stress of wardens is scarce. Of the studies conducted, many determinants have been found to impact job satisfaction and job stress of wardens, such as individual-level attributes (e.g., age, race, gender, educational level, and tenure status) and work environment/organizational features (e.g., career experiences, organizational conditions, nature of the work role, correctional approaches, intrinsic and extrinsic rewards, organizational justice, organizational structure, social support, work-family conflict, and job stress). This entry provides an examination of the determinants of job satisfaction and job stress of correctional officers as well as wardens. It also examines the impact that different leadership styles could have on job satisfaction and job stress.

Fundamentals

Despite substantial growth of the United States correctional system, limited research exists on the leaders who are responsible for the effective and efficient functioning of correctional organizations. Typically, prison wardens are responsible for a wide array of tasks and must answer to constituencies both internal and external to their correctional facility. While ensuring the priority of a safe and secure prison environment for both staff and inmates, wardens must effectively and efficiently respond to macrolevel budget and legislative issues, human resource and staffing issues, facility functioning, as well as concerns of inmates and their families (Ruddell and Norris 2008). To be successful in these and other efforts, wardens must be effective leaders who can successfully convey and inspire their staff with a shared vision for their organization (Heaton and Atherton 2008) without suffering negative affect from intensive job tasks. Yet, the dynamic prison environment presents daily challenges for wardens as many wardens perceive that they are insufficiently prepared (McCampbell 2002).

Insight into promising management practices for prison wardens has been gained in a number of areas including overcrowding, prison gangs, inmate amenities, physical location of the warden's office, and managerial attitudes. Less attention has been paid to the successful functioning of prison wardens insofar as identifying individual or organizational attributes related to a positive work experience and job-related stress (Cullen et al. 1993; Flanagan et al. 1996).

Only in related literature that has assessed correctional officers have researchers examined antecedents of job stress and related coping mechanisms. Job stress has been typically defined in the job stress literature as "the harmful physical and emotional responses that occur when the requirements of the job do not match the capabilities, resources, or needs of the worker" (National Institute for Occupational Safety and Health 1999, p. 6). Stress typically results from exposure to stressors that develop as a result of the workplace and associated duties (Cullen et al. 1985; Lambert 2004). Experiencing high levels of stress especially in a prolonged or regular manner can have damaging outcomes on an individual. These negative outcomes can include poor job performance as well as increased levels of social problems, burnout, divorce, mental health problems, and illness (Griffin et al. 2010; Salami et al. 2010).

Given the importance of prison wardens in the everyday functioning of correctional organizations, a warden's inevitable exposure to job stress may have a damaging effect on both the individual as well as the organization (Hom and Griffeth 1995; Lambert et al. 2007). Negative work experiences such as job stress can result in higher levels of turnover (Shaw 2011) which can be especially concerning when it encompasses leaders of an organization. As Shaw (2011) and others have noted, both negative proximal (e.g., safety, productivity, efficiency) and distal (e.g., organizational performance) impacts of job stress could cause eventual organizational disruption. Consequently, it is important for researchers to consider correlates of prison warden job stress given the significant level of organizational capital held by a person in this position as well as coping mechanisms that may offset job stress.

As noted earlier, the consequences of job stress can be damaging to both an individual employee and the correctional organization as a whole (Lambert et al. 2007). While extensive research in this arena has been conducted in other occupational fields, within corrections the job stress literature has primarily focused on custodial staff, such as correctional or detention officers and to a limited extent noncustodial, correctional treatment staff (see Armstrong and Griffin 2004). Insufficient attention has been paid to prison wardens and job stress, with a very limited literature that has focused on job satisfaction (Cullen et al. 1993; Flanagan et al. 1996). Existing studies have demonstrated that correctional officers report high levels of job stress due in part to individual perceptions of their work environment, which is contemporaneously influenced by their personal characteristics (Mitchell et al. 2001). Given the demanding responsibilities of prison wardens, including maintaining a safe and secure prison environment, managing staff resources, disciplinary incidents and grievance processes, fiscal constraints, upholding public relations, and maintaining professionalism (Ruddell and Norris 2008), it is reasonable to anticipate high levels of job stress exists among prison wardens.

Job stress levels among prison wardens are a unique concern because everyday operations of prisons and their environment could be negatively affected by a warden who experiences significant job stress. If high job stress levels are the norm, prison wardens may be unduly exposed to higher risks of poor decision making, job performance, or turnover (Hulsheger et al. 2010). While turnover is not always a drawback (i.e., some degree of staff turnover can be healthy), when it occurs during a period of organizational change or fiscal conservation, it can be internally damaging to an organization. Alternatively, it could be the case that prison wardens may not experience significant job stress due to unique characteristics of that individual or adaptive coping methods successfully employed. Attrition of those correctional staff may have already occurred for individuals that perceive significant job stress or fail to successfully cope with existing stress, or at minimum those individuals have not successfully navigated and promoted through the correctional system. Stated another way, individuals who perceive the correctional environment to be stressful may not seek or receive career advancement opportunities or be "washed out" at an earlier career point prior to appointment as a warden. Thus, a determination of the level of prison warden job stress, as well as its corollary conditions, is important and significantly understudied.

Correlates of Correctional Officer Job Stress

Factors previously examined in the correctional officer job stress literature have included individual-level attributes (e.g., gender, race, age, education level, tenure status, and position) as well as organizational or workplace characteristics (e.g., organizational justice, conditions of confinement, work roles, organizational and co-worker support, quality of supervision) (see Armstrong and Griffin 2004; Cullen et al. 1985, 1993; Flanagan et al. 1996; Hepburn and Knepper 1993; Lambert 2004; Lambert et al. 2006a, b, 2007; Mitchell et al. 2004; Triplett et al. 1999). While some studies have concurrently examined job stress and job satisfaction (Lambert et al. 2006a, 2007), the distinct influence of the two concepts has been difficult to disentangle.

Within the correctional officer job stress literature, a number of inconsistencies in determining individual attributes that correlate with job stress persist. Specifically, the racial background of an officer has been found to both influence as well as be unrelated to correctional officer perceptions of job stress. For example, Lambert et al. (2007) found correctional officers who were White reported significantly higher job stress (see also Cullen et al. 1985), yet Armstrong and Griffin (2004) found no significant relationship between officer race and job stress (see also Lambert et al. 2010). Gender has been a more consistent indicator of job stress, albeit an interactive effect that is influenced by characteristics of the prison environment. Specifically, female officers as compared to male officers have tended to report significantly more job stress (Armstrong and Griffin 2004; Lambert et al. 2007; Cullen et al. 1985). Regarding gender, Triplett and colleagues (1999) found significant interactive effects between gender and various aspects of the work environment. For example, female correctional officers experienced greater work-home conflict, higher levels of contact with prisoners, and an increased perception of job dangerousness. In turn, these factors were positively correlated with job stress. In comparison, with male officers factors such as tenure, quantitative work overload, and perceived job dangerousness were related to higher levels of job stress.

Interestingly, while officers with greater tenure or “time on the job” have been found to also have higher levels of job stress (Armstrong and Griffin 2004; Lambert et al. 2007; Cullen et al. 1985), beyond number of years of correctional experience, a more textured assessment of prior experience has not been explored. Prior literature has argued that important differences in job stress may exist as well as distinct perspectives between custodial and treatment staff (see Armstrong and Griffin 2004), and these may play a role in how a person experiences subsequent positions. Prison wardens may promote from either type of experiential background; thus, type of prior experience is an important extension in the measurement of the tenure variable.

In addition to individual characteristics, the attributes of the correctional environment have been found to influence correctional officer stress (Mitchell et al. 2004). Studies have found that officers who perceived their job as “dangerous” (Armstrong and Griffin 2004; Cullen et al. 1985; Triplett et al. 1999) or were employed at a higher security level prison (Cullen et al. 1985) also perceived higher levels of job stress. These types of facility effects may extend to the composition of the inmates in a facility in terms of the prison being a single gender or co-ed facility as additional security concerns are presented or minimized as a result.

In contrast to attributes associated with higher levels of job stress, researchers have also advanced an understanding of protective factors thought to be related to lower levels of correctional officer job stress. To date, researchers have studied various forms of social support including co-worker or peer support hypothesized to decrease job stress. Results have not demonstrated a clear linkage such that some studies have found supervisory and family support to be negatively correlated with work stress, while peer support was positively correlated with job stress (Cullen et al. 1985). Other studies have found that co-worker or peer support reduced job stress (Armstrong and Griffin 2004).

While the perspective and daily routines of prison wardens differ from a typical custodial correctional officer, the work environment itself remains the same. That is, the prison warden remains exposed to the same environmental factors of the correctional facility as the correctional officers including the prison’s size, custody level of the population held, and gender of the inmates (i.e., male, female, or co-ed population); therefore, these organizational attributes may influence a prison warden, but the warden's unique perspective as well as additional factors should be considered.

Transformational Leadership as a Protective Factor Against Job Stress

Research has consistently found that correctional officers who perceived the supervision they receive to be of high quality also tended to report lower levels of job stress (Armstrong and Griffin 2004; Cullen et al. 1985; Waters 1999). Despite the importance of supervision quality from the perspective of the correctional officer, good quality leadership is not necessarily an innate attribute of all prison wardens. According to Heaton and Atherton (2008), "becoming a leader in any organization usually involves a process of years of personal and professional development" (p. 14). Moreover, Heaton and Atherton (2008) suggested that a successful leader must understand the challenges confronting staff, maintain good relationships with co-workers, have a balanced life and good personal health, be energetic, have an appropriate emotional outlet, effectively communicate the purpose of the correctional organization to stakeholders, be a mediator, clearly articulate performance expectations, and be invested in their relationships with staff members. What type of leadership style might encompass such positive attributes? The organizational literature on leadership suggests a transformational leader exhibits similar characteristics.

Transformational leaders are individuals who aim to increase their organization's awareness of appropriate tasks and further motivate organization members to perform beyond basic expectations (Bass 1985). A growing body of research on transformational leadership supports the suggestion that a transformational leadership style has a direct, positive impact on performance outcomes and the behavior or experiences of subordinates (Arnold et al. 2007). For example, Mullen et al. (2011) examined transformational leadership as compared to an alternative form of passive or uninvolved leadership, which "are generally considered to be the most ineffective styles of leadership" (p. 42). Their results demonstrated that subordinates of safety managers who consistently demonstrated transformational leadership skills engaged in greater levels of safety compliance and safety participation. Additionally, using an experimental design Bono and Ilies (2006) found that "charismatic leaders enable their followers to experience positive emotions" (p. 331). Sosik and Godshalk (2000) specifically found that transformational leadership led to less job stress as a result of the increase mentoring received by subordinates. Thus, from existing literature, it appears as if transformational leadership can affect both individual well-being of subordinates in the organization as well as performance outcomes. This twofold effect of transformational leadership on performance outcomes as well as individuals was evident in Chin's (2007) meta-analysis of 28 independent studies of transformational school leadership. In the study, Chin examined the effects of transformational leadership on teachers finding higher levels of transformational leadership coincided with higher rates of teacher job satisfaction, school effectiveness as perceived by the teachers, and student achievement.

While the literature on the direct effects of exhibiting transformational leadership on subordinates is well researched, the relationship between transformational leadership skills and the leader's well-being is less clear. In the limited existing research, one study by Ram and Prebhakar (2010) found that within a sample of managers from the telecom industry, the greater the extent to which managers reported having transformational leadership skills, the lower levels of reported job stress. Yet, the mechanism through which this reduction in job stress is achieved is not explained. Arguably those who engage in a transformational leadership style experience more successful organizational functioning overall (i.e., a reduced role stressor) and potentially more support from their subordinates, thereby individually reporting lower levels of job stress. As a first step, however, it must be first considered whether transformational leadership has significant relationship with job stress within a prison warden population.

Overview

It is now widely recognized within criminology that "policing" does not simply equate with the work of "the police," with private security personnel, police auxiliaries, and voluntary bodies featuring among the multiplicity of agencies playing a role in keeping communities safe. This can be seen as part of a general, worldwide trend in which security agencies are expanding and diversifying.

Notable among these developments has been the substantial rise in demand for private security in Western democratic countries, beginning after the Second World War and gaining momentum through the latter decades of the twentieth century in response to a host of social and economic forces. These include rising crime in many countries, especially from the 1970s to the 1990s; increasing prosperity, resulting in more private property and consumer goods needing protection; the expansion of privately controlled, publicly accessible spaces ranging from hypermarkets to airports with their own distinct policing needs; a general growth in the subcontracting of security functions within both the public and private sectors, in order to limit spending and gain from the economies of scale achieved by specialist providers; and increased safety concerns on the part of companies, public institutions, and private individuals in an increasingly risk averse world. Alternative arrangements to the police are also commonplace in poorer parts of the world: in many instances private security or voluntary provision may be a preferred substitute for police forces that lack legitimacy with the public and may be ineffective in the face of high crime levels, compelling rich and poor alike to take matters into their own hands.

Such factors have promoted a growing governmental and social acceptance of private security, as it has become increasingly recognized that the private sector can make a significant contribution to the security of organizations and citizens. At the same time, a prospering security industry has been able to develop products and services better tailored to the needs of its customers, capitalizing on benefits ranging from economies of scale to technological advancement. Criminologists need to recognize these changes and adapt their focus accordingly; hence, the aim of this entry is to analyze and evaluate the restructuring of policing in late modern society with particular reference to privatization trends.

Police or Policing?

It is important to define what is meant by "policing" as it is a term that is often misunderstood. Policing is often seen as a little more than what *the police* do; indeed, it is common to find many books and articles on policing dedicated solely to the police. It is, however, only relatively recently that the two concepts have become so closely associated in the English language. Before the mid-eighteenth century, "policing" encompassed a much broader concept of the regulation of government and the morals or economy of society (Johnston 1992). It was only after the mid-eighteenth century that the word "police," borrowed from French, came to be commonly associated with the maintenance of order and crime prevention, as Sir Robert Peel's model for London's Metropolitan Police was exported throughout Britain, as well as influencing the development of municipal policing in the United States, Europe, and parts of the British Empire.

A problem that has emerged as a consequence is the assumption that solely "the police" can or should undertake "policing." It is important that these terms are differentiated because there are many other agencies engaged in this process. The noun refers to a particular organization, while the verb describes a social process of which the police *and other phenomena* are a part (Reiner 1994). It has indeed been recognized that the vast bulk of policing is carried out by people and organizations other than the police.

Reiner (1994) argues that the essence of policing is those activities aimed at ensuring the security of a particular social order. This distinguishes policing from the broader criminological concept of social control, in that the latter encompasses all those processes and activities that promote and enforce a society's norms and values. Policing is an aspect of social control, encompassing systems of surveillance combined with the threat of sanctions for breaches of criminal law, for the purpose of maintaining a society's security. Reiner defines it as:

> an aspect of social control processes which occurs universally in all social situations in which there is at least the potential for conflict, deviance, or disorder. It involves surveillance to discover actual or anticipated breaches, and the threat or mobilization of sanctions to ensure the security of order. The order in question may be based upon consensus, or conflict and oppression, or an ambiguous amalgam of the two, which is usually the case in modern societies (1994: 722).

In delivering these functions, the police typically conduct patrols, respond to incidents, undertake investigations, apprehend offenders for breaches of the criminal law, and refer cases with sufficient evidence to prosecutors for prosecution. Those found guilty by the courts are then subjected to punishment. Yet there are also many other bodies engaged in these processes. Some citizens form voluntary groups to patrol the streets, in some cases acting as vigilantes to apprehend offenders and hand suspects over to the authorities or even to initiate their own brand of "justice." Many private security firms patrol areas, conduct investigations, and refer some of the offenders they find to the police. There are also other public bodies engaged in these processes that enforce particular areas of the law, conducting investigations and bringing prosecutions, such as the Health and Safety Executive (HSE) in the UK. Policing can alternatively be carried out by new technology controlled by humans, closed circuit television (CCTV) being a good example whereby the presence of such cameras, in town centers, private premises, and even on the roads against speeding drivers, may deter deviant behavior, its recordings able to be used for investigating and prosecuting criminals. The secret activities of intelligence agencies, targeted against espionage, terrorism, or organized crime, form another important dimension of these processes. Thus, when the broader concept of policing is dissected, the wide range of bodies – in both the public and private sectors – engaged in these activities becomes apparent. This entry will focus upon the commercial aspects of this.

History of Privatization?

The history of policing in most countries is largely dominated by private and voluntary forms of policing. It is only with the emergence of modern industrial countries towards the end of the nineteenth century that the public police became the dominant model in the delivery of policing (Johnston 1992). Private and voluntary forms of policing did not disappear but rather were eclipsed by the dominant public arrangements. The emergence of commercial private security companies, however, is relatively new. In the USA such companies can be traced to the late nineteenth century and the rapid emergence of company towns surrounding the coal, iron, and steel industries.

There is a body of literature that is very critical of the emergence of private security companies at this time in the USA. This "radical" perspective views the growth of private policing as an inevitable consequence of the crisis of capitalism whereby the state draws in the private sector to strengthen its legitimacy (Button 2008). The development of the coal, iron, and steel industries took place in rural areas in which the state was not well established. Industrial militancy threatened the corporations of the time, and as a result companies resorted to private policing to maintain control. These measures went well beyond keeping the peace, being employed to ensure the working classes remained obedient. The companies would draw upon their own private forces but also made use of contractors for investigations and policing industrial disputes, most famously Pinkerton, a firm still in operation today across a range of countries as part of the Securitas group of companies.

Companies such as Pinkerton provided a range of services that included general property protection services and a range of strikebreaking services such as labor espionage, strikebreakers, strike guards, and strike missionaries (those who were paid to convince strikers to go back to work) (Weiss 1978). The policing practices that emerged, particularly during industrial action in this period, led to serious confrontations between the forces of capital and labor. There were many disputes in which the civil rights of striking workers were violated, and in some cases individuals were even killed. Such were the problems throughout this period that "private police systems" were the subject of many congressional reports (see United States Committee on Education and Labour 1971, a publication of a 1931 report). As the 1931 Congressional report argued:

> The use of private police systems to infringe upon the civil liberties of workers has a long and often blood stained history. The methods used by private armed guards have been violent. The purposes have usually been to prevent the exercise of civil rights in the self-organisation of employees into unions or to break strikes either called to enforce collective bargaining or to obtain better working conditions for union members.

This extract is typical of a widespread view in America at that time that conceived private security as involving private armies/spies and viewed this as a threat to the public interest, as a danger to society, and as a phenomenon that should be restricted in the roles it undertook.

It is the post-Second World War period, however, that has witnessed the emergence of the modern private security industry and its expansion to the extent that in many countries there are now more private security officers than police officers. Indeed, Johnston (1992) has described the changes as the "rebirth of private policing." For example, G4S, the largest security company in the world employing over 635, 000 personnel in more than 125 countries, emerged during this period. In 1951 Plant Protection Ltd was formed in Macclesfield, England. By 1958 it had over 200 employees and was undertaking its first cash-in-transit work. The name of the company was changed to Factory Guards in 1963, and the corporate member companies Store Detectives Ltd and Securitas Alarms were founded. In 1968 the company's name was changed yet again, to the famous Group 4 Total Security Ltd, and the company has since through mergers and acquisitions grown into the largest in the the world (George and Button 2000), adopting the G4S brand identity in 2006.

What Is Privatization?

Privatization, and what constitutes it, is the subject of much academic and political debate. It can vary from very wide understandings relating to the shrinking of the state to the more precise definition of replacing public sector workers with identical private sector personnel. The underlying theme, however, is the reduction in the role of the state and a priori belief that the private sector is more efficient and effective at providing goods and services (Button 2008). Butler (1991) has identified a range of privatization policies, starting with the most complete – the sale of state assets to the private sector. Secondly, there is deregulation, whereby the regulatory burden on industries is reduced or removed, which may as a consequence lead to greater private sector involvement. Thirdly, there is contracting out, whereby public authorities contract out to the private sector to undertake functions that previously they provided directly. Finally, Butler distinguishes vouchers, where the government gives recipients of their service vouchers to shop around for the best service. Privatization could even involve the removal or reduction of subsidies or the provision of tax incentives (Johnston 1992). Where direct privatization has not been possible, attempts have been made at introducing market and private sector practices in the public sector. This led to the rise of what has become known as the "new public management" or "managerialism" (Loveday 1999). It is also important to note that privatization does not always mean an increasing role for private companies vis-à-vis the state. There are other non-state organizations that have also benefited (Johnston 1992), such as charities, voluntary organizations, and consumer groups, by replacing the public sector in fulfilling governmental functions such as areas of market regulation or the delivery of welfare or justice services.

Privatization and the Police

In applying forms of privatization to the police, a range of different policies have been pursued in different countries (Chaiken and Chaiken 1987; Johnston 1992; Forst and Manning 1999). They range from the complete replacement of police departments with private security staff (O'Leary 1994) to hiring out officers to private organizations, to the charging of fees for services provided (Johnston 1992), for example, the policing of public events. Before international developments in police privatization are assessed, it is useful to examine scholars' attempts to classify applications of these measures.

In a major study of how public policing could be privately provided in the USA, Chaiken and Chaiken (1987) identified four mechanisms. The first they called **default transfer**, whereby the police are unable for various reasons to meet public demands leading the private sector to step in to fill the gap. The second they called **accommodation and cooperation**, whereby the police informally allow private security personnel to carry out tasks they do not wish to do, in return for which they provide additional services. In an example of this policy, they illustrate how the policing of the homeless in bus and railway stations in some areas has been handed over to the security personnel employed at those venues. In return, if required to deal with an incident at a station, the police will respond immediately. The third type of privatization they termed **legislation**, whereby private security personnel have been given specific roles and powers in statute. For instance, in some US states retail security personnel have been given special powers of arrest and prosecution, meaning the police do not have to become so involved. Finally, they distinguished **contracts**, whereby the government has contracted with bodies to carry out specific tasks. The main criticism that can be leveled against Chaiken and Chaiken's classification is that it does not embrace all the policies of privatization that have been applied to the police. For instance, as Johnston's classification reveals, it does not reflect how the police have embraced commercial practices such as sponsorship and charging fees.

Johnston (1992) identifies three trends exemplifying what he terms the "privatization mentality" that has been applied to policing. Firstly, there is **load shedding**, directly and indirectly. This is where the police relinquish roles directly to the private or voluntary sectors, or these effectively usurp the police because the latter are unable to provide the service the public want. Secondly, there is **contracting out**, whereby government bodies or even the police themselves contract with a private organization to undertake a function for which they remain in ultimate control. Finally, Johnston identifies **charging fees and selling services**, whereby the police have begun increasingly to act in a commercial manner by offering their services for a fee, potentially in direct competition with private security. Johnston's classification can be strengthened by including, within load shedding, Chaiken and Chaiken's example of **accommodation and cooperation**. Further, by widening Johnston's final category to the **embracing of private sector management practices**, the broader range of private sector strategies increasingly being adopted by the police can also be assessed. This entry will now use Johnston's amended trichotomy to evaluate the impact of privatization on policing across the world.

Load Shedding

This is where the funding mechanism as well as the delivery of the service is moved from the public to the private or voluntary sectors. It can happen directly, whereby the police actively abandon certain functions or indirectly whereby, because of constraints on resources, they are unable to supply a service that is wanted and the private or voluntary sector steps in to fill the gap.

One of the most significant areas in which the private sector has sought to provide services when the police are unable to meet demand is in the provision of patrol (see Noaks 2000). One of the best documented examples of the private sector successfully filling this gap is the emergence of the private security firm Intelligarde in Toronto, Canada, to police public housing estates. Rigakos (2002) shows how these deprived estates were largely abandoned by the police to disorder and crime. Intelligarde, modeled as the "parapolice," with a tough, enforcement-focused approach, reestablished a degree of security that the police were unable to guarantee.

Canada is not the only country in which other actors have filled the gaps that the police are unable to address. In South Africa, beset by high crime levels and a historically poor relationship between the police and the community, it is commonplace among rich and poor alike to take matters into their own hands through the hiring of private security or community initiatives (Wood and Shearing 2007; Steinberg 2008; Marks and Bonnin 2010). As Marks and Bonnin (2010) have documented, these can take a number of guises, adopting such descriptions as street committees, neighborhood associations, street patrols, community policing forums, and neighborhood watches depending on their emphases and objectives.

There have also been examples of more purposeful, direct load shedding. Over the last 50 years, the history of the British police has been one of incremental reduction of tasks. The police no longer check unoccupied properties or escort cash-in-transit vehicles, which they once did routinely among many other functions. There are other areas of policing where load shedding has been prominent in more recent years. Public order policing in the UK is a significant dimension in which the police have sought to reduce their role. At football matches up to the late 1980s, it was common for many police officers to be deployed within the grounds to undertake safety and public order policing functions. As a consequence of the Hillsborough disaster, when a human crush resulted in the deaths of 96 people, there were a number of reports into the safety and security strategies at football matches, the most important of which was the *Taylor Report* published in 1990. Following its publication, football clubs agreed to undertake a greater role in safety with the police concentrating on crime, public order, and emergency management. As a consequence, police presence at most routine matches has declined significantly and been replaced by stewards and safety officers. Indeed, there are some Premier League football matches that take place with no police officers within the ground. To illustrate this change, in 1989 Nottingham Forest Football Club would typically have had 150 police officers supported by 75 stewards in the ground. In 1995 this had fallen to 22 police officers along with around 250 stewards inside the ground (Frosdick and Sidney 1997).

A further area where the police have effectively shed their role in the UK is the investigation of fraud. During the 1950s and 1960s, if an organization suffered a fraud internally, it would be common for the police to undertake the investigation. Such is the extent of fraud in many organizations today that the police will normally require prima facie evidence before they become involved. They may, indeed, even expect the investigation to have been completed by private means. Indeed, the recent Fraud Review Team (2006: 69) in the UK uncovered the following response from a chief constable to an organization that had reported a £100,000 employee fraud:

> The investigation of fraud is extremely expensive in terms of hours spent obtaining statements and preparing a prosecution case. The Constabulary is required under the Crime and Disorder Act to produce a crime reduction strategy. Our strategy identifies priority areas and police resources are directed to those priority areas. Fraud is not one of them.

As a consequence of this – and often a reason to keep control of the investigation – many organizations have turned to the private sector to undertake the initial and sometimes the whole fraud investigation (Fraud Review Team, 2006). This type of load shedding has exhibited both direct and indirect tendencies. The police have been able to avoid having to investigate some frauds, which can be labor intensive, but may capitalize on the benefits of a successful investigation by the private sector.

At the international level, the limitations of military provision in unstable regions of the world, as well as corporate advancement into emerging markets including areas of high security risk, have also opened up substantial opportunities for the private security sector. O'Reilly (2010) notes how the longer established of the international security consultancies, such as the British firm Control Risks Group, emerged in the 1970s as many corporations began to extend their reach into high-risk regions of the world and faced, in particular, the threat of executive kidnap and ransom. With respect to this problem in Latin America, he explains, "By making this threat manageable, they also made it insurable" (p. 185). Since that time, the relationship between such consultancies and the insurance sector has been fundamental to their existence and development. O'Reilly observes that these early successes began to assuage initial corporate fears about moving into hazardous environments and encouraged further ventures that, in turn, required additional specialist services and cross-selling of tailored insurance products.

One element of the security industry's international expansion that has evoked particular controversy is the provision of military-related services. Avant (2009) notes how the accelerated expansion of this sector can be observed to have occurred in two distinct phases, associated with Africa's adjustment to a post-Cold War, postcolonial era in the 1990s, and the conflict in Iraq in the new millennium. The earlier phase saw the sector and its activities constructed as a matter of growing political concern, whereas the latter has seen it establish itself as serving an essential role in an era of uncertainty, albeit with acknowledged and often serious limitations still remaining. The downsizing by many countries of their military forces after the end of the Cold War has provided extensive opportunity, indeed an expressed need, for the private sector to play a role in defense, security, peacekeeping, and reconstruction. With respect to Iraq, Isenberg (2009) identifies the three main roles of private security companies as being as follows: personal security for senior civilian officials, nonmilitary security of buildings and infrastructure, and nonmilitary logistics security, often through subcontracting by US government or Coalition Provisional Authority (CPA) contractors or employment by Iraqi or foreign companies. It should be noted that, for the security industry today, Iraq is a somewhat unique case in that the demand for private security is closely tied to the Western military intervention in that country. Of the two main leading supplier countries of private security, the USA and the UK, British industry spokespersons Bearpark and Schulz (2007) argue that most UK private security providers along with other European companies largely refrain from providing frontline services in conflict zones, placing more reliance on private sector clients who are protective of their corporate reputations. Thus, the UK security sector is gaining much ground in another area of burgeoning marketplace demand: global maritime security.

Contracting Out

In this form of privatization, a governmental body retains responsibility for the funding of the activity but contracts with a third party to deliver the service. The Confederation of European Security Services (CoESS), a joint initiative of European trade associations for the security industry, observed that the UK is the country that has gone furthest in transferring traditionally public security functions to the private sector (Palmer and Button 2011), applying not only to police organizations but the justice system as a whole. Its immigration detention functions have been contracted out since the 1970s, and a wave of subsequent outsourcing commenced in 1992 with the privatization of prisoner escort services, certain prisons (reported to number 11 of 130 at the time of writing of the CoESS report), and some security functions within public prisons, such as the monitoring of offenders under curfew, the security of the lower courts of law (magistrates' courts), and the securing of many police custody suites or police premises as a whole. In the case of police organizations, such practices have gradually extended from relatively uncontroversial functions such as catering, cleaning, and maintenance to "back office" tasks hitherto undertaken by police officers (Button, Williamson and Johnston 2007).

Embracing Private Sector Management Practices

The third aspect to privatization is the embracing of private sector management practices. In the UK throughout the Conservative periods of government of the 1980s and 1990s, and continuing under the Labour governments from 1997 to 2010, there has been a gradual application of market principles within the public sector, including the police. This process has been termed "managerialism" or "new public management" (NPM) (see Loveday 1999). Most public sector organizations were subject to a Financial Management Initiative which emphasized the "three Es": economy, efficiency, and effectiveness. The rudimentary basis of this initiative was the setting of objectives and determining priorities and, ultimately, the encouragement of modes of working more characteristic of the private sector. These principles were further cemented with the encouragement of what later became known as "policing by objectives" in the issuing of a Home Office Circular (114/1983), a means of offering central government "guidance" to police forces on a wide variety of operational and policy issues that came to be regarded as binding by most forces due to the authority held by the Home Office in police governance structures.

By the early 1990s the pace of reform had intensified. The Police and Magistrates Courts Act 1994 shifted the balance of power in the "tripartite" structure of police governance (comprising the chief constable, the Home Office, and the police authority, made up of locally elected councilors and magistrates), still further in favor of central government. It emphasized the "chief executive" role of the chief police officer (in the UK known as the chief constable or, in the two London forces, the commissioner), who was responsible for managing the police service rather than administering it. The Act also reconstituted chief constables as budget holders, enabled the Home Secretary to set national performance targets, and introduced greater business interest into the police authorities, by reducing the number of democratically elected councilors at the expense of independents (expected to be from the business community) (Loveday and Reid 2003). Another significant event was the Sheehy Inquiry into Police Rewards and Responsibilities, tasked with critically examining the thorny issues of the police rank structure, remuneration, and conditions of service and remuneration. Following considerable police resistance to the recommendations, these were largely rejected, although some changes, such as performance-related pay for top-ranking officers, were implemented. Some constabularies appointed accountants to key positions in the hierarchy, and in Merseyside the chief constable's team became known as the "Board of Directors" (Loveday 1999).

In the government plan for the criminal justice system, more secondments in the private sector for senior managers in the criminal justice system (including the police) were advocated and have now began to be implemented through the Workforce Modernisation Agenda.

The application of NPM to the public police has been the subject of much research (Loveday 1999; Loveday and Reid 2003); however, the focus of this entry will be the selling of policing services, charging of fees, and pursuit of sponsorship. The police have long charged for "special services," particularly for the officers they provide at football matches and public order events (Gans 2000). Under the Police Act 1964 (now section 25 of the Police Act 1996):

> The chief officer of police of any police force may provide, at the request of any person, special police services at any premises or in any locality in the police area for which the force is maintained, subject to the payment to the police authority of charges on such scales as may be determined by the authority.

Under section 18 of the same Act, the police authority can also supply goods and services to local authorities. It is not the aim here to explore the debate over what constitutes "special policing services," rather to illustrate some of the services the police have provided. As mentioned, it has been a long-standing practice for the police to charge for the services they provide at football matches and other public events on private land.

Such practices extend much further in the USA, where Reiss (1988) found three models of employment of the public police for private purposes. The first was where the officer found secondary employment and charged for his/her services directly. The second was through police unions who coordinated their secondary employment. Finally, a model exists where the police department contracts with the organization for secondary employment, for which they receive fees and then pay the police officer.

Through sponsorship, police forces can also raise an additional 1 % of their budget. An expose by the British national newspaper the *Sunday Times* illustrated some of the more bizarre sponsorship deals many forces would apparently consider. Posing as executives from a fictional firm called "Keystone Security" (Keystone Cops!), for the appropriate fee several forces offered to emblazon their name on their vehicles. One force offered to name an anti-burglary campaign after the company, and in another it was suggested their name could be displayed on the wall of a new police station shared with the local authority. Many forces have indeed been successful in acquiring money in return for advertising. London's prestigious department store Harrods has in the past sponsored a police patrol car, and a liquor store chain called Thresher sponsored a police van for £10, 000.

Linked to the charging of fees and selling of services, Bryett (1996) has also identified four methods in which privately owned non-police resources have been expended to the public police. At its simplest level, monies and physical resources have been given to the police. Clearly, the donation of large sums of money or resources raises concern over the independence of the police should an investigation into the donor ever become necessary. At a second level, another donation is that of space, which can also be a form of physical resource. Bryett provides one example from the USA where the McDonald's food chain gave part of one of its stores as premises for a police station. A third type of private sector aid is giving time. This most frequently takes the form of private individuals offering their time as police auxiliaries, termed "special constables" in the UK. At another level it might be helping the police in a search for a missing person or for evidence. The pursuit of cooperative ventures between the public and private sectors is the fourth means of cooperation. For instance, in Montgomery County in the USA, the local police department cooperated with IBM to produce a sophisticated computer disaster and security capability. In the UK the Private Finance Initiative has also enabled some forces to contract with the private sector to design, finance, build, and manage police facilities. Some of these have included police stations and firearms ranges.

Assessing the Impact of Privatization

The emergence of a substantial private security industry undertaking functions that, in modern times, came to be associated with the state has not been without its problems. Before some of these are examined, however, it is important to note that the outlook is not entirely negative. Private security personnel provide services that are essential to public safety and which, if the private sector did not provide them, would in many cases not be supplied at all. The private security industry can be a strong partner to the state to enhance the overall resilience to crime and terrorism, as in the case of Project Griffin, an initiative launched by the UK's City of London and Metropolitan forces in 2004. Its approach is to train private security officers to provide their own companies with better protection against terrorism, as well as to assist the police and other organizations through information sharing and securing cordons in the event of an emergency. The project has subsequently been extended around the UK, and the model exported to a number of other countries, including Canada and Australia. There is also the strong argument, based on some of the examples of outsourcing provided above, that in some circumstances the private sector can supply an equal or even better service to the state at a lower cost. This brings benefits to society as a whole, particularly in an era of fiscal constraint.

Yet it would be wrong to ignore some of the challenges associated with private security. In some countries there has been evidence of significant problems arising in association with the burgeoning size and role of the private security (Palmer and Button 2011). These have included, among others, criminal infiltration of the industry, little or no training for security personnel, abuses of authority including the excessive use of force, and generally low standards of professionalism. Some of these will be briefly considered.

There are a number of countries that do not regulate private security, or do not regulate all the private security activities in an industry, or where the enforcement of regulation is minimal. As a consequence, in some countries there are problems with individuals of inappropriate character, namely, significant criminal records, working in the private security industry. At a more serious level, on occasions, organized crime has captured control of security companies enabling them to use company resources and staff for their criminal means (SEESAC 2005). The collapse of the Soviet Union and its satellite countries has also led to the dominance of security companies by former state security services operatives in that region. In Russia between September 1991 and June 1992, over 20, 000 KGB officers left or were discharged. Many of these personnel moved to the private sector to work for and establish private security operations. Indeed, Volkov (2000) estimated that nearly 50, 000 former officers of state security and law enforcement were working for private security agencies. Many of these personnel have taken the culture and tactics of their old employers to their new private masters.

Some of the most disturbing examples of abuse and excessive force by private security personnel have been documented in South America. At the most disturbing end of the spectrum, private security has been implicated in repressive social control, including organized death squads, most notably in the slums of Brazil. In São Paulo during the last 3 months of 1999, of the 109 citizens killed by the militarized police, 69 were recorded as having been dispatched by off-duty officers working part time in private security. As Huggins (2000: 121) has argued.

> In Brazil today, death squads continue to operate, paralleled by a growing 'rent-a-cop' industry, with each social control entity directly 'serving' different population segments to the benefit of one over the other. The poor are treated as undifferentiated 'criminals' by death squads and 'rent-a-cops', and richer Brazilians are protected from the poor by their private security forces.

A major critique that has been raised by leading security scholar Clifford Shearing and a number of his collaborators is that the expansion of private security has highlighted and exacerbated security inequality (see Wood and Shearing 2007).

They do not discount the value of private security in certain circumstances, and the potential for poorer sectors of society to harness its resources in circumstances in which public provision is lacking. Yet they also observe how, in developing countries, the rich are able to purchase their own security measures to supplement slender state provision, while poorer areas are often left with a security deficit.

In addition, in many countries the private security industry also is characterized by poor quality security personnel, lowly paid, poorly trained, and lacking motivation (Button 2008). This has highlighted the need for effective regulation and control of the private security industry. Most countries do regulate the industry but the standards vary considerably (Palmer and Button 2011). The need to raise standards has invited the concern of a number of international bodies, most notably the United Nations. Work by the United Nations Office for Drugs and Crime in 2011 culminated in an intergovernmental expert group making preliminary draft recommendations on the principles of a model regulatory system for the private security industry.

Conclusion

In Western democratic countries, policing is rapidly evolving against a backdrop of significant and ongoing political and economic change. This is creating a need for police forces to establish new ways of working in order to meet the burgeoning demands upon them, as well as substantial opportunities for commercial security companies to address areas of deficit. In financially austere times and under the shadow of global terrorism, more active partnership between the public and private sectors is becoming a necessity, the counter terrorism initiative Project Griffin being a key example as to how the public sector can harness private security resources.

In parts of the developing world, police forces may be ineffective, lack legitimacy with the public, or even present a threat to citizens' security, making private or community security provision a necessity. Business opportunities in emerging economies, more politically and economically volatile than traditional markets since their legal and institutional systems are less well developed, are promoting the security industry's international expansion as it serves the needs of enterprise. A substantial, and growing, international private security industry is now an established fact of life in a globalized world.

These changing drivers of insecurity, and responses to them, illustrate that neither the providers of security nor those who study them can stand still. Criminologists need to recognize the changes and their implications in terms of the functions of policing and who delivers these, which will vary from one jurisdiction to the next. They must also take account of their ramifications for the oversight and accountability of policing agencies, both public and private, as well as the partnerships they are entering into. The pace of social change is presenting enormous challenges for policy makers, practitioners, and researchers and the need for innovative solutions.

Probability and Inference in Forensic Science

Franco Taroni and Alex Biedermann
School of Criminal Justice, Institute of Forensic Science, University of Lausanne,
Lausanne, Switzerland

Overview

Various members of the justice system encounter uncertainty as an inevitable complication in inference and decision-making. Inference relates to the use of incomplete information (typically given by results of scientific examinations) in order to reason about propositions of interest (e.g., whether or not a given individual is the source of an evidential trace). In turn, judges are required to make practical decisions which represent a core aspect of their professional activity (e.g., deciding whether or not a given suspect is to be considered as the source of a given crime-related trace). Both aspects, inference and decision-making, require a logical assistance because unaided human reasoning is known to be liable to bias. From a methodological point of view, these challenges should be approached within a general framework that includes probability and (Bayesian) decision theory.

Introduction

Since the early 1960s, the forensic science community started to take a more explicit position with respect to the existence of a problem of interpretation and evaluation of data. In a now widely known quote, Kirk and Kingston from the University of California, Berkeley, note:

> When we claim that criminalistics is a science, we must be embarrassed, for no science is without some mathematical background, however meagre. This lack must be a matter of primary concern to the educator [. . .]. Most, if not all, of the amateurish efforts of all of us to justify our own evidence interpretations have been deficient in mathematical exactness and philosophical understanding. (Kingston and Kirk 1964, pp. 435–436)

Today, interpretation and data evaluation are still held as a neglected area, mainly in fields that involve so-called physical evidence. This is acknowledged, for instance, by institutions such as the National Research Council (2009) (see ► Critical Report on Forensic Science). In its report from 2009 (at pp. 6–3), the Council notes that "[t]here is a critical need in most fields of forensic science to raise standards for reporting and testifying about the results of investigations." In many contexts, this perception is reinforced by the fact that scientists' assessments of evidential value consist of a largely "subjective" component and a connotation of "arbitrary." This should be contrasted, however, with an alternative interpretation that views the term "subjective" as a coherent state of personal belief held by an individual about something uncertain (see also Sects. 5 and 6).

As mentioned by Kirk and Kingston (1964), it was indeed rare at their time of writing – and it probably still is often so today – that a scientist's opinion was based on a quantitative study. Besides some notable exceptions, such as forensic DNA (that is beyond the scope of this text), this is still so today even though the presentation of a general model for inference was already put forward by Darboux et al. (1908) and rediscovered later by Kingston (1965). In a more formal sense, that model is known in current days as the "Bayesian perspective" to reasoning and inference in forensic science. It constitutes a main part of an approach to accepting that forensic science as well as science in general should abandon the expression of certainty. By moving away from the notion of certainty, it becomes a logical necessity to determine the degree of belief that may be assigned to a particular event or proposition of interest. In this context, the general branch of statistics can offer a valuable contribution to science. When uncertainty exists, and data are available, then it offers the possibility to assess and measure the uncertainty based upon a precise and logical line of reasoning (de Finetti 1993). Although statistics can offer a viable contribution to data evaluation by providing methods and techniques, it is not sufficient only by itself. Statistics concentrates primarily on data, whereas the retrospective meaning of an observation relies on the more general concept of inference which focuses on the notion of uncertainty. A concise expression of this is due to an influential writer in forensic interpretation, I. W. Evett, who noted that "[p]eople call this statistics – [but] it is not actually statistics, it's inference, it's reasonable reasoning in the face of uncertainty" (I. W. Evett, "Clarity or confusion? Making expert opinions make sense," presentation held on June 24, 2009, at the event of his award of a Doctorate *Honoris Causa*, issued as part of the celebration of the 100th anniversary of the School of Criminal Justice of the University of Lausanne).

In view of these limiting aspects of contemporary uncertainty management in forensic science, this entry will cover six arguments underlying the evaluation of forensic science data. First, Sect. 3 emphasizes the inevitability of uncertainty in day-to-day scientific work, followed in Sect. 4 by an outline of the necessity to deal with such a constraint through the use of a model that helps reasoners in a legal context – be they scientists or recipients of expert information – to manage the uncertainty about issues they are faced with. Next, probability and Bayes' theorem are introduced as the essential ways of learning from experience, a process interpreted here as the updating of beliefs about an event of interest in the light of newly acquired information (Sect. 5). Some discussion is developed on how to interpret the notion of probability as a consequence of the use of the laws of probability. Section 6 introduces the personalistic (subjective) viewpoint which finds applications also beyond law and forensic science, such as economics and other scientific disciplines. A particular aspect of the probabilistic approach allows scientists to provide a measure of the value of forensic science data that a Court of Justice may incorporate in a more general framework of reasoning about ultimate target propositions. This is described in Sect. 7, followed by a general conclusion in Sect. 8. It reiterates the fundamental benefit of an approach (Bayesian) to deal with uncertainty as an indissociable feature of human activities in general.

This entry avoids a dense presentation in terms of a list of mathematical formulae to deal with different forensic scenarios and scientific data as they may be encountered with, for example, DNA, shoe marks, glass and paint fragments, and textile fibers. Full treatises as given by, for instance, Aitken and Taroni (2004) and Buckleton et al. (2005), offer detailed formal developments of this kind. The perspective here is broader and seeks to offer a more general account on the relationship between inference, probability, and forensic science.

Uncertainty in Forensic Science

Human understanding of the past, the present, and the future is inevitably incomplete. This implies what is commonly referred to as a state of uncertainty, that is, a situation encountered by an individual with imperfect knowledge. Uncertainty is an indissociable complication in daily life, and the case of forensic science epitomizes this.

The criminal justice system at large, along with forensic science, is typically confronted with unique/singular events that happened in the past, which cannot be replicated. Due to spatial and temporal limitations, only partial knowledge about past occurrences is possible. Throughout history, this circumstance substantially troubled, and continues to do so, both scientists and other actors of the criminal justice system. This discomfort clearly illustrates the continuing need to give this outset a careful attention.

Despite this substantial drawback, “the problem of uncertainty” may not necessarily be considered as unsurmountable. Indeed, the careful reader may invoke the fact that past events leave one with distinct remains and vestiges, in particular, as a result of criminal activities. These may generate tangible physical entities such as blood stains, patterns, signals, glass fragments, or textile fibers that scientists may discover, seize, and examine. Results of such examinations have a potential for informing about and retracing past and ongoing events. Moreover, one may invoke developments in science and technology that offer vast capabilities for providing scientists with valuable information. While systematic analytical testing and observation may indeed produce abundant quantities of information, much of this information may substantively lack in qualities sufficient to provide an evaluative opinion that would be needed to entail (or make necessary) particular hypotheses that are of interest to legal reasoners.

A technocratic view of forensic science in terms of machinery and equipment under controlled laboratory settings is largely artificial. Actually, forensic science operates under a general framework of circumstances that makes testing and analyses a rather challenging undertaking. It suffices to note that material related to crimes and many other real-world events may often be affected by degradation or contamination. In addition, it may also be present in only low quantities so that only limited methods or measurements can be applied. A further aspect is that specimens submitted for laboratory analysis may be of varying relevance. In short, there is uncertainty about a true connection between the material at hand and the offense or the offender. In summary, thus, questions about laboratory performance are undoubtedly important, but they are not a general guard against the rise of uncertainty in attempts to reconstruct the past.

Generating data, observations, measurements, and counts constitute a core part of forensic science practice, but it is equally important to inquire about the ways in which such information ought – in the light of uncertainty – be used to modify a reasoner's states of belief in a specific case. Legal actors have a natural interest in this inferential topic because it represents a vital step to guarantee that scientific information meaningfully serves the purpose of a particular application. This connects closely to the agreed requirement according to which procedures for learning about past events in the light of new information should be in some sense rational and internally consistent.

Scientific Inference and Induction

Learning from experience represents as much a fundamental problem of scientific progress as it presents one in everyday life. In part, experience leads to knowledge that is merely a description of what has already been observed. However, one can take this outset a step further and consider, based on past experience, prediction of future experience, referred also to as induction. Stated otherwise, on the basis of what one sees, one seeks to evaluate the uncertainty associated with a particular event of interest, even though this kind of reasoning for learning new things provides only an incomplete basis for a conclusion. In inductive reasoning, conclusions contain elements not present in the premises, and go beyond these premises, and this means that one's knowledge is extended and the inference is said to be ampliative.

Humans tend to be well accommodated with operating under and dealing with situations involving uncertainty. Thus, the mere presence of uncertainty does not hinder the practice of science in principle. Accordingly, debates should focus on uncertainty explicitly and seek to distinguish between what is more likely and what is less likely, rather than attempting to endorse a concept of certainty. With that being said, the very relevant need of science is that of learning how to deal quantitatively with "probabilities of causes" (Poincaré 1896). Indeed, a main aim of the experimental method is that of discriminating between events of interest, or "causes," in the light of particular acquired information.

The so-called Bayesian theory (Sect. 5) claims that the inferential steps involved in inductive reasoning must be accomplished by means of probability, and in particular by means of Bayes' theorem that shows how the probability assessments of future events are to be modified in the light of observed events. This is said to represent the meaning of the phrase "to learn from experience" in a mathematical formulation of induction (de Finetti 1972).

A Model for Inference: Bayes' Theorem

As argued so far, learning from experience is central to scientific inference. According to a now widely accepted view, scientific reasoning essentially amounts to reasoning in accordance with the laws of probability theory (Howson and Urbach 1993) with Bayes' theorem providing a solution to the general problem of induction. The latter is seen as an appropriate logical scheme for characterizing inferences designed to establish scientific case hypotheses. To state this more formally for a finite case setting, start by considering a set of mutually exclusive and exhaustive hypotheses $H_1,\ldots,H_n$, the collection of background knowledge B, and a set of experimental results or effects E. Bayes' theorem then says that the probability of a hypothesis of interest H_i, given E and B, is obtained as follows:

$$Pr(H_i|E,B) = \frac{Pr(E|H_i,B)Pr(H_i|B)}{Pr(E|H_1,B)Pr(H_1|B)+\ldots+Pr(E|H_n,B)Pr(H_n|B)}. \quad (1)$$

Broadly speaking, Bayes' theorem tells one how to update prior beliefs (i.e., prior to data acquisition) about hypotheses in light of data. This leads one to posterior beliefs, that is, a state of belief after that data has been acquired.

It is worth emphasizing at this juncture that the conceptual meaning of a posterior belief is not that of a rectification. On this issue, de Finetti noted the following: "For convenience, brevity, and seeming clarity, I have just spoken of opinion as being 'modified'. It would not be exact, however, to interpret this as 'corrected'. The probability of an event conditional on, or in the light of, a specified result is a different probability, not a better evaluation of the original probability. [. . .] [p]robabilities are not corrections of the first one; each is the probability relative to a specific state of information [. . .]" (de Finetti 1972, at pp. 149–150).

In the above equation, the notation Pr represents "probability" and the vertical bar | denotes the conditioning. Thus, $Pr(H_i|E,B)$ expresses the probability that H_i occurs, given that data E has occurred and background information is as described. This conditional probability of the given hypotheses H_i, after obtaining the data, is usually referred to as the posterior probability of H_i. In turn, $Pr(H_i|B)$ is the corresponding prior probability of H_i, that is, before considering data E. Each probability is conditioned on the background knowledge B.

It is possible to consider an effect E also in terms of its influence on the belief about the truth or otherwise of a hypothesis, say H, that is:

- E *confirms* or *supports* H when $Pr(H|E,B) > Pr(H|B)$.
- E *disconfirms* or *undermines* H when $Pr(H|E,B) < Pr(H|B)$.
- E *is neutral* with respect to H when $Pr(H|E,B) = Pr(H|B)$.

One can thus interpret the difference $Pr(H|E, B) - Pr(H|B)$ as a measure of the degree with which E supports H, and Bayes' theorem constitutes a logical scheme to understand how the observation of an effect supports or undermines hypotheses. On a conceptual account, Jeffrey (1975) has noted the following:

> Bayesianism does not take the task of scientific methodology to be that of establishing the truth of scientific hypotheses, but to be that of confirming or disconfirming them to degrees which reflect the overall effect of the available evidence - positive, negative, or neutral, as the case may be. (at p. 104)

For applications in forensic science, it is common to consider hypotheses in pairs. For example, H_1 may denote the hypothesis proposed by the prosecution, while H_2 denotes the hypothesis proposed by the defense. In such a setting, an alternative version of Bayes' theorem, known as the odds form, is often used. In that version, H_2 denotes the complement of H_1 so that $Pr(H_2) = 1 - Pr(H_1)$. Then, the *odds in favor of* H_1 are $Pr(H_1)/Pr(H_2)$, denoted $O(H_1)$, and the *odds in favor of* H_1 given E are denoted $O(H_1|E)$. Note that the conditioning on B is omitted for simplicity of notation. The odds form of Bayes' theorem then is

$$O(H_1|E) = \frac{Pr(E|H_1)}{Pr(E|H_2)} \times O(H_1).$$

The left-hand side of this equation is the odds in favor of the "prosecution" hypothesis H_1 after the scientific evidence has been presented, $O(H_1|E)$. This is referred to as the *posterior odds*. The odds $O(H_1)$ are the *prior odds* as held by a reasoner before considering the observation. The ratio which converts prior odds to posterior odds is the fraction

$$\frac{Pr(E|H_1)}{Pr(E|H_2)},$$

known as the *Bayes' factor*, or often also called *likelihood ratio*. It is commonly denoted by the letter V, short for "value." It can take values between 0 and ∞. A value greater than 1 lends support to the prosecution's hypothesis H_1 and a value less than 1 lends support to the defense's hypothesis H_2. Effects for which the value is 1 are neutral, that is, it does not allow one to discriminate between the two competing hypotheses. Note that if logarithms are used, the relationship becomes additive. This has the very appealing and intuitive interpretation of weighing evidence in the scales of justice. In statistical literature, the logarithm of the Bayes' factor became known as the *weight of evidence* and is generally acknowledged to Good (1950).

In forensic and legal settings, the value of scientific data is most beneficially assessed by finding a value for the Bayes' factor, a task commonly assigned to forensic scientists. In turn, it is the role of judge and jury to assess the prior and posterior odds. In this view, the scientist can assess how prior odds are altered by the evidence, but he cannot actually assign a value to the prior or posterior odds. In order to assign such a value, all the other evidence in the case also needs to be considered. Although the adequacy of such a perspective continues to be debated in both literature and practice, this tends to be less the case today than during the past decades (Redmayne et al. 2011). Probably, it is also fair to say that there currently appears to be no other method that is of better overall assistance to evidential reasoning in judicial contexts. This is maintained, for example, by Ian W. Evett, a pioneer forensic statistician, who has been quoted as saying (Joyce 2005, at p. 37), "That framework – call it Bayesian, call it logical – is just so perfect for forensic science. All the statisticians I know who have come into this field, and have looked at the problem of interpreting evidence within the context of the criminal trial, have come to see it as centring around Bayes's Theorem." It is not claimed, however, that Bayesian inference is a panacea for all problems in legal reasoning. But it can be maintained that it is the best available model for understanding the interpretation of scientific evidence.

Besides discrete propositions, forensic scientists may also need to deal with continuous parameters. Examples include the mean of a continuous variable or a proportion. For such applications, Bayes' theorem as defined in Eq. (1) takes a slightly different form. In the context, an unknown parameter is commonly written Θ and data available for analysis as $\mathbf{y} = (y_1,\ldots,y_n)$. In the case of a continuous parameter, beliefs are represented as probability density functions. Denoting the prior distribution as $\pi(\Theta)$ and the posterior density as $\pi(\Theta|\mathbf{y})$, Bayes' theorem for a continuous parameter is

$$\pi(\Theta|\mathbf{y}) = \frac{f(\mathbf{y}|\Theta)\pi(\Theta)}{\int f(\mathbf{y}|\Theta)\pi(\Theta)d\Theta}.$$

Subjective Probabilities in the Bayesian Model

Independent of the way in which probabilities are interpreted, they take values in the range between 0 and 1. The value 0 corresponds to an event whose occurrence is impossible. An event whose occurrence is certain has probability 1. In a common, and for various reasons appropriate, interpretation of the theory, all probabilities are considered as subjective – in the sense of "personal" – expressions of degree of belief, held by an individual. Probabilities thus reflect the extent to which an individual's knowledge is imperfect, and it is important to acknowledge that such personal belief is graduated. One can believe in the truth of an event more or less than at another one at a given time, essentially because observations can accumulate to modify the perception of the probability of its happening.

A main aspect of this interpretation is that the degrees of belief held by an individual, in order to be said "rational," need to conform to the rules of probability. As such, probability represents the quantified judgment of a particular individual. This is in opposition to other interpretations of probability, known, for example, as the "classical" or "frequentist" interpretations that consider probability in terms of a long-run frequency. These latter views may encounter problems in applicability when settings refer to non-repetitive or singular situations (Press and Tanur 2001). Indeed, the frequentist view strictly supposes a relative frequency obtained in a long sequence of trials that are assumed to be performed in stable conditions and physically independent of each other. This is typically incompatible with events and parameters encountered in such diverse fields such as history, law, economy, forensic science, and other contexts where inductive inference plays a central role. In the latter branches, the entities of interest are usually not the result of repetitive or replicable processes. On the contrary, they are singular and unique, and this makes the idea of repeating the course of time over and over again, and to note the number of occasions on which some happening in the past occurred, inconceivable.

Such complications do not arise with the personalistic interpretation because it does not consider probability as a feature of the external world, but as a notion that describes the relationship between a person issuing a statement of uncertainty and the real world to which that statement relates, and in which that person acts. For the belief-type perspective, it is therefore perfectly reasonable to assign probability to non-repeatable events. This feature renders probability as a measure of belief a particularly useful concept for judicial contexts.

An direct implication of considering probability as personal degree of belief is that the knowledge, experience, and information on which the individual at hand relies become important. That is, more explicitly formulated, an individual's assessment of the truth of a given statement or event (i) depends on information, (ii) may change as the information changes, and (iii) may vary among individuals because different individuals may have different information or assessment criteria.

Although this perspective most closely embraces the actual situation faced by an individual in a situation of uncertainty, personal probabilities are sometimes viewed cautiously. As a concept, it may appear abstract and nontrivial to capture, and typically scientists may be irrationally suspicious of articulating, yet admitting to hold genuine subjective probabilities. In the same context, people may also be reluctant to express probabilities numerically and suggest that this approach to probability is both arbitrary and, from a practical point of view, an inaccessible concept. Such perceptions are restrictive because they disregard the fact that personal degrees of belief can be elicited and investigated empirically. One possibility to effectuate this is to measure probabilities maintained by an individual in terms of bets that the individual is willing to accept. For example, an individual's probability of a proposition can be elicited by comparing two lotteries of the same price.

In order to illustrate the usefulness of such a procedure for quantifying judgments, consider a situation in which it is of interest to find a probability for rain tomorrow (Winkler 1996, e.g.; at 18). For this purpose, define the following two offers:

- Lottery A: Winning € 100 with probability 0.5, and winning € 0 with probability 0.5
- Lottery B: Winning € 100 if it rains tomorrow, and winning € 0 if it does not rain tomorrow

With this outset, one can assume that one would choose that offer which presents the greater chance of winning the price. Clearly, if one prefers Lottery B, then this signifies that one considers the probability of rain tomorrow to be greater than 0.5. By analogy, choosing Lottery A would imply that one's belief in rain tomorrow is lower than 0.5. Moreover, in a case in which one is indifferent between the two gambles, one's probability for rain tomorrow would equate the probability of winning the price in Lottery A. Therefore, one can conceive of a procedure in which one adjusts the chance of winning in Lottery A so that the individual, whose probability for a proposition of interest is to be elicited, would be indifferent with respect to Lottery B. Similarly, one can elicit an individual's personal probability for any event of interest.

Another question relates to the "appropriateness" of a set of probabilities held by a particular individual. In this context, the possibility of representing subjective degrees of belief in terms of betting rates is often forwarded as part of a line of argument to require that subjective degrees of belief should satisfy the laws of probability. This line of argument takes two steps. The first one of these proposes that betting rates should be coherent, in the sense that they should not be open to a sure-loss contract. The second one is given by the fact – established by twentieth-century writers in probability (e.g., Ramsey 1990) – that a set of betting rates is coherent if and only if it satisfies the laws of probability. Thus, if an individual assigns degrees of belief in such a manner that, as a whole, they do not respect the laws of probability, then their beliefs are not coherent. In the context, such incoherence is also called "logical imprudence."

The Bayesian Model and the Desiderata for Evidential Assessment and Interpretation

In the context of framing scientific evaluation in legal contexts, scientists and jurists wish their analytical thoughts and behavior to conform to several practical precepts, and interestingly, the

Bayesian model allows to conceptualize these precepts explicitly. It is common to refer to essentially six desiderata upon which the majority of current scientific and legal literature as well as the practice converge in their opinion, namely, balance, transparency, robustness, added value, flexibility, and logic. These notions represent desirable properties of an evaluative procedure for scientific opinions. They have been advocated and contextualized, to a great extent, by some quarters in forensic science and from jurists from the so-called New Evidence Scholarship.

For an inferential process to be *balanced* or, in the words of some authors, impartial, attention cannot be restricted to only one side of an argument. Evett (1996) has noted, for instance, that "[. . .] a scientist cannot speculate about the truth of a proposition without considering at least one alternative proposition. Indeed, an interpretation is without meaning unless the scientist clearly states the alternatives he has considered." The requirement of considering alternative propositions is a general one that equally applies in many instances of daily life (Lindley 1985), but in legal contexts, its role is fundamental. The Bayesian framework allows one to cope with this requirement in an integral way as it provides for an explicit treatment of a collection of rival propositions within a coordinated whole.

The proposal of considering alternatives should not be taken to mean, however, that scientist should address propositions in terms of probability. This is a task left to other legal actors as mentioned earlier in Sect. 5. A likelihood ratio-based approach for ascribing evidential value suggests that forensic scientists should primarily be concerned with their observations and results and not with the competing propositions that are put forward to account for such data. This distinction is crucial in that it provides for a sharp demarcation of the boundaries of the expert's and the court's areas of competence. Failures in recognizing that distinction are at the heart of pitfalls of intuition that have caused – and continue to cause – much discussion throughout the judicial literature and practice since (e.g., Koehler 1993).

Besides balance, a forensic scientist's evaluation should also comply with the requirement of *transparency*. This amounts to explain in a clear and explicit way what scientists have done, why they have done it, and how they have arrived at their conclusions. Closely related to this is the notion of *robustness*, which challenges a scientist's ability to explain the grounds for his opinion, together with his degree of understanding of the particular data type. These elements should help work towards *added value*, that is, a descriptor of a forensic deliverable that contributes in some substantial way to a case. Often, added value is a function of time and monetary resources, deployed in a way such as to help solve or clarify specific issues that actually matter with respect to a given client's objectives. These desiderata characterize primarily the scientist, that is, his attitude in evaluating and offering opinions, as well as the product of that activity.

The degree to which the scientist succeeds in meeting these criteria depends crucially on the chosen inferential framework, which may be judged by the two criteria *flexibility* and *logic*. These descriptors relate to properties of an inferential method rather than behavioral aspects of the scientist as mentioned in the previous paragraph. In a broad sense, flexibility is a criterion that demands a form of reasoning to be generally applicable, that is, not limited to particular subject matter (Robertson and Vignaux 1998). In turn, logic refers to a set of principles that qualify as "rational." There is a broad agreement among legal and forensic researchers and practitioners that the Bayesian framework for reasoning acceptably complies with these requirements nowadays. On a conceptual account, this view is supported by the fact that the paths of reasoning used to evaluate propositions in judicial contexts can be reconstructed as inferences in accordance with Bayes' theorem.

General Appreciation and Outlook

As a key point, probability is shown to be a formal quantitative framework with solid logical grounds that usefully assists legal actors, including forensic scientists, to make plain inferential subtleties that common language and unaided intuitive reasoning cannot achieve and to explain these issues. In this general framework, it is preferable to employ probability as degrees of belief, a standpoint commonly known as the subjectivist (or personalist) interpretation of probability. Such degrees of belief are personalized assessments of credibility formed by an individual about something uncertain, given information that the individual knows or can discover. This usage of the probability apparatus implements a concept of reference in which personalized weights may be assigned to the possible states of selected aspects of real-world problems. This closely embraces the actual situation encountered by legal practitioners. Even though uncertainty is inevitable in principle, the position of legal actors is one which allows at least some further evidence to be gained by enquiry, analysis, and experimentation. As a consequence of this, some means is required to adjust existing beliefs in the light of new information.

As a second main element, this entry favors the requirement of adjusting personal beliefs according to Bayes' theorem, essentially because it is a logical consequence of the basic rules of probability. This perspective is normative, in the sense that if one accepts the laws probability as constraints to which one's beliefs should conform, then one also needs to accept the ensuing properties – among which is Bayes' theorem. Interpreting these rules as a norm, or a standard, allows for a prescription of how a sensible individual ought to reason, to behave, or to proceed. Although practical experience shows that people in general, including scientists, may not conform well in their reasoning with the laws of probability – in fact, descriptive studies actually show that people's intuitive judgments diverge from the probability standard – the argument is that the concept *should* guide in the inferential processes in which one engages. It provides a defensible framework that allows one to understand how to treat new information, how to critically analyze, and how to revise opinions in a coherent way. Arguably, probability as a measure of uncertainty takes the role of fundamental quality criteria in forensic science. The benefits of a probabilistic framework are both immediate and uncontroversial because of the direct effect that uncertainties may have on a line of reasoning which matters in some way to an evaluator or decision maker.

From a historical perspective, Bayes' (1702–1761) theorem came about 250 years ago, but the attribute "Bayesian" as a descriptor of a particular class of inference methods appears to have gained more widespread use only since the middle of the twentieth century (Fienberg 2003). In the legal context, there now is a growing community that has spent many years applying Bayesian principles to infer from evidence. This interest in Bayes' theorem is reinforced because of its supportive capacity in explaining the concept of evidence and proof in both science and law and other inferential contexts, but also because formal procedures can be easier to explain and justify than informal ones.

Still within a historical perspective, practical applications of patterns of reasoning corresponding to a Bayesian approach can be found, for example, as early as the beginning of the twentieth century (Taroni et al. 1998). For example, at the Dreyfus's military trial held in 1908, Henri Poincaré invoked Bayes' theorem as *the only* way in which the court ought to revise its opinion about the issue of forgery. Subsequently, Bayesian ideas for inference entered legal literature and debates more systematically only in the second half of the twentieth century. Kingston (1965), Finkelstein and Fairley (1970), and Lindley (1977) are some of the main reference publications from that period. Later, within the 1990s, specialized textbooks from Aitken and Stoney (1991) and Robertson and Vignaux (1995) appeared. During the past decade, further textbooks along with a regular stream of research papers focusing on Bayesian evaluations of particular categories of evidence, such as glass or DNA (Buckleton et al. 2005) were published. But yet, if one looks at science more generally, the interest in Bayesian methods to solve problems relating to data analysis appears to be relatively scarce, with forensic science being no exception (Taroni et al. 2010).

Although much of the current discussion essentially focuses, in one way or another, on the evaluation and manipulation of personal beliefs held in propositions about which one is uncertain, reality shows that what one believes is essential, but not only in its own right. Along with a reasoner's preferences, personal beliefs – typically expressed in terms of probabilities – are a fundamental ingredient of considerations that seek to analyze what one ought to decide. Indeed, for the criminal justice system, reasoning about propositions of interest is not the end of the matter. It is commonly understood that, ultimately, decisions must be taken and that these are at the heart of judicial proceedings. For instance, a court may have to decide if it finds a suspect guilty of the offense for which he has been charged, with the obvious aim that such decisions are made accurately (Kaplan 1968). In this broader perspective, probability can be taken as a preliminary to decision-making. On a formal account, this logical extension is embedded in decision theory, which provides the means for dealing with the key elements of decision analysis processes. Since both forensic scientists and recipients of expert information encounter the recurrent need to *decide* on matters that relate to their respective areas of competence, Bayesian decision analysis represents a topic of ongoing interest. Although its relevance from a legal point of view has already been recognized decades ago (e.g., Kaplan 1968; Lempert 1977), it is only more recently that genuine forensic applications (Taroni et al. 2005; Biedermann et al. 2008) have been approached.

Conditional conviction; Parole; Suspended sentence

Overview

Both terms "probation" and "community sanctions" referred during more than a century to different realities and practices according to the country where it proceeded. Nevertheless, it is striking to notice that these two concepts became essential to criminal policies following similar developments based on the same grounds. Whereas probation consists in an institution supervising an offender who has been sentenced to certain obligations and constraints, community sanctions are a practical extension of it and can be defined as a penal punishment situated between imprisonment and financial penalties ("intermediate sentence"; Bottoms et al. 2001). Whereas custodial sentence is served inside prison structures, community sanctions are executed in the free society along any form of social interaction. As long as the common sanction was of a custodial nature, its implementation was fulfilled by the prison services. But as soon as other types of sanction appeared in criminal justice systems, a new form of penal punishment had to emanate. Thus, the link between probation and community sanctions goes back to the nineteenth century at a time where modern modalities of sentence execution had to be combined with the emergence of supervising agencies.

In order to understand how it arose in this frame, one way to consider a community sanction considered as "normal" is to expect it to comply with the following criteria: It should not be custodial; it has to reach a balance between harshness and laxity (also proportionality, see Bagaric (1999)); it should not be too onerous and has to be transferred to social services; it has not to be supervised by over-skilled staff; it should be simple and quick in its implementation, and the community sanction and its supervision shall have a control and disciplinary aspect per se (Normandeau 1979). This definition has been shaped over decades through different types of classification. One approach differentiates three types of rationality in which the probation system has prospered: the discipline rationality during the 1850–1940s period; then the welfare rationality along the 1950–1970s, also called the "probation's golden years"; and lately the security rationality as from the 1980s (da Agra 2010).

Beyond that, a more differentiated and comprehensive step-by-step approach highlights the evolution of probation work. The early days were heavily influenced by the church and charity organizations from origins until 1878 with religious missionaries. The years of professionalization with focus on personality and training arose during the first half of the twentieth century: Probation became a professional undertaking rather than a mission. The third wave is the years of casework including good relationship and diagnosis around the 1960s and consisting in a direct method of intervention relying on a strong and open relationship between the probationer and a trained probation officer. A backlash nourished some years of pessimism and to the necessity to help in the client's terms (1970 and 1980s): high rates of recidivism conducted to a more personalized but also control-oriented supervision. A way out was then meant as rehabilitation revival insisting on "what works" along with limited "transfer" into the practitioners' daily work (1990s): The policy emphasis was on procedure and technicality. The current phase concentrates on desistance and other emerging approaches, especially with the return to morality (2000s): Desistance is placed at the intersection between structure, agency, and reflexivity (Durnescu 2012).

The development of community sanctions has followed a parallel path since they are inherently interdependent with probation services, the former being generally supervised by the latter. An attempt to analyze its emergence underlines six rather consecutive phases starting with the origins at a time when community sanctions were considered as privileges. After World War I (1914–1918), supervised community sanctions were introduced. It took half a century to introduce intermediate sanctions characterized by intensive surveillance (1970–1980s), developing then restorative community sanctions in the 1980s, technological community sanctions as of 1990s and postmodern community sanctions with extended supervision as of the end of the 1990s (Durnescu 2009).

Brief History of Probation Services

Probation, despite all differences among countries around the world, has one "common penal cornerstone" represented by the prison, and its development, besides various independent socio-political characteristics, is contingent to critical opinions toward the use of imprisonment and its effectiveness, and "the normative aspirations originally invested in the prison were transferred symbolically (if not always in substance) to non-custodial measures and, in particular, probation in its various forms" (Vanstone 1998, p. 751).

Still, the first practical steps of probation were due to philanthropy, and religious and humanitarian concerns that led to the first probation model in England (Jarvis 1972; van Kalmthout and Durnescu 2010). However, social control and the maintenance of social order remained primordial in the definition and implementation of probation and community sanctions. Criminology at the end of the nineteenth century fed with its new concepts the ideology of promising penal policies while permitting welfare at the same time that it kept control over poor and marginalized social groups (Vanstone 2008). Besides, the post-first-world-war period was an exciting time for new penal ideas in such a way that two major scientific reviews were launched: the British "Probation Journal" in 1929 and the US "Federal Probation" in 1936.

Until the end of the eighteenth century, there was no kind of help or support foreseen for released prisoners, also because deprivation of liberty as a penal punishment, (conditional) release, and aftercare measures were not regulated by criminal law. In countries where these types of sanctions existed, charity organizations took care of prisoners and, incidentally, of the released ones. The origins of probation go back to England and the philanthropist John Howard (1726–1790) as one of its key-thinkers. He believed in the importance, even the necessity for a society to provide released prisoners with law-abiding resources to survive. His concept led shortly after his death to a law dealing with patronage (1792). In many countries, charitable clubs and societies were the only bodies officially recognized to deal with detained or released offenders by giving them material and spiritual (often Christian) support (van Kalmthout and Durnescu 2010). Their work involved a strong moral component and focused deeply on the offender's personality.

Two Founding Fathers of Probation

Matthew Davenport Hill, at that time a young British lawyer, assisted in a court in 1820 at a new way for magistrates to prevent juvenile criminals going to prison. The idea was to condemn to solely 1 day of imprisonment, provided that the juvenile has to be given back to his father or tutor with the obligation to be kept and surveyed more carefully (United Nations 1951). Later in 1840, as a judge at the Birmingham court, he kept practicing this symbolic 1-day sentence under the condition that the offender remains under supervision of an adult. M. Hill regarded individual cases as hopeful, because he thought that most of the people are not entirely criminals and it is always possible to "correct" them. Moreover, the supervision by responsible and willing persons who are in position to commit themselves to support young offenders shall, in Hill's mind, give better reintegration opportunities than custodial facilities. There was no system of legal surveillance, but Hill requested the police head officer to proceed to steady inquiries on offenders' behavior. This can be seen as an early form of police surveillance in the area of community sanctions. After 7 years of practicing this experience, the judge Hill presented his results as follows: "[. . .] young offenders who kept to the straight and narrow are much more numerous among those who have been treated this way than those who haven't had this privilege and served prison sentences (United Nations 1951). Another judge, Edward William Cox, developed the concept with the designation of an inquiry agent who was in charge of supervising several offenders. This task was then taken over in 1876 by the Church of England Temperance Society that appointed "police court missionaries" who tried to keep offenders away from consuming alcohol and help them to resettle (van Kalmthout and Durnescu 2008, p. 4). The first mentioning of probation is to be found in the 1886 "Probation of First Offenders Bill," definitely structuring the field with the 1907 "Probation of Offenders Act" creating probation services all around the country.

A second character has also shaped the probation history (Vanstone 2008) since John Augustus (1784–1859) is considered as being the first probation officer. Born in Woburn, Massachusetts, he was a thriving shoemaker living in Boston. Taking part as a spectator at a police court audience in 1841, he asked the judge to guarantee a patronage to a drinking offender during a period of probation. After extending his supervision activities to other types of offense, he published a sum of his achievements under the title "A report of the Labors of John Augustus, for the last 10 years, in aide of the unfortunate." He instituted during this period some working criteria for modern probation services such as the selection of probationers (he favored first-time offenders), social enquiries with criminal background, and personality check, he controlled individuals' behavior and made sure that they would go to school or to work (United Nations 1951). In the wake of Augustus' experiences, Massachusetts became the first US State to pass a law on probation in 1878. The development in other states was so dynamic that within 60 years, both the federal State and 34 US states had also introduced probation laws.

Creation of Probation Services in Other Countries

Probation was introduced in national legislations around the world mostly between 1878 and 1920 (Vanstone 2008) under the influence of modern criminal law that emphasized on individualization of the sentence execution and reintegration of the offender. New penal instruments arose: conditional and suspended sentence, conditional release and parole, bail, house arrest, etc. (van Kalmthout and Durnescu 2010).

In the Netherlands, the establishment of probation in 1823 took example to the English system. It offered school training and religious support, conducted with private funding and voluntary workers. In 1910, the State undertook the tasks of probation, focusing on the criminal's treatment in order to protect the society and involving a national association dealing with offenders (Jäger 2010). The probation officers gained professionalization with a 1947 regulation (*Reclaseringsregeling*) that structured their activities and curriculum. After some back and forth, the probation associations and the state justice agencies found in the mid-1980s a balance between autonomy and control.

In Germany, influenced by the French and Belgium systems, the first practice of probation (*Bewährung*) took place at the end of the nineteenth century in the frame of supervision for juveniles (Schöch 2003). Even if some associations already accompanied released prisoners, today's German probation structure was experimented in 1951 and then implemented in 1953 in both penal code and juvenile court law (Jäger 2010, p. XIV). Confined to a control aspect of the probationers, probation duties extended 1969 to further help and support activities, connecting with the extension of suspended sentences (up to 2 years) that came into force the same year. Federal statistics show since 1963 and their first data an increase of probationers, from 27,401 up to 131,381 in 1990 and 180,074 in 2010, which represents a growth of 37 % within the last 20 years, much more than the general population evolution with 2.6 % between 1990 and 2010. Though, the lack of performance or efficiency evaluation has remained controversial (Dünkel and Spiess 1983).

In France, probation is a recent institution in relation with other countries. Even if conditional release was already adopted in 1885 and supervised freedom (*mise en liberté*) in 1908, special structures for released prisoners were introduced only after the Second World War in 1946. Called "comities for help and placement of released prisoners" and placed under the hierarchy of the court president, they supervised conditional released and supported released prisoners having served the complete sentence. The contemporary probation scheme was formed by a 1958 governmental law creating the enforcement judge responsible for the execution of sentences (*Juge de l'Application des Peines* (JAP)), the suspended sentence with obligations (*Sursis avec Mise à l'Epreuve* (SME)), and the comity of probation and help to release prisoners (*Comité de probation et d'assistance aux libérés* (CPAL)). The professionalization of educators (1966) was a further step toward more numerous, and better trained staff, assimilating then in 1967 the probation functions of social workers to educators delegated to probation.

In Switzerland, albeit the Fribourg canton organized actions to support released prisoners as early as 1842, the probation movement appeared in some districts (so in Basel or Zurich) only at the end of the nineteenth century, during which societies acted to protect released prisoners from banishment – hence its appellation *Schutzverein* (protection association). At the same time, a priest named Meyer, who was during years intervening in prisons, published a brochure entitled "Call and project of status for the creation of a patronage society in favor of released prisoners," which took some decades until its first creation in 1888. Eventually, this private body was integrated and transformed into a public service in 1941 and structured in its contemporary shape in 1967, taking its current denomination of "probation service" in 2005.

On the other side of the Atlantic, directly inspired by the 1887 British "Probation of First Offenders Act," probation has been developed in Canada as of 1889 through the law enabling conditional release for first-time offenders with neither surveillance nor time limit. The first Canadian criminal code from 1892 stipulated that offenders convicted of a petty crime and sent to prison could have their sentence suspended and be released with the obligation to sign an agreement in which he commits himself to behave properly. The Canadian Parliament added in 1921 the notion of surveillance operated by a person nominated by the court. Ontario was the first province to legislate on the creation of probation services in 1922, later followed by British Columbia in 1946, which was still not the case for Quebec in 1956, even if there were already functioning help associations for released prisoners and further social agencies to control offenders under supervision. It is only in 1967 that the Ministry of Justice hired the first probation officers, embedded in a 1969 law on probation and custody. The evolution of Quebec probation services can be observed aid of the number of probation officers: 28 in 1970, then a considerable increase within 4 years (140 in 1974) and 335 in 2011.

Probation Services Today

Probation services become a reality in almost every jurisdiction in the world, especially in Europe. The comments in this section are based on the survey conducted by van Kalmthout and Durnescu in 2008 (where the source is different, it is indicated accordingly). Depending on the country size, the administrative structure, or the judicial traditions, probation services are organized either by the prosecution service (The Netherlands, Luxembourg), by the social service (Scotland), or independently close to the court system. A special group of countries have their probation service located in the third sector (The Netherlands, Austria). In their case although the probation activity is delivered by the NGOs, they are contracted and monitored by the Ministry of Justice. At the national level, some of them are coordinated by independent departments within the Ministry of Justice (Portugal, Romania) or by the prison and probation departments (France, Denmark, Estonia, England and Wales, some Federal States in Germany). Looking at the recent history, one could claim that as a European trend, probation services tend to be more and more associated with the prison departments. Most of the time, reasons for amalgamating these two structures have to do with reducing the administrative costs and with the need for a better and closer relationship between these two institutions.

The federal states however tend to display a more mixed picture. In Switzerland, for instance, the probations services are organized at the canton level. In Germany, probation service is structured around the regional courts in some Landers while in others, it is incorporated within the social services but still under the coordination of the Ministry of Justice. In the USA, probation activities are delivered by hundreds and hundreds of organizations and structures, sometimes at the federal or state level but other times even at the municipal level. As a result, probation systems in the USA are highly fragmented and local oriented with no standards and no coherence at the federal level (Burrell 2010).

Under the umbrella of "probation," a lot of activities are delivered or enforced. What they all seem to have in common is the desire to prevent re-offending. Some of these activities are based on a court decision (supervision, enforcement, programs, electronic monitoring, etc.). Some other activities are based on the law (victim assistance, half-way houses) or on a more general vision that probation service should serve the community (prevention in schools or other hot spots). There are also countries that are more and more involved in diversionary measures or even provide mediation services (Czech Republic, Slovakia, etc.). Probation services in Scotland and England and Wales deliver bail advice and supervision to prevent pretrial detention. Having admitted the huge variety of tasks that probation service is called upon, there are core probation activities that can be found in almost all the jurisdictions. They are decision support (presentence reports, social inquiry reports, etc.), supervision of offenders in the community, and they provide assistance to cover the so-called criminogenic needs. Since the early 1970s, more and more countries have introduced community service orders as an intermediate sanction (see the chapter of Dünkel and Lappi-Seppälä on community service in this volume). The organization and supervision of community service belongs to the tasks of the probation services (as far as it is not transferred to private organizations of the third sector).

Aiming at changing the offending behavior, most of the probation services recruit probation staff among the graduates of social/behavioral sciences. In some countries, probation staff has to graduate from a social work school (Denmark, Germany, Italy, the Netherlands, Norway, Scotland, etc.) or other related fields. In England

and Wales, there is a special Diploma on probation that trains probation officers in a blended model: education and practice.

One major difficulty admitted by a large majority of the European jurisdictions is work overload. Depending on geographical distribution, judicial practice, or the season of the year, the workload varies between 35–50 clients (in Denmark, Estonia, etc.) and 50–100 clients (Switzerland, Luxembourg, etc.). In most cases, the maximum number of cases that one probation worker could supervise is not regulated firmly in any regulation. As it was shown in the literature, work overload has a significant impact on probation effectiveness (see Petersilia, this volume). Another side effect of probation is the one noticed especially in the USA where intensive supervision was introduced. It seems that the more surveillance probation service provides, the more recall into prison it produces (see for instance Solomon et al. 2005).

A Future for Probation?

Looking at the history of probation around the world, one can project a future of it obviously with a high level of generalization and oversimplifications.

As suggested in the first section of this entry, probation services were called initially to "save the souls" of offenders. Increasingly, over the years, probation services started to treat and to supervise sick or unadapted deviants. Probation orders and latter suspended sentences were invented locally and diffused around the world with some local adaptations. What is almost common around Europe is that in the last 20 years, the supervision element of probation became more and more prevalent. Electronic monitoring and extended supervision are only two examples of how surveillance and controlling captured the probation discourse in some Western countries. In other countries, like in the German-speaking or Scandinavian states, probation service is still seen predominantly as a rehabilitation agency. Central and Eastern European countries seem to develop probation services according to their local needs and to what it seems to be fashionable in the West. One example of this mood is the risk assessment tools that were exported massively and sometimes uncritically from the West to the Central and Eastern European countries. Sometimes, this policy transfer comes within the evidence-based rhetoric (see the ▶ RNR Model), but sometimes, it comes with the package in different EU programs. There are reasons to believe that penal policy transfer will intensify on a short and medium run.

Apart from the national or regional diversity drivers, there are also more and more forces acting toward Europeanization. The European Council adopted in 2008 a framework decision (2008/947/JHA) aiming at facilitating rehabilitation through transferring supervision among EU countries. The Conference European of Probation (CEP), an intergovernmental association of probation, also fights for a common set of principles and values for probation in Europe. The EU Commission funds many projects that support states to develop probation systems with the help of other states. An Erasmus project is also running, aiming at setting up a European probation curriculum for probation. These are only a few examples of how harmonization forces work toward a European probation system.

Once electronic monitoring was introduced either as a stand-alone measure or as a tool to implement other measures (like house arrest), it was created the premises of involving the private sector into the control industry. In most of the European countries, handling of the electronic monitoring equipment is in the hands of the private sector (see the entry on electronic monitoring of Haverkamp in this volume).

There are countries where electronic monitoring is delivered fully only by the private sector (see England and Wales). Within the context of neoliberalism and facilitated by the budgetary austerity, the private sector becomes more and more visible in delivering probation activities. For instance, Serco, a security company, in partnership with London Probation Trust, has started in October 2012 to carry out "community payback" sentences (or community service or unpaid work, in other jurisdictions). Although this probation privatization is not necessarily a general trend, it might be an indication of how probation and probation activities could look like in the future.

Fortunately, as it was illustrated above, developments in the probation world are, sometimes in spite of the harmonization drivers, incremental and local. It took decades from the moment suspended sentence was introduced in France and Belgium till the moment of upgrading it to the suspended sentence under supervision in almost all over Europe. Electronic monitoring was also introduced after several years of piloting. The time between the introduction and testing of a new penal technology until this technology is fully implemented is shorter and shorter, but still one cannot hope for revolutionary changes in the probation world. Every change will be introduced slowly, with a lot of resistance from many levels and in the end the core idea of probation – to rehabilitate offenders – will probably rise again and again in different shapes and forms.

Probation and Human Rights

Rob Canton

Life Sciences, De Montfort University,
Leicester, UK

Overview

Human rights are those rights that all people have in virtue of our common humanity. They include *liberties* and *claims*, being used in political debate to remind governments both of the limits of their powers over their citizens (liberties) and of their obligations to create circumstances in which people can thrive and prosper (claims). International treaties and conventions have been established to clarify rights, to set standards, and to attempt to make all countries accountable to the international community. Human rights are especially important in criminal justice and punishment, where the coercive powers of the state are so manifest. Punishment may even be defined as a deprivation or suspension of rights. Yet hard questions arise about which rights are forfeit and which should be protected. The rights of serving prisoners are especially vulnerable, but there must also be concern for those subject to community sanctions and measures. At the same time, the rights of other people, in particular actual and potential victims, must also be part of an adequate ethical account. Principled ways must be found of dealing with circumstances where rights are in conflict, although such conflicts may be less common than political debate seems to assume. Some contemporary developments have particular implications for human rights – notably the policy in many countries to make community punishments as "prison-like" as possible in a quest for punitive credibility, the political predominance of risk, and preventive interventions. Such trends must be scrutinized with special care because of their potential not only to deprive offenders of their rights but to trespass on the rights of other members of the community without adequate justification. While debate often centers on offenders' liberties, their claim-rights must also be affirmed. The discourse of human rights offers a way of framing guiding ethical principles for probation and could constitute a foundation for policy and practice.

What Are Human Rights?

Human rights are those rights that we all have by virtue of our common humanity. Since human rights are intimately bound to humanity and personhood (Griffin 2008), to fail to give weight to someone's rights is to risk treating them as less than human. Earlier philosophers sometimes referred to *natural rights* – a conception that was found by critics (e.g., Jeremy Bentham) to be obscure and perhaps incoherent. Even so, the idea that people have rights that are not granted by the state – and which consequently may not be taken away by the state – implies the critical possibility of an ethical position from which the laws and practices of government can be appraised, circumscribed, and directed. In these ways, the language of rights can be deployed to remind governments of their limits and of their obligations, that ends may not be assumed to justify means, that individuals and minorities may not simply be disregarded in a proclaimed pursuit of the state's conception of the general welfare, and that it is a duty of government to strive to create circumstances in which all may flourish.

Like most serious moral questions, the matter of which rights we have remains open, indeterminate, and inherently contested, and the rights that people have asserted for themselves and for others are many and diverse. Historically and politically, rights have been invoked in two main ways: to take a stand against cruelty and injustice and to articulate claims – aspirational statements about the social and economic conditions that should be created so that people may thrive (Gearty 2006). Most notably, for example, the United Nations Universal Declaration of Human Rights (UDHR) (1948) first sets out articles prohibiting oppression and cruelty, then articulates claims to human well-being.

This corresponds to a philosophical distinction between *liberties* and *claims*. Liberties include the right to life, a prohibition on torture, on inhuman and degrading treatment, on cruel or unusual punishment, bans on slavery, forced labor, and servitude. Claims express a commitment to human flourishing, to propitious circumstances and meaningful opportunities – for example, rights to education, employment, and participation in government – and to an adequate standard of living. These are claims that require more than the state's forbearance and call for positive action by government.

By no means all rights are absolute – probably very few are. The European Convention on Human Rights, for example, distinguishes absolute rights (which may never be taken away), limited rights (which may only be compromised in explicitly identified, specific circumstances), and qualified rights (where individual rights must be considered alongside broader social and community interests). To assert a right, then, even convincingly, does not by itself entail that it would be unjustifiable to infringe that right, though it does mean that there is a need for moral judgement. But a human right may not be ignored or merely set aside as inconvenient: if it must be infringed (because other moral considerations turn out to be more compelling), then this calls for moral justification and should take place with a sense of regret and with an attempt to mitigate the implications for the right-bearer. This should also stimulate a search for other solutions which better respect the right.

International Perspectives

The modern promulgation of human rights has been accomplished through international charters and conventions. The best known of these – and the foundation of most others – is the United Nations Universal Declaration of Human Rights (UDHR). In its Preamble, the Declaration begins with a clear statement that the "recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world." Drawn up as it was in the aftermath of the Second World War, it goes on to assert that "disregard and contempt for human rights have resulted in barbarous acts which have outraged the conscience of mankind."

The International Covenant on Civil and Political Rights (ICCPR), monitored by the United Nations Human Rights Committee, developed the principles of UDHR and, in particular, delimits the powers of states with regard to the rights of liberty and security of persons (article 9). It also affirms rights to justice and to a fair trial (article 14). Like the UDHR, the ICCPR is signed and ratified by countries from all parts of the world. Over time, international regions have drawn up their own conventions, notably the African Charter on Human and Peoples' Rights, the American Convention on Human Rights, and the European Convention for the Protection of Human Rights and Fundamental Freedoms. These seek to apply UDHR and ICCPR principles to the specific characteristics of each region, taking account of differences of culture and tradition. The charters and conventions are guarded by international courts – the European Court of Human Rights and the Inter-American Court of Human Rights (a protocol establishing the African Court on Human and Peoples' Rights is in force, but this Court, to be merged with the African Court of Justice, has yet to be established). Courts adjudicate, hearing and ruling on allegations of violations referred to them, but may also advise: the Inter-American Court of Human Rights, for example, advises on points of legal interpretation referred to it by the member states.

Signatories to these conventions have sometimes incorporated the same articles, or at least their principles, into their domestic law. There are still many reasons why an international framework remains essential. In particular, where there are conflicts between human rights and a government's conception of the common good, it is not clear that the state is an even-handed judge in its own cause. The protection of the law is accordingly required and accountability to an international community is a crucial bulwark.

Punishment and Human Rights

Human rights are an especially important consideration for criminal justice and punishment, where the coercive powers of the state are always near to the surface and often manifest. The censures and "hard treatment" of punishment necessarily involve at least a degree of deprivation of some rights. Rights that states are in other circumstances expected to protect vigilantly are taken away or compromised – not only contingently but deliberately, as punishment. But which rights are forfeit and which retained? How is punishment to be determined and administered in a principled way that respects the offender's humanity?

Prison is a total institution and the conditions of imprisonment impact on all aspects of prisoners' lives. The complete dependence and vulnerability of prisoners make their rights especially precarious and much of the literature on human rights and punishment accordingly focuses on imprisonment (for summary and discussion, see van Zyl Smit 2007). Yet developments in a number of countries over the past 40 years or so have started to raise hard questions about the human rights implications of probation and parole as well.

Parole, Probation, and Intermediate Sanctions

To guard against suspicions that early release constitutes an inappropriate reduction in the length of the prison term, parole is sometimes characterized as the continuation of a sentence, though now in the community. The emphasis of resettlement/reentry interventions is accordingly on tight supervision requirements, risk management, and strict enforcement. If parolees are seen as serving prisoners, the disciplines of imprisonment can legitimately be invoked and many of the rights enjoyed by other citizens may be withheld. In some parts of the United States, for example, parolees are not entitled to vote. The voting entitlement of convicted offenders varies considerably between countries, and indeed among the states of the USA, representing different views about the standing and rights of convicted offenders.

As well as post-release measures, changes in the character of community sanctions have raised comparable questions. Traditionally, probation was seen as a measure of support, assistance, and rehabilitation: in England and Wales, for most of its history, probation was *instead of* a sentence – not a punishment in its own right. But since the late 1980s, community sanctions have often been presented as *punishment in the community*, with the restrictive and punitive aspects of these sanctions deliberately emphasized. The idea is that tough community sanctions may reduce the prison population by persuading courts and the public that these are credible alternatives to custody. This aspiration, however, has a disappointing history: it is hard to find times or places when the introduction or toughening of community sanctions can be shown to have made significant reductions in the numbers of people in prison.

Similarly, the USA has seen a range of *intermediate sanctions* – sanctions, that is, intermediate between prison and community punishment. Michael Tonry (1998) attributed this development to three factors: the loss of confidence in the effectiveness of rehabilitation; the rise of a penal philosophy of *just deserts*, under which all court disposals had to be seen to be punitive in proportion to the offense(s); and the increased politicization of crime and punishment that led politicians to be very wary of an accusation that they might be *soft on crime*. These influences combined to lead to the emergence of a range of sanctions and measures that make clear demands on people's time and (in the case of community service/unpaid work) their labor and can constrain their freedoms – for example, by requiring them to be at (or stay away from) particular places at certain times, to participate in programs, and to submit to tests for drug or alcohol use.

It should be emphasized that the treatment philosophy of an earlier time had quite as much potential to trespass upon individual rights. One of the reasons why America and other countries, partly under US influence, repudiated the treatment model of corrections was because of its disregard for due process and human rights constraints: interventions that were ostensibly designed to offer treatment (and could therefore be argued to be in the offender's best interests) could countenance intensive and disproportionate interventions. While treatment has been disavowed in many countries, and even though *just deserts* should set limits, attempts to demonstrate punitive credibility have warranted increasing levels of intervention.

In short, the more "prison-like" community supervision aspires to be, the more likely it is to impinge upon offenders' human rights. Liberal criminology's opposition to imprisonment must remain principled, however: human rights matter here too and it is not true that anything goes so long as it is not prison.

Specific Issues for Community Punishment

Trends in the *enforcement* of community supervision and parole licenses are a matter for particular disquiet. In some countries, increasing numbers of people are in prison not because of the substantial harms they have been responsible for, nor even on the basis of assessed risk, but because of their failure to comply with the requirements of supervision (Padfield and Maruna 2006). This has implications for proportionality in sentencing and could also raise concerns about the processes of recall and the grounds on which such decisions are taken.

Another example is *disclosure*. There are complex questions about the proper boundaries between disclosures of personal information about offenders who are believed to pose a risk to the safety of potential victims and the rights of such (ex-)offenders to privacy and safety from harassment. Provisions like Megan's law (laws in the United States requiring law enforcement authorities to notify the public about registered sex offenders) raise these questions starkly. It can also be argued plausibly that exposing these offenders to opprobrium and perhaps to vigilante reprisal will lead to some very dangerous people "going underground," concealing their whereabouts from those authorities who need to monitor them. It is increasingly recognized that offenders' cooperation and compliance depends on *legitimacy*, on their perception that they are being dealt with fairly. Due regard for their human rights is one indispensable component of this legitimacy.

While some infringements of rights are deliberate and intrinsic to the lawfully determined penalty, punishment normally has other consequences besides. Walker (1991) uses the term *incidental* punishments to refer to those consequences that are not intrinsic to the punishment, but side effects, as it were. For example, intensive community supervision (perhaps a requirement to report daily to probation) could interfere with the legitimate pursuit of employment – and in the process delay desistance from offending. This is not an intentional result of the lawfully determined punishment. Where rights are avoidably (even if not deliberately) infringed, it is arguable that these infringements should be recognized, minimized, and maybe compensated.

One immediate difficulty here, however, is that punishment, notoriously, has many purposes, including a just imposition for the wrong that has been done, the reduction of further offending (by rehabilitation, deterrence, or incapacitation) and reparation. In many countries, these purposes are often not defined, so that it is hard to tell the loss of rights that is intended to be part of the punishment and which is "incidental." It might be possible to argue that a right is justifiably removed if, but only if, its removal is a necessary consequence of the sentence and contributes to a legitimate purpose of punishment. This is probably an incomplete safeguard: claims about public protection and an exaggerated confidence in the efficacy of deterrence could continue to countenance punitive excesses. Meanwhile the test of proportionality – that punishment must be in proportion to the crime – is probably the single most secure safeguard against undue infringement of the rights of offenders (van Zyl Smit and Ashworth 2004).

Walker (1991) also notes that punishment commonly has effects that fall upon other people – for example, offenders' children, whose own rights to a family life and general well-being may well be prejudiced by the imprisonment of a parent. Stigma, surveillance and disclosure are likely to have their impact not only upon offenders but upon their families and associates as well. Their human rights too must be respected and not merely seen as part of the punishment of the offender.

Prevention, Risk, and Human Rights

Several scholars have drawn attention to and debated the significance of a shift in many countries from the traditional criminal justice tasks of the just punishment and rehabilitation of offenders towards an emphasis on crime prevention (e.g., Garland 2001). The identification, assessment, and management of risk have become a uniting objective for the several agencies of criminal justice and a priority for each of them. In the penal system, this has led to a range of preventive sanctions and measures that are less a response to what an individual has done than a preemptive intervention in anticipation of what it is believed that s/he might do. This same trajectory has led to modifications and compromises to the safeguards of due process (see, e.g., Ashworth and Zedner 2008 and references there cited).

In practice preemptive interventions in the penal system are taken mostly against those with a (typically significant) previous record of offending, so that it is not always easy to distinguish what is retributive (due punishment for wrongs done) and what preemptive. But plainly these developments raise hard questions about proportionality. Proportion used to be understood to relate to an appropriate fit between the crime and the sanction. There was a guiding principle of *limiting retributivism* such that the punishment may never exceed the seriousness of the crime (although in some circumstances it may be reduced because of mercy or mitigation). But this is now significantly complicated by the emphasis on prevention. One argument is that proportionality may be exceeded to prevent crimes – perhaps even the term *proportionality* should be understood to mean proportionate not only to wrong done but to wrong anticipated. If the term is extended in this way, however, it becomes a much less effective constraint upon excesses of punishment.

Probation is centrally implicated in these debates. An influential probation model, arguably dominant in most English-speaking countries, focuses on risks, needs, and responsivity (RNR) in assessment and intervention. The risks in question are mainly risks of reoffending; the relevant needs are known as criminogenic needs (those associated with offending); responsivity is the principle that interventions with offenders are to be delivered in a manner that engages them, encourages full participation, and takes account of their individuality. Among criminogenic needs are problems like homelessness, unemployment, substance misuse, and poverty. Since these are amenable to change, they have been sometimes redefined as *dynamic risks*, with the result that social exclusion and disadvantage could come to be seen not as reasons to provide support and fair access to resources but as an occasion for more intrusive intervention. Where RNR prevails, risk assessment and management are at the center of probation practice. Assessed risk is now most likely to determine the nature and intensity of intervention, which again has the potential to challenge the limits of proportionality.

In targeting potential offenders, preventive justice (Steiker 1998) goes beyond the penal system and has largely developed without the due process safeguards of criminal justice or legal regulation (Janus 2010). Since the category of potential offenders could be limitless, preventive strategies make a difference to everyone. Ways of thinking about crimes and victims and technologies of crime prevention pervade civil institutions – families, schools, and the workplace – to an extent where states may be said to be *governing through crime* (Simon 2007). Modern technologies offer unprecedented opportunities of surveillance, monitoring, and data collection and collation, and the "commodification" of security adds a commercial impetus to these developments. Crime prevention thus lends legitimacy to actions that would otherwise be seen as an unwarrantable trespass on people's human rights.

When Human Rights Conflict

Proponents of preventive justice commonly defend their position by setting the rights of actual and potential victims and/or "community safety" in rhetorical opposition to the rights of offenders. Yet many offender rights – including almost all rights relating to the realities of sentencing implementation – do not in any way infringe the rights of victims or the community. The habit of supposing that the rights of potential or actual offenders must be in tension with the rights of victims or with community safety should be resisted. Such an assumption too readily slides into a belief that any enhancement of offender rights must entail some diminution of the rights of victims. Nor may it be assumed that practices that infringe human rights make for a safer community.

Where there are conflicts of rights, they should be considered carefully and managed in a principled manner. There is no easy formula – like "the rights of victims always outweigh the rights of offenders" – that will enable a decision to be taken summarily: it will depend upon the rights in question and of all those affected (see Ashworth 1996). As we have seen, asserting a right is unlikely to settle a moral problem – and indeed any way of talking about ethics that purports to dissolve substantial moral dilemmas should be viewed with suspicion. Meanwhile it is necessary to guard against the possibility that offender rights are gratuitously disregarded because they turn out to be inconvenient or are deliberately withheld as additional punishment – beyond, that is, the lawful imposition of the court – on an unexamined pretext that this is necessary to protect the community.

Challenges and Difficulties

It has been suggested that some misgivings about human rights – for example, that all rights are absolute, that offender and victim rights are intrinsically in opposition – rest on misunderstandings. Other objections need to be addressed. The first of these is that human rights, at least in penal affairs, are too general or even vague. Ethical principles ought to be action-guiding but can human rights offer sufficient guidance? Unless it is clear what these very general rights really amount to, if they cannot be deployed to guide policy and practice, they are at risk of becoming not much more than rhetorical claims.

Perhaps most importantly, court judgements establish a body of precedent that gives authoritative clarification to the articles of human rights conventions. But since this is a reactive (and slow) process, there have been attempts to develop instruments that apply the articles and principles of the conventions to the specific context of criminal justice and punishment (for discussion of the development of the international regulation of punishment in these ways, see van Zyl Smit forthcoming). The ICCPR takes significant steps in this direction. Again, the UN Standard Minimum Rules for Non-custodial Measures (*The Tokyo Rules*) seek to specify the implications of the UDHR for the position of defendants and offenders, while the European Prison Rules apply the European Convention to the particular circumstances of prisoners. European Probation Rules have also now been adopted (Canton 2010). In principle, such rules *draw out* what it will mean in practice to respect the rights of offenders, victims, and the community – and how to resolve conflicts of rights in a principled way. Rules thus contribute to a solution to this challenge of generality and remoteness.

A second objection is that rights are minimal: they are what is left when all else fails and are therefore of limited assistance in guiding the strategies and practices of a civilized and decent criminal justice system (see Nellis and Gelsthorpe 2003). Here, however, the legal principle of *positive obligations* becomes salient: both victim and offender rights can call for positive action, not merely forbearance – claims as well as liberties. This idea has the potential to challenge and to stretch the state's duties. For example, in *E. and others versus United Kingdom*, the court held that the UK had violated Article 3 (prohibition of inhuman and degrading treatment) by failing to accord E. adequate protection from abuse at the hands of her mother's cohabitant (Hofstotter 2004). In this way, a basic liberty-right may progressive evolve into something much stronger.

This is a principle with clear and significant implications for – in particular – the rights of victims of crime (as in the case of E.), but the principle should apply to offenders as well. Many offenders have experienced substantial social and economic disadvantage, and while their crimes entail a liability to punishment, their rights to fair opportunities should also be affirmed. Penal intervention should leave people better fitted to live well and without offending, and this could be conceptualized as a right with a corresponding duty that the state should assume. Once the sentence has been fulfilled, the state should accept a responsibility to create opportunities that the punishment may have curtailed – for example, an ex-prisoner may have a right to support to seek employment and accommodation. Rehabilitation through resettlement/reentry/aftercare could be seen as a right – not just a continuation of a punishment (Rotman 1994; Lewis 2005).

This reaffirms one of probation's traditional missions of advocacy on behalf of offenders, encouraging the community to accept its responsibilities towards those of its members who have committed crimes and not only to insist on their putative claims against them. The role of interventions, programs, and services can be invaluable in helping people to learn how to manage the problems that beset them without recourse to crime, to develop the skills they need to thrive. Yet desistance studies show that motivation and skills may not be sufficient: people need genuine opportunities to develop and to lead lives in which offending has no place. Reintegration, after all, implies not only a motivated individual but also a community willing to believe in the possibility of change and to respect the legitimate interests of ex-offenders. As it is, many offenders continue to experience significant stigma and disadvantage long after the completion of the lawfully imposed punishment. At the least, probation should advocate for ex-offenders to have fair opportunity and access to services enjoyed by others in the community.

Conceptualizing rehabilitation as a right, then, lends ethical support to the findings of desistance research, which emphasizes the importance of social capital and social inclusion in giving people genuine opportunities to thrive. The origins of offending are bound up in the social order and responses to it cannot just rely on the mechanisms of criminal justice. Probation has a role here – in advocacy, in the negotiation of access to inclusive services – though the success of its work here will depend on wider socioeconomic factors.

A further objection to be considered is the accusation that the discourse of human rights is culture-bound: an attempt by the West to universalize their own ethical standards and impose them on others. Yet, while recognizing the force of this allegation, Clapham replies that

> Human rights were invoked and claimed in the context of anti-colonialism, anti-imperialism, anti-slavery, anti-apartheid, anti-racism, and feminist and indigenous struggles everywhere. Western governments may recently have dominated the discourse at the highest international levels, but the chanting on the ground did not necessarily take its cue from them, nor did it sing to the West's tune. (2007, p. 19)

To assert rights that belong to everyone, rights that do not have to be "deserved" and are not contingent on gender, race, age, ability, and socioeconomic status, sounds like a promising beginning in challenging oppression.

Human Rights and the Values of Probation

It has already been remarked that human rights have been criticized as too remote and general to guide action. Yet a conception of human rights based on principles of personhood (Griffin 2008) – autonomy, choice, the ability, and liberty to act – could generate some specific guiding values for probation. The list below is an attempt to specify some such principles which could be derived from general rights as they apply to the work of probation. These could be considered as ethical parameters within which probation should be developed or perhaps as a benchmark for current policy and practice:

1. Believing in the possibility of personal change, probation should help to create opportunities for people to lead fulfilling and crime-free lives, enable them to acquire the skills needed to avail themselves of those opportunities, and support them in their motivations to change.
2. Recognizing people's responsibilities and rights, probation should address offenders as responsible, self-determining people.
3. As far as possible, offenders should be fully involved in (informed and consulted about)

any decisions that affect them. They should be actively involved in assessment, planning, interventions, and evaluation.

4. Probation seeks to gain the consent of offenders. Even when probation staff are obliged to take action against someone's wishes, they should always try to secure the offender's understanding of and, so far as possible, consent to any decisions that affect them.
5. The purpose of intervention is to reduce the likelihood of reoffending. Interventions must accordingly be constructive and not punitive in character.
6. Probation should countenance no imposition or limitation of rights unless this can be justified by some legitimate penal purpose.
7. Probation must always have regard to the rights and interests of offenders, even when the rights and interests of others must take priority.
8. Some limitation of rights is a necessary consequence of punishment but any such limitation of rights should be *either* regarded as part of the lawful sentence *or* minimized. Any restrictions on offenders' rights must be proportionate to the offense.
9. Offenders are members of the community some of whose rights have, for the duration of the penalty, been taken away or compromised. Once the penalty has been served, these rights should be fully reinstated (indeed, this is one meaning of the term *rehabilitation* – McWilliams and Pease 1990). In this respect, communities have responsibilities towards those of their members who have committed crimes.
10. Social inclusion is a requirement of social justice and a key guiding principle in probation practice. Since people who do not have fair and reasonable access to the services and institutions of civil society (social exclusion) are more likely to offend, this principle also helps to reduce offending.
11. To achieve the social inclusion of offenders, probation must work in close partnership with the agencies of civil society. Meeting the complex needs of many offenders calls for coordinated and complementary interagency work. Probation should use its expertise to help other agencies to make their services genuinely accessible to offenders. These principles attempt to connect the work of probation to the wider society. They go beyond organizational claims about the advantages of working in partnership to say that the services and institutions of civil society should be genuinely available to offenders as a matter of social justice and their legitimate claim-rights.
12. All probation practices must respect the interests and rights of victims of crime, in work with them or on their behalf, as well as working with offenders to help them to recognize the harm that they have caused.
13. Probation should explain its work and its significance to the public. Its values, policies, and practices must be open and must command the confidence and trust of the community. This is a requirement of legitimacy.
14. Probation policy and practice should be evidence-led. Rigorous research and evaluation should guide the work of probation agencies. If probation's objectives are worth achieving, the extent to which they are indeed being achieved must be appraised.

These principles may be in conflict with other ethical considerations. For example, while interventions should be constructive and not punitive, there are interventions – for instance, constraints on some offenders who seek to abuse or exploit the vulnerable – that will indeed be experienced as punitive and restrictive but are necessary to safeguard the rights of others. Similarly, while completion of the lawful sanction ought normally to restore people to their full rights, the continuing risk posed by some people means that their rights may have to continue to be circumscribed. These principles, then, are best understood as morally relevant considerations that ought always to be marked and allowed for when decisions are to be taken, even where they must give way to other moral considerations.

Conclusions

Probation research and policy have been dominated by the question of *what works*. Effective practice could indeed be seen as a right, shared by offenders (who should be enabled to participate in interventions that will help them to lead law-abiding lives) and by actual and potential victims, to the extent that further offending is thus reduced. A focus on human rights, however, is a reminder that probation should construct an ethical foundation for its policies and practices.

Probation and criminal justice in general give expression to a society's values and are not reducible to their instrumental functions. It has been argued that a respect for people's rights brings a legitimacy to practice that enhances individual offenders' cooperation and compliance. A repressive approach to risk management can lead to strategies that tend to increase risk through stigmatizing and exclusionary approaches. This can endanger a community by undermining the trust and reciprocity on which community safety and well-being ultimately depend. In this way, it may be that a rights-based approach to probation practice could turn out to be its most effective foundation.

Overview

Community supervision involves the monitoring of offenders living in the community, either following an institutional sentence or in lieu of incarceration. Historically offenders have been supervised via monitoring of "conditions" they must meet (i.e., obtaining or maintaining employment, reporting any changes in address/employment, abstaining from drugs and/or alcohol) and perhaps referral to community agencies for substance abuse treatment or other types of treatment. Research into the effectiveness of these strategies has been limited but for the most part suggests little to no impact on recidivism rates. At the same time, emerging research has suggested a new model of supervision (Risk-Need-Responsivity), which focuses on risk of recidivism, offender needs directly related to recidivism, and individual offender issues. Importantly, part of the changing focus has been on the specific officer-offender interaction and how officers might incorporate cognitive-behavioral and social learning principles into their work. Additionally, research has focused on incorporating the principles of motivational interviewing (MI) in criminal justice supervision. The potential impact of this supervision model has been promising, with initial studies suggesting 25-50 % relative reductions in recidivism for some strategies. However, the implementation of these strategies has been challenging, both from an organizational standpoint and the specific training of individual officers. As these are skill-based strategies, it is likely that significant training, coaching, and follow-up are needed in order for officers to become competent in the skills. A number of additional issues have yet to be researched, including which offenders might benefit most from the strategies, how strategies are best learned/incorporated into practice, and optimal levels of use of the various strategies.

Introduction

Community supervision is a broad term that has been used to capture work done by probation and parole officers within a community setting. Offenders on probation have generally served little to no time in an institution, instead being allowed to remain in the community. In contrast, offenders on parole have received institutional sentences but are released early and allowed to complete their sentences in the community. In both instances, offenders are supervised by an officer and are required to abide by certain "conditions" such as obtaining or maintaining employment, reporting any changes in address/employment, abstaining from drugs and/or alcohol, and not committing additional crimes. Offenders may be supervised for varying lengths of time (several months to several years or more) and may be required to report to an officer with varying frequency (i.e., weekly, monthly, or less). Traditionally, the primary mission of community supervision officers has been to monitor the behavior of offenders under their watch, to ensure they abide by any conditions imposed and remain law abiding. If violations occur, supervision may be revoked and the offender sent to an institution.

The effectiveness of community supervision in reducing recidivism has been called into question, with numerous studies suggesting that traditional approaches to supervision have little or no impact on recidivism rates (such as Bonta et al. 2008). At the same time, criminal justice research has focused on learning "what works" with offenders and has distilled this knowledge into what has become known as the Risk-Need-Responsivity (RNR) model (see most recently Andrews and Dowden 2007). Risk involves focusing on those offenders most likely to recidivate, Need incorporates identifying the specific factors related to reoffending, and Responsivity involves delivering treatment and interventions in an individualistic way. A large body of research has indicated that implementation of the RNR model can significantly impact recidivism rates (see Andrews and Bonta 2010 for a review of this research and Lowenkamp et al. 2010 for a review of its application to supervision based programs). A recent meta-analytic review (Andrews and Bonta 2010) demonstrated that adherence to all three principles leads to the greatest reductions in recidivism, while nonadherence with these principles leads to increases in recidivism. Unfortunately, analysis of conversations between officers and offenders demonstrated there was little adherence to the RNR model (Bonta et al. 2008).

The Importance of the Officer-Offender Interaction

To date most research and meta-analyses have focused on the translation of Risk-Need-Responsivity (RNR) into formal treatment programs, with little emphasis on how the model should be implemented within the officer-offender interaction itself, nor what occurs during the actual contact between an officer and offender. In fact, research on officer-offender interactions has suggested that officers focus on monitoring versus changing behavior, and training of officers has typically focused on understanding local laws, policies, and procedures. However, beginning in the early 1990s, more emphasis has been placed on the content of officer-offender interactions, beginning with a focus on risk assessment. Since that time, there has been a move from the traditional monitoring role of community supervision agents to a change-oriented role. The shift has been informed by social learning theory and cognitive-behavioral research on effective ways to engage people in behavior change, as well as research on the nature of helping relationships. Social learning theory emphasizes that people learn not only from their own experiences but also by observing the behavior and resulting consequences of other people's behavior, whether it be actual behavior seen, a description of behavior/consequences, or what they see in television, movies, etc. Additionally, social learning theory notes that the internal rewards someone may experience (pride, satisfaction, etc.) may be just as important, or even more important, than rewards received from others. This focus on the internal thought processes coincides with cognitive-behavioral theory, which emphasizes that our behavior is a result of our thoughts and feelings about an event, rather than the external event itself. Under this theory, behavior change occurs when someone focuses on their internal analysis of an external event (what I thought, how I felt) and the active changing of those thoughts and resultant feelings. Finally, such behavior change must occur within the context of an empathic helping relationship. The translation of these theories into the criminal justice arena has resulted in what has become known as Core Correctional Practice (CCP) (e.g., Andrews and Dowden 2004). These practices include areas such as focusing on high-risk situations (likely to lead to criminal behavior) and analysis of cognitions that support criminal behavior. For example, trained officers frequently respond to positive drug screens by examining the antisocial thoughts of the offender ("I can get away with it," "I won't be tested soon," or "I'm not hurting anybody") and working collaboratively to identify thoughts that reduce the likelihood of the behavior in future high-risk situations. Likewise, the CCP-trained officer looks to identify cognitive responses to prosocial behavior. Trained officers reinforce prosocial behavior by moving beyond simplistic verbal praise (i.e., "good job"), instead asking the offender to identify immediate and long-term internal and external rewards. Identifying the cognitions ("my kids are going to be proud of me," "if I continue to do this I can build toward what I really want") that support the prosocial behavior helps develop meaningful thoughts that can be used in future high-risk situations. The CCP-trained officer also focuses on teaching offenders skills using a structured and graduated learning process complete with rehearsal and practice. Finally, in addition to the special attention paid to the thinking of the offender, the CCP-trained officer deliberately builds a working alliance that focuses on the acquisition and development of skills that reduce risk in potentially risky situations. Utilizing these types of interventions can fundamentally change the work of probation officers. The traditional case management approach, whereby the officer "manages" the case through monitoring and referral, is transformed to one where the officer is now a "change agent" (Bourgon et al. 2011). In this new role, officers actively work to facilitate the change process through their interactions with offenders, rather than relying on interventions by other professionals.

Research on the impact of these behaviorally based interactions is promising. Trotter (1996) found that using empathy, problem-solving, and a prosocial approach reduced recidivism. Taxman (2004) outlined a process of proactive community supervision (PCS) which focused on comprehensive assessment, case planning, setting clear expectations, reinforcement, desistance, and the use of behavioral contracts. Recidivism rates of offenders supervised by those trained in this model were about 30 % (relative risk) lower than offenders supervised by officers not trained in PCS. Bonta (2010) utilized the Strategic Training Initiative in Community Supervision (STICS) curriculum to teach and evaluate CCP by categorizing various officer actions/techniques into four areas: structuring skills includes items such as "checking in" with the offender, reviewing homework, and prioritizing needs; relationship building includes skills such as role clarification, active listening, and effective feedback; behavioral techniques focus on modeling, the effective use of reinforcement and disapproval, problem solving, and self-management skills; and cognitive techniques, including specific targeting of procriminal attitudes, the application of a behavioral model, and cognitive restructuring. Officer training in these skills included a 3-day training followed by monthly maintenance sessions which allowed officers to discuss the use of skills, receive feedback on their use of skills, and provide "refresher" training. Officers trained in STICS used the skills more often, and their offenders had lower recidivism rates, than those officers who did not receive training. Subsequent studies using STICS have found similar increases in officers' focus on procriminal attitudes, the use of cognitive interventions, and subsequent lower recidivism rates. A similar curriculum, Staff Training Aimed at Reducing Rearrest (STARR), has also been developed. The STARR skills include specific strategies for active listening, role clarification, effective use of authority, effective disapproval, effective reinforcement, effective punishment, problem solving, and teaching, applying, and reviewing the cognitive model. For each strategy, skill cards outline the specific activities officers need to do to successfully deliver the strategy. A fundamental focus for each skill is the internalization of strategies so that offenders begin to learn and apply the strategies on their own. Initial research on STARR demonstrated comparable results to STICS: officers used the skills significantly more than officers not trained in STARR, and offenders had a 50 % relative reduction in recidivism (Robinson et al. 2011). Importantly, in each of these studies, interactions remained relatively brief (around 20 min) yet still impacted outcomes. In total, the research on the use of CCP by community supervision officers has spanned 15 years, three continents, and four very different locations with results consistently yielding a 25-50 % relative risk reduction in recidivism rates.

An additional area of officer training which has received significant attention is motivational interviewing (MI). MI is a communication style that involves strategic use of questions and statements to help clients find their own reasons for change (Miller and Rollnick 2002). MI borrows from client-centered counseling in its emphasis on empathy, optimism, and respect for client choice. MI also draws from self-perception theory, which says that people become more or less interested in change based on how they talk about it. Thus, an offender who talks about the benefits of change is more likely to make that change, whereas an offender who argues and defends the status quo is more likely to continue in the present behavior. Finally, MI is also logically connected to the Stages of Change model, which says that people go through a sequence of stages when considering change (Prochaska et al. 1992). Because MI is a communication style, it is usually introduced as a set of stylistic principles: (1) express empathy, which involves a sincere attempt to understand the offender's point of view; (2) roll with resistance, which emphasizes avoiding arguments whenever possible and finding other ways to respond when challenged; (3) develop discrepancy, which means working to elicit the offender's own reasons for change; and (4) support self-efficacy, which emphasizes positive language and an environment that is supportive of change. From its beginnings in addiction counseling, MI has been translated into a number of behavior-change areas. MI currently has strong research support in areas such as alcohol and drug use, smoking cessation, medication compliance, HIV risk behaviors, and diet/exercise. Two meta-analyses of more than 70 MI outcome studies in different areas suggest an overall significant and clinically relevant effect (Hettema et al. 2005; Rubak et al. 2005).

Many criminal justice agencies have embraced the idea of MI, and numerous articles have been written encouraging its use by community corrections agencies (e.g., Alexander et al. 2008; Walters et al. 2007). However, few studies have focused on the effectiveness of MI within criminal justice settings. McMurran (2009) identified 13 published studies and six dissertation abstracts evaluating the use of MI within correctional settings, with only ten studies using randomized controlled trials. Due to the lack of studies and the significant variation within existing studies, McMurran concluded that "no overall definitive conclusion about the effectiveness of MI with offenders can be drawn." A recent randomized trial of MI within a probation setting indicated no impact on outcome (Walters et al. 2010), though it is noted that the level of MI skill demonstrated by officers may have been below accepted proficiency levels.

Effective Implementation of Core Correctional Practices

Despite the large body of research supporting the RNR model, and the emerging research on officer-offender interactions, the model has not yet become entrenched in the everyday practice of community corrections. The problem of translating research into practice is not something new; other behavioral fields (e.g., medicine, substance abuse, mental health) have experienced similar issues. As such, many have begun focusing on how to effectively implement practices so they do become routine. Klein and Knight (2005) suggest that six key factors will determine if an intervention is effectively implemented. These include (1) the quality and quantity of training; (2) a positive organizational climate; (3) administrative support; (4) financial resources; (5) learning orientation that supports staff skill development, competence, and growth; and (6) patience with the inevitable stumbling blocks that will occur during implementation. We focus on the issue of training, while noting that the other factors are equally important in leading to full-scale adoption of the practice.

Skills Training

Historically, training of officers has focused on brief (1–3 day) trainings with little to no follow-up. Unlike trainings focused on imparting knowledge (i.e., facts about substance use), the interventions noted above all involve the development of a new *skill* to be used. Research on skill development in practitioners has demonstrated that ongoing feedback and coaching is essential if new skills are to be translated into everyday practice. A review of implementation research consistently demonstrates that trainings focused simply on knowledge transfer, with no skill training or follow-up, do not lead to changes in everyday practice (Fixsen et al. 2005). For example, Joyce and Showers (2002) found that only 5 % of participants translated skill use from training to the practice environment if no follow-up was included, while 95 % of participants subsequently used the skills if they receive on-the-job coaching. Research specific to MI suggests that officers may go through as many as eight stages in learning MI (Miller and Moyers 2006). Failure to provide officers the necessary time and support to develop through these stages will likely lead to officers failing to become proficient in the skill. Preliminary research suggests that many officers who only receive workshop training and little or no follow-up/coaching do not meet minimum proficiency levels for MI (Lowenkamp 2010). Similarly, research on training in cognitive-behavioral therapy suggests that the use of follow-up/coaching is essential to increased knowledge and use of the skill (Cully et al. 2010). Importantly, it is noted that several studies of cognitive therapy have shown that outcomes improve as therapist skill level improves (Shafran et al. 2009).

Current Issues

The above research covers a number of different skills that could be used in a multitude of combinations. Consistent with the Responsivity aspect of the RNR model, all skills/interventions may not be needed by all offenders. Further research is needed to determine which skills/interventions may be critical for most, if not all, offenders and which skills may be less important. Additionally, interventions may be effective for some offenders, but not others. Further understanding the nuances in these skills will be critical to moving these practices forward. Similarly, it is unclear whether all officers can, or should, be able to learn all of these skills. Anecdotal evidence suggests that some skills, like MI, may be more difficult for officers to learn than others. Officer orientation, prior training, and experience will all likely influence an officer's interest and ability to learn these skills.

Research in other areas suggests that having a mentor and participating in discussions with others regarding new practices is more likely to lead to integration of new techniques into daily practice (Cook et al. 2009), pointing to the importance of developing an environment of colleagues that support the new intervention. In order to ensure successful skill transfer from the classroom to the community, agencies must also have access to trainers who can provide not only classroom training but also on-the-job coaching (Cully et al. 2010; Miller et al. 2004). Additionally, agencies must provide staff with the time necessary to practice skills and receive feedback. In an era of budget cuts and increasing caseloads, it becomes difficult for officers to focus on spending time on skill development.

In order to determine effectiveness of these intervention skills, actual use of the skill must be documented. Two facets must be considered: adherence and competence. Adherence suggests that the skill is being done, while competence indicates *how well* the skill is performed. While such ratings can initially be done through role-play situations, in order to be truly meaningful ultimately, the ratings must be on actual offender-officer interactions. Miller and Rose (2009) note "We know of no reliable and valid way to measure MI fidelity other than through the direct coding of practice samples. Clinicians' self-reported proficiency in delivering MI has been found to be unrelated to actual practice proficiency ratings by skilled coders (Miller and Mount 2001; Miller et al. 2004), and it is the latter ratings that predict treatment outcome." Coding of interactions can be accomplished through either direct observation or audio/videotaping of interactions. Only recently has the practice of audiotaping and coding interactions between officers and offenders been introduced (e.g., Bonta et al. 2008, 2010; Robinson et al. 2011). Prior to initiating audiotaping of interactions, several legal issues must be considered, including whether offenders have the right to refuse to be taped, who will have access to tapes, whether tapes will become part of an offender's official record, and whether tapes can be used in future legal proceedings. Since the purpose of taping is the skill development of the officer, we strongly advocate for tapes being accessible only to the extent that they are needed and used for training purposes. If tapes become a part of the legal case against the offender, the ability to obtain tapes may become difficult, and the usefulness of tapes will likely be diluted.

Conclusions and Future Research

The impact probation officers can have through their direct intervention with offenders is promising and supports the transition from compliance monitoring case management to a more comprehensive approach focused on the development of new skills that reduce risk. This finding is important given the incredible costs of recidivism, the typical responses to it (prison), and the costs typically associated with treating offenders. In an environment with seemingly always decreasing resources, it is important that we maximize the resources we continue to have available to us. Intentional CCP-based officer-offender interactions may support offender learning and skill mastery that is occurring via formal treatment programs, or may be stand-alone interventions. The purposeful skill-focused interaction allows agencies to extend the therapeutic environment beyond the traditional and often less effective treatment setting. This is important given the number of hours typically necessary to facilitate the change process for many high-risk offenders and the ability of most agencies to meet the demand. In order to ensure that these promising practices become routine, there must be a significant focus on effective implementation. To date, it is unclear exactly how long skill development will take, how many coaching sessions should occur, etc. Future research needs to focus on delineating these issues so the field has a clear vision of how to achieve effective practice.

Probation Officer Decision-Making

Arthur J. Lurigio
Department of Psychology, Loyola University Chicago, Chicago, IL, USA

Overview

Imposed in lieu of incarceration, probation is the most common sentence in the United States for convicted adults. A probation sentence orders convicted offenders to adhere to conditions of release that are specified by statute (mandatory conditions) or leveled in response to the particular circumstances of the case (special conditions). The former require probationers, for example, to report to their probation officers and to seek permission from the court to move from the sentencing jurisdiction. The latter require probationers, for example, to pay restitution to victims or to obtain treatment for drug or alcohol addiction. Probation officers are agents of the court responsible for enforcing the mandatory and special conditions of probation.

In the initial appearance stage of the court process, probation officers evaluate arrestees for bail. These evaluations are based on arrestees' charges as well as their criminal histories, ties to the community, and previous records of court appearances. Those with the most severe charges and criminal histories – especially those involving sex or other types of violent crimes – and records of failing to appear in court are the least likely to be recommended for bail or for a low amount of bail, ensuring that they will be detained in a jail until their cases are adjudicated. Before a sentence is rendered, probation officers conduct presentence investigations that inform the court in rendering the most appropriate sentence in light of a defendant's criminal and social histories. Officers typically recommend a sentence to probation for those who can be supervised safely in the community and benefit from social and behavioral healthcare services.

As part of their duties, probation officers also engage in assessments that guide their case management strategies at the post-adjudication stage of the court process. Based on an assessment of risk (i.e., the likelihood of continued criminal activity while on probation), officers decide on the level and frequency of contacts for each member of their caseloads. Higher-risk offenders are seen more often in the office and in home visits compared with lower-risk offenders who may be allowed to report by phone, mail, or computer. Based on an assessment of need (i.e., the rehabilitative and treatment services required to help offenders reintegrate into the community as law-abiding citizens), officers decide on the nature and intensity of services brokered in the community or provided in-house. Other decisions rendered by probation officers include the filing of petitions to the court requesting to revoke probation for offender rule breaking or to terminate an offender early for rule adherence. Whether officers are more inclined to monitor or counsel their cases depends in part on their backgrounds (e.g., law enforcement or social work) and styles of supervision.

Introduction

Of the numerous correctional reforms and innovations that emerged in the nineteenth century, few were as broadly or readily embraced as probation. Rooted in common law practices, such as suspended sentences and judicial reprieves, the first use of probation in the courts is widely attributed to the voluntary efforts of an altruistic Boston boot maker, John Augustus (1784–1859), who is considered the father of probation. Between 1841 and 1859, Augustus acted as advisor, advocate, and surety for nearly 2,000 people. Augustus was an early and ardent proponent of rehabilitation, declaring that the purpose of the law is to reform criminals and to prevent crime, not to punish criminals for the sake of retribution or vengeance. He was known to rebuke police officers, judges, and others who challenged his correctional philosophy; many officials regarded Augustus as an interloper in the court system and interfered with his efforts to persuade judges to release defendants to his guardianship. Augustus's progressive, humanitarian approach to supervision was designed to encourage offenders to repudiate their destructive habits (rehabilitation) and return to the community as law-abiding citizens (reintegration).

Augustus assisted lawbreakers by counseling and supervising them during periods of release from court custody. According to his records, among the first 1,100 probationers under his authority, only one forfeited bond. If any of his charges were too poor to pay court costs, Augustus advanced them a loan and provided them with lodging and subsistence. Rudimentary assessment strategies appear in his informal evaluations of offenders' intentions to remain sober and to become upright, law-abiding citizens. During Augustus's time, other concerned Bostonians emulated his efforts by putting up bail for defendants and offering employment to those who were jobless. These voluntary endeavors greatly impressed the court and were instrumental in leading Massachusetts to become the forerunner in probation legislation. Almost 20 years after Augustus's death, the Probation Act of 1878 called for the appointment of a paid probation officer (PO) to serve the courts, thereby creating the basic model of probation that remains in operation today. POs were given authority to investigate cases and recommend probation for people who could be reformed without punishment.

Probation, a sentence in lieu of incarceration that orders convicted offenders to adhere to conditions of release, is the most common sanction in the United States. At the end of 2009, more than four million adults were on probation. In general, the conditions of probation can be categorized as mandatory, punitive, or service oriented. All people sentenced to probation are subject to mandatory conditions as dictated by state statute, such as reporting to a PO and refraining from criminal activity and gun ownership. Mandatory conditions also prohibit offenders from leaving the jurisdiction without the express permission of the sentencing judge. Punitive and service-oriented conditions – known as special conditions – are tailored to the specific circumstances of the case and the special needs of probationers. The former include allowing unannounced home visits, fulfilling community service hours, paying fines and restitution, and obeying a curfew. The latter include being referred to treatment for psychiatric or substance use disorders and participating in vocational or educational programs. Conditions of probation must be reasonable and constitutional and serve a legitimate purpose in terms of rehabilitating offenders and protecting community safety. Throughout the period of supervision, the court retains the right to modify the conditions of probation and to resentence the offender when those conditions are violated.

Probation Officers' Roles

POs are agents of the court, responsible for a variety of activities before sentencing (pre-adjudication), as well as monitoring and enforcing the conditions of probation after sentencing (post-adjudication). To serve the court, POs must make several decisions that affect probationers throughout the criminal justice process. Like most other criminal justice professionals, these officers exercise discretion in rendering decisions about defendants and offenders. However, also like most other criminal justice professionals, their decisions must be bound by the law and in accordance with departmental policies, standard operating procedures, and professional standards.

The responsibilities and case management decisions of POs and parole agents are highly similar; they both strive to protect community safety by monitoring the conditions of release and reintegrating offenders into the community by brokering services. Unlike probation, which is a sentence in lieu of incarceration, parole is early release from prison (post-sentence). Probation officers enforce the mandates of the court system; parole agents enforce the mandates of the corrections system. Although parole agents are never involved in pretrial or presentencing decisions, they are involved in making decisions pertaining to assessment, supervision, and revocation. Unlike probation officers, parole agents struggle to help formerly incarcerated persons with the many and varied challenges of prisoner reentry.

Pretrial Decisions

The Federal Bail Reform Acts of 1966 and 1984 significantly changed the mechanisms for setting bail and were enacted to protect the constitutional rights of all defendants, especially the indigent who were languishing in jail because they were unable to afford the bond amount needed to secure their freedom before their cases were heard. An experiment by the Vera Institute of Justice, known as the Manhattan Bail Project, played a significant role in the bail reform movement and was instrumental in POs' participation in the bail decision-making process. The project examined whether judges could release defendants safely without monetary bail (on their own recognizance), contingent upon their providing the court with verifiable information about their families, jobs, and associates (criminal and noncriminal). The study found that defendants who had been released on their own recognizance were more likely to appear in court than defendants released with monetary bail, setting the stage for POs' evaluations of defendants for pretrial release and bond amounts.

The Bail Reform Act of 1966 enjoined the court to first consider releasing defendants on their own recognizance and to use a cash bond only in cases in which a recognizance release was deemed insufficient to guarantee a defendant's appearance in court. In addition, the court was required to select bail release options that were responsive to the needs of each defendant. The Act also defined the factors that should be considered in pretrial release decisions: the nature and circumstances of the current offense; the weight of evidence against the defendant; the defendant's social history and personal characteristics, including the defendant's character, mental health problems, family ties, employment status, and financial resources; the defendant's length of residence in the community; the defendant's criminal history and previous failures to appear before the court; and whether the defendant was on probation or parole or had other pending cases at the time of the arrest.

The Bail Reform Act of 1984 amended the previous reform act in order to permit the court to consider preventive detention as a means to protect the public from high-risk defendants. In such instances, a defendant could be denied bail and detained if the defendant was likely to pose a serious risk to public safety or to obstruct justice or intimidate witnesses or jurors. Bail also could be denied to defendants with lengthy criminal histories or to those accused of a felony, or a violent or drug offense that carried a potential life sentence or the death penalty.

At the pre-adjudication or pretrial level, POs present judges with information that helps them determine whether to release a defendant on bond. The process of collecting and presenting information to the court is based, in part, on bail legislation and research. POs' recommendations also inform judges in setting the type and amount of bond ordered. Officers conduct a comprehensive evaluation of defendants to arrive at these recommendations. The first area of investigation involves a defendant's risk of continued criminal activity and threat to public safety. To render decisions in this area, POs examine a defendant's current charge(s) and criminal history. In general, those who pose the greatest risk for committing a future crime have lengthier criminal records and are charged with more than one offense. Other risk factors include gang membership and addiction to drugs or alcohol.

The second area of investigation involves the risk of absconding (the failure to appear on the designated court dates), which is based on an assessment of community ties or connectedness. Defendants who have ties to social institutions (school, family, job) are considered a lower risk of absconding than defendants with weak or no ties (single, unemployed, and out of school). POs' decisions take the form of a recommendation to the court to release defendants on bail or keep them confined to jail pending court hearings or trial. A decision to recommend bond also can include a recommendation of bond type (cash, deposit, or recognizance) and dollar amount (high, moderate, or low).

Several studies have created and tested statistical tools for bail decision-making, which consist of factors that are related to pretrial outcomes. POs assess defendants for bail by scoring them on each factor – for example, current charges, criminal histories, and community ties – for the purpose of determining the likelihood that the defendant will appear in court and refrain from criminal activity while awaiting trial. The scores are added, and the sum equates to the level of risk. Defendants who score higher on such assessments usually are considered a higher risk for committing a future crime or absconding. In such cases, POs are likely to recommend detention or a high bond amount. Inversely, defendants who score lower are considered a lower risk. In such cases, POs are likely to recommend release to the community or a low bond amount. POs have the discretion to override the score and recommend a decision to the court that is based on their informed judgment of the defendant's suitability for release.

The Vera Institute of Justice introduced its "points system" of bail decision-making in the Manhattan Bail Project. In this system, more points predict lower risk. Specifically, defendants are awarded points for having no criminal record, living with immediate family in the area, being employed, or attending school. Defendants who have lived at same residence for several years or are cooperative during the bail interview also are awarded more points in the system.

The most common factors incorporated in bail assessment tools include prior court appearances, nature of the offense, and criminal history. Courts also examine defendants' employment and financial status, family and community ties, psychiatric and substance use disorders, length of residency, and evidence of dangerousness to the community. In addition, the court may order defendants to participate in pretrial supervision programs, which were implemented to relieve jail overcrowding by monitoring defendants in the community. POs' decisions about the level or closeness of pretrial supervision are based on their evaluation of roughly the same factors considered in POs' decisions about bond. Defendants who present the highest risk for criminality and absconding are monitored at the highest level of supervision, and vice versa.

Presentence Decisions

After a defendant has been convicted, POs shift the focus of their decisions from the pretrial to the presentence level, at which POs conduct a thorough evaluation of convicted offenders, or presentence investigation (PSI) – usually required for offenders convicted of a felony. The PSI consists of interviews with offenders and crime victims, as well as reviews of court and criminal records. POs compile this information into a PSI report, covering the offender's criminal, social, educational, military, and employment histories; current charges and the circumstances surrounding his or her arrest, such as the use of a weapon and victim harm; current living arrangements; and previous experiences in prison and on probation or parole. POs decide whether to recommend probation, and, if so, they prepare a supervision plan that specifies how the offender should be monitored and serviced. POs' decisions to recommend probation are highly important in cases in which a judge may sentence an offender to a term of either probation or imprisonment, that is, when the statute imposes no mandatory prison sentence for a given charge (Class X Felony) or a given offender (repeat felon statutes or "three strikes" laws).

Postsentence Decisions

POs' postsentencing decisions relate to the case management of offenders, which involves monitoring offenders in order to minimize their risk of continued criminal activity and responding to offenders' needs for services and treatment in order to assist them in living more productive and crime-free lives. POs also are interested in helping offenders to reintegrate into the community and restore their good citizenship. As the first step in the case management process, risk and needs assessment guide officers in rendering decisions about the nature and frequency of offender contacts, as well as the provision or brokerage of services. POs' assessment strategies have evolved through three generations of decision-making protocols.

Risk assessment is the cornerstone of effective offender management. The first generation of risk assessment was based on subjective or clinical judgments in which officers trusted their "gut instincts" and experiences in the formulation of case management plans. Early studies of PO and parole officers' supervisory decisions demonstrated that they used stereotypes and beliefs that crystallized through repeated contacts with offenders and were situated in the professional climates and cultures in which officers functioned. For example, one study showed that POs stored their information about probationers into stereotypic categories known as schemata, which consisted of information about offenders' past criminal behaviors, social histories, pathways to crime, and drug and alcohol use. Schemata are abstract cognitive representations of organized prior knowledge, extracted from experiences with specific cases. Types of probationer schemata have included "the gang member," "the professional burglar," "the white-collar criminal," "the drug addict," "the career criminal," and "the violent man." Experienced POs produced fewer but richer (more detailed) schemata than inexperienced POs. Research has shown that stereotypic categories, for example, "dangerous men," "criminals," and "sincere clients," also are used by parole agents to guide supervisory strategies, treatments, and prognoses, and to render decisions about the nature and frequency of offender contacts.

Decisions about schematic cases usually are made more quickly, easily, and confidently than decisions about non-schematic cases. Despite these advantages, the use of informal or stereotyped decision-making is fraught with limitations and errors. Clinical judgments – especially those that involve predictions of future risk – are mostly invalid (inaccurate) and unreliable (inconsistent).

Such professional judgments are unstructured and unstandardized. In addition, they are subject to personal bias and difficult to correct because of their deeply practiced and entrenched nature. Furthermore, professional assessments are difficult to study because each PO's decision-making procedure is idiosyncratic, and individual judgments have never been systematically tracked to determine their predictive value.

The second generation of risk assessment was based on actuarial (statistical) assessments of risk. Since the 1950s, research has found consistently that actuarial or statistical methods of risk assessment that are empirically derived predict criminal behavior more accurately than those that are clinically derived. As a result of their demonstrated predictive superiority, actuarial assessment and classification models have been implemented by correctional agencies in order to guide supervision practices. Based on prediction tools that were developed to gauge offender risk for parole release (e.g., the Salient Factor Score Model), probation departments created case classification systems that assigned probationers to levels of supervision, establishing a fairer and a more rational and effective use of department resources than could be achieved with clinical approaches to offender assessment. With such statistical models, officers' time could now be properly allocated to monitor the highest-risk and highest-need offenders. More intensive surveillance and services could be dedicated to manage offenders at higher levels of risk and with greater needs for services. A uniform classification system can also be used to describe the client population, to allocate department resources, and measure the effectiveness of community supervision practices.

The development of second-generation risk assessment tools often involves a multistep process of research/analysis. A sample of closed cases is selected randomly from a recently terminated population of probationers, yielding information about the predictive or outcome variable, such as rearrests during the probation period and status at termination (successful or unsuccessful fulfillment of the conditions of the sentence). The sample is split evenly between probationers who had a positive (no rearrests, completion of conditions) or a negative (rearrest or violation of conditions) outcome. Information on the outcome and a variety of predictor variables (e.g., age at intake, number of previous arrests, juvenile record) are collected and coded from the case files.

The sample is then divided in half, preserving in each half equal numbers of successful and unsuccessful probationers. The data in the first half of the sample, called the construction sample, are analyzed to identify factors that are statistically related to the outcome.

The data in second half of the sample, called the validation sample, are analyzed to test how well the factors can predict the outcome with a new group of cases. In this stage of the analysis, the accuracy of the variables is determined by comparing the percentages of correct and incorrect classifications, which include false-positive errors (predicting a failure when the case was actually successful) and false-negative errors (predicting a success when the case was actually a failure). Other measures of the accuracy of a prediction tool are its sensitivity (its power to select true positives) and specificity (its power to predict true negatives).

If the tool has a high rate of correct classifications (a low rate of errors), the next step in the process is to scale the factors and place them in an instrument. In a pilot test of the tool, POs score a sample of probationers on each variable and add up the scores to determine the probationer's level of risk: high, medium, or low. The pilot test results suggest a cutoff score for each of the risk categories.

In the final step of the process, POs are trained to use the tool and asked to complete questionnaires about its practicality and effectiveness. They also are also asked to track the amount of time they spend supervising offenders in each of the risk categories and to recommend improvements to the tool. Such feasibility studies are critical in encouraging the proper use of the tool and ensuring that changes are made before mistakes and poor practices become embedded in everyday usage.

Undertaken by the National Institute of Corrections (NIC) in the early 1980s, the Risk Classification Initiative encouraged the adoption of case classification systems in probation. NIC offered training and technical assistance to probation agencies nationwide in an effort to implement case classification systems as tools for accurate assessment and efficient resource allocation. The NIC Model Risk Classification system consisted of both risk and needs assessment instruments, which were developed in Wisconsin. The risk component of the assessment evaluates the likelihood that probationers will commit an offense while on probation. The Wisconsin Risk Assessment tool contained items such as age at first conviction, number of prior periods of probation and parole supervision, number of prior felony convictions, and convictions/adjudications for a violent crime.

The needs component of assessment evaluates the nature and extent of offenders' problems and the amount of time necessary for supervision and resource brokerage for cases with varying degrees of problems. The needs scale contained the following items: academic/vocational skills, employment problems, financial management, marital/family relationships, companions, emotional stability, alcohol use, other drug use, mental ability, health, sexual behavior, and officers' impressions of offender problems. Based on scores from the risk and needs assessment scales, offenders are assigned to maximum, medium, or minimum levels of supervision. POs place probationers in the highest supervision category indicated by either scale. However, with approval from their supervisors, POs can override the level of supervision dictated by the scales if individual circumstances warrant the reassignment of a probationer to a higher or lower level of monitoring. Maximum supervision probationers exhibit either a high potential for continued criminal activity or a substantial need for services, or both. Medium supervision probationers exhibit either a moderate potential for continued criminal activity or a moderate need for services, or both. Minimum supervision probationers exhibit little potential for continued criminal activity and few problems and therefore are likely to successfully complete probation.

In tandem with the Wisconsin risk and needs instruments, the NIC model used the Client Management Classification tool (CMC), which was a structured interview that helped POs formulate case plans for working with different types of offenders. The CMC identified four treatment/supervisory modalities for different types of probationers: selective intervention, environmental structure, casework/control, and limit setting.

Although second-generation actuarial prediction tools contained risk factors that are related statistically to outcomes, these factors consisted mostly of static or historical factors, which are unchangeable. For example, juvenile record, history of conduct disorder, and parental involvement in crime are all strong predictors of early adult offending. However, they also are immutable. In other words, such variables can explain criminality and reoffending but are unresponsive to probation officers' interventions. In contrast, criminogenic needs are dynamic factors, which form the building blocks of third-generation risk assessment batteries. When properly addressed by POs, dynamic factors can reduce offender risk. For example, if an offender is unemployed (dynamic risk factor), then the PO can help the offender find a job. Examples of other dynamic factors are educational status, faulty cognitions, deviant sexual fantasies, family relationships, leisure activities, criminal associates, and substance use disorders. The third-generation approach to risk assessment is known as "structured professional judgment."

According to research, the eight major risk factors associated with criminal conduct are antisocial/procriminal attitudes, values, and beliefs; procriminal associates and isolation from prosocial people; temperament and personality factors, such as impulsivity, adventurousness, and pleasure-seeking tendencies; history of antisocial behavior; family criminality or lack of family caring or cohesiveness; low levels of educational, vocational, or financial achievement; lack of prosocial leisure activities; and abuse of drugs and alcohol. All of these considered critical predictors but the first four, as also known as the

"Big Four," and are deemed the most predictive risk factors among the set. Third-generation tools often contain many of these factors.

The Level of Service Inventory-Revised (LSI-R) is the best-known and most widely adopted third-generation assessment tool. Like its second-generation predecessors, the LSI-R is used to evaluate offenders for case management decisions. Unlike earlier models of risk assessment, the LSI-R focuses on criminogenic needs; it also has a theoretical basis and considerable empirical support, attesting to its accuracy, reliability, and usefulness in several areas of correctional practices. In addition to the principles of risk and needs, the tool incorporates the principle of responsivity: tailoring interventions to each offender's motivational level, abilities, strengths, and learning style. The tool consists of 54 items, divided into ten dimensions or subscales: criminal history, employment/education, finance, accommodations, family/marital, leisure/recreation, friends/associates, drug/alcohol use, mental health, and attitude/orientation. Information to score the LSI-R is drawn from a thorough case review and semi-structured interview. Offenders who score higher on the LSI-R have a higher risk of recidivism, and vice versa.

Caseload Management Decisions

Offender case management strategies are predicated on discretionary decisions about the nature of the officer-offender relationship and the status of probationers during the supervisory period. These decisions cover the areas of supervision, treatment, early termination, and revocation. The surveillance or control aspect of the supervisory decision consists of two components. The first component is the frequency with which probationers report to their officers. The frequency of contacts is modified in accordance with the officer's assessment of the offender's level of risk or likelihood of continued criminal behavior. Probationers can report monthly (the most common frequency), bimonthly, or weekly. Higher-risk offenders report more often than lower-risk offenders.

The type or mode of supervision is the second component of the decision. POs can monitor a probationer through office visits, telephone contacts, mail-in reports, or computer-screen reporting at a kiosk. The offender's assessed level of risk can also determine the supervisory mode. For example, felony probationers are generally required to visit the probation office regularly, whereas less serious offenders are allowed mail-in or kiosk reports. Related to the determination of the supervisory mode are officers' decisions to assume a particular professional posture with different members of their caseloads.

POs adapt their attitudes, focus, and emotional tone to different offenders. Specifically, officers' supervisory styles are influenced by offenders' reporting demeanor; willingness to cooperate in the rehabilitation process; and desire to lead a productive and law-abiding life, for example, by finding a job, finishing school, and refraining from gang-related activity. These factors comprise what is known as the probationer's "attitude." Offenders who are honest in their self-disclosures and accept the conditions of their sentence are viewed as progressing satisfactorily and possessing a "positive attitude." A "negative attitude," on the other hand, is displayed in a probationer's continued belligerence, indifference, sarcasm, or blatant attempts to curry favor with an officer. Such behaviors are indicative of a poor adjustment to probation. In short, offenders with positive and negative attitudes are treated differently during office and home visits.

At any point during the probation period, POs can contact probationers' spouses, parents, teachers, friends, employers, or other professionals with whom the probationers are in contact. These contacts are often initiated to verify information, such as residence, employment, and the fulfillment of special conditions. POs also attempt to enlist the aid of others in efforts to control, rehabilitate, and reintegrate offenders. If POs suspect that a probationer is involved in illegal activities, they can obtain reports about subsequent arrests.

The second discretionary decision consists of an assessment of offenders' major problems, for example, emotional, medical, interpersonal, and financial. During initial meetings with a probationer, POs search for signs of drug/alcohol abuse, symptoms of serious psychological disorders (e.g., disorientation, bizarre ideation, or odd behaviors), intellectual deficits, or lack of social or vocational skills in order to evaluate probationers' needs for counseling or other services. Using the assessment tools described above, POs also can rely on their own sensitivity and experience to identify offender needs and to devise problem-solving strategies accordingly. Counseling sessions with officers follow a didactic, instructional style that fits better within a guardian-ward model than a therapist-client model. Officers' educational backgrounds rarely prepare them to conduct therapy with probationers who have mental health or substance use problems. In such cases, POs broker services, referring offenders to community-based programs that treat a variety of specific disorders. POs link offenders to these services, ensuring that they obtain access to interventions for their most pressing problems. Given their large caseloads, POs can spend only limited time counseling or advising offenders. The choice of available referrals is dictated by situations or factors outside the POs' control, for example, economic conditions that affect the number of job referrals and budget cuts for social service programs. Hence, officers must choose probationers for referrals who are most in need of treatment and the most likely to benefit from it. Offenders who request services, have minor criminal records, and display a "positive attitude" are generally considered the best candidates for counseling and other programs.

POs can recommend early terminations for offenders who pose no risk to the community. Early termination is warranted for probationers who have complied with their conditions and are on track for continued success in school or at work; for example, early termination can be recommended for an offender who asks to leave the state in order to accept a job. In contrast, for noncompliant probationers, officers can ask judges to extend periods of supervision up to the maximum sentence allowed by statute for the original offense.

Early termination is an incentive for "good behavior" and a demonstration to other probationers that cooperation and compliance with rules are rewarded. A key factor in the decision to recommend early termination is consistent offender reporting, which increases the likelihood that a case will be reviewed for early termination. Indeed, the "best probationers" are those who routinely report at their scheduled times. If a cancellation is unavoidable, these probationers promptly call their officers to inform them about the circumstances that prevented or that will prevent them from reporting at their scheduled times. POs take a dim view of probationers who are frequently late, skip appointments, and who call at the last minute or after the fact with implausible excuses for failing to report. When queried about the progress of a case, POs are likely to respond with a quick tally of the number of times a probationer missed a report day.

Release on probation is conditional and subject to compliance with the court-ordered terms or conditions of release. When probationers violate those terms, POs can initiate revocation proceedings. In most circumstances, the commission of a new crime during the probation term, known as a law violation, results in the filing of a violation of probation (VOP) petition, which is especially likely for a felony arrest. Technical VOPs involve no new offenses and are considered less serious infractions. In such cases, POs exercise discretion when deciding whether to file a VOP petition with the court. They do so by evaluating the infraction as well as offenders' performance on probation, criminal history, attitude, family relationships, and employment status. Probationers with a consistent record of reporting to their POs and of gainful employment are usually allowed to continue on probation for relatively minor transgressions.

After filing a VOP petition, POs must decide to recommend the imposition of a more serious sentence or a continuation of probation with more stringent conditions of release. This determination is based on the same set of factors as the decision to file a VOP. Officers might recommend a jail term for probationers during which they can receive more intensive services and contemplate the value of their freedom. The court can reject POs' recommendations and dismiss the VOP petition, thereby allowing the offender to continue serving the term under the original conditions of release. Nonetheless, as in the case of early termination, the court often abides by officers' recommendations to revoke probation and to impose a more serious penalty. In three landmark cases, the Supreme Court ruled that probationers and parolees retain their due process rights in revocation hearings (Morrissey v. Brewer, Gagnon v. Scarpelli, and Mempa v. Rhay).

Probation Officer Typologies and Styles

POs wear many hats in pursuing the primary goals of probation. Different typologies describe the various roles of officers, such as the punitive/law enforcement officer, the social worker, the civil servant, and the synthetic officer. Punitive/law enforcement POs are concerned overwhelmingly with exercising their legal authority and enforcing the conditions of probation. These POs regard probation as a privilege, not as a right. The second type of officer is the social worker or therapeutic agent, who strives to rehabilitate and reintegrate offenders into the community. Social workers cultivate a helping relationship with offenders by formulating plans for treatment and services. In contrast, civil servants or timeservers exhibit little concern for the welfare of the community or the probationer. They concentrate on maintaining or advancing their position in the probation bureaucracy with the ultimate goal of retirement, pension, or entry into another field, for example, law or police work. Civil servants observe rather than initiate behavioral changes in their clients. Synthetic/protective officers' supervisory styles reflect the basic orientations of the rule enforcer and social worker, recognizing the importance of both the treatment and control components of probation. Synthetic/protective officers integrate monitoring with rehabilitation. A more fundamental distinction has been made between the probation officer as a law enforcement agent and as a service broker and client advocate. In most cases, POs shift their emphasis to one role or the other depending on their assessment of each probationer's risk and needs as well as his or her progress on probation.

Problem Solving Policing

Overview

Problem-oriented policing is an alternative approach to crime reduction that challenges police officers to understand the underlying situations and dynamics that give rise to recurring crime problems and to develop appropriate responses to address these underlying conditions. Problem-oriented policing is often given operational structure through the well-known SARA model that includes a series of iterative steps: Scanning, Analysis, Response, and Assessment. Police officers often find it difficult to implement problem oriented policing properly with deficiencies existing in all stages of the process. The existing evaluation evidence shows that problem-oriented policing generates noteworthy crime and disorder reduction impacts. These crime reduction impacts are generated even when problem-oriented policing is not fully implemented; this confirms the robustness of the problem-oriented approach in addressing crime and disorder problems.

Introduction

Most police departments have historically engaged incident-driven crime prevention strategies. In dealing with crime, these departments were aimed at resolving individual incidents instead of addressing recurring crime problems (Eck and Spelman 1987). Officers responded to repeated calls and never looked for the underlying conditions that may be causing like groups of incidents. Officers often became frustrated because they answered similar calls and seemingly made no real progress. Citizens also became dissatisfied because the problems that generate their repeated calls still existed (Eck and Spelman 1987). In a seminal article that challenged existing police policy and practice, Herman Goldstein (1979) proposed an alternative; he felt that police should go further than answering call after call and search for solutions to recurring problems that generate the repeated calls. Goldstein (1979) described this strategy as the "problem-oriented approach" and envisioned it as a department-wide activity. Problem-oriented policing is now a common police crime prevention and control strategy.

Problem-oriented policing seeks to identify the underlying causes of crime problems and to frame appropriate responses using a wide variety of innovative approaches (Goldstein 1979). Using a basic iterative approach of problem identification, analysis, response, assessment, and adjustment of the response, this adaptable and dynamic analytic approach provides an appropriate framework to uncover the complex mechanisms at play in crime problems and to develop tailor-made interventions to address the underlying conditions that cause crime problems (Eck and Spelman 1987; Goldstein 1990). Since the publication of Goldstein's article, many police departments have experimented with the approach and the available evaluation evidence suggests that problem-oriented policing is a fundamentally sound approach to controlling crime and disorder problems (Skogan and Frydl 2004; Braga 2008; Weisburd et al. 2010).

The Principles of Problem-Oriented Policing

Beginning in the 1940s and continuing through the emergence of community policing, police departments followed what many have come to call the "standard" or "professional" model of policing (see e.g. Skogan and Frydl 2004) that was characterized by rigorous professional standards, militaristic organizational structures, the use of technology, and other important historical reforms. Under this model, police departments attempted to prevent serious crimes by advancing three operational strategies: preventive patrol, rapid response, and investigation of more serious cases by specialized detective units. The limits of these strategies are, by now, well known (Skogan and Frydl 2004). Research studies found that varying levels of preventive patrol did not reduce crime, rapid response to calls for service did not increase the probability of arrest as very few crimes are reported in progress, and follow-up investigations solved only a relatively small proportion of reported crimes.

The findings of these studies had a strong impact on a generation of police scholars and practitioners. By the early 1990s, there was a broad consensus among criminologists and police scholars that crime was a product of larger social forces, and the police could do little if anything to impact upon crime or crime rates (Gottfredson and Hirschi 1990; Bayley 1994). The police as "crime fighters" might have been a popular idea in the media and among the public, but the idea that the police could do something about crime had little credence in the universities or research institutes that were concerned with policing.

In 1979, Herman Goldstein, a respected University of Wisconsin law professor and former aide to Chicago police chief O.W. Wilson, made a simple and straightforward proposition that challenged police officers to address problems rather than simply respond to incidents. According to Goldstein (1979, 1990), behind every recurring problem there are underlying conditions that create it. Incident-driven policing never addresses these conditions; therefore incidents are likely to recur. Answering calls for service is an important task and still must be done, but police officers should respond systematically to recurring calls for the same problem. In order for the police to be more efficient and effective, they must gather information about incidents and design an appropriate response based on the nature of the underlying conditions that cause the problem(s) (Goldstein 1990).

It is important to note here that Herman Goldstein (1979, 1990) intended problem-oriented policing to be a general approach that could be applied to a wide range of police business problems. This includes non-crime problems such as personnel issues, budgetary concerns, and police-community relations. Most problem-oriented policing research and practical experience, however, has focused on applying the approach to addressing crime and disorder problems. As such, this entry examines our existing knowledge base on police use of the problem-oriented approach to tackle recurring crime and disorder problems.

The Process of Problem-Oriented Policing

The problem-oriented policing approach was given an operational structure in Newport News, Virginia. Researchers from the Police Executive Research Forum (PERF) and a group of officers selected from the various ranks of the Newport News Police Department crystallized the philosophy into a set of steps known as the SARA model (Eck and Spelman 1987). The SARA model consists of these stages: *Scanning*- the identification of an issue and determining whether it is a problem; *Analysis*- data collection on the problem to determine its scope, nature, and causes; *Response*- information from the analysis is used to design an appropriate response which can involve other agencies outside the normal police arena; and *Assessment*- the response is evaluated and these results can be used to re-examine the problem and change responses or maintain positive conditions (Eck and Spelman 1987). In practice, it is important to recognize that the development and implementation of problem-oriented responses do not always follow the linear, distinct steps of the SARA model (Capowich and Roehl 1994; Braga 2008). Rather, depending on the complexity of the problems to be addressed, the process can be characterized as a series of disjointed and often simultaneous activities. A wide variety of issues can cause deviations from the SARA model, including identified problems needing to be re-analyzed because initial responses were ineffective and implemented responses that sometimes reveal new problems (Braga 2008).

Scanning. The process of scanning involves the identification of problems that are worth looking at because they are important and amenable to solution. Herman Goldstein (1990) suggests that the definition of problems be at the street-level of analysis and not be restricted by preconceived typologies. Goldstein further clarifies what is meant by a problem by specifying the term as: “a cluster of similar, related, or recurring incidents rather than a single incident; a substantive community concern; or a unit of police business” (1990, p. 66).

Analysis. The analysis phase challenges police officers to analyze the causes of problems behind a string of crime incidents or substantive community concern. Once the underlying conditions that give rise to crime problems are known, police officers develop and implement appropriate responses. The challenge to police officers is to go beyond the analysis that naturally occurs to them; namely, to find the places and times where particular offenses are likely to occur, and to identify the offenders that are likely to be responsible for the crimes. Although these approaches have had some operational success, this type of analysis usually produces directed patrol operations or a focus on repeat offenders. The idea of analysis for problem solving was intended to go beyond this. Goldstein (1990) describes this as the problem of “ensuring adequate depth” in the analysis.

Situational crime prevention has further developed the methodology of analyzing problems, and provided important examples of how crime problems may be closely analyzed. Situational crime prevention measures are tailored to highly specific categories of crime. As Clarke (1997) describes, distinctions must be made not between broad crime categories such as burglary and robbery, but between the different kinds of offenses that comprise each of these categories. For example, in their analysis of domestic burglary in a British city, Poyner and Webb (1991) revealed that cash and jewelry burglaries tended to occur in older homes near the city center, while burglaries of electronic goods, such as TVs and VCRs, generally occurred in newer homes in the suburbs. Analysis further revealed that offenders on foot committed cash and jewelry burglaries. In the electronic goods burglaries, offenders used cars that had to be parked near to the house, but not so close that they would attract attention. The resulting crime prevention strategies differed accordingly. To prevent cash and jewelry burglaries in the city center, Poyner and Webb (1991) recommended improving security and surveillance at the burglar’s point of entry; in contrast, to prevent electronic good burglaries in the suburbs, they suggested improving the natural surveillance of parking places and roadways in the area.

Response. After a problem has been clearly defined and analyzed, police officers confront the challenge of developing a plausibly effective response. The development of appropriate responses is closely linked with the analysis that is performed. The analysis reveals the potential targets for an intervention, and it is at least partly the idea about what form the intervention might take that suggests important lines of analysis. As such, the reason police often look at places and times where crimes are committed is that they are already imagining that an effective way to prevent the crimes would be to get officers on the scene through directed patrols. The reason they often look for the likely offender is that they think that the most effective and just response to a crime problem would be to arrest and incapacitate the offender. However, the concept of problem-oriented policing as envisioned by Herman Goldstein (1990), calls on the police to make a much more “uninhibited” search for possible responses and not to limit themselves to getting officers in the right places at the right times, or identifying and arresting the offender (although both may be valuable responses). Effective responses often depend on getting other people to take actions that reduce the opportunities for criminal offending, or to mobilize informal social control to drive offenders away from certain locations.

Assessment. The crucial last step in the practice of problem-oriented policing is to assess the impact the intervention has had on the problem it was supposed to solve. Assessment is important for at least two different reasons. The first is to ensure that police remain accountable for their performance and for their use of resources. Citizens and their representatives want to know how the money and freedom they surrendered to the police are being used, and whether important results in the form of less crime, enhanced security, or increased citizen satisfaction with the police has been achieved. A second reason assessment is important is to allow the police to learn about what methods are effective in dealing with particular problems. Unless the police check to see whether their efforts produced a result, it will be hard for them to improve their practices.

In general, problem-oriented police should strive to conduct more rigorous assessments of their responses with due consideration to time and resource constraints. Depending on the availability of funds, police departments should consider partnering up with independent researchers to conduct systematic evaluations of their efforts. In the absence of such a partnership, Clarke (1998) suggests that police should take care to relate any observed results to specific actions taken, develop assessment plans while outlining the project, present control data when available and reasonably comparable to the subject(s) of the intervention, and, as will be discussed further, measure crime displacement. While the degree of rigor applied to the assessment of responses may vary, what must not be sacrificed is the goal of measuring results. This will keep the police focused on results rather than means, and that is one of the most important contributions of the idea of problem-oriented policing.

Community Policing and "Problem Solving"

During the late 1980s and throughout the 1990s, problem-oriented policing and community policing were heralded as revolutionary alternatives to the professional model. The terms are sometimes referred to as essentially the same strategy (Kennedy and Moore 1995), however others maintain a distinct separation between the two concepts (Eck and Spelman 1987; Goldstein 1990). Problem-oriented policing is typically defined as focusing police attention on the underlying causes of problems behind a string of crime incidents, while community policing emphasizes the development of strong police-community partnerships in a joint effort to reduce crime and enhance security (Moore 1992). Indeed, community-oriented police officers use problem solving as a tool and problem-oriented departments often form partnerships with the community.

The term "problem solving" is often conceptualized as what an officer does to handle small, recurring beat-level problems, and it is distinguished from problem-oriented policing based on its rudimentary analysis of the problem and lack of formal assessment (see, e.g., Cordner 1998). In short, some observers suggest the term "problem solving" does not adequately capture the substance of problem-oriented policing as envisioned by Goldstein (1990). Scott (2000) reports that Goldstein himself has been especially careful to avoid the term "problem solving" because many, if not most, problems the police confront are too complex for anything approaching a final solution; reducing harm, alleviating suffering, and/or providing some measure of relief are ambitious enough aims for the police.

Situational Crime Prevention and Supporting Theoretical Perspectives

The field of situational crime prevention has supported the problem-oriented policing movement since its genesis in the British Government's Home Office Research Unit in the early 1980s (Clarke 1997). Instead of preventing crime by altering broad social conditions such as poverty and inequality, situational crime prevention advocates changes in local environments to decrease opportunities for crimes to be committed. Situational crime prevention techniques comprise opportunity-reducing measures that are: "(1) directed at highly specific forms of crime (2) that involve the management, design, or manipulation of the immediate environment in as systematic and permanent way as possible (3) so as to increase the effort and risks of crime and reduce the rewards as perceived by a wide range of offenders" (Clarke 1997, p. 4). Like problem-oriented policing, the situational analysis of crime problems follows an action-research model that systematically identifies and examines problems, develops solutions, and evaluates results. Applications of situational crime prevention have shown convincing crime prevention results when applied to a variety problems ranging from obscene phone callers to burglary to car radio theft. This simple but powerful perspective is applicable to crime problems facing the police, security personnel, business owners, local government officials, and private citizens.

Problem-oriented policing and situational crime prevention draw upon theories of criminal opportunity, such as rational choice and routine activities, to analyze crime problems and develop appropriate responses (Clarke 1997; Braga 2008). Most criminological research focuses on why some people become persistent offenders. However, as Eck (2000) observes, by the time a problem comes to the attention of the police, the questions of why people offend are no longer relevant. The most pressing concerns are why offenders are committing crimes at particular places, selecting particular targets, and committing crimes at specific times (Eck 2000). While police officers are important entry points to social services for many people, they are best positioned to prevent crimes by focusing on the situational opportunities for offending rather than attempting to manipulate socio-economic conditions that are the subjects of much criminological inquiry and the primary focus of other governmental agencies (Braga 2008). Theories that deal with the "root causes" of crime focus on interventions that are beyond the scope of most problem-oriented policing projects. Theories that deal with opportunities for crime and how likely offenders, potential victims, and others make decisions based on perceived opportunities have greater utility in designing effective problem-oriented policing interventions.

The rational choice perspective assumes that "crime is purposive behavior designed to meet the offender's commonplace needs for such things as money, status, sex, and excitement, and that meeting these needs involves the making of (sometimes quite rudimentary) decisions and choices, constrained as these are by limits of time and ability and the availability of relevant information" (Clarke 1995, p. 98). Rational choice makes distinctions between the decisions to initially become involved in crime, to continue criminal involvement, and to desist from crimina offending, as well as the decisions made to complete a particular criminal act. This separation of the decision-making processes in the criminal event from the stages of criminal involvement allows the modeling of the commission of crime events in a way that yields potentially valuable insights for crime prevention.

The emphasis of the rational choice perspective on concepts of risk, reward, and effort in criminal decision making has been used to inform the development of problem-oriented policing and situational crime prevention strategies that seek to change offender appraisals of criminal opportunities (Clarke 1997; Braga 2008). Of particular importance, the decision processes and information utilized in committing criminal acts can vary greatly across offenses; ignoring these differences and the situational contingencies associated with making choices may reduce the ability to effectively intervene (Clarke 1995). For example, a robber may choose a "favorite" spot because of certain desirable attributes that facilitate an ambush, such as poor lighting and untrimmed bushes. One obvious response to this situation would be to improve the lighting and trim the bushes.

Rational choice is often combined with routine activity theory to explain criminal behavior during the crime event. Rational offenders come across criminal opportunities as they go about their daily routine activities and make decisions whether to take action. The source of the offender's motivation to commit a crime is not addressed (it is assumed that offenders commit crimes for any number of reasons); rather, the basic ingredients for a criminal act to be completed are closely examined. Routine activity posits that a criminal act occurs when a likely offender converges in space and time with a suitable target (e.g., victim or property) in the absence of a capable guardian (e.g., property owner or security guard) (Cohen and Felson 1979).

The routine activity approach was used to demonstrate that increases in residential burglary in the United States between 1960 and 1970 could be largely explained by changes in the routine activities of households (Cohen and Felson 1979). During this time period, the number of empty homes during the day increased as the number of single-person households and female participation in the workforce grew. At the same time, households increasingly contained attractive items to steal, such as more portable televisions and other electronic goods. Burglary increased, as fewer capable guardians were present in the home to protect the new suitable targets from burglars. These kinds of analytical insights on the nature of crime problems are very valuable to problem-oriented police officers seeking to develop appropriate responses.

The Practice of Problem-Oriented Policing

Although the problem-oriented approach has demonstrated much potential value in improving police practices, research has also documented that it is very difficult for police officers to implement problem-oriented policing strategies (Eck and Spelman 1987; Clarke 1998; Braga and Weisburd 2006). Cordner (1998) identifies a number of challenging issues in the substance and implementation of many problem-oriented policing projects. These issues include: the tendency for officers to conduct only a superficial analysis of problems and rushing to implement a response, the tendency for officers to rely on traditional or faddish responses rather than conducting a wider search for creative responses, and the tendency to completely ignore the assessment of the effectiveness of implemented responses (Cordner 1998). Indeed, the research literature is filled with cases where problem-oriented policing programs tend to lean towards traditional methods and where problem analysis is weak. In his review of several hundred submissions for the Police Executive Research Forum's Herman Goldstein Award for Excellence in Problem-Oriented Policing, Clarke (1998) laments that many recent examples of problem-oriented policing projects bear little resemblance to Goldstein's original definition and suggests this misrepresentation puts the concept at risk of being pronounced a failure before it has been properly tested.

Deficiencies in current problem-oriented policing practices exist in all phases of the process. During the scanning phase, police officers risk undertaking a project that is too small (e.g., the lonely old man who repeatedly calls the police for companionship) or too broad (e.g., gang delinquency) and this destroys the discrete problem focus of the project and leads to a lack of direction at the beginning of analysis (Clarke 1998). Some officers skip the analysis phase or conduct an overly simple analysis that does not adequately dissect the problem or does not use relevant information from other agencies (such as hospitals, schools, and private businesses) (Clarke 1998). Based on his extensive experience with police departments implementing problem-oriented policing, Eck (2000) suggests that much problem analysis consists of a simple examination of police data coupled with the officer's working experience with the problem. In their analysis of problem-oriented initiatives in 43 police departments in England and Wales, Read and Tilley (2000) found that problem analysis was generally weak with many initiatives accepting the definition of a problem at face value, using only short-term data to unravel the nature of the problem, and failing to adequately examine the genesis of the crime problems.

Given the limited analysis that many crime problems, it is not surprising that the responses of many problem-oriented policing projects rely too much on traditional police tactics (such as arrests, surveillance, and crackdowns) and neglect the wider range of available alternative responses. Read and Tilley (2000) found that officers selected certain responses prior to, or in spite of, analysis; failed to think through the need for a sustained crime reduction; failed to think through the mechanisms by which the response could have a measurable impact; failed to fully involve partners; narrowly focused responses, usually on offenders; as well as a number of other weakness in the response development process. Finally, Scott and Clarke (2000) observed that the assessment of responses is rare and, when undertaken, it is usually cursory and limited to anecdotal or impressionistic data.

Reflecting on these practical issues, Eck (2000) comments that the problem-oriented policing that is practiced by many police department diverges significantly from the original concept that was envisioned by Goldstein. Braga and Weisburd (2006), however, find value in the imperfect implementation of problem-oriented policing. They argue that there is much evidence that what might be called "shallow" problem solving responses can be effective in combating crime problems. Apparently, weak problem-oriented policing is better than none at all. This being the case, Braga and Weisburd (2006) question whether the pursuit of problem-oriented policing as it has been modeled by Goldstein and others, should be abandoned in favor of the achievement of a more realistic type of problem solving. While less satisfying for scholars, it is what the police have tended to do, and it has been found to lead to real crime prevention benefits.

"Ideal" Applications of Problem-Oriented Policing

Herman Goldstein (1979, 1990) originally suggested that problem-oriented policing efforts should be located within a headquarters unit rather than assigned to police officers in operational units. The decentralization of the approach to street police officers may have reduced the quality of routine problem-oriented policing efforts as busy officers handled too many problems and had little time to conduct the extensive analysis and search for appropriate responses. Ideal applications of problem-oriented policing tend to involve larger scale problems, the involvement of academic researchers and crime analysis units, and the solid support of the police command staff to implement alternative responses. Two examples of these types of "ideal" problem-oriented projects are briefly reviewed here: The Boston Police Department's Operation Ceasefire intervention to prevent gang violence (Braga et al. 2001) and the Charlotte-Mecklenburg Police Department's program to reduce theft from construction sites (Clarke and Goldstein 2002).

The Boston Gun Project was a problem-oriented policing enterprise expressly aimed at taking on a serious, large-scale crime problem — homicide victimization among young people in Boston. Like many large cities in the United States, Boston experienced a large sudden increase in youth homicide between the late 1980s and early 1990s. The Boston Gun Project proceeded by: (1) assembling an interagency working group of largely line-level criminal justice and other practitioners; (2) applying quantitative and qualitative research techniques to create an assessment of the nature of, and dynamics driving, youth violence in Boston; (3) developing an intervention designed to have a substantial, near-term impact on youth homicide; (4) implementing and adapting the intervention; and (5) evaluating the intervention's impact (Kennedy et al. 1996). The Project began in early 1995 and implemented what is now known as the "Operation Ceasefire" intervention, which began in the late spring of 1996.

The trajectory of the Boston Gun Project and of Operation Ceasefire is by now well known and extensively documented. Briefly, the working group of law enforcement personnel, youth workers, and researchers diagnosed the youth violence problem in Boston as one of patterned, largely vendetta-like ("beef") hostility amongst a small population of chronic offenders, and particularly among those involved in some 61 loose, informal, mostly neighborhood-based groups. These 61 gangs consisted of between 1,100 and 1,300 members, representing less than 1 % of the city's youth between the ages of 14 and 24. Although small in number, these gangs were responsible for more than 60 % of youth homicide in Boston.

The Operation Ceasefire "pulling levers" strategy was designed to deter violence by reaching out directly to gangs, saying explicitly that violence would no longer be tolerated, and backing up that message by "pulling every lever" legally available when violence occurred. Simultaneously, youth workers, probation and parole officers, and later churches and other community groups offered gang members services and other kinds of help. The Ceasefire Working Group delivered this message in formal meetings with gang members, through individual police and probation contacts with gang members, through meetings with inmates at secure juvenile facilities in the city, and through gang outreach workers. The deterrence message was not a deal with gang members to stop violence. Rather, it was a promise to gang members that violent behavior would evoke an immediate and intense response. If gangs committed other crimes but refrained from violence, the normal workings of police, prosecutors, and the rest of the criminal justice system dealt with these matters. But if gangs hurt people, the Working Group concentrated its enforcement actions on their members.

A large reduction in the yearly number of Boston youth homicides followed immediately after Operation Ceasefire was implemented in mid-1996. A US Department of Justice (DOJ)-sponsored evaluation of Operation Ceasefire revealed that the intervention was associated with a 63 % decrease in the monthly number of Boston youth homicides, a 32 % decrease in the monthly number of shots-fired calls, a 25 % decrease in the monthly number of gun assaults, and, in one high-risk police district given special attention in the evaluation, a 44 % decrease in the monthly number of youth gun assault incidents (Braga et al. 2001). The evaluation also suggested that Boston's significant youth homicide reduction associated with Operation Ceasefire was distinct when compared to youth homicide trends in most major US and New England cities (Braga et al. 2001).

To many observers, the analysis phase is the critical step in the problem-oriented policing process as it unravels the nature of recurring problems and points police towards innovative responses that go beyond traditional enforcement activities. Clarke and Goldstein (2002) document the vital role played by innovative crime analysis in a problem-oriented policing project undertaken by the Charlotte-Mecklenburg Police Department to address a sharp increase in the number of kitchen appliances stolen from new houses under construction. A detailed analysis of security practices and risks for theft among 25 builders in one police service district was conducted. The analysis led to the recommendation that the installation of appliances should be delayed until the new owners moved into the residence. Removing the targets of theft was found to be an effective response: as appliance theft declined markedly in the police service district and there was no evidence of displacement to surrounding district (Clarke and Goldstein 2002).

A key moment in the analysis of the theft problem occurred when the crime analyst discovered that a "certificate of occupancy" had to be issued by the county before a new owner could move into the residence. Compared to the building permits that had been used in earlier iterations of the problem analysis, these certificates provided a better measure of when a house was ready to be occupied and, therefore, a timelier basis for calculating the risk of theft. Building permits measured only planned construction. Builders may obtain 100 permits to build houses, but only actually build a fraction in a given year. That is why building permit data could not be used to accurately assess the stage when a house was completed and, thus, at-risk for theft of newly installed appliances.

Crime Prevention Effects of Problem-Oriented Policing

There is a growing body of evaluation evidence that problem-oriented policing generates noteworthy crime control gains. The US National Academy of Sciences' Committee to Review Research on Police Policy and Practices recently concluded that problem-oriented policing is a promising approach to deal with crime, disorder and fear and recommended that additional research was necessary to understand the organizational arrangements that foster effective problem solving (Skogan and Frydl 2004; Weisburd and Eck 2004). Several published volumes on problem-oriented policing case studies provide a good sense for the work being done as well as the strengths and weaknesses of some of the better problem-oriented efforts. Indeed, the widespread use of problem-oriented policing as a central crime prevention and control strategy in police agencies across the world is a strong indicator of the practical value of the approach.

However, the strongest empirical evidence available in support of problem-oriented policing comes from three Campbell Collaboration systematic reviews. Formed in 2000, the Campbell Collaboration Crime and Justice Group aims to prepare and maintain systematic reviews of criminological interventions and to make them electronically accessible to scholars, practitioners, policy makers and the general public (www.campbellcollaboration.org). The Crime and Justice Group requires reviewers of criminological interventions to select studies with high internal validity such as randomized controlled trials and quasi-experiments.

David Weisburd and his colleagues (2010) recently completed a Campbell Collaboration systematic review of the crime prevention effects of problem-oriented policing on crime and disorder. Despite reviewing a very large number of empirical studies on the approach, they identified only ten problem-oriented policing studies that used more rigorous randomized experimental and quasi-experimental evaluation designs. Given the popularity of problem-oriented policing, Weisburd et al. (2010) were surprised by the small number of rigorous evaluations studies that examined the crime prevention benefits of the approach. A meta-analysis of these ten evaluations revealed that problem-oriented policing programs generated a modest but statistically-significant impact on crime and disorder outcomes. These results were consistent when Weisburd et al. (2010) examined randomized experiments and quasi-experiments separately.

The Campbell problem-oriented policing review also reported on the crime prevention effects of simple pre/post comparison evaluation studies. While these studies did not include a comparison group and were less methodologically rigorous, Weisburd et al. (2010) found that they were far more numerous and identified 45 pre/post evaluations. 43 of these 45 evaluations reported that the approach generated beneficial crime prevention effects. These studies also reported much larger crime reduction impacts associated with problem-oriented policing when compared to the effects reported by the more rigorous research designs.

Policing crime hot spots represents an important advance in focusing police crime prevention practice (Braga and Weisburd 2010). Since crime hot spots generate a bulk of urban crime problems, it seems commonsensical to address the conditions and situations that give rise to the criminal opportunities that sustain high-activity crime places. The available evaluation evidence also suggests that problem-oriented policing holds great promise in addressing the criminogenic attributes of specific places that cause them to be crime hot spots. A recently updated Campbell Collaboration review of 19 rigorous evaluation studies found that hot spots policing generates modest crime reductions and these crime control benefits diffuse into areas immediately surrounding targeted crime hot spots (Braga et al. 2012). A moderator analysis of the types of hot spots policing programs found that problem-oriented policing interventions generate larger crime control impacts when compared to interventions that simply increase levels of traditional police actions in crime hot spots.

The Campbell hot spots policing review also reported that the problem-oriented policing interventions generated larger diffusion of crime control benefits into areas immediately surrounding the targeted hot spots areas (Braga et al. 2012). Many of the problem-oriented policing interventions used to control crime hot spots were described as suffering from superficial problem analyses, a preponderance of traditional policing tactics, and limited situational crime prevention responses. However, these generally "shallow" problem-oriented policing programs still generated crime reduction gains. This finding supports the assertion made earlier by Braga and Weisburd (2006) that limited problem-oriented policing, also known simply as "problem solving," is a stronger approach to crime prevention when compared to traditional police crime prevention strategies.

A number of US jurisdictions have been experimenting with new problem-oriented policing frameworks, generally known as pulling levers focused deterrence strategies, to understand and respond to serious crime problems generated by chronically offending groups, such as gun violence among gang-involved offenders (Kennedy 2008). These approaches include the well-known Boston Gun Project and its Operation Ceasefire intervention (Braga et al. 2001) discussed earlier in this entry and typically represent carefully implemented problem-oriented policing projects. Another recently completed Campbell Collaboration systematic review of focused deterrence strategies found that 10 out of 11 rigorous evaluations reported significant crime reduction effects associated with this problem-oriented approach (Braga and Weisburd 2012). A meta-analysis of these programs reported that focused deterrence strategies were associated with an overall statistically-significant, medium-sized crime reduction effect. This review provides additional evidence that the general problem-oriented policing approach can inform innovative violence reduction strategies and generate impressive crime control gains.

Conclusion

Problem-oriented policing represents an important innovation in American policing. Indeed, the advocates of this young and evolving approach have accomplished much since Herman Goldstein first presented the concept in 1979. Early experiences in Madison, London, Baltimore County, and Newport News demonstrated that police officers could greatly improve their handling of crime problems by taking a problem-oriented approach. Since then, many police agencies in the United States, the United Kingdom, Canada, Scandinavia, Australia, and New Zealand have continued to implement problem-oriented policing, to apply it to a wide range of crime and disorder problems, and to change their organizations to better support problem-oriented policing (www.popcenter.org).

The practice of problem-oriented policing sometimes falls short of the principles suggested by Herman Goldstein (1979, 1990). While the approach is more than 30 years old, it is important to recognize that problem-oriented policing is still in its formative stages and its practice is still developing. Progress in policing is incremental and slow, and that does not make problem-oriented policing unrealistic. Police departments should strive to implement problem-oriented policing properly but recognize that even weak problem solving can be beneficial when applied to recurring crime problems. Within police departments, it seems like a balanced problem-oriented policing agenda would include both a commitment among officers in the field to apply problem-solving techniques to address problems that they encounter on a routine basis and a commitment to maintaining a centralized problem-oriented policing unit capable of conducting high-quality analyses of larger and more persistent problems and developing more creative responses to reduce them.

In closing, it also seems important to point out that the demonstrated crime reduction efficacy of problem-oriented policing is a striking result considering the large body of research that shows the ineffectiveness of many police crime prevention efforts. The robustness of the problem-oriented policing is underscored by the observation that, even when it is not implemented properly, the approach still generates noteworthy crime reduction gains (Braga and Weisburd 2006). It is tantalizing to think that had the police more fully implemented the problem-oriented approach and took a more specific, more focused approach to crime and disorder problems, crime control benefits might have been greater. Of course, this requires the development of such skills from both "trial and error" experience of problem solving on the street and additional training in the problem-oriented model, particularly in the area of problem analysis. The investment in the acquisition of these skills could be well worth the effort.

Alternative courts; Problem-oriented courts; Specialty courts; Therapeutic courts

Overview

The label "problem-solving courts" refers to a movement of court specialization that began in 1989 and subsequently dominated criminal court reform discussions and agendas in the United States. The label encompasses a legal theory of adjudication and a set of practices that have been applied in pursuit of better individual and societal-level outcomes in court cases involving offenders with underlying psychological, public health, and social problems perceived as hindering a desistance from crime. Problem-solving courts began by addressing the problem of substance abuse. In turn, the problem-solving court movement expanded to address mental health, domestic violence, and, most recently, the difficulties military veterans are experiencing in adjusting to civilian society. Other examples include the creation of reentry courts (to support offenders released from prison due to prison overcrowding or cost-saving programs of early release) and community courts (responding to persistent low-level offenses that are seen as harmful to the quality of life of residents and businesses). Problem-solving courts have also been created to deal with problems associated with guns, drunk driving, tobacco, and noise abatement (environmental courts).

By the end of 2009, there were an estimated 3,649 operational problem-solving courts, two-thirds of which were drug courts (Huddleston and Marlowe 2011:1). This movement began with the opening of a single court, the Miami (Florida) Drug Court. The early problem-solving courts were in many respects judicial innovations, the creations of a few judges who were dissatisfied with what they could accomplish by adhering to the traditional judicial role and using conventional sentencing options. Wider interest from state and federal policy-makers followed almost immediately. The rapid diffusion of problem-solving courts and the fervor of its advocates can be compared in some ways to the launch of the juvenile court movement 100 years prior. It is only recently, and only definitively for adult drug courts, that research has confirmed that the impacts such as recidivism in problem-solving courts improve upon what is typical in misdemeanor courts.

The problem-solving concept has also been well received outside of the United States. A diverse range of countries – including Australia, Canada, Great Britain, the Netherlands, and South Africa – embraced the concept. By the most recent available international count (for 2007), drug courts are the most prevalent (in eight countries), followed by community courts (in seven countries), domestic violence courts (in four countries), and mental health courts only in Australia (Nolan 2009). The adoption of American problem-solving court principles has not been uncritical; modifications have been made to reflect local culture. Therefore, "in the United States, the courts are characterized by enthusiasm, boldness and pragmatism; whereas in the other five countries, [cited above] the contrasting disposition is one of moderation, deliberation, and restraint" (Nolan 2012:156).

Definition

Properly understood, problem-solving courts consist of court dockets, a courtroom, and a judge that, for a period of time ranging from a half-day per week to a 5 full days a week, exclusively adjudicates cases that have been selected for special processing. There are only a handful of stand-alone drug courts or any other type of problem-solving court. This distinction is not always recognized in discussions of problem-solving courts. In some respects, problem-solving courts are a continuation of one of the oldest approaches to court reform, caseflow management, in which types of cases are grouped together in order to secure more efficient and effective case processing.

There is no authoritative definition of what constitutes a problem-solving court. Most would agree, however, with this formulation: a problem-solving court must demonstrate "(1) close and ongoing judicial monitoring, (2) a multidisciplinary or team-oriented approach, (3) a therapeutic or treatment orientation, (4) the altering of traditional roles in the adjudication process, and (5) an emphasis on solving the problems of individual offenders" (Nolan 2010:32).

Problem-solving courts can be distinguished from the types of courts and dockets that emerged in earlier periods to specialize adjudication in criminal court cases. The distinctiveness stems, first, from a package of practices and beliefs on how to wean substance abusers and others from persistent offending associated with an underlying psychological or physical problem and, second, from a new legal theory that justifies their practices. The difference is one of degree, but it is consequential. By a similar logic, some commentators exclude domestic violence courts from the ranks of problem-solving courts: there is little expectation that the actions of the court can reduce recidivism in such cases. The distinction is well captured in the standard court terminology which refers to adults as defendants or offenders, while in a problem-solving court, we hear talk of "clients," "participants," and "graduations," rather than defendants, offenders, and sentences.

Origins

Today's problem-solving courts are products of several trends that came together in the late 1980s. Those trends included reformist judges, a legal theory supporting a more expansive judicial role, enthusiastic government support and funding, and the emergence of a new profession.

First, a significant minority of United States judges were frustrated by their inability to intervene in such a manner as to reduce persistent re-offending by addressing the underlying psychological or social problems that prevented progress. Substance abuse was the primary cause of dissatisfaction. Nothing worked. The same judges often were dissatisfied with the limitations imposed by the traditional role of the judge and looked for a way of defining the judicial role that they would find more personally and professionally satisfying (Baum 2011:116). In key respects, problem-solving courts in the United States are products of the judiciary itself: they represent the most recent effort to create specialized courts to achieve faster and more effective responses to particular types of cases. Outside of the United States, the introduction of problem-solving courts tends to be the product of government initiatives, working with the courts.

Second, there was a legal theory available to justify deviation from the judicial role as defined by the adversarial process. The emerging theory came from the field of therapeutic jurisprudence developed by United States law professors David Wexler and Bruce Winnick. Therapeutic jurisprudence asks "whether the law's antitherapeutic consequences can be reduced, and its therapeutic consequences enhanced, without subordinating due process and other justice values" (Wexler and Winnick 1996:xvii); see also (Hora et al. 1999).

The concept of therapeutic jurisprudence quickly attracted a following among judges in other common law countries, easing the diffusion of problem-solving courts to those jurisdictions.

Third, the problem-solving court movement had important advocates in high places. With the vocal support came access to government funding and sponsorship. The first problem-solving court, the 1989 Dade County Drug Court, was a joint project by then Dade County prosecutor Janet Reno and Judge Herbert Klein. When Reno became attorney general, drug courts became incorporated into Department of Justice policy. Community courts followed as an early addition to the Department of Justice's programs supporting drug courts, with funding made available to support visits to what were designated as "demonstration projects." Thereafter, all federal budgets have made significant funding available for drug courts and subsequently other types of problem-solving courts as they arose. Additionally, problem-solving courts were not entering a crowded field with powerful interests likely to obstruct a newcomer promising to contend with problems like substance abuse. There was a general recognition that previous approaches to the problem had failed.

Finally, problem-solving courts were nurtured by a very active professional association, the National Association of Drug Court Professionals (NADCP), which was founded in 1994. NADCP's annual conferences bring together judges, social workers, and probation officers but also representatives from federal and state government agencies, judicial organizations, US senators and congressmen, rock stars, and movie stars. NADCP also has a research arm, the National Drug Court Institute. The NADCP has taken the lead in developing ten key components for drug courts, a formulation other problem-solving courts have modified. In recent years, the NADCP has also taken a leadership role in determining what configurations make for effective drug courts and developing standards a drug court must meet. As it matured, NADCP has proved willing to abandon some of its original assumptions and policy prescriptions through the application of evidence-based practices. The NADCP has increasingly broadened its focus to include other types of problem-solving courts and judges, court staff, and public officials from other countries.

Types of Problem-Solving Courts

The seven most common types of problem-solving courts are distinctive applications of problem-solving legal theory and practice. Listed by the order in which they emerged, these are adult drug treatment courts, juvenile drug courts, community courts, domestic violence courts, mental health courts, reentry courts, and veterans' courts. Short descriptions of their origins and distinctive features supplement longer presentations elsewhere in the encyclopedia. A guide to the key elements and the main dimensions of the most common types of problem-solving courts, along with a description of how they vary, is available (Casey and Rottman 2005). It should be noted that in Australia and several other countries, indigenous sentencing courts were established to accommodate traditional non-adversarial models of justice, resulting in courts that have clear problem-solving court features (King et al. 2009:178–183).

Drug Courts

In response to an increase in case filings in the 1980s and 1990s, drug courts began as diversion and treatment programs designed to get at the "root cause" of drug abuse and decrease recidivism. Today, drug courts integrate alcohol and drug treatment services as offenders are processed through the justice system. Drug courts emphasize a non-adversarial approach, where prosecution and defense counsel collaborate on treatment options while protecting participants' due process rights. Offenders are subject to frequent alcohol and drug testing and have access to rehabilitation services and other related treatment. Frequently, drug courts emphasize ongoing judicial interaction, where offenders meet regularly with a judge for updates on progress. Interaction with the community is also an important aspect of drug courts, as they frequently establish partnerships with agencies or community-based organizations in order to increase effectiveness. Over 2,600 drug courts are in operation in the United States today; most (58 %) follow a model in which a defendant must first plead guilty before being admitted to the program (Huddleston and Marlowe 2011:1). One 2005 estimate posited that 53,000 defendants/offenders were enrolled in drug courts. To put that presence in perspective, estimates show that drug courts are serving about one-half of offenders meeting current criteria for enrollment but serving only about 3.8 % of all offenders who use or are addicted to illegal substances (Bhati et al. 2008:34). Drug courts have themselves become specialized, notably through the establishment of juvenile and family drug courts.

Community Courts

Community courts are, in part, a reaction to the centralization and consolidation of trial courts, which was perceived as creating a gap between courts and communities. They were also a response to the prominence of the "broken windows" approach to responding to low-level crime in urban areas. New York City's Midtown Community Court opened its doors 1993. As of 2009, there were 38 community courts in cities across the United States. There are nearly as many community courts outside of the United States, located in Australia, England, Scotland, and South Africa (Turgeon 2011). England and South Africa in particular have embraced the concept. In Australia, only one community court (named a Neighborhood Justice Center) has been established. Community courts focus on replacing jail and fines with community service and alternative sanctions. Offenders in community court generally receive more attention than do those in the general court system. An increase in court time and resources devoted to minor misdemeanors, coupled with extensive gathering of information about defendants and strict monitoring of compliance, is designed to reduce recidivism. Offenders in community courts have access to a comprehensive package of social services and treatments through a mix of government and nonprofit agencies. Ultimately, community courts are committed to a dual approach: changing the lives of individuals and improving the quality of life in communities. As the subject of four comprehensive evaluations, community courts are among the most studied type of problem-solving court.

Mental Health Courts

Mental health courts began as a response to both high recidivism and high rates of homelessness, unemployment, alcohol and drug use, and physical and sexual abuse among persons with a mental illness. The first mental health court was founded in 1997 in Broward County, Florida. Like the over 288 other mental health courts in the United States, it is centered on diverting defendants with a mental illness into treatment, instead of simply incarcerating them (Huddleston and Marlowe 2011:40). Mental health courts emphasize voluntary participation, early identification and intervention, and a therapeutic environment to reduce the trauma that is often experienced by persons with a mental illness in the criminal justice system. Part of this approach includes implementing practices that reduce the stigma that often accompanies mental illness. Like drug courts, mental health courts use a dedicated team approach that involves the judge, counsel, and court and treatment professionals in a less-formal setting. A treatment plan will be developed that is centered on the individual's specific needs, with regular status hearings and assessments. Mental health courts have not as proved popular in other countries compared to other types of problem-solving courts. In Australia, for example, the primary objective of government policy is to avoid involving mentally ill offenders with the criminal justice system (King et al. 2009:150).

Domestic Violence Courts

Created in order to promote victim safety and make offenders more accountable, domestic violence courts typically emphasize a collaborative approach through cooperation with community-based organizations. Domestic violence courts typically have a dedicated judge and staff who receive ongoing training in domestic violence dynamics. Victims in domestic violence courts typically receive specialized intake services and receive early access to advocacy, while efforts are made to ensure that defendants understand court conditions. Domestic violence courts in the United States also closely monitor compliance pre- and post-disposition, a practice not followed in other countries such as Australia (King et al. 2009: 156). The first domestic violence court was established in Dade County (Miami), Florida, in 1992. Public funding for domestic violence courts became available in 2000, and there are now more than 200 such courts nationally (Huddleston and Marlowe 2011:40). Many observers, however, doubt the applicability of the label "problem-solving" to these specialized dockets because there is no consensus on what, if any, treatment can predictably intervene successfully in the cycle of abuse. Domestic violence courts, instead, focus on providing protection and services to the victims of family violence rather than the treatment of the offender.

Reentry Courts

In 2000, the US Department of Justice, Office of Justice Programs, introduced a Reentry Court Initiative (RCI) to address the rise in incarceration during the previous decades. Specifically, the RCI adapted the drug court model to create community-based programs to oversee the transition from prison to parole supervision and to "establish a seamless system of offender accountability and support services throughout the reentry process" (Lindquist et al. 2003). Nine pilot programs were established. Their common elements were assessment and planning, active oversight, accountability to community, management of support services, graduated and parsimonious sanctions, and incentives for success. A reentry court's jurisdiction over offenders can begin as early as the sentencing process, and in some cases offenders remain in a reentry program until post-release supervision is terminated. The first reentry courts became active in 2000. In 2011, 26 reentry courts and 29 reentry drug courts – reentry courts that are combined with drug courts – were in operation within the United States (Huddleston and Marlowe 2011). Although a few program evaluations have been conducted, definitive evidence that reentry courts reduce recidivism or are cost-effective is not available.

Veterans' Courts

A more recent addition, veterans' courts are a response to the frequency of veterans who return from service with mental illness and/or substance addictions. The first veterans' treatment court began in Buffalo, New York, in 2008. This court has been followed by more than 80 of its kind (Shevroya 2011; Center for Court Innovation 2011). Veterans' courts are an amalgam of practices from drug courts and mental health courts. Similar to the process in mental health courts, offenders who are veterans are identified early in judicial proceedings, and participation in a veterans' court is voluntary. Veterans' courts integrate alcohol, drug treatment, and mental health services with justice system case processing. A comprehensive treatment plan is decided on through a non-adversarial approach in which the prosecution and defense work together to promote public safety while preserving participants' due process rights. Abstinence is monitored by frequent alcohol and drug testing, and judges continue to interact with offenders throughout the program. Veterans' courts frequently monitor and evaluate effectiveness, and staff often engage in interdisciplinary education in order to achieve maximum effectiveness. Like drug courts, veterans' courts form partnerships with public agencies such as the Veterans Administration and community-based organizations that support veterans.

Research Evidence on the Effectiveness of Problem-Solving Courts

A large body of research evidence, much of it using quasi-experimental designs, demonstrates the ability of problem-solving courts to generate better, more cost-effective outcomes than traditional courts. There are several notable features of this body of evidence. First, nearly all of the research has been carried out on adult drug courts, with only a small number of studies available for community courts and mental health courts. We can generalize from what we know about drug courts to the universe of problem-solving courts with only modest expectations of accuracy. Second, as one observer notes, "scholarly and quasi-scholarly writing on problem-solving courts is heavily tinged with advocacy, especially by their proponents" (Baum 2011:27). For drug courts, and to some extent for community courts, the extant research can address two questions. Do problem-solving courts work? And, if they work, why (how?) do they work?

Do They Work as Intended?

This summary of the available research does not seek to be comprehensive. Other entries in this encyclopedia give comprehensive descriptions of what the available evidence says about the efficacy of specific types of problem-solving courts.

Initially, research on problem-solving courts was inconclusive. The rapid expansion in the number of problem-solving courts took place before definitive research was available to demonstrate their efficacy. Early research on problem-solving courts tended to be single court studies. By 2005, sufficient evidence had accumulated for proponents of problem-solving courts to report significant success in the form of reduced recidivism and compliance with court requirements. The state of the evidence as of 2005 was the following: "There have been more than 100 research studies about adult drug courts, and if you look at the best, most rigorous 25 of those, you probably come to the conclusion that drug courts reduce criminal offending by 15–20 %. And what that means is that if you have 30 % of your population you would expect to see rearrested in the next year or so, then instead they go through drug court, it's more like 24 %" (Bathi et al. 2005).

A 2012 comprehensive evaluation of the Red Hook Community Justice Center compared recidivism rates at that court and its downtown trial court counterpart. The evaluation used quasi-experimental methods and matching using propensity scores to conduct a survival analysis following offenders over a 3-year period (Lee et al. 2013). Recidivism rates at Red Hook were 10 % less than those found at the downtown court.

Attention is also placed on the costs and benefits that accrue from problem-solving courts relative to traditional misdemeanor courts. The basic finding here is that problem-solving courts are more costly to operate, but from the point of view of the taxpayer, they are cost-effective compared to the processing of such cases in regular courts once reduced recidivism and savings in the health-care system are taken into account. One estimate (Bathi et al. 2008:xv) identifies an annual cost of $515 million to operate drug courts, while the reduction in recidivism results in more than $1 billion in savings.

How and Why Do They Work?

The initial compelling evidence of positive impacts did not lead to a clear understanding of which drug court features delivered the best results. The studies were also unable to answer the question of *why* drug treatment courts generate better outcomes. Some possible factors have not been significant in studies of drug courts and community courts. The unexpected finding from research to date is that neither the treatment provided nor any deterrent effect could be identified as a cause for the reduction in recidivism rates.

The explanation appears instead to lie in the nature of the interaction between the judge and the offender that occurs in the context of a problem-solving court. The difference in interaction styles may be attributable both to the type of judges who seek assignment to a problem-solving court or to the way in which problem-solving courts structure that interaction. The latter explanation is more plausible as an individual-level explanation seems unlikely to produce the pattern of findings in the available research.

A study of the Baltimore Drug Treatment court provided some of the initial evidence pointing to an "interaction" explanation. The researchers concluded that "the DTC [Drug Treatment Court] program, especially the judicial hearings, contributes to an offender's perception of fairness and due process, thereby increasing his or her willingness to fulfill his or her part of the negotiated DTC agreement" (Gottfredson et al. 2007:28). This was consistent with the perspective of procedural fairness. Procedural fairness is a theoretical approach to explaining satisfaction and compliance with decision-makers, buttressed by a very large supportive body of research. It is most closely associated with social psychologist Tom Tyler. Procedural fairness is present when people perceive that they are experiencing a decision-maker who treats them with respect, neutrality, allows participation, and is trustworthy (Tyler 2004:443–447). Some decision-makers and decision-making forums are perceived as following a more fair process than others.

Judge-to-offender interaction was highlighted as the advantage inherent in problem-solving courts by National Institute of Justice's *Multi-Site Adult Drug Court Evaluation* (Rossman et al. 2011). This study found that drug court participants across 23 sites were more likely than a matched comparison sample to perceive their treatment by the judge as fair; the study then found that these more positive perceptions of the judge comprised an influential factor in explaining why the drug court sample was less likely than the comparison sample either to commit further crimes or to use drugs during the follow-up period (Rossman et al. 2011).

Findings from evaluations of community courts also point to a procedural fairness explanation. A study of defendants at the Red Hook (Brooklyn, New York City) Community Justice Center found that defendant perceptions of procedural fairness were stronger at RHCJC than among a comparison group of defendants processed in a centralized court (Frazer 2007). The study found that Red Hook defendants were more likely to perceive the court process as fair, but the proportion of defendants perceiving the centralized court as fair was also high. However, at Red Hook, positive perceptions of the judge appeared to influence overall perceptions of the court process. In another community court study, it was noted that "in the community court, the judge spoke directly to the defendant in 45 % of the observed appearances, while in the traditional court this occurred in only 19 % of appearances" (Frazer 2007:22).

A more recent Red Hook Community Justice Center evaluation reinforces the focus on procedural fairness. The reduction in misdemeanor defendants' likelihood of recidivism was not attributable to deterrence effects, treatment and social services, or to connections forged with the local community. Based on interviews conducted as part of the ethnographic component and other research, procedural fairness appears to be the mechanism that makes a difference (Lee et al. 2013).

The core finding is that the advantage problem-solving court processing has over traditional low-level criminal court processing is due to the judge – or, more specifically, to the nature of the interaction between the judge and offender in the courtroom.

Controversies

Critics and proponents of problem-solving courts have displayed comparable levels of fervor in making their arguments. The most influential and persistent critic from the academic work has been James Nolan (Nolan 2001, 2009, 2010, 2012). Within the judicial world, Denver trial judge Morris Hoffman has also engaged in sustained criticism (Hoffman 2002). Among national organizations, the National Association of Criminal Defense Lawyers has consistently criticized the ethical status of problem-solving courts (National Association of Criminal Defense Lawyers 2009). Proponents of problem-solving courts are too numerous for it to be sensible to single out a few individuals. It is easier to focus on organizations, noting the large volume of material produced by the Center for Court Innovation, National Drug Court Institute, and NPC Research. Both sides are well represented in a special issue of the *Fordham Urban Law Journal* that appeared in 2002.

Do Problem-Solving Courts Extend the Reach of Government?

A common controversy surrounding problem-solving courts is whether they are a social control mechanism that, whether by design or not, increases the reach of the government into peoples' lives. There are several dimensions to this concern. One criticism is that drug courts wrongfully politicize health and addiction, becoming wrongfully engaged in the process of a "management of pleasures" (Mackenzie 2008). Another dimension is that of "widening the net so people are prosecuted when they otherwise wouldn't be" (Miller 2004; Hoffman 2002). Others argue that, while there is no evidence that net widening is taking place, net widening would be a good thing because it would result in people getting the treatment that they need (Berman and Gulick 2003).

Yet another dimension is the tendency of problem-solving courts to keep offenders under court supervision for longer periods of time than if they had been processed through a traditional misdemeanor court. Most misdemeanor defendants receive short jail sentences, fines, or "time served." In most circumstances, they leave the court with little or no supervision. Offenders processed in problem-solving courts spend longer periods of time under court supervision and are exposed to enhanced risks of failure because the court's expectations are more demanding.

Do Problem-Solving Courts Weaken the Adversarial Process?

To some United States critics, problem-solving courts relax the adversarial process to the extent that they are no longer courts. To one critic, "They are not concerned with due process or adjudicating guilt, either by plea or trial. They are correctional agencies and as such might be an excellent new model of correctional agency. But as post-adjudicative bodies, they must be called what they really are, and it is *not* courts" (McCoy 2006).

The majority of drug courts today are indeed post-plea. But whether pre- or post-plea, problem-solving courts relax certain aspects of the traditional role of a judge in deciding a case. There are also some shifts in the balance of power in the courtroom. In a problem-solving court, the judge is the best-informed person in the courtroom about an offender and supplants the power traditionally held by the prosecutor in a plea bargaining context.

Critics also find fault with various aspects of problem-solving courts that raise ethical issues for judges and attorneys. First, being processed through a problem-solving court exposes a defendant to a greater risk of failure because of the strict criteria for success. Failure may be met with a punishment more severe than if they had opted for a traditional misdemeanor court for processing. Second, problem-solving courts accumulate far more information on defendants that would be the case in a traditional court, and that information is shared among a wide group of stakeholders. Third, entering a problem-solving court generally requires that the defendant waive the right to discovery. Fourth, the decision to enter a drug court must be made within a shorter time frame than is usually available before a trial in order to get the offender immediately into treatment, potentially preventing counsel from fully investigating the case. Fifth, the use of teams in the decision-making process can often lead to ex parte communication about a case in the absence of the defendant or their defense counsel. Sixth, defending a client in a problem-solving court imposes additional workload burdens on public defenders. In many problem-solving courts, there are an increased number of post-plea hearings and "team" meetings in which consequential decisions about problem-solving court participants are made. In order to properly represent their client, defense counsel must not just be present, but be prepared and involved during these meetings (National Association of Criminal Defense Lawyers 2009:31–32).

A major criticism of problem-solving courts (really, drug courts) is that a defendant is denied zealous advocacy. It has been claimed that problem-solving courts unduly limit the time that defense counsel has to investigate or prepare a defense because in the United States but not elsewhere, they are moving in a post-plea direction (Finigan et al. 2007). The ongoing nature of cases may create an extra burden for public defenders, thus not allowing them to adequately represent their clients. The participant in a problem-solving court is under pressure to be "team player" and advance team goals, yet the participant's short-term interest and drug court team's goals may diverge (Meekins 2007:108). There is also concern that firmly asserting a client's rights in a team environment could lead to economic repercussions for the lawyer who may become less likely to be appointed to future cases in that court (Meekins 2007:110).

In order to be balanced, claims that problem-solving courts are not adversarial should be considered in reference to the often feeble nature of the adversarial process as practiced in traditional misdemeanor courts based on plea bargaining (Hessick and Saujani 2002). One important difference may be that in traditional courts the pressure to move forward with the case comes from the prosecutor in the form of decisions to pursue charges and other trial/violation considerations, whereas in a problem-solving court, the most powerful player in the courtroom is invariably the judge. In a problem-solving court, judges make use of their authority to promote compliance with court orders while the prosecutor helps to address participants' problems. Also, it can be argued that in the post-adjudication phase of monitoring, the definition of appropriate advocacy may differ from that during adjudication. Nonetheless, concerns persist concerning the degree to which the very nature of problem-solving courts raises genuine ethical issues for judges, defenders, and prosecutors (Leben et al. 2013). Concerns over the possible deviations from a strict adversarial model have not proved as problematic outside of the United States.

Who Belongs in a Problem-Solving Court?

Another controversy is the issue of who belongs in a problem-solving court. Early drug courts and government policy reserved space for offenders with relatively minor involvement in drug use – users but not addicts. By 2010, the consensus among researchers and policy-makers is that drug courts should be reserved for the more serious offenders, as indexed by their prior criminal history, involvement in substance abuse, and mental health. Policy-makers in other countries such as Australia focused from the start on more serious offences and addicts, perhaps because of the existing pre- and post-plea dispositions available for minor offenders.

The new consensus as led by the National Drug Court Institute is that drug courts should be focused on offenders who "are dependent on alcohol or other drugs and are also at risk for failure in standard correctional rehabilitation programs" (Marlowe 2009). Under this approach, admitting low-level offenders to drug courts is to be discouraged. Individuals who are not substance dependent, but who are substance users and have a low risk for failure in standard settings, are unsuitable for drug courts. Participation in drug courts could expose this population to substance abusers and antisocial values while pulling them away from school or work (Marlowe 2009).

What Should Be a Problem-Solving Court's Goal?

There is a degree of American exceptionalism in the world of problem-solving courts. Nolan argues that while in the United States problem-solving courts seek "total abstinence" or "demand reduction," other common law countries have a philosophy of "harm reduction" or "harm minimization" (Nolan 2010). This explains, in part, the general aversion of drug courts in the United States to making use of medication-assisted treatment. If the goal is to eliminate the harm, there is likely to be opposition to promoting reliance on any type of medication, even if the purpose is to ease or speed the withdrawal process for substance users upon entry into the program, inhibit cravings to use illicit substances or the effects of such use.

Conclusion: The Future of Problem-Solving Courts

Overwhelmingly, what we know about problem-solving courts is based on studies of adult drug courts in the United States. This limits our ability to draw conclusions about problem-solving courts in general, or even about the future for juvenile drug courts. Much depends on whether evaluations of mental health courts, veterans' courts, and community courts are as positive in their findings as the research on drug courts. Even now, however, there are a few indicators of what is to come.

For one thing, it is likely that in the near future, problem-solving courts will start to look different than the ones in the current landscape. The emphasis on evidence-based practices is steering drug courts into new directions. Other problem-solving courts are likely to follow suit. Long-standing assumptions on the types of offenders who should be processed through a problem-solving court are being undone by research evidence and debate over whether harm abstinence or minimization should be the goal of the court. The National Association of Drug Court Professionals is developing standards all drug courts will be expected to follow. There has even been talk of accreditation. The willingness to change the nature of problem-solving courts is nearly as impressive as the sheer doubling and tripling of their numbers experienced in recent decades.

There is also uncertainty on whether government policy in the United States will continue to foster more problem-solving courts and apply them to more "problems." In one scenario, problem-solving courts will become the norm as the mainstream criminal courts are encouraged to incorporate problem-solving theory and practices. Problem-solving courts might then simply dissolve into the larger court system. In another scenario, the large-scale underwriting of the problem-solving concept by state and federal governments might slow to a point where problem-solving courts can no longer be sustained.

Outside of the United States, the prospects also are mixed. Only in the United States have problem-solving courts significantly altered the landscape of how lower-level criminal cases are processed. Such courts are not proliferating even in the common law countries that adopted them. To one observer, a critic of problem-solving courts but also the author of the most significant comparative work on them, this is to be expected: "To import problem-solving courts is to import elements of the particular culture out of which the programs first emerged–and from which they are not easily extricated" (Nolan 2012:164). This might be an unduly negative reading of the potential for the spread of problem-solving courts internationally. After all, the problem-solving courts in Australia and in other countries have adapted the basic model to fit their distinctive legal and other circumstances. Today's problem-solving courts, on balance, seem likely to remain influential features in criminal justice policy and practice in the United States and elsewhere.

Overview

Recent discussions of the relationship between legal authorities and the people within their communities emphasize the benefits to legal authorities of gaining voluntary deference and willing cooperation from the people with whom they deal. A key element in gaining such cooperation is being viewed as legitimate. Legitimacy is based primarily upon the fairness of the manner in which legal authorities exercise their authority, i.e., procedural justice. If legal authorities exercise their authority fairly, they build legitimacy and increase both willing deference to rules and the decisions of the police and courts, as well as the motivation to help with the task of maintaining social order in the community.

Procedural Justice and Cooperation

In the United States the dominant model for the exercise of legal authority is deterrence. Its goal is to encourage public compliance with the law. The mechanism for achieving this goal is through the threat or use of punishment for rule breaking. The traditional objective of the law and of the actions of legal authorities is to gain first public compliance with the law, and second acceptance of the particular decisions made by legal authorities such as judges and police officers. In both cases, public compliance cannot be taken for granted.

The problems involved in obtaining compliance in everyday life are exhibited inter alia in traffic laws, drug laws, illegal immigration, and the payment of taxes. While most people comply with the law most of the time, legal authorities are confronted with sufficient noncompliance to challenge the resources normally devoted to social control. In situations such as the illegal use of drugs and the downloading of music and illegal copying of movies, levels of noncompliance are so high as to make effective regulation very difficult.

Similar problems arise with the decisions of legal authorities. Studies of personal encounters with the police demonstrate that people often resist and even defy legal and judicial orders (Mastrofski et al. 1996). Compliance can never be assumed. The ability to manage encounters with members of the public without provoking conflict and resistance is a core competency issue for police officers. As Mastrofski et al. (1996, p. 272) note: “Although deference to police authority is the norm, disobedience occurs with sufficient frequency that skill in handling the rebellious, the disgruntled, and the hard to manage – or those potentially so – has become the street officer’s performance litmus test.” Based upon observational data, these authors estimate that the general noncompliance rate is around 22 %.

The willingness of litigants to accept the decisions made by judges is also a long-standing issue in the courts. A major motivation for the alternative dispute resolution movement, which uses non-adjudicative forums such as mediation instead of traditional adjudication, is to find a way to increase the willingness of the involved parties to accept the decisions made by third-party authorities. Alternative procedures do so by replacing judges with mediators and adjudication with a more informal and cooperative problem-solving procedure. Within all types of adjudicative settings, judges have struggled to find ways to make decisions that are acceptable to the parties who bring cases into court.

In recent decades the exercise of legal authority to obtain compliance has become primarily associated with the use of threat and punishment aimed at deterring people from engaging in criminal behavior (Nagin 1998). Irrespective of the type of case involved, the traditional means of obtaining compliance is via attempts to deter rule breaking by threatening to punish wrongdoing. The argument driving this perspective is threefold: that fear of possible future punishment leads to compliance with the law, that risk calculations are partly shaped by both the anticipated likelihood of punishment and by judgments about its severity, and that the focus is (and should be) on the power of legal authorities and institutions to shape behavior by threatening to deliver (or by actually delivering) negative sanctions for rule breaking. Within legal circles, this way of viewing the relationship between legal authorities and citizens is referred to as the "deterrence" or "social control" model. It is this model of human behavior that – for better or worse – currently dominates law and public policy.

In this entry we argue that a deterrence model of legal authority is not only expensive and minimally effective; it also undermines forms of social capital that promote long-term public commitment to the law and, crucially, the public cooperation on which legal authorities fundamentally rely. The exercise of authority via the application of fair process strengthens the social bonds between individuals and authorities. Procedural justice promotes normative modes of compliance and cooperation that are both more stable and more sustainable in the long run. Using the example of the UK, we show how specific policing contexts can modulate – but not fundamentally alter – these associations. We consider moral alignment with the London Metropolitan Police – one of a broader range of motivations to cooperate with legal authorities that are based not on material interests but on social values and normative commitment.

Deterrence-Based Legal Policy

There are two aspects of deterrence policy. First is the idea that people's law-related behavior is shaped by their expectations about the likely punishment that will result from rule breaking. According to this perspective, people are influenced by their estimates of the likelihood of punishment, the severity and certainty of punishment, or both. Second, deterrence models suggest that if people are caught and punished, the probability of punishment shapes the likelihood of post-punishment wrongdoing.

Judges, for example, attempt to influence people's acceptance of their decisions by threatening fines or jail time for failure to comply. Similarly, police officers carry guns and clubs, and they are empowered to threaten citizens with physical injury and incapacitation, among other penalties. The goal is to establish legal authority. As Reiss (1971, p. 46) points out: "The uniform, badge, truncheon, and arms all may play a role in asserting authority" in the effort to "gain control of the situation." The police thereby seek to gain control over the individual's behavior "by manipulating an individual's calculus regarding whether 'crime pays' in any particular instance" (Meares 2000, p. 396).

More generally, agents of the legal system who are charged with producing compliant behavior concern themselves with shaping environmental contingencies in such a way that citizens will be faced with the prospect of heavy losses (e.g., fines, arrest, incarceration) that are intended to outweigh the anticipated gains of engaging in criminal behavior. The deterrence model dictates that the responsibility of lawmakers is to decide which acts should be prevented and then to specify sufficiently strict penalties, generally fines or prison term, so that the prohibited behavior is rarely enacted.

At the heart of an institutional model of compliance is rational choice theory, which is derived from neoclassical economics (Blumstein et al. 1978). It is assumed that people calculate expected utilities by multiplying the probability of an outcome (e.g., getting caught for armed robbery or drunk driving) by its valence (very, very bad), and then balance the result against the benefits of crime (Paternoster 2006). Rational self-interest is the motivational engine of the deterrence/social control model. If laws and sanctions are well calibrated, people will arrive at the desired conclusion that they should follow the law. It follows that to regulate behavior, decision-makers should adjust criminal sanctions to the needed level, so that the expected losses associated with lawbreaking will minimize the likelihood that people will break the law.

This model has several problems. First, it is a costly and minimally effective system of social control. The high cost of the system stems from the need to create and maintain a credible threat of punishment. People will only change their behavior when they feel that there is a reasonable risk of being caught and punished for wrongdoing. And, of course, they will try to hide their illegal behavior, so a system of surveillance will be needed to identify wrongdoing. Such surveillance is often not possible.

Second, even when surveillance is possible, the magnitude of influence found is at best weak. There is some evidence that variations in the perceived certainty of punishment do affect some people's compliance with the law – at least to some degree, in some circumstances, at some points in time (Paternoster 2006). People's behavior is sometimes – though certainly not always – shaped by their estimate of the likelihood that, if they disobey the law, they will be caught and punished (see Nagin and Paternoster 1991; Paternoster 2006). But, overall, the body of evidence is mixed. According to Piquero et al. (2011, p. 1; see also Paternoster 2006): "…some studies finding that punishment weakens compliance, some finding that sanctions have no effect on compliance, and some finding that the effect of sanctions depends on moderating factors."

Crucially, when perceptions of the likelihood of being caught and punished do influence people's behavior, the effect seems to be relatively small. Consequently, social control strategies that are based exclusively on a deterrence model of human behavior have had at best limited success. An example is the analysis by MacCoun (1993), which shows that variations in the certainty and severity of punishment for drug use account for approximately 5 % of the variance in drug use behavior. This is a finding consistent with the suggestion of Paternoster (1987, p. 191) that "perceived certainty [of punishment] plays virtually no role in explaining deviant/criminal conduct."

In summary, deterrence is a high-cost strategy that at best yields identifiable but weak, results. A system for detecting wrongdoing must be created and maintained, but this is itself unlikely to be effective unless vast sums are spent on it. Further, it is not realistic to substitute draconian punishments for a yet more costly system that creates credible risks of being detected while engaging in wrongdoing. For this reason, as Meares (2000, p. 401) notes, the effectiveness of "instrumental means of producing compliance always depend[s] on resource limits." The relevant questions are the following: how much in terms of financial and other benefits and burdens authorities are willing to expend in order to control crime? And how much power to intrude into their lives are citizens willing to grant to the authorities?

Deterrence and Social Capital

In addition to being costly and minimally effective, the deterrence model is problematic from a social capital perspective. Social scientists have coined the term "social capital" to refer to the reservoir of psychological (positive values, attitudes, identities) and sociological (dense social networks) factors that predispose communities to be able to work collectively to address community issues more effectively. In this vein, this entry focuses on the psychological predispositions that promote compliance and facilitate cooperation, i.e., the values, attitudes, and identities that lead people in communities to more willingly work with others to address the needs of their community (Tyler 2011).

From a social capital perspective, the deterrence model is problematic because threat and punishment do not build positive values, attitudes, and identities. The central negative consequence of deterrence approaches is that they define people's relationship to law and legal authorities as one of risk and punishment. This dampens peoples' focus upon other aspects of their connection to society – such as shared values and concerns – and encourages people to act in ways that are linked to personal gains and losses.

A further negative consequence of deterrence approaches is that, because people associate law and legal authorities with punishment, the instrumental relationship between the public and the legal system is antagonistic. People become more likely to resist, more likely to avoid legal authorities, and less likely to cooperate with them. Social psychologists have long pointed out that punishments and rewards do not create positive psychological dispositions.

Strategies based upon external contingencies rely upon the continuing ability to deliver credible threats, to enforce rules with punishments, and – when incentives are promised – to deliver those incentives (Tyler 2011). As a consequence, when authorities manage people by surveillance, there is no basis for building a sense of trust. For example, employees who have been given the opportunity to follow rules for internal reasons demonstrate to workplace authorities when they do so that they can be trusted. Subsequently, authorities are more comfortable allowing those individuals to work without supervision. However, when authorities are constantly present, they have no basis for trust and can suspect that the moment they leave, people will stop following the rules. Hence, their very behavior of surveillance creates the conditions requiring future surveillance.

Recent research findings have moved beyond the statement that the deterrence model does not build supportive attitudes and values. Scholars have argued that the policies and practices associated with this model may actually undermine existing social capital. Crucially, the use of surveillance systems has deleterious effects on the social climate of groups. The use of surveillance implies distrust, which decreases people's ability to feel positively about themselves, their groups, and the system itself (Kramer and Tyler 1996). Furthermore, people may experience intrusions into their lives as procedurally unfair, leading to anger and other negative emotions often associated with perceptions of injustice (e.g., Gurr 1970).

Whether surveillance works or not, it is often demotivating. Surveillance introduces new costs in terms of distrust and perhaps even paranoia in subsequent social interaction. Such costs are borne by groups, organizations, and societies to which people belong, as they lose the gains that occur when people are willing to cooperate with each other. Research suggests that the increasing use of deterrence strategies and social control has exerted precisely this type of negative influence on the US social climate.

These issues can be illustrated by decisions about child custody and child support (Bryan 2006). Judges can issue orders concerning custody and child support payment and can back them up in a variety of ways. However, to maximize the favorability of the climate within which children are raised, it is important to make decisions that will be willingly followed by both fathers and mothers. Further, to the degree to which it is possible, it is important to create positive post-separation dynamics in which both parents take responsibility for supporting their children financially and emotionally (Bryan 2006). Hence, family law cases involving child custody and child support have been a particular focus of efforts to find ways to create acceptable decisions. And those efforts point to the potentially destructive role played by adversarial dynamics, which can lead to a negative relationship among parents who need to cooperate to raise their children.

Deterrence has also created an adversarial relationship between legal authorities and members of the communities they serve. This is especially so with respect to racial and ethnic minority group members (Tyler and Huo 2002). An adversarial relationship leads the public to grow less compliant with the law and less willing to help the police to fight crime (Sunshine and Tyler 2003). Those people who feel under surveillance by the police or who have been stopped while driving or walking to be questioned and potentially arrested have more negative feelings about the police and the law (Tyler and Fagan 2008; Bradford et al. 2009).

An analysis of people's connection to law in terms of general principles of human motivation further suggests that if people comply with the law only in response to coercive power, they will be less likely to obey the law in the future because acting in response to external pressures diminishes internal motivations to engage in a behavior (Tyler and Blader 2000). This follows from the well-known distinction in social psychology between intrinsic and extrinsic motivation. Research on intrinsic versus extrinsic motivation shows that when people are motivated solely by the prospect of obtaining external rewards and punishments (i.e., extrinsic motivation), they become less likely to perform the desired behavior in the absence of such environmental reinforcements (e.g., Deci 1975). On the other hand, if people are motivated by intrinsic reasons for behaving in a certain way, then their compliance becomes much more reliable and less context-dependent.

Studies of regulatory authorities demonstrate that seeking to regulate behavior through the use of threat serves to undermine people's commitment to rules and authorities. From a motivational perspective, instrumental approaches are not self-sustaining and require the maintenance of institutions and authorities that can keep the probability of detection for wrongdoing at a sufficiently high level to constantly motivate the public through external means (i.e., the threat of punishment). Over time it becomes more and more important to have such external constraints in place, for whatever intrinsic motivation people originally had is gradually "crowded out" by external concerns.

And while the focus of the rest of this entry is on legitimacy, the normative commitment to cooperate and the psychological aspects of social capital, it is equally important to recognize that deterrence approaches undermine the sociological elements of social capital by damaging communities. Because of the widespread belief that crime is deterred by the threat and/or the experience of punishment, a massive number of American citizens have been convicted and sentenced to serve time in American prisons. Today the USA is a world leader in the proportion of citizens it holds in prison. The United States has the highest prison population rate in the world, 756 per 100,000 national population in 2007, much higher than those in equivalent countries such as England and Wales (153 per 100,000), France (96 per 100,000), and Germany (89 per 100,000) (Walmsley 2008). This imprisonment has a strong impact upon American communities, especially urban communities and especially among members of racial and ethnic minority groups that are overrepresented in the prison system. Families and the communities in which they live are undermined as social units by the loss of large numbers of young and predominantly male members of these communities.

Focusing upon Voluntary Cooperation

Discussions of all types of social institutions have focused upon trying to understand how institutions can best encourage citizens to act pro-socially, and these discussions are also relevant to public cooperation with the police and courts. The focus of study has broadened to include not just compliance – motivated by concerns about costs and gains – but willing deference to the law and the decisions of legal authorities and the general willingness to cooperate with legal authorities. The legal system benefits when people voluntarily defer to regulations and continue to defer over time. In the context of personal experiences with police officers or judges, the legal system is more effective if people voluntarily accept the decisions made by legal authorities. Absent such acceptance, legal authorities must engage in a continuing effort to create a credible threat of punishment to assure long-term rule-following/decision acceptance. These types of voluntary activity are not effectively motivated by the risk of punishment. Threats can sometimes compel obedience. But they do not motivate voluntary deference.

The Importance of Legitimacy

How can legal authorities generate voluntary deference? Studies show that people cooperate when they believe that agents of the law are rightful holders of authority and when they imbue the legal system with the corresponding duty to obey (Tyler 2006a, b). Feelings of identification with the police and courts – and a willingness to defer to their instructions – generate the belief that authorities have the right to dictate appropriate behavior and that authorities are justified in expecting feelings of obligation and responsibility from citizens. Importantly, legitimacy activates self-regulatory mechanisms: people defer to, and cooperate with, legitimate authorities because they feel it is right to do so (Tyler 2006a, b).

The legitimacy of the law and of legal authorities resides most fundamentally in the recognition that the criminal justice system has the right to exist and dictate behavior, and use its authority to determine the law, use force, and punish those who act illegally in justifiable ways. While definitions of legitimacy vary widely, a key feature of many is that it confers the right to command and to dictate behavior and that it promotes the corresponding duty to obey (Weber 1968; Tyler 2006a). Modern discussions of legitimacy are usually traced to the writings of Weber (1968) on authority and the social dynamics of authority. Weber, like Machiavelli and others before him, argued that successful leaders and institutions use more than brute force to execute their will. They strive to win the consent of the governed so that their commands will be voluntarily obeyed (Tyler 2006a).

Kelman and Hamilton (1989) refer to legitimacy as "authorization" to reflect the idea that a person authorizes an authority to determine appropriate behavior within some situation, and then feels obligated to follow the directives or rules that authority establishes. As they indicate, the authorization of actions by authorities "seem [s] to carry automatic justification for them. Behaviorally, authorization obviates the necessity of making judgments or choices. Not only do normal moral principles become inoperative, but – particularly when the actions are explicitly ordered – a different type of morality, linked to the duty to obey superior orders, tends to take over" (Kelman and Hamilton 1989, p. 16).

Legitimacy, according to this general view, is a quality that is possessed by an authority, law, or institution that leads others to feel obligated to accept its directives. It is "a quality attributed to a regime by a population" (Merelman 1966, p. 548). When people ascribe legitimacy to the system that governs them, they become willing subjects whose behavior is strongly influenced by official (and unofficial) doctrine. They also internalize a set of moral values that is consonant with the aims of the system. And – for better or for worse – they take on the ideological task of justifying the system and its particulars.

As Kelman (1969) puts it: "It is essential to the effective functioning of the nation-state that the basic tenets of its ideology be widely accepted within the population.... This means that the average citizen is prepared to meet the expectations of the citizen role and to comply with the demands that the state makes upon him, even when this requires considerable personal sacrifice" (p. 278). Widespread voluntary cooperation with the state and the social system allows authorities to concentrate their resources most effectively on pursuing the long-term goals of society. The authorities do not need to provide incentives or sanctions to all citizens to get them to support every rule or policy they enact.

Perceptions of legitimacy are based on feelings of obligation that are disconnected from substance and material interest. Legitimacy is linked not to the authorities' possession of instruments of reward or coercion but to properties of the authority that lead people to feel it is entitled to make decisions and be obeyed. People will abide by the law and follow police directives even if they disagree with specific guidelines and instructions. In an increasingly pluralistic and diverse society, it is important that legal authorities enjoy a sort of social influence that transcends particular moral values. Remaining salient in situations where authorities and subordinates disagree, legitimacy is an important source of governance, especially in complex societies. For example, the moral beliefs of anti-abortion activists directly conflict with the views of the Supreme Court. But the legitimacy of a Supreme Court ruling on abortion is still conceded. Because legitimacy is based upon the fairness of the procedures used by authorities to govern, rather than upon the substance of their decisions, legitimacy allows authorities to make decisions that are widely accepted even by those who disagree with them.

Procedural Justice

Why do people confer legitimacy to legal authorities? Research shows the importance of procedural justice. The most immediate context of procedural justice is the direct experience that citizens have with police and court officials. The primary factor shaping decision acceptance (when legal authorities make decisions concerning the individual in question) is the procedural justice of the process through which a decision was reached (Tyler 2006a, b). This factor is approximately seven times as important as either the favorability or the fairness of the outcome. Similar findings emerge when we consider why people have positive or negative views about the authorities involved. Again procedural justice is the key antecedent. In particular, procedural justice shapes views about the overall legitimacy of the law and the legal system. Research indicates that people's view that the legal system is legitimate increases following a negative outcome, as long as people experience the procedures used by authorities as being fair (Tyler and Fagan 2008).

In studies of the general population, people are also found to regard the police as legitimate if they believe that the police exercise their authority through fair and impartial means (Sunshine and Tyler 2003; Jackson et al. 2012a, b). Importantly, available evidence suggests that the perceived procedural fairness of the police (the belief that the police would treat me with respect and dignity if I were to come into contact with officers, e.g., and the belief that the police generally treat people with respect and dignity) procedural justice judgments are more central to judgments of legitimacy than are such factors as the perceived effectiveness of the police in combating crime. To the extent that people perceive law enforcement officials as legitimate, they are significantly more willing to comply with the law in general (Sunshine and Tyler 2003; Tyler 2006a).

The procedural basis of legitimacy is especially strong with respect to public opinion concerning political and legal institutions. Studies of the presidency, the legislature,, and the Supreme Court all suggest that when citizens are evaluating government institutions, they focus primarily on the fairness of the procedures by which the institutions make policies and implement its decisions. Research on work organizations also shows that perceived legitimacy has a strong procedural basis (Tyler and Blader 2000).

Procedural justice also plays a critical role in securing compliance over time (Paternoster et al. 1997). It is by now clear that people's reactions to law and legal authorities are heavily influenced by their assessments of the fairness of legal procedures. The most reliable way of attaining legitimacy and maintaining support for legal institutions and authorities is by establishing and protecting procedural safeguards. Indeed, the need for procedural safeguards is one of the strongest arguments for the constitutional separation of executive, representative, and judicial branches of government. To the extent that procedures for insuring genuine fairness are compromised, the system will begin to lose legitimacy and – over time – fail to inspire the kind of cooperation and deference that is often taken for granted during periods of stability.

What is particularly striking about procedural justice judgments is that they shape the reactions even of those who are on the losing side of cases. If a person who does not receive an outcome that they think favorable or fair feels that the decision was arrived at in a fair way, they are more likely to accept it. Longitudinal studies show that people continue to adhere to fairly arrived at decisions over time, suggesting that their acceptance of those decisions is genuine and not simply the result of fear or coercion (Tyler et al. 2007). Further, people who experience procedural justice in court rate the courts and court personnel more favorably, indicating higher levels of trust and confidence in the courts and the court system.

What Makes a Procedure Fair?

As understood in US communities, procedural justice is defined in terms of four issues (also see Murphy, this volume). First, people want to have an opportunity to explain their situation or tell their side of the story in a conflict (voice). Second, people react to evidence that the authorities with whom they are dealing are neutral.

Third, people are sensitive to whether they are treated with dignity and politeness and to whether their rights as citizens are respected. Finally, people focus on cues that communicate information about the intentions and character of the legal authorities with whom they are dealing ("their trustworthiness").

Legitimacy and trust matter because they motivate voluntary deference both with the decision of legal authorities and with the law in everyday life. When people feel responsibility to defer to legal authorities, they do so because it is the right thing to do, not out of fear of punishment or expectation of reward. Hence, legitimacy is a key to self-regulation.

Cooperation

Beyond deference, legal authorities are increasingly focusing upon the benefits of active public cooperation with the police, the courts, and the law. The legal system – and particularly the police – needs voluntary help from the public (Tyler and Fagan 2008). Studies of crime and policing make clear that the police benefit when members of the community voluntarily work with them to manage social order in their community. First, the police need community members who are familiar with the neighborhood and its residents to report crime and criminals to the police. Second, the police need community residents to join them in town meetings and neighborhood watch organizations to identify and deal with community problems.

The shift from compliance to cooperation requires us to expand the scope of our instrumental model – a model that can potentially involve both costs and benefits. While the legal system is based upon highlighting the cost of rule breaking, law and legal authorities also offer benefits that can strengthen social capital. For example, Tyler and Huo (2002) found that the primary reason for people having contact with the police and courts is having gone to them for help. Legal authorities can create benefits by their performance in resolving disputes and maintaining social order. Unlike the relationship of the police to regulation, in which they are primarily the dispensers of punishment, when we consider cooperation, we can also see the police as a group able to provide people with desirable outcomes, by helping them to solve problems and address problems in their communities. The police can provide desirable rewards such as high performance in solving crime, maintaining order, or addressing public problems. Members of the public can – and should – have an active interest in police success that does not rest on sanctions directed at them.

An extension of the traditional view of legitimacy is to also consider moral alignment – the belief that the police share the moral values of individuals, i.e., they believe that justice institutions have a just and moral purpose (which creates a normative justifiability of police power and authority). When people feel aligned with the moral values of an authority in a group setting, they will act in ways that support the group that the authority represents. Institutions can encourage cooperation by activating the ethical motivations that lead people to adhere to group rules and to act on behalf of the group (Tyler 2006a, b; Tyler and Huo 2002).

The powerful influence of procedural justice, legitimacy, and moral alignment on public cooperation with legal authorities is just one example of a broader set of motivations based on social connections rather than material interests (Tyler 2011). Studies demonstrate the importance of five types of normative commitment to cooperate with legal, managerial, and political authorities. These are attitudes, values, identity, procedural justice, and motive-based trust.

Individuals also cooperate with organizations when those organizations serve the social function of providing individuals with a favorable identity and a positive sense of self (Blader and Tyler 2009). Pride and respect within the group are important. If people feel pride in the group and believe that they are accorded respect, then their motives will be transformed from the personal to the group level. If individuals identify with the group that the police represent (i.e., the society and nation), then they merge their sense of self with the group. Defining themselves in terms of their group membership, they will be more willing to act cooperatively on behalf of that group. The goals of the police become one's own goals.

The effect of these two values – legitimacy and moral alignment – on willingness to cooperate with police and criminal courts has been demonstrated in recent UK-based work (Jackson et al. 2012a, b). First, legitimacy was an important predictor of cooperation with the London Metropolitan Police. People who voluntarily deferred to the police, who felt obligated to obey the decisions and directives of officers and who felt the police had a right to determine appropriate behavior, also reported being willing to call the police, to come forward as witnesses, and to identify suspects in court. The correlation between legitimacy and cooperation was particularly strong among a specific subset of the sample (young male from particular ethnic minorities) who tend to have a more fractious, situated, and confrontational relationship to the police.

But the same study also identified a second factor linked to cooperation. People who felt aligned with the moral values of the police (cf. Sunshine and Tyler 2003; Jackson and Sunshine 2007) also reported being motivated to aid the police and courts. In turn, procedural justice was a strong predictor of moral alignment. Participants in the London study valued fairness, decency, and transparency (in interpersonal treatment and decision-making) over instrumental concerns (cf. Tyler and Huo 2002; Gau and Brunson 2010). Social psychological research shows that people want to feel valued members of social groups and they derive self-relevant information through the quality of their interactions with group representatives. Fair, decent, and respectful treatment fosters motive-based trust and identification with the group (Tyler and Blader 2000), as well as a sense of shared moral values.

In Jackson et al. (2012a), moral alignment was also related to a particular collection of relational concerns and social characteristics of the neighborhood in which individuals lived. The level of collective efficacy in a neighborhood – the sense of trust and shared values, and the willingness of residents to act upon those values on behalf of the common good – and disorder in that community (i.e., signs of the lack of community oversight and the inability of officials to maintain low-level social order) explained a good deal of variation in moral alignment with the police (cf. Jackson and Sunshine 2007; Jackson and Bradford 2009). By contrast, neighborhood levels of crime and fear of crime were not related to moral alignment with the police. When subtle, informal social controls are strong, community members believe the police are aligned with their values. Conversely, poor social conditions may encourage the feeling that the police are not representing and defending group norms, values, and identities.

Overall, these findings support the idea that moral alignment with the police is not an instrumental motivation – based on material interests and personal concerns about crime and risk – but a normative motivation rooted in social connections and identification. Moral alignment seems to strengthen the motivation to cooperate because (a) the goals accord with one's moral values, (b) the interests of the group become more of one's own interests, and (c) two people value the social connection they have with the police and the group the police represents. This seems to be an additive effect, on top of the effect of legitimacy on cooperation.

Widening the Definition of Legitimacy?

Is legitimacy both obligation and moral alignment (Jackson et al. 2012a, b)? Individuals may confer the right of the police to dictate appropriate behavior when they believe that the police are legitimate in the authority they possess and legitimate in the moral values they defend and represent. People may obey the police, even if they disagree with the specific context of the instructions, because of the authority the police possess and because of a shared moral purpose. This is the idea floated recently in Europe (Jackson et al. 2011; Hough et al. 2013).

Including moral alignment in the definition of legitimacy certainly makes sense in England and Wales, given the specific symbolism and the legitimizing foundation of the British police. The cultural symbolism of the police is rooted in the foundational myths of the London Metropolitan Police and the "bobby on the beat." When considering the history of British policing, it is commonplace to refer to Robert Peel's principles of policing operation for the Metropolitan Police. While doubts exist as to the primary source of these principles, which Lentz and Chaires (2007) suggest may be somewhat the "invention" of twentieth-century textbooks, their theme and spirit remain important. Phrases like "the police are the public and the public are the police" and "the ability of the police to perform their duties is dependent upon public approval of police actions" (e.g., Reith 1952, p. 154) speak to a close social connection between what were then "subjects of the crown" and the police.

In the eyes of many citizens, the continued justification of the existence and moral authority of a police force in England and Wales may rest on the idea that the police reflects and defends a common sense of shared values. People look to the police to defend and typify moral values; they assess its right to determine appropriate behavior partly on the basis of shared values. It follows that the legitimacy of the police rests in part on a moral link between people and police – a link that may remain strong despite the decline in public trust in the police over the past few decades.

Defining legitimacy as duty to obey and moral alignment also accords with the work of David Beetham (1991). Beetham insists that legitimacy is not simply a property of an authority or something which exists only in the subjective experiences of citizens. It is also *constituted by* normative assessments of authorities and the actions of those they govern. When citizens grant legitimacy to the police, they do so on the basis that the relationship between individual and authority is founded on common shared values. When individuals act in ways congruent with recognition of this commonality, their behavior serves to confirm and reproduce the legitimate role of the authority. Beetham outlines three dimensions of legitimacy, each of which must be fulfilled for an authority to be considered legitimate. First is conformity to a set of rules. Second is the justifiability of these rules in terms of shared beliefs. Third is the expressed consent of those governed or otherwise affected by the authority. In the case of the psychological state of legitimacy, these will be beliefs about the lawfulness and legality of an authority, a sense of shared moral values, and a positive duty to obey.

Whether moral alignment is important in other countries, and whether it can be reasonably thought of as legitimacy, remains an open and empirical question (although see Hough et al. 2013). In many societies the police may be seen less as a connected to shared moral values and more an agent of last resort. Such an institution requires from citizens obligations and feelings of responsibility, but does not draw its authority from any kind of value congruence.

And the difficulty with viewing moral alignment as an aspect of legitimacy may arise particularly in diverse multicultural societies. If the people within a political entity do not share a common set of moral values, then it will be harder for government authorities such as the police or the courts to represent shared values, and harder for them to invoke values as a source of authority. It is also harder for legal authorities to enforce laws that do not reflect moral values, shared or not. When the police are trying to enforce laws against using drugs or illegally downloading music and films, they will have difficulty drawing upon shared value structure because many people do not view such behaviors as immoral. As with parking violations or speeding, many people do not view breaking such laws as wrong, and adopt a more instrumental "try to catch me" attitude toward their behavior.

It is for future empirical research to assess, but it may be that people's sense of "moral alignment" is based primarily on procedural justice, namely, the values that police express by the actions and decision-making of officers. Extant research shows extremely strong associations between trust in police fairness and moral alignment (Jackson et al. 2012a, b), suggesting that procedural justice is a central way in which authorities demonstrate their moral values. If this is so, then legitimacy may still not have to depend too strongly on consensual views among different communities. Procedural justice sits above diverse value positions; two parties in an interaction (indeed, in an argument) do not have to agree with each other on the specific issue at hand to treat each other with respect and dignity, allow each other a voice, and develop a sense of mutual trust. Fair treatment and fair decision-making may demonstrate to citizens that police officers respect their views and values and are thus working to a broad set of appropriate moral standards that recognize the worth of citizens and which give then officers a rightful claim to power and authority.

Final Words: Social Capital, Regulation, and Citizenship

As the results of the UK study indicate, when the police can draw upon shared values, moral alignment provides an important additional normative force beyond legitimacy that aids their efforts. The British example underlines the extent to which the primary aim of policing – the reproduction of normative social order – can be secured via coproduction involving police and community. When police behave in a procedurally fair manner, people are encouraged to feel ready and able to cooperate with officers. They are more likely to feel it is right and proper to support the police, and they are more willing to engage with them to address the problems they face in their communities. They do so not when they are incentivized by aggressive policing, nor necessarily when they see the possibility of a direct material return, but when such cooperation becomes valid in itself, because it seen as an effort to work toward a common goal.

Furthermore, individual and collective propensity to cooperate with the police can itself be a form of social capital. Despite the growth in forms of private policing, in the UK as elsewhere (Jones and Newburn 2002), for most of the population, the police are the only option. Those who feel unable or unwilling to draw on the services of the police at times of need – perhaps because they have experienced police unfairness in the past – are denied a core element of the assistance the state can provide to them. Attempting to deal personally with problems that might indicate a need for the police may incur significant economic, social, and personal costs.

It may also cause problems in the community when people take the law into their own hands (Huq et al. 2011). Police acts that are unfair damage citizen's sense of alignment with police and trigger withdrawal from an important form of social support, a form of capital all citizens should feel able to draw upon when needed. When this happens, police are less likely to be able to solve problems in the communities in which they live in an effective and equitable manner. This may serve to initiate a downward spiral of failure, as social cohesion is undermined, disorder is felt to increase, and police legitimacy is further undermined.

Across the social sciences, there has been a widespread recognition that it is important to understand how to motivate cooperation on the part of people within group settings. This is the case irrespective of whether those settings are small groups, organizations, or communities (Tyler 2011). Studies in management show that work organizations benefit when their members actively work for company success. Within law, research shows that crime and problems of community disorder are difficult to solve without the active involvement of community residents. Political scientists recognize the importance of public involvement in building both viable communities and strong societies. And those in public policy have identified the value of cooperation in the process of policy making – for example, in stakeholder policy making groups. Hence it is important to ask whether the actions of legal authorities can aid in the production of social capital that might more generally engage cooperation.

Recent discussions of legal authority focus on a broader conception of the relationship between community residents and legal authorities. This broader framework suggests a new and broader conception of citizenship. Rather than concerning simply deferring to authorities, citizenship is increasingly seen as connected to the willing and active cooperation with authorities in creating and maintaining order in the community. For example, Tyler and Fagan (2008) identify two distinct forms of cooperation that benefit the police. The first is cooperation in solving particular crimes, for instance, by reporting crime in the community. The second is cooperation in co-policing the community, by working with the police in discussions about community issues and problems and through general willingness to work with the police, for example, by joining neighborhood watch and helping to patrol areas in one's neighborhood. Tyler et al. (2010) make a similar distinction in their study of anti-terror policing in the Muslim American community. They note that the same two types of cooperation are valued by legal authorities: reporting potentially dangerous actions and generally working with the police to help police the community against terror threats.

Both of these forms of cooperation are essentially voluntary. Noncooperation risks little or no sanction. In particular, *not* reporting threats to the community is something that is virtually undetectable. People's willingness to do so is therefore linked to a broader loyalty or sense of duty to the community and its authorities. Such cooperative behaviors are therefore general civic activities akin to the more traditionally studied forms of political participation. The issue that is being raised in respect to crime, in other words, is the same type of issue raised with regard to any matter affecting a community. How can citizens be motivated to become involved in deciding how to manage their community and in engaging in behaviors oriented toward doing so?

It is also clear that the actions of legal authorities have an impact on people's views about government. Because the actions of legal authorities generalize to views about society and government, it should be possible to develop strategies of law enforcement that are more socially beneficial by building identification with government and society as well as the type of supportive values that lead to feelings of obligation. For example, the police might be able to help build the values that would lead people to pay their taxes or act as volunteers. Further, they might build the type of connections that lead people to work willingly and enthusiastically in their communities. In other words, rather than being viewed as a (necessary) cost that has negative implications for society, the legal system could generate supportive attitudes and values that would resonate more broadly through society.

Legal authorities can produce the benefits of building public support, benefits which include success in fighting crime and also general support for the community. People are more likely to come to and revisit communities in which they feel that they will be well treated by the representatives of government they are most likely to encounter – the police. This benefits communities economically because people more willingly come to them to work and to shop, as tourists, and for entertainment and sporting events. Hence, the police play a central role in creating the reassurance that makes a community inviting and desirable to the general public. In other words, the law provides a framework for building vibrant, alive, successful communities. If people feel reassured by the presence of the police and believe that they will be protected and, if they need it, helped, then they will be encouraged to engage in their communities socially and economically. When people engage in such behaviors, they build social capital and the sense of efficacy that we have already noted has broad social value. If people engage in their communities, they come to know others and to know how to work with them when problems arise in the community. They build trust in others and develop the police that others can and will join together to address issues when they arise. By providing a framework of reassurance, the police are creating the climate that allows the community to develop valuable psychological and sociological characteristics.

Underlying these comments is the question of how legitimacy, trust, and values such as collective efficacy are related. It may be that strong government and legitimate institutions help foster collective efficacy (LaFree 1998; Kochel 2012). Equally, work in the UK suggests that people infer the moral values of the police from the strength of the values and social ties they experience in their community. We would suggest that to some extent, both of these are true. A feedback loop may exist between collective efficacy and institutional legitimacy.

Tyler and Blader (2000) explore the relationship between people and groups in the context of work organizations. They demonstrate that identification with authorities and institutions is central to motivating the development of supportive attitudes and values, as well as to motivating cooperative behavior. Hence, to the degree that the police can build identification with legal authorities and with the community itself, they promote supportive public attitudes and voluntary cooperative behaviors. Studies in work settings widely suggest that, as with law, when authorities exercise their authority in fair ways, they motivate employees to identify with their companies, and this identification in turn leads to voluntary cooperation with management. Our argument is that the police and the courts can similarly build identification with society and social institutions and through that identification can motivate members of the community to more actively work on its behalf.

A value-based perspective on human motivation suggests the importance of developing and sustaining a civic culture in which people more willingly abide by the law because they feel that legal authorities are legitimate and ought to be obeyed. For this model to work, society must create and maintain public values. Psychological social capital must be created. Political scientists refer to this set of values as a “reservoir of support” for government and society. But however labeled, a value-based model is consistent with a social psychological understanding of how authorities can effectively regulate citizen behavior, maintain social order, and promote an effective, well-functioning society – by developing and maintaining a culture of supportive social values that will be internalized by the citizenry (Tyler 2011).

As we have noted, such values include feelings of obligation and responsibility to the state. They also include judgments about the degree of moral alignment that people feel with the police, the courts, and the law. And they include broader types of social connections to society, for example, identification with authorities and institutions. All of these values potentially provide an alternative basis for the effective operation of the legal system.

Procedural fairness

Overview

A significant amount of police work involves face-to-face interactions with the public. The nature of these interactions can vary considerably from encounter to encounter. Police are often faced with situations in which they have to deliver unfavorable outcomes to the individual or group they are dealing with. This can sometimes lead to overt resistance or aggressive behavior. Citizen compliance with police directives is therefore important and can help police to resolve issues more efficiently. Research in the procedural justice field has shown that if police treat citizens respectfully and make decisions in a fair way, then it can enhance public perceptions of police legitimacy. This in turn has been shown to shape compliance-related behavior during and after a police encounter and has even been shown to promote long-term compliance with the law. This entry provides a summary of procedural justice research that has been conducted in the policing context and highlights future directions and controversies that have emerged in the field.

Fundamentals

A long-standing debate has existed in the criminology literature which contrasts the work of those who believe that individuals will comply with authorities and the law only when confronted with harsh sanctions and penalties and those who believe that alternative models that seek to encourage voluntary compliance will be more successful (see Ayres and Braithwaite 1992). Traditional crime control models that place an emphasis on deterring potential offenders from breaking the law have tended to dominate policy making and enforcement approaches in the criminal justice field, including policing. The basic premise of such models is that people are rational actors who behave in a manner that will maximize their expected utility. In other words, individuals assess opportunities and risks and disobey the law when the anticipated fine and probability of being caught are small in relation to the profits to be made through noncompliance. The view is that if an individual is a rational decision-maker whose aim is to maximize expected gains, authorities should respond by deterring them from acts of noncompliance by ensuring the benefits to be obtained through noncompliance are lower than those obtained through compliance. Advocates of this perspective therefore suggest that compliance can be best achieved in two ways: (1) by increasing the probability of detecting noncompliers and (2) by increasing sanctions to the point where noncompliance becomes irrational (Becker 1968). According to supporters of this deterrence-based approach, authorities need to find an appropriate balance between these two measures to make compliance behavior the rational choice.

Although some research supports the basic premise of the deterrence model and its ability to deter people from noncompliance, other research also suggests that these factors have, at best, a minor influence on people's law-related behavior. Some studies suggest that such estimates do not independently influence behavior when the influence of other factors – such as socialization processes, social norms, or moral reasoning – is considered. Critics of the deterrence model also suggest that such an approach to crime control is costly to maintain. Further, they suggest that it cannot satisfactorily explain the high levels of voluntary compliance observed in situations where the probability of detection is small. If people were simply rational actors motivated purely by self-interest, one would expect that compliance with the law would be significantly lower than what has currently been observed. Finally, some research has also demonstrated that deterrence-based enforcement strategies can be counterproductive in the long term and can undermine the relationship between legal authorities and those they regulate. For example, research has shown that the use of threat and legal coercion, particularly when perceived as illegitimate, can produce the opposite behavior from that sought. Such actions have been found to result in further noncompliance, creative compliance, criminal behavior, or overt opposition. In fact, a growing body of research has shown that individuals comply with the law for reasons other than an instrumental calculation of benefits and risks of offending. This research shows that most people obey most laws most of the time because they believe it is the right thing to do.

In the 1980s, therefore, many scholars began to question the value of deterrence alone in regulating behavior. Criminologists began to focus their attention on researching compliance rather than deterrence and began to realize the importance of using alternative approaches for securing compliance. One such approach can be found in the procedural justice literature. According to *procedural justice* models of compliance, institutions responsible for enforcing the law can play a major role in influencing citizens' compliance behavior through using procedurally fair practices.

Procedural justice has been shown to be extremely effective in shaping people's compliance-related behaviors because procedural justice can increase people's perceptions of an authority's *legitimacy* (Tyler 1990). If people view an authority as legitimate, they agree that the authority has the right to govern them. Providing an authority with legitimacy transfers to them the authority and right to define what constitutes acceptable forms of behavior. As such, citizens will be more willing to defer to a legitimate authority's directives or rules. While procedural justice scholarship has been conducted across many different contexts (workplaces, courts, taxation, policing, etc.), this entry focuses specifically on the role that the institution of policing can play in encouraging citizens to comply with both police directives and the law more generally.

Scholarly interest in perceptions of police treatment and the legitimate authority of the public police is not new. However, it is the contemporary stream of policing research by Tom Tyler and his colleagues that has shaped the field today. Since the publication of Tyler's (1990) influential book *Why People Obey the Law*, there has been a rapidly expanding literature around the importance of procedural justice to effective policing practice and in particular how the police can use procedural justice principles to encourage citizens to defer to their authority and comply with the law.

In the policing literature, procedural justice has usually been defined in terms of four issues: (1) neutrality, (2) respect, (3) trustworthiness, and (4) voice. First, people react positively to evidence that the police with whom they are dealing are neutral. Neutrality involves making decisions based upon consistently applied legal rules and principles and the facts of the case, not upon personal opinions and biases. Transparency or openness about how decisions are being made facilitates the belief that decision-making procedures are neutral when it reveals that decisions are being made in rule-based, principled, and unbiased ways. Second, people are sensitive to whether they are treated with dignity and politeness and to whether their rights as citizens are respected. The issue of interpersonal treatment consistently emerges as a key factor in reactions to dealings with police, with many complaints being made about police involving inappropriate verbal conduct by an officer. People believe that they are entitled to treatment with respect and react very negatively to dismissive or demeaning interpersonal treatment. Third, an authority's trustworthiness is also an important component for determining whether they have acted in a procedurally fair manner. People focus on cues that communicate information about the intentions and character of the legal authorities with whom they are dealing (i.e., "their trustworthiness"). People react favorably to the judgment that the police officers with whom they are interacting are benevolent and caring and are sincerely trying to do what is best for the people with whom they are dealing. Authorities communicate this type of concern when they listen to people's accounts and explain or justify their actions in ways that show an awareness of and sensitivity to people's needs and concerns. Finally, voice has also been shown to be important to people. People want to have an opportunity to explain their situation or tell their side of the story in a conflict. They are interested in having a forum in which they can tell their story. For procedural justice to take place, the opportunity to make arguments and present evidence should occur before a police officer makes a decision about what to do.

Early theorizing postulated that procedural justice was important to people because it was able to maximize their instrumental gains. For example, having the opportunity to express one's opinion through voice can increase one's control over outcomes and may maximize the probability of a favorable outcome. This instrumental view of procedural justice can be traced back to the seminal work of Thibaut and Walker (1975). Thibaut and Walker's control theory suggested that people do not focus directly on the favorability of the outcomes they receive from authorities. Instead, they focus on the degree to which they are able to exert influence over an authority's decisions. If people feel they have control over decisions, they will believe the procedure has been fair. In contrast, if they feel they lack control over the final outcome, they will believe the process has been unfair.

More recent social justice theories, however, have steered away from such an instrumentally focused view of individuals to suggest that procedural justice matters to people for reasons above and beyond self-interest concerns and the outcomes they receive. Lind and Tyler's (1988) Group Value Model has dominated theorizing in the procedural justice field. The Group Value Model suggests that procedural justice conveys a symbolic message that carries self-relevant implications. Drawing on psychological theories of social identity, the group value approach suggests that people are motivated to develop a positive sense of self. Unlike traditional social identity theories, however, which propose that people develop a strong sense of self through acquiring membership in high-status groups, the Group Value Model perspective suggests that one's status within a group can also add to the sense of self. According to this view, individuals will assess their status within groups by evaluating the extent to which important group representatives (such as police) treat them fairly. When people feel they are treated with procedural fairness, their sense of self-worth is bolstered, and their attachment to the group is reaffirmed. Unfair treatment, in contrast, signals marginality and exclusion and conveys to the recipient that they are not a valued member of the group.

Scholars who have examined the effects of procedural justice in a policing context have consistently found that people are much more likely to view police as legitimate when they feel they have been or will be treated in a fair, respectful, and impartial manner by police. Conducted primarily in the United States, this research shows that building police legitimacy by using procedural justice can lead to greater public respect for legal authorities and stronger felt obligation to obey the law (Tyler and Huo 2002; Sunshine and Tyler 2003). This research also shows that when police are viewed as more legitimate, citizens will be more likely to comply with the law and will be more likely to defer to police directives as a result (Murphy et al. 2008). By having legitimacy, police can encourage law-abiding behavior not just during a police-citizen encounter but also outside of encounters through everyday compliance with the law. Social theorists argue that legitimacy is effective in shaping compliance behavior because it reflects an important social value that is distinct from self-interest concerns. Tyler (1990) makes the point that when behavior flows from one's own internal values about what one *ought to do*, rewards and punishments or self-interest concerns are not the central determinants of behavior. It has therefore been argued that compliance which is garnered through a procedural justice-based approach will be economically more viable and more stable over time than instrumental deterrence-based approaches to regulation.

Inherent in most social regulation is the delivery of negative outcomes, and policing is no exception. Policing sometimes involves limiting people's ability to behave as they wish, or imposing sanctions on those who behave inappropriately. While receiving an unfavorable outcome can sometimes lead to feelings of resentment and possible defiance toward police, research consistently finds that procedural justice is more important to citizens than obtaining outcomes that they regard as fair or favorable to themselves. Research by Tyler and Huo (2002) shows just how important police use of procedural justice can be to citizens. Tyler and Huo (2002) examined survey responses from a sample of Americans who were stopped by the police. While people were somewhat more willing to accept police decisions that were favorable or that had fair outcomes, Tyler and Huo found that they were most strongly influenced by procedural fairness. People were about 15 %

more willing to accept decisions that were favorable, compared to those that were unfavorable. However, people were about 70 % more willing to accept decisions when they received fair treatment as opposed to when they received unfair treatment. This difference was found irrespective of whether the outcome was good or bad. So while both factors mattered, fairness of treatment dominated people's reactions to personal encounters with the police.

Police stops are not the only way that people have contact with the police. In fact, the most typical form of police-citizen interaction other than police stops occurs when people seek help from the police. In this type of situation, the issue is not compliance or deference to police directives but satisfaction with police efforts to help. Researchers have found that procedural justice can also be important for shaping general attitudes toward police and satisfaction with an encounter. Tyler and Huo (2002) examined people's reactions to police actions after requests for help, and the findings are essentially the same as those already noted concerning stops. People's satisfaction with police actions in response to requests for help is greater if the police solve their problems, but the primary factor shaping satisfaction is the fairness of police treatment.

Future Directions

Procedural justice researchers consistently find that citizens are more likely to comply with police directives and with the law more generally when they view police as legitimate. They also find that legitimacy is shaped predominantly by procedurally fair treatment. A number of recent developments in this field of research have occurred in the past 5–7 years which appear to be shaping scholarship in the field. These developments include (1) more sophisticated theorizing around the concept of legitimacy, (2) a divergence away from studying compliance with police and the law to understanding citizen willingness to cooperate and engage with the police, (3) understanding the contingencies surrounding procedural justice effects, and (4) implementing procedural justice and legitimate policing in applied settings. While procedural justice research in the nonpolicing field has led to other developments not mentioned here, the developments highlighted here are the ones that have emerged in the policing literature and warrant further discussion in this entry.

Conceptualizing Legitimacy

As already highlighted, procedural justice shapes satisfaction with police and compliance with police directives and the law because it increases the perceived *legitimacy* of police. Legitimacy is a judgment people make about the status of an organization as an authority that has the right to command others and be obeyed. Police legitimacy has traditionally been conceptualized in the procedural justice literature as reflecting two judgments. The first is public trust and confidence in the police. Such confidence involves the belief that the police are honest and that they try to do their jobs well and are able to protect the community against crime and violence. Second, police legitimacy reflects the public's willingness to defer to the law and to police authority. Where police are judged to be legitimate, people feel that they ought to defer to their decisions and rules, cooperate with them, and follow them voluntarily out of obligation rather than out of fear of punishment or anticipation of reward.

Tyler's empirical work in policing has dominated research in the field. His work has tended to focus specifically on the legitimacy of the police. In other words, Tyler's research has tended to conceptualize legitimacy as originating in the innate properties of the police that leads people to trust the police and feel obligated to cooperate or comply with them. Only recently, Murphy, Tyler, and Curtis (2009) have argued that past procedural justice research has overlooked how people may also perceive the legitimacy of the *laws and rules* that the police are enforcing (i.e., what they termed *legal legitimacy*). Legal legitimacy is the belief that laws should be obeyed, regardless of whether the content of those laws align with one's own moral beliefs about what is right or wrong. Murphy and colleagues suggest that individual police officers or the institution of policing more generally may be seen to have legitimate authority (with people feeling obligated to follow police directions), but the legitimacy of the policies, rules, and laws that the police enforce can be called into question. They argued that if people question the legitimacy of the laws they are being asked to obey, then compliance with laws or voluntary cooperation with police may be less likely (see also Murphy and Cherney 2012).

Using Australian survey data collected across three different regulatory contexts (including policing), Murphy and her colleagues (2009) found that the perceived legitimacy of the law did indeed influence people's compliance with the law and/or their willingness to cooperate with an authority. Those who questioned the legitimacy of the law were found to be less likely to comply. More importantly, however, perceptions of legal legitimacy were found to moderate the effect of procedural justice on compliance. Procedural justice was found to be *more* important in shaping people's compliance-related behaviors in a positive way when they questioned the legitimacy of the law than when they saw the law as legitimate. These findings demonstrate the importance of considering a broader definition of legitimacy in procedural justice research.

Scholars from the United Kingdom have also recently recognized the importance of legal legitimacy for understanding compliance with police (see Jackson et al. 2011). However, while Jackson and his colleagues distinguish between police legitimacy and legal legitimacy, they also expand on the traditional definition of police legitimacy. They have recently defined and measured police legitimacy as a multidimensional concept with three interlinked elements: (1) obligation to obey, (2) moral alignment, and (3) legality. Obligation to obey is consistent with Tyler's definition of legitimacy, with a legitimate police force being able to garner obedience from the public. Moral alignment reflects the belief that the police and the public share broadly similar moral positions about appropriate law-abiding behavior. Jackson and his colleagues argue that legitimacy needs a moral foundation; otherwise, compliance with authority directives is blind. Jackson's third conceptualization of police legitimacy reflects whether police themselves follow their own rules. If police are seen by the public to be acting in an ethical manner or exercising their authority according to established principles, then they will be seen to be legitimate. Research examining these new notions of legitimacy has only just commenced (see Jackson et al. 2012). By exploring empirically the link between the different forms of police legitimacy and legal legitimacy, future research can begin to tease apart the separate roles that each might play in explaining compliance-related behaviors.

From Compliance to Cooperation

To be effective police need to ensure that citizens comply with the law. To maintain social order the police must be widely obeyed, and this obedience must occur in both personal encounters with police and in people's everyday compliance with the law. At the same time, however, effective policing also requires the ongoing support and *voluntary cooperation* of the public. Police cannot be everywhere at all times. Their ability to detect and deal with social disorder and crime is also dependant on the publics' willingness to cooperate and assist the police by reporting crimes and passing on information about suspicious persons, events, and other information. While the police can use strategies to enforce legal compliance or compliance with police directives, as can be seen from the information presented earlier in this entry, strategies such as these can have negative consequences for people's subsequent willingness to cooperate with police in the future. Coercive approaches can destroy altruistic cooperation almost completely, with research showing that in disadvantaged communities where police are often perceived to be heavy-handed with locals, residents generally resist talking to police, or fear contacting them to report a crime or even one's own victimization (Weitzer and Brunson 2009). The benefit to both police and society of a public that is willing to assist and support them in collaborative crime control efforts is obvious.

In a review of policing and policing practices in the United States, it was suggested that understanding how to motivate public *cooperation* with the police is the most important future research topic in policing (Skogan and Frydl 2004). Identifying approaches that can intrinsically motivate and encourage people to want to voluntarily cooperate with police has therefore been identified as an important avenue for future procedural justice research.

A recent set of studies show that fair treatment of citizens by police is particularly important for shaping such voluntary behavior. Sunshine and Tyler's (2003) study was the first empirical study to demonstrate a link between procedural justice and people's willingness to cooperate with police. Sunshine and Tyler utilized longitudinal survey data collected from 1,600 New Yorkers. They found that procedural justice shaped people's compliance with the law, their willingness to cooperate with police, and their willingness to empower police with a wider range of discretion in their duties through shaping their views of the legitimacy of the police.

Since the publication of Sunshine and Tyler's study, the emphasis on studying legal compliance in the procedural justice literature has decreased in favor of studying the impact of procedural justice and police legitimacy on willingness to voluntarily cooperate with police (Murphy et al. 2008). Such cooperation and engagement could include contacting the police to report a crime, a general willingness to assist police if asked or required, and participation in crime prevention programs. Tyler and his colleagues have also recently found that procedural justice is the primary factor shaping the Muslim's willingness to cooperate and work with US police in anti-terror policing (Tyler et al. 2010; see also Cherney and Murphy forthcoming). This emerging body of research suggests that if police adhere to principles of procedural justice in their dealings with the public, then they may be able to successfully engage people and shape their willingness to cooperate with police in a range of different matters. Identifying the situations and circumstances surrounding when people would be willing to cooperate with police, work with police in crime prevention, or report crimes to their local authorities is therefore emerging as a fruitful and important avenue for future procedural justice and police legitimacy research.

Contingencies Surrounding Procedural Justice Effects

In the past 10 years, there has been a growing amount of scholarly interest in procedural justice theory and its relevance to policing. A key concern of this body of work has been to understand the antecedents of police legitimacy and people's willingness to comply or cooperate with police. Much of the published research on procedural justice to date has aimed to establish whether Tom Tyler's model of procedural justice can be replicated. For example, researchers have begun to assess the applicability of Tyler's procedural justice model in different countries. Tankebe (2009a) made the point that the majority of procedural justice and police legitimacy scholarship has occurred in the West. Considering that the history of public-police relations can differ significantly across different countries, it begs the question of whether procedural justice may have different effects across particular sociopolitical and cultural settings. Similarly, very little procedural justice research has been conducted across different groups within the United States or other Western societies (e.g., new migrants, youth, victims vs. offenders) or whether the effectiveness of procedural justice may relate to certain forms of compliant behavior. Whether procedural justice proves to be more or less effective across these different contexts or groups remains largely untested. While the research in this area generally supports the conclusion that Tyler's model can be generalized across various groups or countries, a handful of recent studies also indicates that Tyler's model may not hold true across all conditions and contexts, or across different groups. For example, Tankebe (2009a) has shown that in the African context, instrumental factors and personal outcomes are far more important in shaping police legitimacy than procedural justice-based concerns. Murphy and her colleagues have also recently shown in the Australian context that procedural justice can be counterproductive with some ethnic minority groups (Murphy and Cherney 2011, 2012). Murphy's research has also shown that procedural justice matters more to people in police-initiated encounters but matters less when they initiate contact with police. Here, instrumental factors, such as whether the police fix a problem or solve a crime, appear to be more important (Murphy 2009). Research with victims of crime has also found that reutilization of police services is shaped by whether victims have received a favorable outcome from police in the past, not by whether they had received procedural justice from police during the investigation (Hickman and Simpson 2003). While not a complete repudiation of Tyler's model, this work does indicate that attention needs to be given to the possibility that procedural justice effects vary across groups or under certain conditions or contexts. These contingencies have only just begun to be explored and open up a major avenue for future research in the field.

Operationalizing Procedural Justice into Policing Practice

The fourth major development in the police legitimacy and procedural justice field relates to the testing and evaluation of procedural justice-based policing approaches in applied settings. The overwhelming majority of procedural justice and police legitimacy studies rely on survey methodology (for a review, see Mazerolle et al. 2010). Almost no studies in the policing context use experimental field designs that attempt to ascertain the relevance of procedural justice theory to policing practice. Hence, research that seeks to examine how procedural justice can be operationalized into police practice and that also seeks to evaluate the effectiveness of such practice on citizen behavior offers another potential and important avenue for future procedural justice work. Only a handful of studies purporting to do this have emerged in the literature.

A recent Australian example is perhaps the most impressive of the studies that has been conducted to date (Mazerolle et al. 2012a). In partnership with the Queensland Police Service in Brisbane, Australia, the study's researchers implemented a change in police procedure which adopted procedural justice elements. The study varied police actions during encounters with drivers in Random Breath Testing contacts. In Australia, a police stop for the purposes of random breath testing for alcohol is the most common reason people have contact with police. The study used a randomized field trial design to examine whether introducing elements of procedural justice into the breath testing encounter could increase perceptions of procedural justice and police legitimacy. Police in the experimental condition were provided with a scripted procedural justice protocol. This protocol was longer than the standard control protocol. In the procedural justice protocol, officers were trained to focus on four procedural justice elements: voice, neutrality, trustworthiness, and respect.

To provide voice the officer gave the stopped driver a newsletter with recent crime news from their area. They asked if the driver had any questions or suggestions about crime issues or how to conduct policing in their area. To communicate neutrality the officers explained the procedures being followed. They told the driver that they had not been singled out for the random drink driving test. Instead, they had been stopped randomly. They also explained that the purpose of the police procedure was to reduce alcohol-related accidents. To develop trustworthiness officers communicated concern for people in the community. They noted that their actions were motivated by concerns about the driver and the community. Officers indicated the number of deaths from drunk driving incidents and noted that police hated to have to tell a family that someone they care about had died. They asked the driver to help the police reduce accidents by driving carefully. After the driver took the breath test, the officers were instructed to try to end the interaction on a respectful note with a gesture of courtesy toward the driver (e.g., "thank you for maintaining your car"). The officer then invited all drivers to complete a short survey of their experiences of the encounter and to return it in a provided reply-paid envelope in their own time. In the control condition, in contrast, drivers were pulled over by a police officer and simply instructed to provide a specimen of their breath for alcohol content testing. If the recording came back negative, drivers were handed a survey and were allowed to continue with their journey. A total of 21,000 drivers were involved in the study.

Survey responses from 1,645 drivers exposed to the experimental condition and 1,102 drivers from the control condition were received. Evidence from the study suggests that the procedural justice approach yielded a number of desirable benefits. Relative to the control group who did not receive the procedural justice protocol, it increased the view that the police are fair and trustworthy and left citizens more satisfied with the encounter. It also raised levels of confidence in the police and increased subsequent willingness to cooperate with police. Hence, the police were able to implement an enforcement action while building legitimacy through procedural fairness (see also Mazerolle et al. 2012b).

While the Queensland Random Breath Testing Study involved a specific police-citizen interaction, building police legitimacy need not be linked to such a specific encounter. Police programs that aim to build police legitimacy can also apply to general police efforts to engage with the community. For example, the police can conduct meetings with people in the community to hear about community concerns. They can also communicate with the public through newsletters, bulletins, or through the media. A recent study from the United Kingdom has found that the police can communicate concerns effectively and improve confidence in police by creating and disseminating newsletters (see Hohl et al. 2010). The study found that trust and confidence in police in London was much higher among people living in suburbs that received newsletters about police engagement in their neighborhoods. For people living in neighborhoods that did not receive the newsletters, perceptions of police legitimacy were lower. While both these examples support the idea that police legitimacy can be enhanced by direct police communication showing concern for the public, more research is needed in this space to ascertain whether procedural justice-based policing can be put into practice effectively for different groups of people, or in different contexts.

Controversies

The discussion presented above suggests that procedural justice-based policing shows much promise for shaping public perceptions of police legitimacy and for shaping people’s willingness to cooperate with police and comply with the law. However, despite the apparent success of procedural justice as an effective policing strategy, research in this field is not without its limitations. Several continuing problems or controversies with this body of research remain. Three of the main issues will be highlighted here.

First, Reisig et al. (2007, p. 1006) have noted that much of the survey research in this area has inconsistently operationalized key constructs and has done little to evaluate the construct validity of existing scales. They noted that measures of procedural justice and police legitimacy have differed from one study to the next. They state that this is an important concern given the interest in procedural justice policing, the number of police-citizen interactions every day, and the need for police to secure citizen cooperation and compliance. They argued that given the lack of attention by researchers to develop reliable and consistent scales across different studies, it raises a concern as to whether the measured variables across different studies reflect the theoretical constructs of interest. If measures are inconsistent or not measuring what is intended, it may lead to misleading and inaccurate conclusions across different studies. To rectify this issue, Reisig and his colleagues suggest that more needs to be done in future research to refine the scales commonly used to study police-citizen relations and to test the key propositions of the procedural justice-based model of policing using these refined measures. If the results continue to be consistent and continue to reveal the importance of procedural justice to shaping police legitimacy and compliance-related behaviors, then practitioners and researchers can be more confident in the findings.

A second major limitation of the procedural justice literature is the tendency for researchers to (1) overemphasize the relationship between procedural justice and compliance, not only in the short term but also in the long term, and (2) to underemphasize the role of instrumental factors such as outcome favorability or deterrence in shaping behavior (for a detailed critique of the procedural justice policing literature, see Tankebe 2009b). Teasing apart whether compliance stems from procedural justice or instrumental factors in any given police-citizen encounter is difficult.

Tankebe (2009b) uses research from the field of restorative justice to highlight the first issue. He notes that one of the more robust findings from the restorative justice literature is that offenders who have experienced a restorative justice conference, relative to those who have experienced traditional court procedures, tend to evaluate the experience more positively on aspects of procedural justice. However, studies that have evaluated the long-term effectiveness of restorative justice conferences on offending behavior have tended to find that they reduce recidivism in the short term but that the effect on long-term law-abiding behavior is less conclusive. If procedural justice leads to long-term behavioral improvements, then one should expect to see conclusive evidence for both short- and long-term reduction in repeat offending among participants of restorative justice conferences.

Relevant to the second issue, it has been suggested that procedural justice scholars have tended to underemphasize the importance of instrumental factors in shaping people's views and behaviors toward authorities. By being neutral across all situations, police may be able to enhance the impression that they are being fair, but such a strategy can sometimes seem off-putting to citizens who expect a more assertive response to a problem. For example, Herbert (2006) cited the example of citizens who were calling on police in Seattle to deal with absentee landlords who failed to adequately screen or regulate their tenants and thus enabled ongoing street level crime in the area. Police officers reminded the concerned citizens that they were unable to police private property arrangements. Such a response did not allay citizens' concerns and in fact led to police being viewed as unresponsive and illegitimate. Hence, Herbert argued that in such situations, outcomes may be what matters to people and that on some occasions a procedural justice-based policing approach can "perhaps imperil police legitimacy as much as enhance it" (p. 498). As noted earlier, a growing number of studies have also shown that under some circumstances, outcomes may matter more to people than fair treatment. Understanding the context surrounding when this may be the case is important and should not be underemphasized by future research studies.

Finally, the third major criticism that has been raised in relation to the procedural justice literature is the preoccupation with the utilitarian effect of procedural justice on compliance-related behaviors. It has been noted that police practitioners and researchers often overemphasize the value of procedural justice for securing cooperation and compliance, rather than promoting it as a good in itself (Tankebe 2009a, b). The police have an intrinsic obligation to exercise their authority in a procedurally fair way, irrespective of any instrumental benefit such an approach may have in facilitating their role in maintaining social order. Both researchers and police practitioners need to keep this in mind when advocating a procedural justice-based policing approach.

Despite these criticisms, however, it is clear that procedural justice-based policing has an important role in policing practice. As the review above suggests, such an approach can serve to improve police-citizen relationships; it can improve the public's willingness to cooperate and comply with the law while at the same time being of intrinsic value in and of itself.

Profiling Arson

Katarina Fritzon, Rebekah Doley and Ryan Bell
Australian Centre for Arson Research and Treatment, Bond University, Robina, QLD, Australia

Overview

Criminal psychological profiling is the forensic technique of inferring personal, psychological, demographic, and behavioral characteristics of offenders based on crime scene evidence. While the majority of research concerning criminal profiling has been focused on the investigation of crimes of sexual violence such as murder and rape, criminal psychological profiling is frequently described as being applicable to the investigation of serial arson crimes, and the frequency with which psychological profiling has been used in the investigation of arson crimes has been growing steadily over the past 30 years (Drabsch 2004; Kocsis 2004, 2006; Turvey 1999). This current entry reviews the growing body of literature in relation to arson profiling, especially focusing on approaches that have published a specific methodology that applies to arson, as opposed to approaches that have a generalized methodology that is not necessarily differentiated for arson.

Investigating Arson

The increased interest in the application of profiling techniques to assist arson investigation may be due, in part, to the difficulty associated with the detection and prosecution of arson offenses; in the 2003 Uniform Crime Report, the United States Department of Justice states that arson has one of the lowest clearance rates of any major crime (FBI 2003). Within the United States only 18.2 % of known arson incidents were cleared by arrest in 2010 (FBI 2011), which is comparable to other developed nations including Canada (16.4 %; Statistics Canada 2011) and New Zealand (19.6 %; Statistics New Zealand 2011). The ability, then, to classify arson offenders into discrete offender profiles is innately appealing to authorities tasked with the responsibility of investigating and apprehending arson offenders, allowing fire investigators to narrow down a suspect pool according to assumed characteristics of an offender.

Approaches to Profiling

Historically, the classification of arsonists has often been arbitrary, with categories based on simple characteristics of a fire-setting group (e.g., children) or on the basis of psychological diagnoses (Lewis and Yarnell 1951) or apparent motive (Bradford 1982; Icove and Estepp 1987). It was only in the 1990s that, following the methods and procedures utilized by the Behavioral Science Unit (BSU) of the United States FBI, a typology-based profiling system of fire-setting behavior was proposed that purported to profile offenders based on a relationship between crime scene features and various personal characteristics of the offender (Douglas et al. 1992). While the approach described by the BSU was (and remains) the most commonly used profiling framework employed by police and firefighters to classify arson offenders by investigators around the world (Stauss 1998), it has been criticized by some researchers as lacking theoretical grounding (Canter and Heritage 1990). To address this perceived gap, Canter and Fritzon (1998) attempted to apply a more rigorously scientific approach to the profiling of arson offenders, identifying statistically significant relationships between crime scene behaviors and offender personal characteristics across four main behavioral themes. Kocsis and Cooksey (2002), utilizing a procedure similar to the method employed by Canter and Fritzon, also identified significant relationships between crime scene behaviors and offender characteristics among serial arson offenders only, yielding four additional behavioral themes.

While many classification systems have been described in the literature to typify arson offenders, these three classification systems remain the only widely disseminated frameworks that purport to profile arson offenders by inferring personal and psychological characteristics based on crime scene evidence. While the three frameworks canvassed within this entry have a great deal of similarity, it is important to point out that differences between these classification systems may represent differences inherent in the theoretical background and methodology employed by the authors of each framework and may not reflect strengths or weaknesses when compared to each other. In spite of the research described, there remains a surprising dearth of empirical studies on the topic of profiling arson offenders or arson crimes from criminal investigations, and there has been little progress toward a definitive method of profiling arson. Further research is needed to validate a comprehensive classification framework that can adequately represent the range and depth of arsonist behavior and characteristics.

Motivation-Based Profiling

While criminal profiling efforts have been described in the available literature as occurring during World War II and through the 1950s, psychological profiling was only added as an adjunct to the normal instructional programs of the Behavioral Science Unit at the Federal Bureau of Investigation in the United States in 1980 (Depue 1986). In 1981, the BSU developed the Violent Criminal Apprehension Program, a system to collect, organize, analyze, and disseminate information about violent crimes, which was incorporated with the BSU in 1984, forming the National Center for the Analysis of Violent Crime (NCAVC) within the FBI (Depue). While the principal aim of the NCAVC was the profiling of sexual and violent offenders, the methodologies employed by this program were subsequently applied to the criminal profiling of arson offenses. The NCAVC is presently responsible for the largest body of research examining arson for the purpose of criminal psychological profiling; the profiling methodologies employed by the ATF and FBI in the United States and a number of law enforcement agencies abroad are advised by research produced by the NCAVC (Douglas et al. 1992; Rossmo 2000).

The central theme of the research produced by the NCAVC was the development of discrete offender typologies based on motive categories. According to the NCAVC, recognizing the motivation of an offender can allow an investigator to recognize personal traits and characteristics of an offender; these characteristics can form the basis of discrete offender profiles which can be used to help identify arson offenders or rule out non-offenders (Douglas and Olshaker 1999; Douglas et al. 1986). This research culminated in the description of six motive classifications that appeared to be most effective in identifying offender characteristics: *vandalism*, *excitement*, *revenge*, *crime concealment*, *profit*, and *extremist*. These six categories are detailed in the NCAVC's Crime Classification Manual (Douglas et al. 1992).

Vandalism-motivated arson arises from a malicious and mischievous desire to cause destruction or damage. According to Douglas et al. (1992), the typical crime scene of a vandalism-motivated arsonist will reflect the spontaneous nature of the offense. This can include evidence of poor planning (e.g., leaving evidence at the scene, such as footprints and fingerprints) and the use of direct, handheld ignition to materials available at the scene. Sapp et al. (1995) note that targets of vandalism-motivated arsonists tend to be educational facilities; however, targets tend to be those of opportunity and can include other residential properties and vegetation, which will generally fall within a small geographical area which will be known to the offender. Among fires set in secured structures, offenders will frequently gain access via windows, and evidence will often show mechanical breaking of glass. Other signs suggesting vandalism can include graffiti left at the scene, general destruction of property, and/or property missing from the scene. Time of offending generally occurs in the hours after school or work and on weekends.

Douglas et al. (1992) describe the typical offender as a juvenile male with 7–9 years of formal education. The typical offender will have a record of poor academic performance and vocational history and is likely to be known by police and have an arrest record. It is also likely that the offender will be known to school authorities as being disruptive and have problems with authority. Compared to other motivations, vandalism arson frequently involves multiple offenders although, if the fire is set by a group, one personality tends to be the leader or instigator of the group.

Excitement-motivated arson deals with fires set to resolve a need for psychological excitement that is satisfied by fire setting and can include crimes committed for histrionic/heroic needs, to satisfy sexual feelings, to satisfy a need for stimulation, or as a result of psychotic delusion. A defining feature of this category is that the offender rarely intends the fire to harm people; this is frequently reflected in the type of property reflected (e.g., grass, brush, woodland, deserted construction sites, or vacant residential properties). As this category of fire setting is motivated by excitement, offenders frequently select a location that offers a good vantage point and will frequently interject themselves into the response or investigation of the fire.

Excitement-motivated fires are frequently set on properties adjacent to areas that are known to be frequently occupied. Fires are usually set using materials on hand and, among older offenders, accelerants are frequently used. Douglas et al. (1992) note that a small number of excitement fires are motivated by sexual perversion; finding ejaculate, fecal deposits, and/or pornographic material can help identify the motivation of the fire setter.

Douglas et al. (1992) describe the typical excitement arsonist as a juvenile or young adult male with 10 or more years of formal education. The typical offender within this category is described as socially inadequate, which may contribute to their inability to attain psychological excitement via pro-social means. Serial arson offenders frequently belong to this motivational category as, frequently, the psychological needs met through the fire setting are recurring (Sapp et al. 1994). A history of police contact for nuisance offenses is prevalent, with older offenders typically having a longer record. Excitement arsonists tend to remain at the scene, although those who leave frequently return to observe the results of their fire.

Revenge-motivated arson refers to those arson offenses that are set in retaliation for any real or imagined injustice, perceived by the offender. While this type of arson can span both well-planned, one-time events or serial events, this type of arson, unlike others, is always committed in response to a real or imagined stressor. Consequently, when this motive is suspected, a detailed and accurate analysis of the relationship between the victim and the offender is crucial (Sapp et al. 1995). Douglas et al. (1992) point out that the person or property victimized by a revenge arsonist will generally have a history of interpersonal or professional conflict with the offender. The NCAVC recommends that this motive be immediately considered when a low-risk individual or target suffers arson, particularly when the arson does not appear to be part of a series.

The Crime Classification Manual lists several subtypes of revenge arson that further identify the motivation of the offender: personal retaliation, societal retaliation, institutional retaliation, group retaliation, and others. The targeted property often varies with the subtype of revenge arsonist; an arsonist from the personal retaliation subcategory, for example, is more likely to burn items of significance to their victim such as clothing, bedding, or personal effects (Douglas et al. 1992). Arsonists seeking revenge against society, however, may exhibit displaced aggression by choosing targets at random, while other offenders may retaliate against institutions such as churches, government facilities, and universities. Compared to other categories, revenge arson attacks are more likely to use accelerant and, when accelerant is used, are more likely to use excessive amounts. According to some research (e.g., Sapp et al. 1994), revenge arsonists are the most prevalent among serial arsonists (Sapp et al. 1994).

Revenge arsonists are typically adult males with 10 or more years of formal education.

If employed, they typically hold blue-collar jobs and are of lower socioeconomic status. Douglas et al. (1992) describe a revenge arsonist as having close relationships, but state that these relationships tend to be unstable or short term. A revenge arsonist will often have prior law enforcement contact for property offenses such as burglary, theft, or vandalism. Alcohol use is common prior to committing this offense. The Crime Classification Manual specifies that the revenge arsonist typically acts alone and seldom returns to the crime scene, instead preferring to establish an alibi. Importantly, the offender will frequently express a short-lived sense of relief and satisfaction following the fire.

Crime concealment arsons are arson offenses committed as a secondary criminal activity to conceal a primary criminal activity. The targeted property for this offense can vary depending on the nature of the concealment. While it is tempting to assume that an arson committed for the purpose of crime concealment can demonstrate prior planning or premeditation, fire is notoriously efficient at memorializing evidence and inefficient at destroying biological evidence such as flesh and bone. Consequently, this type of fire is rarely of the organizational or sophistication level of the primary crime and is often set during periods of great stress and emotion which can interfere with an individual's ability to calmly think through their actions.

Liquid accelerant is commonly used when committing crime concealment arson, and the fire is usually set on or at the site of the primary crime. An investigator should expect to find more physical evidence, and a fire set in a more disorganized fashion, than with other arsons; this can lead to an increased risk of incorrectly assuming more than one offender, particularly if the disorganized fire follows an apparently organized burglary or homicide (Douglas et al. 1992).

The Crime Classification Manual states that crime concealment offenders tend to be young adults who live within the surrounding community and tend to be highly mobile. Alcohol and recreational drug use are common among this type of arsonist, as is a lengthy criminal history, frequently spanning a wide range of offenses. An arsonist who uses a fire to conceal burglary or auto theft is frequently accompanied by coconspirators and virtually always leaves the scene immediately and does not return. Generally this type of arson is seen as a one-time event and does not involve serial arson, although Sapp et al. (1994) found that crime concealment accounted for 5 % of the motives reported by serial arsonists.

Profit-motivated arson refers to any arson set for the explicit purpose of achieving material or financial gain. While other motivations of arson are differentiated in that they represent an expression of a psychological need, profit-motivated arson is unique in that it is committed for financial reasons. Consequently, Douglas et al. (1992) point out that, among the motivations for arson, profit-motivated arsonists exhibit the least amount of passion for their crime. This typology describes individuals who set fires to commit fraud (e.g., to collect insurance, to conceal loss, or to liquidate inventory) as well as individuals who set fires for hire (to commit fraud for a third party).

Because the destruction of property is the goal of profit-motivated arson and because this motivation is considered the least passionate, the crime scenes of a profit-motivated arson tend to demonstrate a more organized style, containing less physical evidence and more sophisticated incendiary devices. Crime scenes typically evidence an excessive use of accelerant, and multiple seats are evident. Items of value are often removed, or substituted with items of lower quality. The Crime Classification Manual suggests that fire investigators count the clothes hangers in the closets of burned residences to determine whether items have been removed beforehand.

As with revenge-motivated arson, establishing the victimology is critical in identifying this motive. Examining who is benefiting from the commission of the crime in an apparently motiveless arson could help contribute to an offender profile, and the Crime Classification Manual suggests that an offender's pre-offense conversations may provide indications of premeditation, such as warning co-workers not to attend work that day or a sudden change in an insurance policy. Icove and Estepp (1987) report that profit-motivated arson is less suitable to traditional profiling assistance, as no psychological needs are being met or are driving this behavior. Nevertheless, Douglas et al. (1992) suggest that the typical offender in this category is an adult male with 10 or more years of formal education. This offender likely has no police records, although if the fire is set by a "torch for hire," the primary offender will likely have a prior arrest record which may include a previous arson (demonstrating experience in committing this sort of crime). Offenders typically live more than one mile from the crime scene and are frequently accompanied to the crime scene by coconspirators; most leave the scene and do not return.

Extremist-motivated arsons are committed to further a sociopolitical cause. This includes arsons set for reasons of terrorism or civil disturbance and represents a very narrow range of arson offenses committed. Although few studies to date have found a significant population of arsonists for whom extremism represents a motivation, current NCAVC research suggests that extremist-motivated arson is on the increase, particularly following the terrorist attacks of Sept. 11, 2001.

According to the Crime Classification Manual, analysis of the targeted property is essential in the determination of this motivation category (Douglas et al. 1992). In order to qualify as an extremist-motivated arson incident, the target must represent the antithesis of the offender's beliefs. Examples include research laboratories and fur stores targeted by animal rights groups, abortion clinics targeted by extremist anti-choice groups, or businesses targeted by unions. As with profit-motivated arson, the crime scene typically reflects an organized and sophisticated attack with offenders frequently employing incendiary devices and accelerants, leaving little forensic information. While profit-motivated arson is clandestine, however, extremist arson is frequently committed to deliver a symbolic message and will often be accompanied by some form of message left at the scene or via a communique delivered to the media or local authorities claiming responsibility.

Extremist-motivated arson is difficult to profile due, in part, to the rarity of the crime in comparison to other arson offenders. Extremist arsonists are often more sophisticated offenders and will typically be well educated, literate, and politically active or aware. Of particular relevance to an arson investigator, the extremist offender is frequently readily identified with a cause or group, and interviews with the friends and family of a suspected arsonist may identify membership into a group. Offenders may have previous police contact for civil disobedience, trespassing, criminal mischief, or civil rights violations (Douglas et al. 1992).

A central premise of the profiling research described by the NCAVC is that inferences concerning an offender's motivation can be made from crime scene evidence and that a psychological profile can then be constructed from this motivation (Douglas and Burgess 1986; Douglas and Olshaker 1999). While this assumption has remained implicit within the profiling literature produced by the NCAVC, there is little empirical evidence suggesting that offender motivation can be successfully inferred from crime scene behaviors or that a psychological profile of an offender can be generated from an offender's motivations (Kocsis 2006). Additionally, while the motivational categories (and associated profiles) of arsonists are presented by Douglas et al. (1992) as representing discrete offender profiles, research investigating the clinical utility of these motivational categories suggests that arsonist motivations are frequently multidimensional. In a review of the motivations of 212 convicted serial arsonists, Sapp et al. (1994) found that 12 % of offenders reported multiple motivations spanning two or more motivational categories described by the NCAVC, and similar research has suggested that individual motivations for fire setting tend to be complex and multifaceted: in one landmark study, Lewis and Yarnell (1951) reported that elements of revenge were present in some form in nearly all cases of arson! While the motivations of an offender carrying out a crime would certainly be of interest to an investigator attempting to develop a profile, in light of the multidimensional nature of offender motivations, the number of inferences that can be drawn from this information may be limited.

The Action Systems Approach to Arson Profiling

According to Canter and Heritage (1990), the basic tenet of profiling is that offenders differ in the behaviors they exhibit when committing a crime and that there are associations between offender characteristics and the thematic focus of their crime. Within this framework, criminal profiling is developed solely on the classification of offense behaviors independent from any inferred motivations. Implicit within this framework is the assumption that offenders will show consistency between the nature of their crimes and other characteristics they exhibit in other situations. This is referred to by Canter (e.g., Canter and Youngs 2009) as the A-C equation and is a central tenet of the Investigative Psychology approach to offender profiling. While a single criminal action may be insufficient to make inferences concerning an offender characteristic, a group of actions together may represent a strong predictor of an offender's style.

Using a multivariate statistical methodology, Salfati and Canter (1999) examined the crime scene actions of a sample of 82 homicide offenders who victimized strangers and compared them to known characteristics of those offenders and found that those offenders who made an effort to conceal their crime (e.g., by hiding or transporting the body or theft of non-identifiable property) were more likely to have a previous custodial sentence. Profiling studies utilizing this model thus seek to thematically link crime scene actions to offender characteristics, to develop criminal profiles of offenders.

Canter and Fritzon (1998) explored the crime scene behaviors from 175 solved cases of arson in the United Kingdom for evidence of behavioral themes indicative of discrete offender profiles. Using a combination of multidimensional Scaling and content and thematic analysis, four behavioral themes emerged, and these were interpreted according to Shye's (1985) Action System Model of Functioning. The four themes were correlated with background characteristics of the known offenders. Using this method, four profiles were identified, which varied according to the apparent motive of the fire setting (instrumental or expressive) and the target of the fire setting (object or person). Thus, the four profiles described by Canter and Fritzon were termed *instrumental-object* (arson committed in order to satisfy general criminal goals), *instrumental-person* (arson committed in order to extract revenge against another person), *expressive-object* (arson committed to provide emotional comfort or satisfaction), and *expressive-person* (arson committed to attract attention).

Instrumental-object arson is described by Canter and Fritzon (1998) as any arson set as an "attempt to change aspects of the object where the change will be of direct benefit to the fire setter." Fires set to conceal other crimes would fall under this category; examples include a burglar setting fire to a residence to hide forensic evidence or a business owner setting fire to company records to hide corporate malfeasance. Aspects of this type of arson have a great deal in common with the crime concealment motivational category described by Douglas et al. (1992) as well as the arson-for-profit classification described by Barnett (1992) and Vreeland and Lewin (1980). These arsons are seen as opportunistic, in that the decision to commit the crime may only be arrived at when the individual recognizes the environmental possibilities. The offense is viewed as merely fulfilling general criminal goals or satiating a need to commit damage or vandalism and thus has little personal meaning to the offender.

This arson profile is associated with arson that is set by multiple offenders. It frequently occurs on uninhabited properties and co-occurs with other property crimes such as theft or vandalism. As the goal of the arson tends to be property motivated (as in the destruction of property for gain is the explicit goal), it is rarely associated with fires set in a manner where death or injury is likely to occur. Spree arsonists (i.e., those who set fire at three or more separate locations with no emotional cooling-off period between them) are associated with this profile.

Instrumental-person arson is described as arson that occurs "as a reaction to frustration by another person which the fire setter wishes to hurt or remove" (Canter and Fritzon 1998). This type of arson generally emerges as a consequence of a dispute between the offender and another person, and, as a result, a specific triggering event can usually be identified by the offender. In this case, fire serves as a method with which the offender can retaliate, in order to address feelings of injustice on the part of the offender. Consequently, this type of arson is frequently committed against items of symbolic significance to the victim such as important property, heirlooms, or photographs.

Unsurprisingly, this arson profile is associated with arson that occurs following an argument and following threats of arson. As this arson occurs in response to an argument or conflict, the victim is usually known to the offender and is frequently a close friend or romantic partner. Vehicular arson is associated with this arson profile as is evidence of planning including the use of accelerants.

The third profile of arson described by Canter and Fritzon (1992) is termed *expressive-object* and refers to arson which involves "the demonstration of aspects of the arsonist on the external world." Canter and Fritzon draw a comparison between this category and Geller's (1992) description of fire setting as a means of emotional acting out and suggest that fire setters within this profile will choose targets with symbolic, emotional significance. This type of fire is more likely to proceed in a serial manner, suggesting an inherent fascination with fire or the trappings of fire. This hypothesis is further supported by the observation that fire setters within this profile are more likely to remain at their crime scene to observe their fires.

As this profile is associated with the use of fire for emotional release, it is associated with offenders who remain at the scene. It is also associated strongly with individuals who commit multiple fires (Canter and Fritzon 1998). As this profile is hypothesized to represent offenders who set fires for emotional reasons, nonspecific but identifiable triggers are associated with this profile as offenders may set fires to cope with emotionally charged events. Additionally, this profile is associated with the target of commercial buildings and hospitals which may cause more attention to be focused on the individual or on the event, corresponding to the emotional symbolism the fire may hold to the offender.

The final profile described by Canter and Fritzon (1998) is termed *expressive-person* and refers to arson which is "turned inward to lead to the disintegration of the fire setter him/herself." Broadly, this category refers to arson committed for the purpose of self-harm or suicide or arson committed for the purpose of seeking attention from family or authorities. Canter and Fritzon point out that, typically, this style of arson is addressed in a therapeutic context rather than a forensic context and is thus seldom described within the available forensic literature. It can frequently occur in the context of mental illness, particularly depression or psychosis.

This profile is associated with the use of fire as an avenue to commit some sort of self-harm so, unsurprisingly, it is associated with suicide notes left at the scene of the crime, is frequently directed at the self, and frequently occurs in the offender's own home. Due to the mortal intent of this profile, offenders frequently set fires in a manner where injury or death is likely to occur, and offenders are likely to remain at the scene (presumably to ensure they succeed in their intent).

In a pair of follow-up studies, the four-profile model proposed by Canter and Fritzon has been validated among a sample of adult prisoners (Almond et al. 2005) and a sample of juvenile fire setters (Santtila et al. 2003). Kocsis and Cooksey (2002) point out, however, that the model proposed by Canter and Fritzon was conducted using a sample containing both serial and one-time arson offenders. While the study had enormous implications to the field of arson profiling, several researchers (e.g., Geberth 1996) have pointed out that the technique of profiling has been found to have much more utility in the investigation of serial offenses in general, as non-recidivistic crimes are typically solved via regular investigative procedures.

The Profiling of Serial Arson Offenders

Kocsis and Cooksey (2002) examined 148 incidents of arson committed in New South Wales and Victoria in Australia, in order to determine the extent to which offense behaviors could be used to classify offenders into discrete offender profiles from which offender characteristics could be inferred. Although the methodology, data analysis, and aims were similar to the study conducted by Canter and Fritzon (1998), all cases of arson examined by Kocsis and Cooksey were each part of a series of three or more arsons committed by a serial arson offender. It was thus a methodological aim of Kocsis and Cooksey to develop offender profiles that could be applied to recidivistic arson, on the assumption that development of these profiles would provide greater clinical and investigative utility than the profiles developed through previous research efforts. Using multidimensional scaling techniques and cluster analysis to examine 71 crime scene behavior variables, a total of four offender profiles were generated: *thrill*, *anger*, *wanton*, and *sexual* fire setters.

Kocsis and Cooksey (2002) describe the *thrill pattern* as encompassing those arsons that are set to satisfy nonsexual needs of stimulation and excitement. Within this profile, offenders are not represented to hold any animosity toward their target or victim; rather, they are attracted to the element of risk associated with the act (hence the label of "thrill" for this pattern). This profile can be likened to the "Excitement" profile of arson described by Douglas et al. (1992) although, while Douglas et al. group arsons which sublimate sexual needs in this category, Kocsis and Cooksey specify that sexually motivated arson represents a separate and distinct psychological profile and use the term "recreational fantasy" to describe the theme found within this arson profile. This profile will include arsonists such as firefighters who set fires in order to increase activity for themselves, teenagers who set fires in order to increase sensory arousal, and individuals who set fires in order to interject themselves with the firefighting effort.

Common crime scene behaviors associated with this pattern include variables associated with behavioral sophistication and planning. Offenders will usually be quite mobile, often choosing their target beforehand and travelling more than one mile to set their fire. While accelerants and materials will frequently be brought to the scene in order to create a larger fire, because fire tends to be the goal (rather than the destruction of property or harming another party), targets tend to be bush, grassland, or vegetation where risk of harm to other people will be minimized. As with the excitement profile described by Douglas et al. (1992), offenders within this profile will frequently set their fire in highly visible locations and will frequently remain on the scene (and may be subsequently identified and apprehended). A series of fires set by an offender within this profile will usually have less crime scene behaviors in common from scene to scene than a series committed by other profiles, as offenders within this profile are more likely to vary their choice of targets, methods of ignition, and other crime scene behaviors.

A number of offender characteristics are associated with this arson profile. Thrill arsonists are more likely than other arson offenders to set fires with co-offenders, are more likely to be socially affluent (e.g., they are less likely to live alone and more likely to be involved in social and romantic relationships), and are more likely to be employed. This follows from the observation that this pattern of arson is often committed to create excitement for a group of offenders (as with the example of a fire fighter setting a fire to provide action for his department or a teenager setting a fire with a group of friends). Interestingly, Kocsis and Cooksey (2002) point out that arsonists following this pattern frequently have poor dental work and some type of outstanding physical feature such as scarring according to information contained within the offenders police files. Kocsis and Cooksey surmise that, because these offenders are not physically attractive, their fires may represent the sublimation of possible sexual drives.

The second profile described by Kocsis and Cooksey (2002) is termed the *anger pattern* and comprises arsons in which animosity or rage forms the principal motivation for the offense. In contrast to the thrill pattern, the fire is not the principal focus of this offense; rather, the fire is a vehicle through which the offender can facilitate personal harm to a specific victim. Consequently, offending behaviors associated with this pattern demonstrate an intent to cause specific and personalized harm to a victim. This profile is similar to the *instrumental-person* profile described by Canter and Fritzon (1998) and the *revenge-motivated* arsonist described by Douglas et al. (1992). Kocsis and Cooksey point out, however, that both the instrumental-person and revenge profiles described in previous studies require an identifiable relationship between the offender and the victim. Within the anger profile, the relationship between the offender and the victim is based more on cognitive knowledge or familiarity. Within this profile, offenders may not harbor any previous animosity toward the victim (or have a relationship at all!), but may attack due to a perceived relationship. This pattern, thus, is analogous to sexual murderers or serial rapists, who may choose their victim by type or perceived relationship. The common element between these offenders and arsonists within the anger profile is the presence of an unfocused internal rage. Offenders who commit arson in retaliation for a perceived slight or serial arsonists who target potential romantic partners who they perceive would reject them would both be included within this pattern.

Crime scene behaviors indicative of this pattern include evidence that the offense was designed to cause personal harm to the victim. Common within this profile is the tendency for offenders to physically destroy possessions of the victim prior to committing the offense, particularly items of personal significance to the victim or offender (e.g., photographs, souvenirs, gifts from other individuals). Targets of this pattern of arson commonly include residential properties or motor vehicles, which is unsurprising given the personal nature of this offense. It is also likely that the intended target of the offense will evidence a break-in and that the fire will be started from within the structure. The intent to cause harm will also be evident in the choice of conveyance for the fire; offenders within this profile will frequently use trailers to ensure a thorough spread of the fire.

Kocsis and Cooksey (2002) noted that, compared to other profiles, offenders within this profile tend to be foreign nationals who are more likely to be bi- or trilingual and to possess a foreign accent. As the goal of this pattern of arson is generally the causing of harm to someone else rather than any fascination with the fire itself, offenders within this profile rarely remain on the scene. While Kocsis and Cooksey do not comment on the expected proportion of serial arsonists that may belong to each profile, other researchers (e.g., Sapp et al. 1994) have noted that anger and revenge appear to be the most frequently cited motive among serial arsonists studied.

The third profile described by Kocsis and Cooksey (2002) is labelled the *resentment pattern* and includes arsons set in a generalized sentiment of animosity. Like the anger classification, this profile contains an element of displaced aggression; however, the anger displayed within this category will typically not be directed at a specific target – rather, it will be directed at a vague classification. This profile has some thematic similarity to the vandalism-motivated arson described by Douglas et al. (1992) and the instrumental-object profile outlined by Canter and Fritzon (1998), in that all three profiles refer to an unfocused nature of attack. Consequently, many of the observations made of offenses committed within this profile are similar to the observations made of vandalism and instrumental-object offenders. Examples of offenders who would be included within this profile are juveniles setting fire to a school or areas of bushland.

Within the model proposed by Kocsis and Cooksey (2002), the principal crime scene behaviors indicative of fires falling within this profile are the choice of target. School properties, state-owned properties, and commercial properties are strongly associated with this profile, which is consistent with target choices within the vandalism profile outlined by Douglas et al. (1992).

This choice of targets may be reflective of a general sentiment of displaced aggression against public institutions, which would support the hypothesis that fires within this profile represent a sublimation of anger and resentment toward society. Examination of the MDS plot generated by Kocsis and Cooksey suggests that the majority of behaviors associated with this pattern of arson are deliberate and planned and are committed against more secured targets with access restricted.

Few individual offender characteristics are associated with this profile. Offenders within this profile typically possess a prior criminal record, which follows the hypothesis that these offenders will possess a general animosity toward society, and offenders may present with a pattern of authority issues and general antisocial actions. As with vandalism-motivated arson, individuals following the animosity pattern will light fires on weekends. While vandalism-motivated arson is described by Douglas et al. (1992) as largely being committed by juveniles, Kocsis and Cooksey (2002) do not comment on the anticipated age of this sort of offender, although they note that "school fire arson" (in which educational facilities are attacked by juveniles) is overrepresented within this profile. While the researchers do indicate that an element of animosity or resentment is a necessary ingredient for an offender to be included in this profile, Kocsis and Cooksey suggest that this profile warrants further study, in order to determine *why* this animosity develops.

The final profile outlined by Kocsis and Cooksey (2002) was termed the *sexual profile*; this embodies an offense style associating the ignition of fire with sexual excitement and gratification. The inclusion of this pattern is consistent with early psychodynamic literature (e.g., Freud 1932; Macht and Mack 1968) which typified recidivistic arson as being principally motivated by repressed sexual drives. The most distinguishing feature of this pattern of arson is evidence of sexual activity by the offender at or near the scene of the crime. This profile of arson offending is difficult to reconcile with the profiles furthered by earlier research, which may be attributed to the choice of offenders sampled for Kocsis and Cooksey's study (i.e., only serial arsonists, rather than serial and one-time arsonists). The authors do note, however, that the sexual profile does bear some resemblance to Cantor and Fritzon's (1998) *expressive-object* pattern, in that both profiles are concerned with committing an offense to achieve emotional relief. Additionally, while the excitement profile described by Douglas et al. (1992) describes arsonists who offend in order to achieve excitement, sexual excitement is included as a subclassification of excitement arsonists in the Crime Classification Manual; it may be the case that sexually excited offenders from within this profile are more likely to reoffend, resulting in their being represented in greater numbers within Kocsis and Cooksey's sample.

As expected, the crime scene behaviors with the strongest association with this profile are any evidence of sexual activity such as semen left at the scene, sexual aids (e.g., pornographic material), or fecal matter. Common targets include state-owned property on easily accessible premises or outdoor settings. This is consistent with the hypothesis that offenders will commit this crime in order to attain sexual release; offenders will typically choose targets which are easily accessible and highly visible, so that they can be watched to attain the required level of stimulation. Consequently, offenders will frequently remain at the crime scene in order to observe the fire or participate in its extinguishing. As the focus tends to be on the fire itself rather than the destruction of property, these arson attacks tend to be small in size and rarely escalate to major attacks. Common targets include trash receptacles, post office boxes, and public toilets.

Few offender characteristics are noted for this profile although Kocsis and Cooksey (2002) do point out that, compared to other offender profiles, arsonists following this pattern tend to have dark-colored hair and eyes – although the authors point out that these variables were included in the analysis in order to provide richness of data and were not designed to racially stereotype any group of offenders. Offenders are also likely to have a history of domestic travel, although they typically do not travel far to commit their offense, instead choosing to remain in areas familiar to them.

While the research conducted by Kocsis and Cooksey (2002) identified four major profiles associated with recidivistic arson offenders, a novel finding of their research was a cluster of arson crime scene behaviors that seemed to be common among all arson offenses committed by the offenders within their sample. Termed the *common behavior profile*, this profile provides a core description of the characteristic behaviors common to patterns of serial arson. While the four profiles outlined by Kocsis and Cooksey provide important clues to differentiate serial arson offenders from each other, the common behavior profile can provide important clues to differentiate serial arson offenders from one-time or non-arson offenders.

A central element of all serial arson offenses reviewed by Kocsis and Cooksey (2002) is the elements of planning, an observation matched by the finding that a relationship between the victim and the offender existed in nearly all cases of arson committed in the sample. This finding is inconsistent with the profiles outlined by Douglas et al. (1997) (notably the vandalism and crime concealment profiles) and the instrumental-object profile furthered by Canter and Fritzon (1998), with both studies reporting that planning was not an essential component of an arson offense. Kocsis and Cooksey address this incongruence, however, by pointing out that planning may be an element differentiating serial arsonists in particular and that crime scenes demonstrating planning of the offense may indicate the work of a serial arsonist. Kocsis and Cooksey also point out that serial arsonists across all profiles commonly enter their targets and steal items of value before setting their fire, a constellation of behaviors suggesting a greater disregard for the risk of apprehension or detection. This is in contrast to other crime modalities, such as murder or rape, in which offenders are typically deterred by greater risk of apprehension.

Future Directions and Conclusions

Though underdeveloped, the field of profiling arson offenders appears to hold a number of exciting possibilities for future advancement. In spite of the profiling systems described to date, however, no system has been developed that adequately represents the range and depth of behaviors and characteristics of arsonists. This may be partly attributed to a number of methodological and practical considerations that limit investigation into arson profiling. Within this section, we will outline what we believe are the most significant problems in this area and make suggestions for further advancement within this field.

A concern inherent in the study of arson profiling (and, in fact, arson literature in general) is an innate sample bias. As mentioned previously, arson has a low clearance rate, and what is known about arsonists pertains only to those fire setters who are identified and apprehended and conclusions drawn from such a sample may not be truly representative of the arsonist population. It is worth noting that the profiles developed by Canter and Fritzon (1998) and Kocsis and Cooksey (2002) were derived from an analysis of solved arson offenses in the United Kingdom and Australia, respectively, and the profiles generated by the NCAVC were developed based on case reviews of solved arson offenses (Douglas et al. 1992). While using solved cases represents the only method that can be used to marry crime scene details to offender characteristics, it is impossible to determine the extent to which these profiling efforts can be generalized to unsolved offenses. Future research may address this concern by collecting data from individuals imprisoned for other offenses but who may have fire-setting histories for which they were not apprehended. As investigative techniques evolve, improving the clearance rate of arson and contributing to a larger (and more representative) sample size of solved arson cases, the present frameworks may be found to have inadequate empirical depth to account for the relationships between offender characteristics and crime scene behaviors.

It is important to consider, also, the origins of any classification system developed to profile offenders. Doley (2003) points out that asking questions such as who collected the data and why, the type of sample the information was drawn from, and for what purpose the typology was originally intended for are important for identifying any potential weaknesses that are inherent within that system. While the profiles developed by Kocsis and Cooksey (2002) differ in several fundamental ways from the profiles generated by Canter and Fritzon (1998), the authors point out that this is likely due to their decision to only include serial arson offenders in their sample and the typologies generated by this approach are only applicable to the profiling of recidivistic arson offenders. While this methodological concern may limit the extent to which Kocsis and Cooksey's approach can be generalized to the profiling of arson offenders generally, it also suggests potentially fruitful avenues of future research, for example, further studies investigating the extent to which non-serial arson offenders can be profiled using this framework. Similarly, while the profiles generated by the BSU have been criticized by some researchers as lacking theoretical grounding (Canter 1989, 1994), the methodology used to generate these profiles is the same as the methodology used to generate all profiling frameworks currently used by the United States FBI (Dietz 1987; Rossmo 2000). Certainly, these profiles do result in a series of testable hypotheses and further research could be conducted to determine the extent to which these profiles can be used to profile offenders.

While the research canvassed within this entry represents a series of admirable attempts to provide a framework for the profiling of arson offenders, understanding of this field is underdeveloped and limited to only a handful of published studies. Given the amount of theory proliferation in other areas of offender profiling in recent years, this dearth in the literature is especially remarkable. In spite of a handful of published frameworks purporting to profile arson offenders, research validating these frameworks is virtually nonexistent and crime scene investigators, professional profilers, and mental health professionals are forced to employ profiling methodologies which are not empirically validated. Criminal profiling is frequently cited as being helpful in the criminal investigation of violent and sexual crimes by criminal investigators (Geberth 2006; Holmes and Holmes 1992, 2000, 2008; Turvey 1999). Thus, it is likely that professionals would benefit substantially from further development in the field of arson profiling.

Propensity Score Matching

Ben Grunwald and John M. MacDonald
Department of Criminology, University of Pennsylvania, Philadelphia, PA, USA

Overview

Multivariate regression-based methods dominate the research literature in criminology for estimating the effects of causal variables. As many scholars have noted, however, regression suffers from a number of methodological and practical limitations (Berk 2004). On its own, regression provides a poor analytic framework for conceptualizing causal inference, offers limited tools to address nonlinear relationships, and encourages researchers to cherry-pick models in a manner that may bias the results of a study. Despite these issues, criminologists have failed to take full advantage of other approaches to observational research developed in the fields of statistics and biostatistics.

One alternative is propensity score matching (Rosenbaum and Rubin 1983), an analytic method closely associated with the Rubin Causal Model (RCM; Rubin 2008; Holland 1986). Though a number of criminological studies have used propensity score approaches (e.g., Haviland et al. 2007; MacDonald et al. 2007; Paternoster and Brame 2008), it remains an underused strategy for causal estimation. This entry draws heavily from the work of Rubin and Rosenbaum to outline the RCM and propensity score matching and to demonstrate their application to theoretical and applied criminology (see, e.g., Rosenbaum and Rubin 1983; Rosenbaum 2002, 2010; Rubin 2008).

This entry begins with a brief overview of the RCM and propensity score matching. It then describes an implementation of propensity score matching to answer a traditional question of criminology: what is the effect of gang membership on violent offending? The final section provides a methodological assessment of the advantages of propensity score matching relative to traditional regression-based methods. For many applications, the former is a superior approach that provides substantial benefits over the regression-based methods typically used in criminology.

The General Framework of the Rubin Causal Model and Propensity Score Matching

For most of the twentieth century, the frameworks guiding experimental (Fisher 1935; Cochrane and Cox 1950) and observational studies (Blalock 1964; Kenny 1979; Cochran 1983) were distinct from one another. Social science methodologists developed quasi-experimental approaches to generating causal inference in observational studies, but these involved little mathematical formalization (Campbell and Stanley 1963). The two domains of experimental and observational research were formally unified in the 1970s in the field of statistics by the development of the RCM (Rubin 1974). For current purposes, the RCM contains two relevant parts: (1) the potential outcomes framework and (2) the concept of an assignment mechanism (Rubin 2008).

The potential outcomes framework provides a conceptual approach for understanding causal inference. A causal effect is understood as the difference between the value of an outcome variable subject to different treatments. For example, the causal effect of gang membership on violent offending for some adolescent *i* is the difference between the number of violent crimes that adolescent would commit if he were part of a gang $(Y_i|T_i = 1)$ and the number of violent crimes the same adolescent would commit if he were not part of a gang $(Y_i|T_i = 0)$. It is expressed formally:

$$(Y_i|T_i = 1) - (Y_i|T_i = 0) \qquad (1)$$

Unfortunately, for any single individual, one can only observe the outcome variable subject to the treatment assignment that he or she actually receives; one cannot observe the counterfactual outcome, the outcome one would have observed had the individual not received the treatment. Without observing the counterfactual outcome variable, it is impossible to calculate the treatment effect for any particular individual.

Though calculating the counterfactual outcome for any single individual is out of the question, it is possible to estimate the mean of the counterfactual outcome variable for a sample of individuals: the mean of the outcome variable in the control group can serve as the mean of the counterfactual outcome variable for the treatment group. By calculating the difference between the mean outcome variable for subjects who receive the treatment $(E(Y_i|T_i = 1))$ and the mean outcome variable for subjects who do not receive the treatment $(E(Y_i|T_i = 0))$, one can estimate the mean causal effect of the treatment. It is expressed formally:

$$E(Y_i|T_i = 1) - E(Y_i|T_i = 0) \\ = E([Y_i|T_i = 1] - [Y_i|T_i = 0]) \tag{2}$$

Whether Eq. 2 produces an unbiased estimate of the mean treatment effect depends upon a strong assumption that, aside from treatment assignment, subjects in the treatment and control groups do not differ systematically on variables that influence the outcome. Imagine, for example, that drug use increases offending independently of gang membership and that drug use is twice as common among gang members as non-gang members. Under these circumstances, the treatment and control group differ systematically on an important pretreatment covariate, and the control group cannot provide an unbiased estimate of the mean counterfactual outcome variable for the treatment group.

Randomized experiments are the strongest method for ensuring that the treatment and control group are balanced on pretreatment covariates. In an experiment, the assignment mechanism – the process by which subjects are assigned to the treatment or control group – is explicitly manipulated by the researcher. The researcher randomly assigns subjects to a treatment or control to ensure that subjects' background characteristics do not influence their probability of treatment assignment. In a typical experiment with one treatment and one control group, subjects are given a p probability of assignment to the treatment, and a $1 - p$ probability of assignment to the control. It is expressed formally:

$$\pi_i = \Pr(Z_i = 1) = p \tag{3}$$

where π_i represents some constant probability p of receiving the treatment ($Z_i = 1$) for all subjects i in the study. Where Eq. 3 holds, the treatment and control groups are balanced on all pretreatment covariates, and Eq. 2 provides an unbiased estimate of the treatment effect.

Importantly, Eq. 3 is a sufficient but not necessary condition for unbiased causal estimation. The key feature of a randomized experiment is not that all subjects share the same π_i, but rather that the researcher *knows* the π_i for all subjects in the sample. As long as π_i is known, it is easy to perform statistical adjustments that account for variations in π_i across subjects in the sample, and balance the treatment and control group on pretreatment covariates. For example, if heavy drug users are twice as likely as non-users to receive the treatment, then the influence of heavy drug users in the treatment group can be down weighted by one-half, assuring that heavy drug use will be balanced in the treatment and control groups for purposes of estimating the treatment effect. A number of other ways to balance the treatment and control groups are available including perfect matching, case control designs that match subjects on different groups, and propensity score matching (demonstrated in this entry).

Observational research refers to empirical studies in which the researcher does not control the treatment assignment through randomization. Instead, subjects are assigned to the treatment or control based upon the natural course of their lives. Observational research thus faces two related problems. First, it is unlikely that all subjects share the same probability of treatment assignment, π_i. It is expressed formally:

$$\pi_i = \Pr(Z_i = 1|\mathbf{x}_i, \mathbf{u}_i) \tag{4}$$

where $\mathbf{x}_i$ and $\mathbf{u}_i$ refer, respectively, to the set of observed and unobserved covariates that render subjects more or less likely to receive the treatment. Equation 4 implies that Eq. 3 may not hold. As a result, without statistical adjustment, an estimate of the treatment effect in Eq. 2 may be biased. The second and related problem faced in observational research is that the researcher does not know π_i for all subjects in the study. Given that Eq. 3 may not hold, without information about π_i, it is difficult to perform the statistical adjustments necessary to compute an unbiased causal estimate.

The RCM conceives of observational studies as randomized experiments in which information about the assignment mechanism, π_i, is lost to the researcher (Rubin 2008). The RCM divides observational research into two key stages. In the design stage, the researcher attempts to recover the lost information about the assignment mechanism by modeling the selection process into the treatment and control groups. In the analysis phase, the researcher uses the model of the selection process to make statistical adjustments to the analysis of the outcome variable, thereby ensuring that imbalances on observed pretreatment covariates $\mathbf{x}_i$ do not bias the estimate of the treatment effect.

A number of methods are available for implementing the design and analysis phases of the RCM. Following Rosenbaum and Rubin (1983), this entry focuses on one popular method often called propensity score matching. Propensity score matching has two key steps. In the first step, logistic regression is used to estimate the relationship between violent offending and observed pretreatment covariates $\mathbf{x}_i$ for the purpose of computing $\hat{\pi}_i$, the estimated probability of treatment assignment. In the context of propensity score matching, $\hat{\pi}_i$ is often called a propensity score. In the second step, subjects in the treatment group are matched with subjects in the control group that share the same propensity score, $\hat{\pi}$. One common strategy is to pair one unique subject in the treatment group with one unique subject in the control group. It is expressed formally:

$$\hat{\pi}_j = \hat{\pi}_k = \Pr(Z = 1|\mathbf{x}_i, \mathbf{u}_i) \qquad (5)$$

where subjects j and k are matched subjects in the treatment and control group, respectively, and $\mathbf{x}_i$ and $\mathbf{u}_i$ refer, respectively, to the set of observed and unobserved covariates that render subjects more or less likely to receive the treatment. Other constant matching ratios, such as 2:1 or 3:1, and even variable matching ratios are possible. All subjects in the sample that cannot be matched are excluded from the dataset for the remainder of the study.

Of course, matching subjects on $\hat{\pi}_i$ does not ensure that matched pairs share precisely the same set of pretreatment covariate values. How, then, does matching on $\hat{\pi}_i$ balance the treatment and control group on pretreatment covariates $\mathbf{x}_i$? Matched pairs share the same propensity score, $\hat{\pi}_i$. Thus, differences in pretreatment covariate values among matched pairs do not help predict which subject is more or less likely to receive the treatment. Both theory and practice suggest that, as a result, the distribution of pretreatment covariates $\mathbf{x}_i$ will be roughly balanced in the treatment and control group in the matched dataset (Joffee and Rosenbaum 1999).

The analysis phase of the RCM proceeds by analyzing the matched dataset from the design phase as though it were generated in a randomized experiment. A t-test or Wilcoxon ranked sum test of violent offending in the treatment and control groups can check for statistically significant differences between the groups.

How well can propensity score matching overcome systematic bias from imbalances on pretreatment covariates? The power of propensity score matching is limited by the availability of observed data on pretreatment covariates that influence the true propensity score, π_i. Propensity score matching can only remove systematic bias that arises from imbalances on observed pretreatment covariates, $\mathbf{x}_i$, and not from unobserved pretreatment covariates, $\mathbf{u}_i$. The assumption that differences between the treatment and control group on unobserved variables $\mathbf{u}_i$ do not bias the estimate of the treatment effect is often referred to in the literature as the ignorability assumption.

Some diagnostic methods are available to assess concerns about systematic bias caused by unobserved covariates, $\mathbf{u}_i$. Rosenbaum (2009), for example, describes a useful method for assessing Γ, the level of bias that $\mathbf{u}_i$ would need to produce in order to reverse the findings of the study. This design sensitivity analysis is described in more detail below.

Implementing Propensity Score Matching: An Example

This section describes the application of propensity score matching to a traditional question of criminological theory: what is the effect of gang membership on violent crime? No substantive theoretical conclusions should be drawn from the analysis. The goal is to demonstrate the role of propensity score matching within the RCM, rather than to conduct a rigorous test of theory.

A two-wave dataset on 294 male and 48 female adolescents from Los Angeles County, California, is used to test the effect of gang membership on violent offending. The data were originally collected for the RAND Corporation's Adolescent Outcomes Project (AOP) (Morral et al. 2004). The AOP was designed to assess the effects of a community-based substance use treatment program on adolescents who were assigned to a group home by a probation official. The eligibility criteria for the research subjects are described in detail by Morral et al. (2004: 259).

The observed pretreatment covariates, $\mathbf{x}_i$, are taken from a baseline survey conducted when the subjects were 12 and 13 years old. Demographic data on gender and race were collected. Data on general satisfaction, orientation toward problems, substance use, quality of health, days worked in the last 90 days, and days spent in jail in the last 90 days were also collected. Two additional indexes were collected that measure peer delinquency and family criminality. Finally, two variables capturing the number of violent crimes (robbery, physical fight with and without injuries to victim, sexual assault) and property crimes (destruction of property, forgery, theft, car theft, breaking and entering) committed in the previous 90 days, and a variable indicating subjects' gang membership in the previous 90 days were collected. All of these pretreatment covariates are included as predictors in a logistic regression on gang membership.

Follow-up interviews were conducted 72 months after baseline. Only two variables from that wave are used in the analysis. First, subjects were asked whether they were involved in a gang in the previous 90 days. However, since the primary aim of the discussion is to demonstrate an implementation of the RCM, the data is treated as though it covers the entire 72-month period for clarity of presentation. Subjects that reported gang involvement in the previous 72 months are assigned to the treatment group, and subjects that did not report involvement are assigned to the control group. Second, a variable measuring the number of violent crimes committed in the previous 90 days serves as the outcome variable.

The Design Phase

The primary purpose of the design phase in the RCM is to model the assignment mechanism for subjects in the sample. Once estimated, this information helps remove systematic bias from the estimate of the treatment effect by balancing the treatment and control group on observed pretreatment covariates, $\mathbf{x}_i$. This section demonstrates how propensity score matching implements the design phase in two steps. First, propensity scores, $\hat{\pi}_i$, are estimated by modeling gang membership between baseline and follow-up on observed pretreatment covariates, $\mathbf{x}_i$, collected at baseline. Second, each gang member is matched with one unique non-gang member that shares the same $\hat{\pi}_i$. This matching strategy balances the distribution of $\hat{\pi}_i$ in the treatment and control groups and tends to balance the distribution of $\mathbf{x}_i$ as well.

Though the technical details associated with propensity score matching are somewhat complex, the procedure is easy to implement in a number of statistical packages. Rosenbaum (2009), for example, provides an excellent explanation of how propensity score matching can be implemented in R.

Part I: Estimating Probability of Treatment Assignment

Here, $\hat{\pi}_i$ is estimated through multivariate logistic regression, though other parametric and nonparametric approaches to modeling treatment assignment are available (see Hirano and Imbens 2001; McCaffrey et al. 2004 for other estimators). The following model is used:

$$\log\left(\frac{\hat{\pi}_i}{1-\hat{\pi}_i}\right) = \alpha_i + \mathbf{b}_i\mathbf{x}_i \qquad (6)$$

where $\hat{\pi}_i$ is the estimated propensity score of gang membership for subject i, $\mathbf{x}_i$ is a set of observed pretreatment covariates theoretically linked with gang membership, and $\mathbf{b}$ is a vector of logistic coefficients.

Table 1 displays descriptive statistics on key measures used in the logistic regression. Two kinds of Wilcoxon ranked sum tests were used to compare the treatment and control group on covariates $\mathbf{x}_i$. First, the unadjusted ranked sum test compares the distribution of a covariate x in the treatment ($n = 80$) and control group ($n = 262$). Since each treatment subject will be matched with one unique control subject, $262 - 80 = 182$ cases in the control group will be dropped from the study. As a result, statistical power to detect differences between the groups will drop dramatically after matching. It is important to assess the marginal increase in balance after those cases are dropped, but such a comparison using statistical tests is only meaningful if the tested sample sizes are similar. It can, therefore, be helpful to perform a second adjusted ranked sum test in order to compare the marginal increase in balance on $\mathbf{x}_i$ after those cases are dropped. This can be accomplished by selecting 500 samples, each consisting of 80 randomly selected cases (with replacement) from the control group. A Wilcoxon ranked sum test is then conducted on covariate $\mathbf{x}_i$ for each of the 500 samples, comparing them against the treatment group. The final p-value for covariate x is computed by the mean of the 500 p-values from the 500 ranked sum tests. The absolute standardized mean difference between the treatment and control group for $\mathbf{x}_i$ is displayed later in Table 3.

Propensity Score Matching, Table 1 Descriptive statistics on pretreatment covariates x_i for gang members (treatment) and non-gang members (control) between baseline and 72-month follow-up

Covariate	Treatment mean (SD)	Control mean (SD)	Unadjusted/ adjusted p-values
Male	0.96 (0.19)	0.83 (0.38)	**0.003/0.025**
Race			
Black	0.14 (0.35)	0.16 (0.36)	0.68/0.584
Hispanic	0.62 (0.49)	0.53(0.5)	0.123/0.296
Other	0.15 (0.36)	0.14 (0.34)	0.778/0.582
General satisfaction	2.33 (0.8)	2.22 (0.73)	0.199/0.367
Problem orientation	0.78 (1.57)	0.97 (1.69)	0.379/0.495
Substance abuse	0.47 (0.3)	0.52 (0.32)	0.203/0.393
Days of work	9.41 (22.13)	9.57 (20.21)	0.767/0.59
Days in jail	40.49 (30.52)	36.68 (27.15)	0.512/0.546
Violent crime	5.35 (14.4)	3.11 (9.06)	0.513/0.536
Property crime	11.91 (27.36)	10.78 (28.31)	0.516/0.536
Delinq. peers	2 (0.92)	1.71 (0.86)	**0.011**/0.091
Family criminality	0.31 (0.23)	0.26 (0.22)	0.067/0.214
Gang membership	0.52 (0.5)	0.26 (0.44)	**0/0.004**
Sample size	88	270	

Table 1 provides evidence of imbalance on the pretreatment covariates. Perhaps most strikingly, nearly twice as many subjects in the treatment group were involved in gangs at baseline than the subjects in the control group. Moreover, 13 % more of the treatment group is male than of the control group, and members of the treatment group are associated with having more delinquent peers. Though not statistically significant, the treatment group also has more violent crime and higher family criminality. These differences suggest that failing to balance the treatment and control group on pretreatment covariates may lead to a biased estimate of the effect of gang membership on violent crime. Propensity score matching is an effective method for balancing a large number of pretreatment covariates.

Propensity Score Matching, Table 2 Results of the logistic regression predicting gang membership between baseline and 72-month follow-up

Variable	Odds ratio	Confidence interval	*P* value
Intercept	0.02	(0, 0.1)	**0**

Total mean of absolute values	0.23	0.09	0.665

Equation 6 generates an estimate of subjects' propensity scores, $\hat{\pi}_i$. Table 2 reveals that several variables in $\mathbf{x}_i$ are significant predictors of gang membership. Males, for example, are more likely to be gang members than females (OR = 5.4; 95 % CI = 1.8, 23.7). Quite unsurprisingly, adolescents with peers that engage in delinquency are more likely to be gang members (OR = 1.5; 95 % CI = 1.1, 2.2), as are adolescents who use illegal substances (OR = 0.32; 95 % CI = 0.1, 0.96). Prior gang membership is also a strong predictor of current gang membership. Adolescent gang members at baseline are over twice as likely to be gang members between baseline and follow-up (OR = 2.3; 95 % CI = 1.3, 4.2).

A comparison between the treatment and control group on $\hat{\pi}_i$ confirms the expectation that $\hat{\pi}_i$ is not constant for all subjects in the study. Figure 1 shows that $\hat{\pi}_i$ in the treatment group is substantially higher than in the control group. Any estimate of the treatment effect that fails to take into account the observed pretreatment differences might suffer from substantial systematic bias. Fortunately, there is sufficient overlap between the two distributions to find credible matches in the control group for subjects in the treatment group.

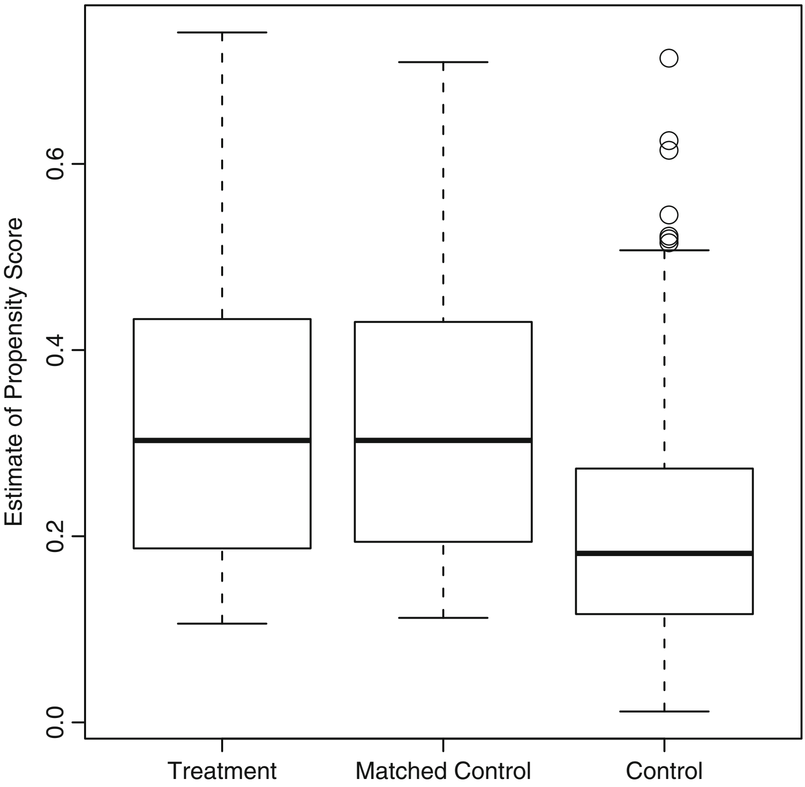
Part II: Matching Treated with Controls

In this section, each treated subject is matched with one unique control on $\hat{\pi}_i$. The basic matching strategy proceeds as follows. First, a distance matrix is constructed with 282 columns and 80 rows. Each column is associated with one unique subject in the control group, and each row is associated with one unique subject in the treatment group. Each cell in the matrix represents the distance in estimated propensity scores, $\hat{\pi}_i$, between the $80 * 282 = 22,560$ possible pairs of treated and controls in the sample. The distance, $\hat{d}_{ij}$, is computed as the squared difference in $\hat{\pi}_i$:

$$\hat{d}_{ij} = (\hat{\pi}_{mT} - \hat{\pi}_{nC})^2 \qquad (7)$$

where $\hat{\pi}_{mT}$ refers to the estimated propensity score for subject m in the treatment group and

Propensity Score Matching, Fig. 1 Propensity scores in treatment, matched control, and control groups



$\hat{\pi}_{nC}$ refers to the estimated propensity score for subject n in the control group.

In 1-to-1 matching, each subject in the treatment group is matched with one unique subject in the control group to minimize the total distance, $\sum \hat{d}_{ij}$, between the matched pairs. The 80 controls selected as matches for subjects in the treatment group are referred to as the matched control group. The remaining 182 unmatched controls are set aside for the remainder of the study.

Having outlined the basic strategy for propensity score matching, other methods are available to improve pretreatment balance including (1) an alternative distance matrix, (2) the rank-based Mahalanobis distance, and (3) exact match adjustments.

Matching on $\hat{\pi}_i$ tends to achieve balance between the treatment and control group on pretreatment covariates, $\mathbf{x}_i$, without ensuring any similarity in $\mathbf{x}_i$ within matched pairs. An alternative distance matrix improves upon traditional $\hat{\pi}_i$ matching by requiring that pairs with suitably similar $\hat{\pi}_i$ also have similar $\mathbf{x}_i$ (Rosenbaum and Rubin 1985). An alternative matrix executes this more sophisticated matching strategy by making adjustments to the original distance matrix described above. In the alternative matrix, all cells with distances exceeding some specified upper bound – referred to as the caliper – are set to infinity, ∞. Pairs associated with cells set to ∞ cannot be matched. Rosenbaum (2010) suggests that one fifth of the standard deviation of $\hat{\pi}_i$ is an adequate caliper value. The present study uses a caliper of 1/20 of the standard deviation of $\hat{\pi}_i$ as it produces closer balance on $\mathbf{x}_i$.

After having set to ∞ all cells in the original distance matrix that exceed the caliper, an alternative distance matrix calculates the Mahalanobis distance for all remaining cells that are not set to ∞. The Mahalanobis distance has two key features: first, a standardized difference of a given size across all uncorrelated variables in $\mathbf{x}_i$ has the same effect on the

Mahalanobis distance. Second, the Mahalanobis distance accounts for correlation between variables. In calculating distances between pairs, two variables that are highly correlated (e.g., with an $r^2 = 0.95$) effectively count as one variable (Rosenbaum 2010).

To calculate the Mahalanobis distance for any pair of individuals, the covariance matrix for observed pretreatment covariates, $\Omega(\mathbf{x}_i)$, is first computed. Second, the vector $(\mathbf{x}_{mT} - \mathbf{x}_{nC})$, where $\mathbf{x}_{mT}$ and $\mathbf{x}_{nC}$ refer to the vectors of pretreatment covariates for treatment subject m and control subject n, is computed. And third, the inverse of $\Omega(\mathbf{x}_i)$ is pre- and post-multiplied by the vector $(\mathbf{x}_{mT} - \mathbf{x}_{nC})$:

$$d_{mahal} = (\mathbf{x}_{mT} - \mathbf{x}_{nC})^T \Omega(\mathbf{x}_i)^{-1} (\mathbf{x}_{mT} - \mathbf{x}_{nC}) \quad (8)$$

Not all data employed in the present study is distributed normally. To address this issue, the rank-based Mahalanobis distance is used (Rosenbaum 2010). The rank-based distance replaces the pretreatment covariate values with ranks to avoid the possibility of unusual behavior in the Mahalanobis distance for variables with extreme outliers.

The alternative distance matrix is an advance over the original distance matrix because it ensures greater similarity in $\mathbf{x}_i$ within matched pairs. Under some circumstances, however, it is desirable to place an even more stringent restriction of a perfect match on some subset of variables. Exact matching can be executed by adding a penalty to any cell in the alternative distance matrix in which both individuals do not share the same value. Perfect matching is not used on any pretreatment covariates in this example.

After computing an alternative Mahalanobis distance matrix, one critical step remains. Each subject in the treatment group must be matched with one unique subject in the control group in such a way that minimizes the sum of the distance between matched pairs, $\sum \hat{d}_{ij}$. Best-first or greedy algorithms rarely minimize $\sum \hat{d}_{ij}$. In contrast, Bertsekas' (1981) optimal pair match algorithm provides an efficient method to identify the set of matched pairs which minimize $\sum \hat{d}_{ij}$. Bertsekas' algorithm can be implemented in R using Hansen and Klopfer's (2006) "optmatch" package.

After forming the matched control group, it is important to assess the balance achieved on $\hat{\pi}_i$ and on $\mathbf{x}_i$. Figure 1 reveals impressive balance between the treatment and matched control group on $\hat{\pi}_i$. Welch's two-sample t-test ($p = 0.861$) and the Wilcoxon ranked sum test ($p = 0.928$) detect no statistically significant difference between the two distributions.

To assess post-match balance on pretreatment covariates, $\mathbf{x}_i$, one can calculate the mean of covariate x in the treatment group, m_{tx}, the control group, m_{cx}, and the matched control group, m_{mcx} (Rosenbaum and Rubin 1985; Haviland et al. 2007). One should also calculate the standard deviation of x in the treatment group, s_{tx}, and the control group, s_{cx}. Finally, an overall standard deviation, s_x, for all subjects in treatment and control is also calculated:

$$s_x = \sqrt{\frac{s_{tx}^2 + s_{cx}^2}{2}}. \quad (9)$$

Balance on covariate x is evaluated using d_x and d_{xm}. d_x represents the absolute standardized mean difference between the treatment group and control group on variable x. An x that is well balanced between the treatment and control group will have a d_x value close to zero:

$$d_x = \frac{|m_{tx} - m_{cx}|}{s_x} \quad (10)$$

d_{xm} represents the absolute standardized mean difference between the treatment group and matched control group on variable x. An x that is well balanced between the treatment and matched control group will have a d_{xm} value close to zero:

$$d_{xm} = \frac{|m_{tx} - m_{mcx}|}{s_x} \quad (11)$$

Table 3 provides data on d_x and d_{xm} for the observed pretreatment covariates, $\mathbf{x}_i$. The matching strategy increases balance on all but two of the covariates. Problem orientation has the greatest post-match imbalance, but even this variable is imbalanced by only a quarter of a standard deviation $(0.28 * s_x)$. Notably, matching decreased the mean of the absolute value of all the d_x values by over 50 % (from 0.23 to 0.09). Wilcoxon ranked sum tests detect only one significant difference in the distribution of $\mathbf{x}_i$ in the treatment group and matched control group. One statistically significant difference among 10–15 covariates would be expected, even in an experiment where assignment to the treatment and control group is fully randomized.

The above analysis suggests that propensity score matching has effectively balanced the treatment and control group on matched pretreatment covariates, $\mathbf{x}_i$.

The Analysis Phase

In this section, the matched dataset produced in the design phase is analyzed. First, a new variable, *dif*, is created by subtracting the outcome variable of each treatment subject from the outcome variable of the respective matched pair in the control group. Second, a parametric estimate of the treatment effect is calculated by the mean of *dif* and by conducting a t-test to assess statistical significance. The parametric estimate indicates that gang membership increases violent offending by an average of 1.3 in a 90-day period. This is a relatively large treatment effect, but no statistically significant difference is detected because of the small sample size and the long-tailed structure of the distribution (p-value = 0.202).

Given the dramatic deviation from the normal distribution, the treatment effect is also estimated with the Hodges-Lehmann estimator and the Wilcoxon signed rank test (Hollander and Wolfe 1999). The Hodges-Lehmann estimator finds a larger and statistically significant effect size of 2.5 violent crimes in a 90-day period (p-value = 0.002).

It is worth wondering what results would have been produced by more traditional methods of multivariate regression. Controlling for the same set of pretreatment covariates, multivariate ordinary least squares regression estimates that gang membership significantly increases violent offending by 1.8 ($p = 0.006$). Propensity score matching, thus, estimates a causal effect that is nearly 40 % larger than the linear regression model.

Similarly, controlling for all the pretreatment covariates, Poisson regression estimates that gang membership multiplies the expected count of violent offending by (B = 0.995; p-value = 0.003) (e^B=) 270 %. Using the matched pair dataset in which all pretreatment covariates are balanced, the Poisson regression estimates that gang membership multiplies the expected count of violent offending by (B = 0.594; p-value = 0.278) (e^B=) 181 %. Assuming the propensity score approach models gang membership correctly, traditional multivariate regression shows clear evidence of biased coefficients, either understating (ordinary least squares) or overstating (Poisson) the size of the gang membership effect on violent offending.

Sensitivity Analysis of Unobserved Bias

If all pretreatment covariates that affect the probability of joining a gang are observed in $\mathbf{x}_i$, it is likely that the design phase matched subjects in the treatment group with subjects in the control group that share the same true probability of treatment assignment, π. In most observational studies, however, it is naïve to assume that all relevant pretreatment covariates are observed. Unobserved variables, $\mathbf{u}_i$, may influence the probability of treatment assignment, and as a result, matched pairs will not share the same probability of treatment. Under these circumstances, some or all of the observed treatment effect may be explained by systematic omitted variable bias rather than the effect of the treatment. It is, therefore, important to consider how large the systematic bias would need to be in order to reverse the statistically significant findings of the study.

Rosenbaum (2009) describes a design sensitivity analysis for assessing the resistance of empirical findings to systematic bias. Γ refers to the ratio between the odds of assignment to the treatment group for a matched pair. If a matched pair shares the same π, then Γ is equal to 1. If Γ equals 1 for all matched pairs, then the treatment and matched control groups are balanced and the observed treatment effect is unbiased. The design sensitivity analysis operates by determining the highest level of Γ at which the findings cannot be reversed by systematic bias. For example, if $\mathit{\Gamma} = 2$ is assumed, then the sensitivity analysis calculates every possible p-value that could be produced when $\mathit{\Gamma} = 2$. If none of the p-values are greater than 0.05, then the observed effect of the treatment is resistant to a level of bias represented by $\mathit{\Gamma} = 2$. See Rosenbaum (2010) for a more in-depth and technical treatment of the procedure.

Here, the observed effect of gang membership on violent offending remains statistically significant for a value of $\mathit{\Gamma}$ as large as 1.5. Thus, the findings are moderately resistant to systematic bias: even if members of the treatment group are 50 % more likely to receive the treatment than their matched pair, the observed effect of gang membership on violent offending remains statistically significant. The observed findings are not resistant to a level of bias greater than $\mathit{\Gamma} = 1.5$.

Assessing the Propensity Score Matching and Regression

This section compares the advantages and disadvantages of propensity score matching and traditional regression-based methods in criminology. For the current purposes, the category of traditional regression-based methods will refer primarily to the parametric regression models that dominate the criminological literature.

The advantages are divided into two categories: methodological and practical. Methodological advantages arise from the inherent mathematical properties of the analytic methods; these are advantages that accrue to a particular method when it is implemented appropriately and in accordance with its own assumptions. The discussion of practical advantages takes into consideration that analytic methods are not always implemented appropriately. Using propensity score matching in the context of the RCM provides the practical advantage of discouraging deviations from accepted scientific practice.

Methodological Advantages of Propensity Score Matching

Propensity score matching has a number of methodological advantages over conventional regression-based methods.

First, propensity score matching uses a stronger method of controlling for confounding covariates. Regression uses indirect adjustment. The adjustment is indirect because regression estimates the effect of confounding covariates and conditions out those effects while estimating the effect of the causal variable of interest. As a simple example, an ordinary least squares regression of gang membership on violent offending would simultaneously estimate how average offending covaries with gang membership and drug use. To estimate the effect of gang membership holding drug use constant, regression simultaneously estimates the effect of drug use on gang membership. In contrast, propensity score matching uses direct adjustment, the same general strategy as in randomized experiments: rather than controlling for the effects of confounding covariates, direct adjustment balances the distribution of those covariates in the treatment and control groups. As long as there are an equal number of heavy drug users in the treatment and control group, for example, heavy drug use is balanced and will not bias the estimate of the effect of gang membership. Direct adjustment is stronger than indirect adjustment because, rather than adjusting for the *unknown and estimated effects* of observed covariates, it adjusts the *known distribution* of those covariates.

Second, direct control enables propensity score matching to better account for nonlinear relationships between controlled covariates and the outcome variable. Regression models can account for nonlinear relationships through functional transformations, but it is difficult to determine whether all nonlinearities have been appropriately modeled. In contrast, nonlinear confounders that are balanced in the treatment and control group do not bias the observed effect of the treatment. This is a major benefit of propensity score matching: whereas regression only accounts for nonlinear relationships that are known and are accurately modeled, propensity score matching accounts for all nonlinearities associated with observed pretreatment covariates when balance is achieved through matching.

Third, the strategy of indirect control renders linear regression susceptible to problems of multicollinearity that are not faced by propensity score matching. Adding multiple correlated covariates into a regression model can inflate standard errors and diminish the detection of statistically significant differences. Propensity score matching circumvents this methodological challenge by avoiding the need to disentangle and estimate the causal effects of specific covariates, and instead simply removes them from the estimated treatment effect by balancing the covariates themselves.

Fourth, propensity score matching can be combined with efficient causal estimators through the use of nonparametric estimation and statistical tests. With some exceptions, regression-based methods in criminology typically entail parametric assumptions about constant and normally distributed errors. Nonparametric regression-based methods are available, but they are rarely used. Some criminological data satisfy these strong assumptions, and other data can be transformed to satisfy them. For these data, the nonparametric Wilcoxon signed rank test is 95 % efficient relative to the t-test commonly used in regression (Lehmann 1998; Haviland et al. 2007). The Wilcoxon signed rank test is substantially more efficient for other distributions, especially skewed distributions typical of criminal offending. Since the true conditional distribution of the outcome measure is rarely known, it makes sense to use an estimator with good performance across different kinds of distributions. Propensity score matching can be combined with nonparametric estimators and statistical tests that perform well across different kinds of distributions.

Fifth, propensity score matching provides a simple method for estimating different kinds of causal treatment estimates, or perhaps more precisely, for estimating causal estimates for treatments in different subpopulations. This is particularly valuable in criminology where the kind of treatment effect estimated is often not considered. Calculating the treatment effect on the treated with regression, for example, requires more computation than simply using the coefficient of the treatment indicator. Propensity score matching can estimate the *effect of the treatment on the treated* (TOT) by retaining all subjects in the treatment group and matching them to one or more subjects in the control group. TOT analyses are especially useful for calculating the causal effect of a treatment that is currently experienced by small and nonrepresentative subsets of the population. Gang membership, for example, is a common experience among young, urban, and historically disadvantaged ethnic minorities, but is uncommon for much of the rest of the population. It is, therefore, perhaps more interesting to examine the effect of gang membership on this specific segment of the population than on the entire population. On the other hand, sometimes it is more important to study the effect of the treatment on individuals who did not receive the treatment. The *effect of the treatment on the untreated* can be calculated by retaining all subjects in the control group and by matching them with one or more members of the treatment group. Though rare, this kind of causal analysis can be helpful when extending a treatment for a subpopulation to the rest of the population. Finally, the *effect of the treatment on the population* (TOP) can be roughly estimated by balancing the treatment and control group to an estimate of the population mean. Linear regression can compute these different kinds of causal estimates, but not without careful efforts in designing the structure of the study. Propensity score matching, on the other hand, calculates these causal estimates with ease by adjusting the matching criteria.

Aside from the modeling advantages already described, propensity score matching has two further methodological advantages. The central problem in observational research is omitted variable bias: the researcher is always left wondering whether some unknown confounding variable leads to unobserved bias in the causal estimate of the treatment. Propensity score matching offers a design sensitivity analysis, which measures the level of unobserved bias necessary to reverse the findings of the study. When that level is high, the data provide more confidence that differences observed between the treatment and control groups are the result of the true effect of the treatment, and not the result of omitted variable bias. Research on smoking offers a strong example of the value of design sensitivity analyses. It is difficult to study the long-term effects of smoking on health through a randomized experiment; thus, observational research is the main avenue for exploring the effects of smoking. Observational studies on smoking come with the usual caveats about unobserved systematic bias. Some observed effect sizes associated with smoking, however, are so strong that it would be implausible to attribute them entirely to unobserved bias. Cornfield et al. (1959), for example, observe that the level of bias necessary to reverse the effect of smoking on cancer would be extremely high (Rosenbaum 2009). Effect sizes in criminology are rarely so large, but that only substantiates the need for design sensitivity analyses. Greater awareness that systematic bias can easily explain some research findings may provide a healthy reality check to a research community focused on small effect sizes and statistical significance.

Finally, propensity score matching permits researchers to control for noncausal variables such as race or gender without making assumptions about the causality of covariates. Zuberi (2001) has argued that in most social science research, race cannot be conceptualized as a causal variable. This is not a trivial methodological problem. Race and other demographic factors correlate strongly with a wide range of crucial social variables, and it is important to ensure that differences in the distribution of those variables do not bias causal estimates in observational research (e.g., Berk et al. 2005). Propensity score matching provides a practical solution to the problem. By controlling for differences in racial groups without measuring the "effect of race," propensity score matching enables social scientists to control for differences across race without problematic assumptions about the "causality" of noncausal variables.

Practical Advantages of Propensity Score Matching

The prior section argued that the RCM and propensity score matching provide important methodological advantages over traditional regression-based approaches. This section suggests that the RCM and propensity score matching also encourage researchers to adhere more closely to sound scientific practice.

First, propensity score matching makes fewer assumptions than the traditional forms of regression that dominate the criminological literature. Propensity score matching, for example, does not necessarily assume (1) linear effects between individual control variables and the outcome variable, (2) normally distributed errors, or (3) homoscedasticity (constant errors). Propensity score matching also requires no test for multicollinearity. Finally, using a nonparametric statistical estimator largely obviates the need to test for high-leverage points. Articles in criminology journals rarely indicate whether key assumptions of regression models are satisfied, but they are critical for estimating unbiased parameters. All of the assumptions needed for regression are less important for propensity score matching. In matching, the researcher primarily needs to check for balance between the treatment and control group on the estimated propensity scores, $\hat{\pi}_i$, and on pretreatment covariates $\mathbf{x}_i$.

Second, propensity score matching implemented in accordance with the RCM is more resistant to the influence of researcher bias. It is well known that a researcher's beliefs and attitudes can influence the findings of a study. Three features of regression-based methods leave the door wide open to these biases (Greiner 2008). First, assessing the goodness of fit of a regression model is partially a subjective judgment, and researchers must often rely upon their own expertise and judgment. Second, adjustments to the model intended to improve fitness – such as the removal or addition of variables – can result in substantial changes in the results of the analysis. Third, the researcher sees the results of the analysis when assessing model fit. As a researcher modifies the model to improve fitness, she sees the effect of those modifications on the results of the study. Because the selection of the "fittest" model is largely subjective, it is easy for the researcher to justify the selection of one model over another. Regression can, thus, encourage a researcher to cherry-pick a model specification that supports a particular hypothesis or theory. Greiner explains:

> A model's fit is never perfect. At each stage of this process of exploration and assessment, the substantive result, the... answer [to the empirical question at hand], stares the analyst in the face. Only the superhuman can completely disregard the temptation to lean towards a result favorable to a chosen side, consciously or no. (Greiner 2008, p. 544)

The structure of the RCM and propensity score matching strongly discourages this form of model pruning for desired results and, if followed strictly, renders it nearly impossible. The RCM divides the development of the design and the analysis of the data into two separate phases. Since the researcher selects the design before estimating the treatment effect, the RCM precludes undesirable forms of model pruning that may bias the findings of the study. In fact, Rubin (2008) suggests deleting the outcome variable from the dataset during the design phase in order to remove any temptation to see the results before finalizing the design. Of course, it is possible to follow all the rules of the RCM and then start over again because the results are undesirable. But at the very least, the RCM and propensity score matching discourage less conscious forms of model pruning that bias the findings of studies.

Disadvantages of the Rubin Causal Model

Propensity score matching has two key practical disadvantages relative to the traditional regression approach.

First, matching subjects in the treatment and control group often results in a decrease in sample size. Subjects in one group who lack a comparable subject in the other are effectively dropped from the study in order to achieve covariate balance. This is less of a problem than it seems: keeping noncomparable subjects in a regression model for the purpose of maintaining a large sample size may not be valuable either and may bias causal estimates if the model is not properly specified.

Second, propensity score matching increases the difficulty of examining the causal effect of quantitative variables that are not binary. Regression is flexible with regard to the structure of all independent variables: they can be nominal, ordinal, or quantitative. Propensity score matching is equally flexible for balancing pretreatment covariates, but not for estimating treatment variables. Because propensity score matching typically separates the sample into two or more discrete treatment and control groups, it has traditionally not been used to measure the effect of a quantitative treatment variable. The same limitation exists in randomized experiments, where the subjects must be grouped into discrete treatment and control groups. However, more recent work by Hirano and Imbens (2004) has extended propensity score matching to continuous treatment variables, thus providing some of the benefits of the generalized linear model in regression.

What Problems Remain Unsolved by the Rubin Causal Model and Propensity Score Matching?

There are several methodological problems associated with all observational research, including propensity score matching.

First, propensity score matching does not solve the problem of omitted variable bias. Excluding a covariate that affects the outcome variable may cause unobserved bias in the estimated treatment effect. Propensity score matching, however, offers a transparent design sensitivity analysis, a tool for assessing the plausibility that unobserved bias has caused the differences observed in the treatment and control groups.

Second, like regression, propensity score matching assumes the stable unit treatment value assumption (SUTVA). SUTVA asserts that the assignment of subjects to the treatment or control group does not affect the outcomes of other subjects (Cox 1958). This is often referred to as "interference" in the experimental literature (Rosenbaum 2010; Sampson 2010). Unfortunately, the problem of interference is difficult to avoid in criminological research – whether experimental or observational – because it is likely that treatment assignment influences social interactions between persons in the study.

Third, like linear regression, propensity score matching does not automatically account for two- or three-way interactions that affect selection into the treatment and control groups. Imagine that using drugs and dropping out of high school independently increase offending. In propensity score matching, one would, of course, need to balance the treatment and control group on these two variables before estimating the effect of gang membership on offending. Imagine further that using drugs and dropping out collectively exert a larger effect on offending than their respective independent effects. Under these circumstances, balancing the treatment and control group on drug use and family structure separately may not balance their co-distribution: it is possible for the treatment or control group to have a substantially larger number of subjects who are both drug users and dropouts. To ensure balance on the co-distribution of the two variables, an interaction variable in the logistic regression model is needed to properly estimate propensity scores for subjects in the sample. Still, one might argue that in some cases, matching better accounts for omitted two- and three-way interactions than linear regression: unless the correlation between two interacting variables is different among those who receive the treatment and those who do not, balancing the independent distributions of the variables may very well balance their co-distribution as well.

Conclusion

The RCM and propensity score matching provide a number of methodological and practical advantages over the more traditional regression-based methods in the criminological literature. Those benefits include a more reasonable strategy for controlling for confounding variables, a better method for accounting for nonlinear relationships, and the straightforward application of nonparametric estimators and statistical tests. Propensity score matching also relaxes the assumptions of linear regression and uses a two-part research design that discourages the practice of model pruning, which may bias the findings of observational research. Criminologists would do well to adopt the propensity score matching in many theoretical and applied research studies.

Before concluding, one note is in order. This entry has suggested that, if criminologists are to choose between regression and propensity score matching, they should often choose the latter. But regression and propensity score matching are not fully at odds with each other. Criminologists can combine both. One option is to match and then regress. In fact, Rubin has argued this two-step strategy will sometimes decrease bias in the estimate of the treatment effect (Cochran and Rubin 1973). Another option is to include the estimated propensity scores as a predictor variable in a regression model (e.g., Berk and Newton 1985). Unlike in propensity score matching, however, this strategy requires the researcher to explicitly model the functional relationship between the propensity scores and the outcome variable. One other option is to use the estimated propensity scores as weights in a regression model (Hirano and Imbens 2001). In some circumstances, weighting is an undesirable approach because it can underestimate standard errors and bias estimates of the treatment effect (Freedman and Berk 2008).

Proportionality

Jesper Ryberg and Thomas Søbirk Petersen
Department of Philosophy and Science Studies,
Roskilde University, Roskilde, Denmark

Overview

Proportionality denotes a relation between crime and punishment, namely, between the seriousness of a crime and the severity of the punishment. As a normative principle for the distribution of punishment – standardly referred to as the principle of proportionality – proportionality implies that the severity of a punishment should fit the seriousness of the crime that has been committed. More precisely, this idea comprises two different aspects of the relation between crime and punishment.

The first aspect of proportionality concerns the requirement that a punishment should reflect the seriousness of the crime, in the sense that its severity should comport with the severity of punishments for other crimes. For instance, if theft is a less serious crime than burglary, then *ceteris paribus* the thief should be punished more leniently than the burglar. And, if two persons are convicted of equally serious cases of criminal conduct, they should be allotted equally severe punishments. This purely comparative requirement is usually referred to as "ordinal proportionality" (von Hirsch 1993; Ryberg 2004; von Hirsch and Ashworth 2005).

The second aspect of proportionality concerns the way punishments non-relatively comport to specific crimes. For instance, a sentencing system which imposes a minor fine for a rape or several years of imprisonment for a parking offense might well be regarded as imposing grossly disproportionate punishments irrespective of what constitute the penal levels for other crimes. This idea of a non-comparative relation between crime and punishment is known as "cardinal proportionality" (von Hirsch 1993; von Hirsch and Ashworth 2005).

This entry concerns the ethical aspects of proportionality in punishment (the enactment of the proportionality principle in penal laws and in relation to court decisions in different countries is not dealt with here (see, for instance, Clarkson and Morgan 1995; Bagaric 2001)). The first section concerns the justification of proportionality. The second section deals with the ranking of crimes in gravity and punishments in severity. The final section concerns the so-called anchor problem, that is, the challenge of how scale of crimes and punishments should be linked.

Justifying Proportionality

Why should the severity of the punishment be proportionate to the seriousness of the crime? Answers to this question can be found in both of the two main rival positions that have dominated penal theoretical considerations of the justification of state punishment, namely, utilitarianism and retributivism.

An early example of a forward-directed utilitarian justification was given by C. Beccaria who held that, if crimes of unequal seriousness – such as assassination, poaching, and forging – were punished equally harshly, this would undermine people's ability to distinguish between the seriousness of these crimes (Beccaria 1964). A corresponding argument was presented by J. Bentham who devoted a whole section of his *The Principles of Morals and Legislation* to considerations of proportionality. For instance, Bentham argued that, in the absence of proportionality, potential criminals would not be deterred from committing serious crimes any more than minor crimes and, therefore, would just as readily commit them. As an illustration of this consideration, he held that "If then, for giving you ten blows, he is punished no more than for giving you five, the giving you five of these ten blows is an offence for which there is no punishment at all: which being understood, as often as a man gives you five blows, he will be sure to give you five more, since he may have the pleasure of these five for nothing"

(Bentham 1988, pp. 181–2, note 3). In the modern utilitarian literature, the main focus has been on the undesirable consequences – e.g., in terms of antipathy or distrust toward legal institutions and practices – that might follow if the legal system is perceived as not observing the conception of justice that seems to lie inherently in the idea that a more serious crime should be punished more harshly than a less serious crime (Bagaric 2001, pp. 185–86). However, whether a utilitarian punishment system should distribute punishment in a proportionate manner depends on whether this sort of penal distribution scheme is in fact the one that maximizes well-being, which is a purely empirical question and a question that has been the object of criticism (von Hirsch 1985).

The main modern discussion of the justification of proportionality has taken place within the framework of retributivist penal theory. The renaissance of Kantian and Hegelian thoughts on punishment – and the corresponding decline of the utilitarian penal theory – that took place in the 1970s not only marked a turning point in penal theoretical thinking but also, as emphasized by A. von Hirsch, led to a change of focus from the question "Why punish?" to "How much?," thereby providing an opening for new and more elaborate thoughts on proportionality (von Hirsch 1991). Modern retributivism – a deontological position according to which punishment is justified in terms of desert – has been presented in many different versions, leading to correspondingly different approaches to the justification of a proportionate penal distribution. The overall idea of the retributivist justification is that a criminal deserves a more severe punishment, the more serious the crime committed is. The differences between the various expositions of this idea lie in various views on why a criminal deserves a punitive response for having committed a crime.

A first and simple answer is to hold that what a criminal deserves is to *suffer* and, hence, that he or she deserves to suffer more, the greater the seriousness of the crime. Since a punishment is more severe the more suffering it inflicts, it follows that a criminal should be punished more severely, the more serious his or her crimes. However, as has been pointed out, this way of justifying proportionality in punishing is vulnerable to the objection that suffering may befall a person in many other ways than by being punished (Ezorsky 1972; Ryberg 2004). For instance, a perpetrator may be racked by guilt, feel anxious about the prospect of imprisonment, or he or she may simply suffer from some sort of disease. However, if there are several ways in which a criminal may suffer after his crime is committed, then it seems that, in comparison with other criminals, who have committed equally serious crimes but who have not undergone some sort of nonpunitive suffering, the criminal has already paid part (or all) of his or her desert debt. But this implies that in this case, equally serious crimes should not be equally severely punished after all. Thus, it becomes less obvious that a proportionate punishment scheme can be justified on the grounds of the view that criminals deserve to suffer.

Another and theoretically more elaborate attempt to justify proportionality within a retributivist framework has been presented by what has become known as the "fairness theory" (Davis 1992). This theory is often presented on the ground of the broader view that, in a cooperative venture, involving costs and benefits of all parties, there should be an equitable distribution of those costs and benefits. Applied to the question of law and punishment, the view is that a criminal, on the one hand, gains a benefit from other people's obedience to the law but, on the other, gains an extra benefit (an unfair advantage) by not restricting his or her action as does the law-abiding person. On this view, the criminal deserves a punishment as a way of outweighing the extra benefit which he or she has unfairly gained. Following this outlook, proportionality has been justified on the ground of the claim that a more serious crime provides the criminal with a greater unfair benefit and that a more severe punishment therefore is required in order to restore the equilibrium of benefits and burdens. As part of the task of justifying proportionality, two of the main challenges facing the fairness theory have been to clarify whether it is always the case that a greater unfair benefit is gained from having committed a more serious crime and, also, whether an appropriate burden can befall a criminal in nonpunitive ways or only be properly imposed as part of a punishment (Burgh 1982; Sher 1987; Davis 1992; Ryberg 2004).

A third retributive approach to the justification of proportionality has been provided by the expressionist theory of punishment. According to this theory, a punishment should not be seen merely as the infliction of suffering. Rather a punishment is perceived as a way of expressing or communicating an appropriate condemnatory message to the criminal (von Hirsch 1993; Duff 1986, 2001). What the criminal deserves is to be appropriately censured or blamed and the punishment is the means to this goal. The step from the expressionist penal theory to a proportionality in punishing has been presented by A. von Hirsch in the following way: “1) The state’s sanctions against proscribed conduct should take a punitive form; that is, visit deprivations in a manner that expresses censure or blame. 2) The severity of the sanction expresses the stringency of the blame. 3) Hence, punitive sanctions should be arrayed according to the degree of blameworthiness (i.e. seriousness) of the conduct (von Hirsch 1993, p. 15).” One of the questions which the expressionist view and its justification of proportionality has given rise to is why, if it is a fact that censure and blame can be expressed or conveyed to someone in many different ways, the state’s sanction should take the form of a punishment. This “why hard treatment” question has been answered in different ways by modern adherents of expressionist approaches to punishment (Matravers 1999).

Ranking Crimes and Punishments

If the severity of punishment should be determined by reference to the seriousness of the crime committed, then the tasks of clarifying what makes one crime more serious than another and what makes one punishment more severe than another become crucial. For instance, unless it is possible to tell whether a rape is more serious than a burglary or whether theft is more serious than reckless driving, the idea of proportionality in punishing becomes vacuous and unable to provide any practical guidance on penal distribution. Similarly, proportionality presupposes that it is possible to determine whether one punishment, say a prison term of a certain length, is more or less severe than another punishment, say, a fine of a certain amount.

Though there does not exist theoretical agreement on how crimes should be ranked in terms of seriousness, a standard view in the modern retributivist tradition is that crime gravity should be determined on the ground of *harm* and *culpability* (von Hirsch 1993; von Hirsch and Ashworth 2005). With regard to the harm dimension, the view is that the relative gravity of a crime increases with the degree of harmfulness. Assault is a more serious crime than theft because it causes much more harm to the victim. Though this seems intuitively appealing, there may be other cases in which it is less clear how to compare the relative harm of different crimes. Thus, one of the theoretical tasks has been to specify what should be understood by criminal harm and to provide some sort of guidelines for the computation of harm (see von Hirsch and Jareborg 1991).

One of the things that complicates estimates on the harm of crimes is that there are several crimes which do not, at least not in any straightforward way, involve harmful conduct. A standard example is conduct which only risks or attempts harm. For instance, even if someone drives hazardously in a crowded street, there may be no one who is actually harmed. The same is the case with the inchoate crime of attempt. For instance, a planned crime may not succeed for the simple reason that the person did not commit all the acts necessary to bring it about. Or the person did all the intended acts but nevertheless did not succeed in bringing about a desired result. One way of dealing with such cases has been to suggest that what matters is not the actual outcome (harm) of a criminal act but rather that the criminal ought to be held liable for what he or she intended, no matter whether this was realized by the crime (Ashworth 1984). Another way of accounting for non-realized harms has been to draw on judgments of risk. On this view, what matters in the determination of crime gravity is the risk-adjusted harm, that is, the product of the harm intended and the risk that it would be realized by the crime that was committed (von Hirsch and Jareborg 1991).

The other dimension of crime gravity is the culpability of the criminal. The first aspect of culpability is the mental state or attitude a person holds when a crime is performed. The law uses the term "mens rea" (the guilty mind) to denote these mental elements. The traditional *mens rea* distinctions are between: intention, knowledge, recklessness, and negligence (and often in the last case no criminal culpability at all). The idea is that different kinds of *mens rea* imply different degrees of culpability. For instance, it is generally agreed upon that intentional harm *ceteris paribus* implies a higher degree of culpability than recklessly caused harm. As H. L. A. Hart illustratively remarks, it seems worse to break someone's Ming china intentionally than to knock it over while walzing wildly round the room not thinking of what might get knocked over (Hart 1968).

The other aspect of culpability concerns what is usually referred to as "excuses" which may take several forms. For instance, a person may be excused if a harmful effect is caused involuntarily, under constraints from defects of knowledge or defects of will, or if a person in different ways lacks sufficient capacity to make judgments (e.g., due to intoxication, infancy, or insanity). A standard view on excuses is that they instantiate an underlying view on responsibility and that different degrees of responsibility imply different degrees of culpability. However, what constitutes the most plausible theory of criminal responsibility is a matter of ongoing dispute.

The fact that computation of the seriousness of a crime is a poly-dimensional enterprise obviously complicates such judgments. One way of illustrating how harm and culpability affect the assessment of crime gravity is to perceive the gravity of a particular crime as the product C times H where H is the harm done or risked, while C is the culpability of the criminal, indicated by the numerical values from zero to one (see Nozick 1981). This formula implies that culpability is a matter of degree and that when there is no culpability – i.e., when $C = 0$ – the gravity of the crime is zero, which implies that the defendant does not deserve a punishment. However, in real life, numerical judgments are not an option. And the question as to how one should rank two crimes in gravity, when the first crime is more harmful than the second, while the second is performed with a higher degree of culpability, remains a theoretically open question (see Ryberg 2004).

The ranking of punishments in severity is generally perceived as a theoretically less challenging task. For instance, it seems reasonable to hold that the severity of a prison term varies with its duration and that severity of fines varies with the amount of money. However, motivated, for instance, by the contention that a punishment system which offers only a few punishment options will often punish criminals either too severely or too leniently relative to the crime committed, there has been a growing interest in intermediate sanctions – including, e.g., home detention, community service, electronic monitoring, etc. – thereby prompting a discussion of how such punishments should be compared in terms of seriousness. The obvious answer is that sanction gravity should be determined on the ground of the amount of suffering, deprivation, or inconvenience which a punishment inflicts on the punished. One of the things that complicates this suggestion is that punishments which are the same in name – say, 1 year in prison – may affect two persons very differently in terms of suffering or deprivation. This fact has led to discussion of whether proportionality implies that two persons, who have committed the same crime, should be punished with objectively different punishments, if there are differences in two persons' vulnerability to a certain type of punishment, or whether an objectivist account of punishment severity – which does not include considerations of differences in the ways a punishment is felt or experienced – is the more plausible (von Hirsch 1993; Kolber 2009; Ryberg 2004, 2010).

Specifying Proportionality

How far can the principle of proportionality guide us when it comes to the distribution of punishment? The idea of proportionality in punishing – as we have just seen – presupposes that it is possible to rank different crimes in seriousness and to rank punishments in severity. Thus, another way of posing the question is to ask how should the scale of punishment and the scale of crime, once they have been constructed, be linked? This question, which has been considered almost exclusively within a retributivist framework, opens up a number of different answers.

One possible answer might be to hold that the scales should be linked by letting the punishment directly mirror the character of the crime that has been committed. This view – referred to as *lex talionis* – is often expressed in the classical biblical formulation "an eye for an eye, a tooth for a tooth." Though this principle was, in the historical context, understood not as prescribing exact retribution but rather as a way of restraining disproportionate cruel retaliation – "several eyes for an eye" – it is obvious that a literalistic interpretation of "like for like" would constitute a simple device for meting out appropriate punishments for different crimes. However, in penal theory, this interpretation has had very few adherents. One of the classical retributivists who came closest to defending this view is I. Kant who insists that a principle of retaliation "can assign both the quality and quantity of a just penalty" (Kant 1996). However, even he recommends a number of punishments, which violates the definiteness of *lex talionis*. One of the reasons for this is probably that *lex talionis* faces the simple practical challenge that there are a large number of cases in which it is impossible to reverse a crime against the criminal himself/herself. For instance, it is hard to see what punishment one should inflict on a blackmailer, a forger, a dope peddler, a multiple murderer, a smuggler, or "a toothless fiend who has knocked somebody else's tooth out" (Kleinig 1973, p. 120).

A possible reaction to this problem might be to interpret *lex talionis* somewhat more loosely by holding that what matters in penal distribution is not that materially the same should be done to the criminal as was done to the victim, but rather that it is the harm that a crime caused to the victim that should be reversed against the criminal himself/herself. This view was defended by G. W. F. Hegel who held that it is only in respect of the "form that there is a plain inequality between theft and robbery on the on hand, and fines, imprisonment, &c., on the other. In respect of their 'value', however, i.e. in respect of their universal property of being injuries, they are comparable" (Hegel 1967, p. 72). By interpreting proportionality as equivalence of harm, the problem as to how one should punitively respond to blackmail, forgery, and several other nonreversible crimes is resolved. However, this is not tantamount to the fact that there are no problems of application. One of the reasons why most modern retributivists do not subscribe to *lex talionis* – in either of the two interpretations – is that the principle seems to ignore the complexity of judgments of what determines the seriousness of a crime. As indicated above, few, if any, modern retributivists would hold that all that matters in the comparison of crime seriousness is the harm that is caused. The culpability of the criminal is usually considered a seriousness-determining factor as well. However, if this is so, then it is no longer clear what "like for like" means. For instance, if person A and person B have each committed a crime that caused the same degree of harm to their respective victims, but it turns out that while A was fully culpable for his/her crime while B was not fully culpable (e.g., because he/she was only partially responsible), then the crime committed by A would be more serious than the crime committed by B. However, this is not captured by an interpretation of proportionality which requires that a crime is either literally reversed against the criminal or reversed in the form of harm-for-harm equivalence. Conversely, if one insists that proportionality should be interpreted as a like for like principle, then it becomes obscure what constitutes the equivalent punishment of a crime for which the perpetrator was only partially culpable.

In fact, this point is what some of the very early opponents of retributivism had in mind in their criticism of the idea of proportionate punishment. For instance, more than a half a century ago, W. G. Maclagan argued that retributivism is impossible in application because it presupposes a notion of equivalence which itself is impossible because "the two things that are to be measured against each other are in their very nature incommensurable" (Maclagan 1939, p. 290). The same objection was presented by H. Rashdall and E. Ferri more than a century ago. However, in the modern penal philosophical discussion, this criticism has had less resonance, for the simple reason that several retributivists themselves reject the idea of an equivalence between crime and punishment. But if proportionality is not interpreted as a "like for like" principle, then how should one determine what constitutes the proportionate punishment for a certain crime? Several attempts at answering this question have been presented in the modern retributively oriented era of penal theory.

One proposal, which has been defended by J. Kleinig and adopted by several other penal theorists, is to link the scales of crimes and punishments by the use of "anchor points" (Kleinig 1973). The proposal is based on the assumption that the two scales are not simply ordinal scales. That is, crimes are not merely ranked in terms of being more or less serious than other crimes. Rather the idea is that differences in the relative seriousness of different crimes should be reflected in the way crimes are ranked. To take a simple example, if out of three crimes, ranked in ascending order of seriousness – say, theft of 50€, embezzlement of 100€, and rape – the second is only slightly more serious than the first while the third is considerably more serious than the second, then these relative differences in gravity between the crimes should be reflected in the way the three crimes are being punished. In more technical terms, there should be an interval matching of the scale of crimes and the scale of punishments. On the ground of this assumption, the proposal is that the poles of the respective scales should serve as anchor points. The idea is presented by D. E. Scheid in the following way: "The main strategy . . . is to consider a scale that includes all crimes and a scale that includes the full range of acceptable punishments, and then anchor the scale to each other at two points. We anchor the most severe punishment to the most serious crime (say, life imprisonment for murder) and the least severe punishment for the least serious crime (say, a fine for petty larceny), with the other crimes falling in between" (Scheid 1997, p. 494).

In the penal theoretical discussion, this way of giving content to the idea of proportionate punishing has given rise to several objections (Ryberg 2004). For instance, it has been held that it is far from clear how one should identify the upper anchor points. First, it is not obvious what should be regarded as the most serious crime. Should this be murder? Why not the murder of ten persons or perhaps of 50? Or what about genocide? The challenge is that for any crime, it always seems possible to imagine another one (in fact sometimes reality lives up to imagination) that is even more serious. Second, the idea of determining the most severe of punishments has also been questioned. There is no straightforward way of making sense of the idea of the most severe of possible punishments. One proposal has been that the upper limit of punishment should be determined at the point at which a punishment would violate human dignity (Kleinig 1973). Critics, for their part, have been skeptical as to whether it is possible to develop a plausible account of dignity on the ground of which it will be possible to determine that, say, the length of a prison term becomes morally unacceptable because it violates human dignity (Ryberg 2004). Moreover, as a further critical comment, it has been held that the outlined method for the anchoring of the two scales is in need of an argument as to why the scales should be pegged at the end points of the scales. Why is it that the most serious crime should be pegged to the most severe punishment? Why not peg it to the punishment just below the most severe on the scale? In the absence of an argument to this effect – the criticism goes – the suggested anchor theory ends up as morally arbitrary (see von Hirsch 1993, p. 39; Ryberg 2004, p. 142).

Another approach to the question as to how the scale of crimes and the scale of punishments should be linked has been developed by A. von Hirsch. This theory combines considerations of desert, prevention, and parsimony in punishing (von Hirsch 1993). The main idea is that a punishment system should start by ordering the crime scale, from the least to the most serious, and by indicating a punishment level which corresponds to the current level in the society. However, von Hirsch further suggests that one should follow a "principle of parsimony," according to which state-inflicted suffering should be kept to the minimum necessary to achieve that purpose of the intervention. On the ground of this principle, one should follow a "decremental strategy" by a *pro rata* reduction of the penalties. Von Hirsch, finally, suggests that this progressive diminution of the punishment levels should stop at a point determined on the ground of considerations of crime prevention. This proposal has led to discussions of the role which crime prevention plays within the overall retributively minded penal theory and of whether this way of anchoring the scale succeeds in providing a sufficient guideline for how crimes of different gravity should be punished (Ryberg 2004). The discussion of this as well as of the former proposal illustrates that, even among penal theorists who subscribe to the principle of proportionality, there exists no general current consensus on how the proportionate punishment for different crimes should be determined.

Overview

This entry explores the relationship between prosecution and wrongful convictions. It begins with an overview of the problem, and then it introduces the means by which wrongful convictions occur. Prosecutorial causes for wrongful convictions are then reviewed, as are pertinent court cases in the area. This entry concludes with policy recommendations aimed at minimizing the role of prosecution in wrongful convictions.

Introduction

In June of 2007, Durham County District Attorney Michael Nifong was disbarred and stripped by the North Carolina State Bar Disciplinary Committee of his license to practice law (*North Carolina State Bar v. Michael B. Nifong*, 06 DHC 35 (2007)). Nifong's disbarment was based on his actions during the infamous and highly publicized Duke University lacrosse scandal, during which he committed a number of professional missteps, including going public with false accusations and refusing to hear exculpatory evidence against the players identified as suspects in the case. According to the disciplinary committee, no other action short of disbarment would have been appropriate under the circumstances. Although the case was not typical, it served as a shining example of what can happen when prosecutors overstep their authority.

Prosecutors represent the government in criminal proceedings. According to the American Bar Association's Code of Professional Responsibility, "The responsibility of a public prosecutor differs from that of the usual advocate; his duty is to seek justice, not merely to convict." Prosecutors also enjoy a significant amount of power in handling their duties, especially considering the fact that they choose which cases to pursue and whether to take cases to trial or to settle matters through plea agreements (Worall 2008). The control they have even plays a role in how cases are handled at each step of the process. Finally, research has shown that prosecutors are often instrumental in case outcomes, including as to whether a wrongful conviction takes place (Huff et al. 1986; Scheck et al. 2000; Schehr and Sears 2005).

Despite the image of prosecutors as hardworking professionals who represent the government and play a major role in the criminal process (Worall 2008), wrongful convictions owing to their actions place a black eye on the justice system. Such injustices undermine people's faith in the ability of the justice system to identify and hold accountable people who break the law (Huff et al. 1986; Ricciardelli et al. 2009). For instance, knowing that wrongful convictions occur may result in jurors and other individuals calling into question the guilt of those being accused of crimes (Huff et al. 1986). Further, they may doubt that convictions secured by prosecutors are valid (Huff et al. 1986). In light of this concern, this entry begins with an overview of the problem of wrongful convictions, and then it introduces the causes and contributing factors of wrongful convictions. Prosecutorial causes for wrongful convictions are also reviewed, as are pertinent (primarily US Supreme Court) cases in the area. This entry concludes with policy recommendations aimed at minimizing the role of prosecution in wrongful convictions.

The Problem of Wrongful Convictions

Wrongful convictions have been defined as "those cases in which a person was convicted. . ., but later is found to be innocent beyond a reasonable doubt, generally due to a confession by the actual offender, evidence that had been available but was not sufficiently used at the time of conviction, new evidence that was not previously available, [or] other factors," (Huff et al. 1986, p. 519). This definition highlights a number of means by which a person can be convicted for a crime he or she did not commit. It also highlights particular features of a case that a wrongfully convicted individual may seize upon in order to challenge the trial verdict.

Conservative estimates suggest that wrongful convictions occur in about one-half of one percent of all felony convictions (Huff et al. 1986). Other estimates suggest that the rate of wrongful convictions reflect the particular type of crime at issue. For example, Gross (2008) estimated that the rate for capital murder, rape, and robbery could be from 2 % to 5 %. Focusing on capital rape murder, Risinger (2007) estimated that wrongful convictions occur in between 3 % and 5 % of such cases.

It is not clear which miscarriage of justice does the most harm. Is it worse to wrongfully incarcerate an individual for several years than tarnish a prosecutor's reputation because he/she wrongfully convicted someone with no malicious intent whatsoever? In truth, each and every instance of wrongful conviction is an injustice, making it difficult to rank them from least to worst based on harm. That being said, most would agree that wrongfully executing an individual is the ultimate miscarriage of justice.

A defendant who is wrongfully convicted may eventually be exonerated. An exoneration is "an official act declaring a defendant not guilty of a crime for which he or she had previously been convicted" (Gross et al. 2005, p. 524). Identifying the total number of exonerations in this country is difficult, but evidence suggests that approximately 600–700 exonerations have occurred over the past 35 years (Gross 2008). Of the exonerations examined by Gross and his colleagues (2005), 96° % were for either murder or rape (or sexual assault).

The reasons for which the wrongfully convicted are exonerated also vary. For example, as of September 24, 2011, there were 273 individuals exonerated through the use of deoxyribonucleic acid (DNA) evidence in the United States, 17 of whom were sitting on death row prior to being exonerated (Innocence Project n.d.).

According to Gross (2008), it should come as no surprise that wrongful convictions occur. No system is perfect. Indeed, one can argue that trials are not supposed to be perfect, only fair. Even so, some people have a difficult time believing the criminal justice system can make such egregious mistakes. Were it not for the press attention high-profile exonerations receive, the problem might go relatively unnoticed. The sheer incidence of exonerations has increased from "an average of 12 a year from 1989 to 1994, to an average of 42 a year since 2000" (Gross et al. 2005, p. 527), making the problem of wrongful convictions all the more apparent.

The Death Penalty and Wrongful Convictions

Wrongful convictions in death penalty cases are especially worrisome and arguably the most serious type of mistake the justice system can make. For example, former Illinois Governor George Ryan placed a moratorium on the death penalty in 2000 because at one point, 13 individuals on the state's death row had been exonerated (Zalman 2006). Since that time, seven more death row inmates have been exonerated, bringing the grand total to 20 (Center on Wrongful Convictions n.d.). These 20 exonerations amount to a rate of more than 6° %, which is the highest exoneration rate among states with the death penalty (Center on Wrongful Convictions n.d.). Partly in response to this problem, Illinois Governor Pat Quinn signed a bill into law during 2011 that abolished the death penalty in Illinois (Schwartz and Fitzsimmons 2011).

Unfortunately, researchers have been able to identify cases in which individuals were executed in spite of compelling claims of innocence (Bedau and Radelet 1987). Once a person is executed, there is obviously no going back to correct mistakes; the only way to correct the mistake would be to issue a posthumous exoneration, which would do nothing for the wrongfully convicted person who has been executed.

Notwithstanding the prospect of executing an innocent individual, there is also great concern about forcing the wrong person to sit on death row for an extended period of time. Death row exonerees have pointed to the "fear, anger, loneliness, and feelings of inhumanity that come with facing execution for crimes they did not commit" (Westervelt and Cook 2010, p. 266). Exonerees also speak about the fear that comes along with watching a fellow death row inmate be removed from his cell to face execution, the issues that come along with having one's execution date set, and the anxiety and stress that come from coming within hours of actually being executed (Westervelt and Cook 2010).

The Innocence Movement

Barry Scheck and Peter Neufeld helped draw attention to the issue of wrongful convictions by launching the Innocence Project in 1992. Housed in the Benjamin N. Cardozo School of Law at Yeshiva University in New York, the Innocence Project focuses on helping exonerate the wrongfully convicted, primarily through the use of DNA testing (Innocence Project n.d.). The Innocence Project is able to pursue its mission with the help of the funding it receives from individuals, foundations, its annual benefit dinner, corporations, and the Cardozo School of Law (Innocence Project n.d.).

The Innocence Project is not alone. Other such projects across the country conduct similar work, investigating cases and fighting for individuals they have reason to believe were wrongfully convicted.

The Innocence Movement, as it has been called (Hughes 2011; Zalman 2006), has taken on a significant amount of power with the creation of the Innocence Network. The network is an "affiliation of organizations dedicated to providing pro bono legal and investigative services to individuals seeking to prove innocence of crimes for which they have been convicted and working to redress the causes of wrongful convictions" (Innocence Network n.d.). Each year, the Innocence Network holds an annual conference that brings together member organizations and provides training and information for attorneys working on wrongful conviction cases. In addition, these conferences welcome exonerees from all over the country and invite them to participate, usually through the provision of special activities in which exonerees are able to take part.

Causes of Wrongful Convictions

Several causes of wrongful convictions have been identified. Some are incidental to prosecutorial misconduct. Others are not. Often, what contributes to the problem of wrongful convictions is a series of actions involving the prosecutor and other individuals inside and outside the criminal justice system.

Eyewitness misidentification has been noted as the leading cause of wrongful convictions (Innocence Project n.d.). According to the Innocence Project, eyewitness misidentification was a factor in 75° % of the convictions overturned through DNA evidence (Innocent Project n.d.). Although not necessarily identified as a cause, race has been identified as a factor involved in wrongful convictions, as well; plenty of evidence suggests a defendant's race is associated with whether the individual will be convicted (Bedau and Radelet 1987; Gross et al. 2005).

Judicial errors have also proven responsible for wrongful convictions. They include instances in which judges "allow incompetent defense attorneys, overzealous police and prosecutors, and questionable forensic evidence to permeate the courtroom" (Ramsey and Frank 2007, pp. 446–447). This could include judges improperly allowing prosecutors to make improper and inflammatory statements during the trial.

So-called junk science has been linked with wrongful convictions, as well. This refers to scientific evidence that is either faulty or analyzed improperly and is introduced into evidence. It also refers to forensic testing that is "inaccurately conveyed in trial testimony" (Innocence Project n.d.).

Another cause of wrongful convictions is "snitch testimony," or statements made by a witness who has an incentive to lie. "Snitches" are usually either jailhouse informants who receive some sort of leniency in exchange for their testimony or killers who are trying to divert suspicion from themselves (Warden 2004). According to Warden (2004), snitch testimony is the leading cause of wrongful convictions in capital cases.

Yet another cause is confirmatory bias, which is "the tendency to emphasize and believe experiences which support one's views and to ignore or discredit those which do not" (Mahoney 1977, p. 161). This can be especially troublesome when prosecutors, those working in law enforcement, or even jurors allow confirmatory bias to guide their decision-making.

Still other causes of wrongful convictions include juror bias, juror neglect, community pressure for conviction, errors made by medical examiners and forensic science experts, false confessions, the mental capacity of the accused, and inadequate defense representation (Huff et al. 1986; Scheck et al. 2000; Schehr and Sears 2005).

In general, a single wrongful conviction case will involve more than one of the aforementioned causes (Huff et al. 1986). An example of this can be found in the case of Charles Chatman, who, before he was exonerated in 2008, served over 26 years of a 99-year sentence for a rape he did not commit. The factors that contributed to his wrongful conviction included inadequate defense representation and eyewitness misidentification (Innocence Project n.d.).

Prosecutorial Misconduct

Prosecutorial misconduct involves "the intentional use of illegal or improper methods for attaining convictions against defendants in criminal trials" (Lucas et al. 2006, p. 97). The prevalence of prosecutorial misconduct has been documented in cases of wrongful convictions. For example, in an examination of DNA exonerations conducted by the Innocence Project, researchers found that in 63° % of cases, police and prosecutorial misconduct played a significant part in the wrongful conviction (Scheck et al. 2000).

Prosecutorial misconduct occurs by several means. One common form of misconduct has been identified as withholding exculpatory evidence from the defense (Innocence Project n.d.), in violation of *Brady v. Maryland* (373 U.S. 83 [1963]). In *Brady*, the Supreme Court held that "the suppression by the prosecution of evidence favorable to an accused upon request violates due process where the evidence is material either to guilt or to punishment, irrespective of the good faith or bad faith of the prosecution" (p. 87). The Supreme Court has since explained that *Brady* only applies to pretrial disclosure and does not extend to the post-conviction context (see *District Attorney's Office for the Third Judicial District v. Osborne*, [129S.Ct. 2308, 2319 (2009)]).

How serious is the problem of withholding exculpatory evidence? In their study of 340 wrongful capital convictions, Bedau and Radelet (1987) determined that prosecutor errors occurred in 50 of them. Of those 50, 35 involved the suppression by the prosecutor of exculpatory evidence.

Other methods of prosecutorial misconduct include deliberately mishandling, mistreating, or destroying evidence, allowing witnesses they know or should know are not truthful to testify, pressuring defense witnesses not to testify, relying on fraudulent forensic experts, and making misleading arguments that overstate the probative value of testimony (the Innocence Project n.d.). For example, consider the case of Steven Linscott, who was wrongfully convicted of murder and sentenced to 40 years in prison. During his trial, the prosecutor overstated the strength and importance of forensic evidence and also mischaracterized the state expert witness's testimony (Innocence Project n.d.; West 2010). Or consider the case of Curtis McCarty, who was wrongfully convicted and sentenced to death for a crime he did not commit (Innocence Project n.d.; West 2010). The prosecutor in his case failed to disclose evidence to the defense in a timely manner, made improper comments about facts that were not in evidence, expressed his personal opinion about the guilt of the defendant, and made comments that were found to be improper and inflammatory (West 2010). McCarty served 21 years in prison before he was released (Innocence Project n.d.).

Causes of Prosecutorial Misconduct

Identifying why prosecutorial misconduct occurs could be helpful in preventing future problems. It has been suggested that prosecutorial misconduct may result from insufficient training coupled with a focus on winning, as opposed to a focus on doing the right thing (Ridolfi and Possley 2010). In addition, it is possible that the use of a lower evidentiary standard in the early stages of a case (such as anything other than the "proof beyond a reasonable doubt" that is required at trial) can make it easier for prosecutors to convict someone who is innocent (Forst 2008).

Researchers have also called attention to the high occurrence of procedural errors that take place during the course of prosecutions of serious crimes (Bedau and Radelet 1987; Lucas et al. 2006). This may be as a result of the significant pressure that prosecutors face when dealing with difficult cases, leading them to engage in misconduct partly because they have convinced themselves that these defendants are guilty, thereby justifying their behavior (Lucas et al. 2006).

It has even been suggested that prosecutors engage in misconduct because of the heavy burdens and responsibilities placed on them and not because of any sinister intention to secure a conviction by any means necessary. For example, the expectation of securing convictions may lead prosecutors to naturally view certain evidence in an inculpatory light, thereby preventing them from being able to see the exculpatory value of that evidence. Again, it is not necessarily the case that each instance of prosecutorial misconduct can be traced to intentional acts on the part of the prosecutor.

The Courts and Wrongful Convictions

Appellate courts are especially important in the discussion of wrongful convictions and prosecution because if an innocent individual is convicted, his or her next course of action is to file an appeal. The decisions handed down by appellate courts, especially the US Supreme Court, greatly influence how cases will be decided at the appellate level.

The US Supreme Court has decided a number of cases dealing with all facets of wrongful convictions. These cases have considered a number of issues, including DNA testing, the proper claims to file when seeking certain types of relief, and whether or not it is unconstitutional to execute an innocent person. In addition to Supreme Court cases, the North Carolina State Bar held a disciplinary hearing that was extremely important in reference to the behavior of prosecutors during their quest to obtain convictions. Though not a Supreme Court case, it ranks highly among key wrongful conviction cases.

Key US Supreme Court Cases

Under the doctrine of harmless error, it is possible for an appellate court to affirm a person's conviction, even though prosecutorial misconduct or some other errors were present, so long as the reviewing court believes that the outcome of the case was not affected by errors (Ridolfi and Possley 2010). This was the rule announced in *Chapman v. California* (386 U.S. 18 [1967]), a case in which the Supreme Court decided that "there may be some constitutional errors in a conviction which, in the setting of a particular case, are so unimportant and insignificant that they may, consistent with Federal Constitution, be deemed harmless and which will not require automatic reversal of the conviction" (p. 22). The *Chapman* decision has had a significant effect on those seeking to prove their innocence on appeal. Why? If a number of errors were made at trial, someone who is wrongfully convicted may have serious trouble asserting his or her innocence if the errors made were "harmless." In fact, these errors deemed as harmless may have actually contributed to the person being wrongfully convicted (West 2010).

Another Supreme Court case that has a serious impact on those that are innocent and appealing their convictions is *Strickland v. Washington* (466 U.S. 668 [1984]). *Strickland* dealt with the issue of ineffective assistance of counsel, which, as discussed earlier, is one of the causes of wrongful convictions. In *Strickland*, the Supreme Court set forth the two-prong test for appellate courts to use in analyzing a convicted individual's claim that trial counsel was ineffective. A convicted defendant must show (1) that counsel's performance was deficient, meaning that counsel made errors so serious that it was not functioning as the "counsel" guaranteed by the Sixth Amendment and (2) the deficient performance prejudiced the defense, meaning that counsel made errors so serious as to deny the defendant a fair trial. This test can make it difficult for convicted defendants to prevail on appeal because appellate courts often defer to the judgment of the trial counsel (see, e.g., *Premo v. Moore*, 131S.Ct. 733 [2011]). Therefore, even if defense counsel is ineffective at trial, that attorney's actions may be seen as merely strategic and therefore treated with deference, meaning that a court of appeals will not likely overturn a guilty verdict.

In *Herrera v. Collins* (506 U.S. 390 [1993]), the Supreme Court considered the issue of whether, based on the Eighth Amendment's prohibition against cruel and unusual punishment and the Fourteenth Amendment's due process guarantee, it is unconstitutional to execute someone who was actually innocent of the crime for which he or she is convicted. In that case, Herrera filed a petition for a writ of habeas corpus claiming that, based on new evidence, he was innocent and that his brother, who was deceased at the time the case was heard, actually committed the murders. Although the court ruled against Herrera, holding that his claim of actual innocence did not entitle him to federal habeas relief, it did not clearly articulate whether it would be unconstitutional to execute an innocent person, thereby leaving the key issue unresolved.

In *District Attorney's Office v. Osborne* (129S.Ct. 2308 [2009]), the Supreme Court held that the defendant had no constitutional right to obtain post-conviction access to the state's evidence for DNA testing. Osborne's goal was to obtain restriction fragment length polymorphism (RFLP) DNA testing on the forensic evidence used in his case, as his attorney had failed to do so during trial. Even though Osborne had filed a request under Alaska's post-conviction relief statute, the state would not allow for the evidence to be tested, claiming that the statute did not apply to DNA testing that had been available at trial. The Supreme Court sided with the state. The practical result of the court's decision is that individuals seeking to prove their innocence in posttrial review are at the mercy of state law.

In *Skinner v. Switzer* (131S.Ct. 1289 [2011]), the petitioner was sentenced to death and was trying to obtain DNA testing of previously untested evidence by filing a civil rights action under 42 U.S.C. § 1983. The narrow issue the court decided concerned whether this avenue for relief was proper. It held that a post-conviction claim for DNA testing is properly pursued in a § 1983 claim, meaning that Skinner was permitted to pursue his claim in the federal courts. This provides convicted individuals with the opportunity to file a civil rights claim to seek post-conviction DNA testing, which at the very least allows for a remedy other than filing a writ for habeas relief. Even so, post-conviction review is not guaranteed in light of this decision.

Arizona v. Youngblood (488 U.S. 51 [1988]) offers yet another interesting look into the Supreme Court and the issue of wrongful convictions. *Youngblood* dealt with the issue of a prosecutor/police department's duty to preserve evidence. The police in that case improperly stored evidence, causing it to be degraded. This prevented them from obtaining information that could have identified the offender. Youngblood argued that the destruction of evidence, which he claimed was potentially exculpatory, violated his due process rights. The Supreme Court, however, held that the prosecution and/or police's failure to preserve potentially useful evidence did not amount to a denial of due process of law unless the defendant was able to prove bad faith on the part of the prosecution and/or police. The *Youngblood* decision was handed down in 1988, but in 2000, Youngblood's attorneys were able to persuade the police to test the evidence using a new type of DNA technology. This testing revealed that Youngblood had in fact been wrongfully convicted, which led to his eventual release from prison. In addition, the DNA testing disclosed the identity of the true assailant, which led to that individual's conviction.

The North Carolina Experience

The matter of *The North Carolina State Bar v. Michael B. Nifong* (06 DHC 35 (2007)) is also extremely important to the discussion of prosecution and wrongful convictions. The decision, which was rendered by the North Carolina State Bar, came on the heels of inappropriate actions by then-Durham County District Attorney Michael Nifong in connection with the infamous Duke lacrosse scandal, mentioned at the beginning of this entry. Although the case did not involve a wrongful conviction per se, it is relevant in the present context because, before the North Carolina State Bar become involved, it was a wrongful conviction waiting to happen.

The matter began when an alleged victim reported to the police that she had been sexually assaulted at a party attended by a number of players for the Duke lacrosse team. Early on in the investigation, Nifong decided to prosecute the case himself, and it was believed he had ulterior motives in that he was trying to take advantage of the media attention the case was bound to receive (*The North Carolina State Bar v. Michael B. Nifong*, 06 DHC 35 (2007)). Indeed, it was determined that Nifong continued to proceed with the case and secured indictments against three members of the lacrosse team, even though there was a significant amount of evidence suggesting that the defendants were innocent. Such evidence included (1) questions about the alleged victim's credibility, (2) inconsistent statements made by the alleged victim, (3) being told by law enforcement officials that there was no evidence a rape had occurred, (4) failure of the alleged victim to identify her attackers even though she had viewed two photo arrays, (5) testing from a rape kit that yielded no semen, blood, or saliva evidence in spite of the fact that the alleged victim claimed her attackers did not wear a condom, (6) the alleged victim identifying her alleged attackers on her third try under questionable circumstances, (7) and further DNA testing revealing DNA from four separate males, all of which were inconsistent with members of the lacrosse team.

In spite of all of this evidence, Nifong made repeated statements to the media, speaking about the fact that he was certain there was a rape and that it was racially motivated, talking about the harm and pain suffered by the alleged victim, and described the attack as "gang-like rape activity" (North Carolina State Bar v. Michael B. Nifong and 06 DHC 35 2007, p. 6). The disciplinary committee also found that Nifong had intentionally withheld exculpatory evidence and made false representations to the court – and to opposing counsel. As a result of his actions, the committee found that the only proper punishment was disbarment and ruled that Nifong would have to surrender his license to practice law in North Carolina. In hindsight, it appears that Nifong had every intention of continuing to pursue prosecution, regardless of evidence that the accused lacrosse players were innocent. He went beyond that, however, and even engaged in a campaign to withhold evidence, smear the defendants, and lie to the court. The facts of this case suggest that it had the potential to be a wrongful conviction and demonstrate what can happen when a prosecutor engages in a gross abuse of discretion.

Improving Prosecution

The US Supreme Court noted the following in its majority opinion in *Berger v. U.S.*:

> The [prosecutor] is the representative not of an ordinary party to a controversy, but of a sovereignty whose obligation to govern impartially is as compelling as its obligation to govern at all, and whose interest, therefore, in a criminal prosecution is not that it shall win a case, but that justice shall be done. As such, he is in a peculiar and very definite sense the servant of the law, the two-fold aim of which is that guilt shall not escape or innocence suffer. He may prosecute with earnestness and vigor – indeed, he should do so. But, while he may strike hard blows, he is not at liberty to strike foul ones. It is as much his duty to refrain from improper methods calculated to produce a wrongful conviction as it is to use every legitimate means to bring about a just one. (295 U.S. 78, 88 [1935])

This language highlights the important role of the prosecutor in criminal cases. Although the prosecutor may fight to win the case, the goal is to bring about a just result. In the process, prosecutors must avoid improper conduct that is intended to bring about a wrongful conviction.

As previously discussed, prosecutors enjoy a great deal of power. This is not to say, however, that all prosecutors abuse this power or that the majority of prosecutors do not care about whether they convict an innocent person. Instead, the point is that prosecutors possess a great deal of control in how cases are handled. This points to the fact that their power and discretion can be utilized to ensure that cases are handled properly and in accordance with all ethical guidelines and legal requirements. If prosecutors do make the decision to focus their efforts on seeking justice rather than thinking only about conviction rates, this could change the culture of district attorneys' offices around the country. Such a cultural change could foster an environment in which future wrongful convictions are seen as both unacceptable and preventable. Indeed, there are two key means by which prosecutors' offices can ensure that they seek justice and avoid contributing to wrongful convictions: the establishment of conviction integrity units and by support for post-conviction DNA testing.

Conviction Integrity Units

In January of 2007, newly elected Dallas County District Attorney Craig Watkins was sworn into office. After realizing that Dallas County led the nation in wrongful convictions, he established a Conviction Integrity Unit (Dallas County District Attorney n.d.). Working with the Innocence Project of Texas, the unit now reviews and reinvestigates legitimate post-conviction claims of innocence. It also reviews and prosecutes old cases, those that are DNA and non-DNA related, when there is evidence identifying different or additional perpetrators. To date, the Conviction Integrity Unit has reviewed more than 300 cases and has helped contribute to the running total of more than 20 wrongly convicted inmates coming out of Dallas County (Dallas County District Attorney's Office n.d.).

Dallas County's Conviction Integrity Unit conducts investigations of valid claims, which may require the review of case files, interviewing witnesses, and conducting DNA testing. The county also maintains an open-file policy, which allows defense attorneys to have access to all case files, even at the post-conviction stage (Dallas County District Attorney's Office n.d.). In a number of instances, investigations have led the district attorney to even support the exoneration and release of individuals who have been wrongfully convicted (Dallas County District Attorney's Office n.d.). In addition to exonerating those who have been wrongfully convicted, the unit has also reported instances of confirming the guilt of previously prosecuted individuals.

The Dallas County experience has encouraged similar reforms around the country. For example, in March of 2010, Manhattan District Attorney Cyrus R. Vance, Jr. created a Conviction Integrity Program with the goal of addressing claims of actual innocence and preventing future wrongful convictions. In addition to reinvestigating cases it deems as having meaningful claims of innocence, the unit also utilizes senior members of the staff in order to ensure that the policies of the office are proper in terms of preventing errors, such as false confessions and eyewitness misidentifications. The program also solicits advice from criminal justice experts who serve on the unit's policy advisory panel and who offer advice on the best practices for minimizing wrongful convictions (New York County District Attorney's Office n.d.).

Post-conviction DNA Testing

Prosecutors should refrain from challenging requests that have been filed by convicted defendants seeking post-conviction DNA testing, especially when these requests are properly filed. In addition, prosecutors should support these requests in the sense that they are an opportunity to determine the truth. Although some prosecutors chose not to oppose requests early on, some exonerees report having faced resistance when they attempted to obtain DNA testing to prove their innocence (Garrett 2008).

Prosecutors have become more open to post-conviction DNA testing as a result of changes in state law (Garrett 2008). Forty-eight states currently have some sort of legislation that allows for access to post-conviction DNA testing (Innocence Project n.d.). Some of the elements of these statutes (depending on the state) involve appointing counsel to indigent defendants, setting forth the requirements to qualify for testing, providing information on which laboratory will be used for testing, and specifying who will shoulder the costs of testing (Swedlow 2002).

Despite the benefits associated with such statutes, a number of deficiencies need to be overcome. Several have been identified: (1) not allowing for DNA testing if the person seeking relief entered a guilty plea, (2) not making allowances for individuals that are no longer in custody, (3) not making allowances for individuals who want to challenge one conviction in spite of the fact that they are serving time for a second conviction, (4) not taking into consideration issues that may arise concerning the timing of when these requests should be filed, (5) not allowing successive petitions, and (6) failing to set forth what the proper procedural steps will be if the DNA testing exonerates an individual (Swedlow 2002).

Regardless of their potential limitations, DNA testing statutes play a pivotal role in the criminal process. Without such laws, individuals seeking DNA testing would be at the mercy of law enforcement (Kreimer and Rudovsky 2002). Moreover, access to DNA testing could be blocked, such as out of a desire to uphold the finality of a court's decision, because of testing cost concerns, or due to a belief that a guilty verdict is solid and should be upheld (Kreimer and Rudovsky 2002).

Other Policy Recommendations

To the extent that prosecutors' offices have a role in the incidence of wrongful convictions, they should take aggressive steps to ensure that actual perpetrators are held accountable. Of course, prosecutors are not solely to blame for wrongful convictions; additional justice system reforms are necessary. Several such reforms are readily identifiable.

First, prosecutors should ensure that evidence is being properly preserved, even after an individual is convicted. It has been noted that DNA evidence is not preserved in a large percentage of cases (Garrett 2008). A lack of DNA evidence creates a roadblock for convicted persons who wish to prove their innocence, making it more difficult or even impossible to secure an exoneration. Further, DNA testing has resulted in finding the actual perpetrator in almost 40 % of the DNA exonerations (Innocence Project n.d.). The failure to preserve evidence could prevent the police and prosecution from finding the actual offender once the innocence of the exoneree is proven.

Second, prosecutors should support police reforms that have been based on research identifying factors leading to wrongful convictions. Consider lineups. As previously mentioned, eyewitness misidentification has long been identified as a leading cause of wrongful convictions. Research has suggested that "double-blind" lineups should be utilized so that police officers cannot be suggestive in any manner during lineup administration (Gould and Leo 2010). Double-blind lineups reduce the likelihood of suggestion because neither the officer nor the eyewitness knows the identity of the suspect (Gould and Leo 2010). Prosecutors should push for the implementation of lineup reform in police departments across the country. Doing so can only serve to improve the evidence with which they get to work.

Third, encouraging prosecutors to play some sort of role in the innocence movement could be beneficial. They need to further grasp the extent of the wrongful conviction problem and gain additional awareness of the role of prosecution in past wrongful convictions. Requiring prosecutors to "participate" in the innocence movement to a certain degree could also add to its credibility. This participation could be as simple as establishing a program or policy that resembles the Conviction Integrity Unit in Dallas County. Since prosecutors will likely have access to special resources that defense attorneys may not, establishing a specialized unit within the prosecutor's office could result in not only uncovering miscarriages of justice but also confirming the guilt of convicted individuals.

Fourth, the importance of leadership in prosecutors' offices cannot be overemphasized (Scheck et al. 2000). District attorneys and assistant district attorneys in positions of leadership could set the example for other prosecutors in their offices. They could make it clear that their office respects the law and intends to adhere to ethical guideline*s* and all applicable legal requirements. This could serve as a catalyst in creating the appropriate culture in prosecutors' offices that may be lacking such qualities. At the very least, instilling in prosecutors the notion that although convictions are important justice is only served when the correct person is convicted for the crime could play a major role in improving some of the aforementioned problems associated with prosecution and wrongful convictions.

Fifth, in an effort to address some of the concerns associated with prosecutorial misconduct, prosecutors' offices around the country should consider implementing written policies to ensure that misconduct will not be tolerated. These policies could include guidelines that set forth monitoring and disciplinary procedures that offices rely on when misconduct is suspected or occurs (Ridolfi and Possley 2010).

Sixth, prosecutors' offices and law enforcement agencies could implement written policies that dictate how exculpatory evidence will be handled. These policies should include proper training for prosecutors and law enforcement officials. In addition, they should provide guidelines regarding the disclosure of evidence to ensure that law enforcement is making prosecutors aware of exculpatory evidence and, in turn, that prosecutors hand that evidence over to the defense (Ridolfi and Possley 2010). Written policies, along with proper training, could assist in preventing or reducing the failure of prosecutors to hand over exculpatory evidence.

Seventh, the immunity protection enjoyed by prosecutors should be narrowed, allowing for lawsuits to be filed based on intentional misconduct (Scheck et al. 2000). This would allow for wrongfully convicted individuals to file civil suits against prosecutors that, for instance, let a witness testify against a defendant when the prosecutor knows he or she is lying or intentionally conceals evidence that demonstrates a defendant's guilt (Scheck et al. 2000). Permitting these lawsuits to proceed would prevent prosecutors from asserting immunity as a defense in order to get a suit dismissed. The filing of such lawsuits could serve as a deterrent to "the most outrageous practices, while not interfering with conscientious officials" (Scheck et al. 2000, p. 181).

Lastly, in the interest of justice, prosecutors should support and encourage the provision of adequate assistance to exonerees upon their release from prison. The post-incarceration needs of exonerees and the impact of wrongful convictions have been amply documented. Exonerees often face difficulty finding housing, lack sufficient resources, and are often unable to obtain reintegration services that would have been available to them had they been paroled (Scheck et al. 2000). In addition, exonerees have to deal with feelings of anger, may become anxious when out in public, may suffer from post-traumatic stress disorder, and have to deal with the fact that personal relationships were damaged or destroyed as a result of them being sent to prison (Denov and Campbell 2005). According to the Innocence Project, only 27 states currently have compensation packages that offer monetary (and possibly other types of assistance) to exonerees once they are released from prison, and some of these packages are extremely limited (Innocence Project n.d.). At a minimum, prosecutors could acknowledge that wrongful convictions occur and that exonerees are in need of assistance once they are released from prison. As such, prosecutors should support both the creation of statutes in states that have none and the improvement of existing statutes that are lacking in the services provided to exonerees.

Conclusion

Wrongful convictions have garnered considerable attention over the past few decades, and the role that prosecutors may play in them has been of increasing interest. Prosecutors enjoy considerable authority and autonomy in the criminal justice system. Unfortunately, their authority and autonomy are sometimes abused. At the same time, however, the tremendous power and discretion that prosecutors enjoy can be used to ensure that each case is handled properly and that justice is sought.

Fortunately, progress is being made. DNA testing statutes, court decisions clarifying rights and setting forth certain paths for individuals to take to seek relief, and the implementation of innovative policies like Dallas County's Conviction Integrity Unit are designed to ensure that those who are wrongfully convicted (or even think they are) have some mechanism for challenging their convictions. With continued efforts on the part of everyone involved in the process, including prosecutors, positive change will continue to take place.

Prosecutorial Discretion

Kay Levine
Emory University School of Law, Atlanta,
GA, USA

Overview

This entry addresses the nature of prosecutorial discretion in the United States, with a particular focus on the discretionary behavior of state-level prosecutors (as opposed to federal). After describing the two most prominent forms of discretionary decision-making by prosecutors – filing and plea bargaining – the entry addresses external institutions' ability and willingness to constrain prosecutorial discretion and the role of the prosecutor's office in enabling and shaping discretionary choices by individual employees. Lastly, the entry discusses the case- and offender-level characteristics that seem to influence prosecutorial decisions, and the risk that these considerations lead to discrimination and reinforce stereotypes of crimes, criminals, and victims.

Introduction

Among nations that formally subscribe to an adversarial model of the criminal process, the prosecutor has come to be regarded as the most powerful player in the criminal court. Interest in prosecutorial power is nowhere more prevalent than in the United States, a nation that has witnessed the explosion of its prison population at the same time as its crime rates have shrunk. The responsibility of the prosecutor for mediating between crime and punishment thus has inspired countless investigations of prosecutorial decision-making, including the factors that influence individual choices about the pursuit of criminal charges and the availability of structural constraints to limit those choices in furtherance of equalized treatment of similarly situated offenders.

The Source and Nature of Prosecutorial Discretion

As members of the executive branch of government, prosecutors enforce criminal laws by initiating and pursuing criminal cases against alleged violators. This enforcement duty is not a mandate, though; in most jurisdictions for most crimes, prosecutors have discretion to decide which alleged offenders merit prosecution – and ultimately punishment – by the state. Beyond simply initiating a case against a suspect, prosecutors have the authority to decide how many charges to file for a given episode or transaction, and whether those charges should be felonies (subjecting the offender to more than 1 year incarceration), misdemeanors (subjecting the offender to no more than 1 year incarceration), or merely infractions (subjecting the offender to monetary penalties but no incarceration). For those suspects deemed not worthy of prosecution, the prosecutor has three options: decline to file altogether, pursue the crime as a probation or parole violation if the offender was already subject to probation or parole, or divert the offender into some form of rehabilitation program. (Rarely do prosecutors affirmatively declare a suspect innocent; they simply abstain from prosecuting those cases that seem unmeritorious.) This initial filing decision forms the essence of what is meant by prosecutorial discretion.

In some civil law jurisdictions, prosecutors have no such discretion; once they conclude that a reasonable amount of evidence exists to support the charges, they must initiate a criminal case. (In these nations, undesired consequences of overly broad laws are meant to be handled by code amendments rather than by selective charging strategies.) Whether prosecutors in compulsory jurisdictions vigorously pursue all the cases they file is another matter, however. They might allow a weak case to lapse or fail to diligently conduct further investigation, thereby forcing the court to dismiss the case at some later date. Given these tendencies, even jurisdictions that formally subscribe to compulsory prosecution manifest variations in prosecutorial decision-making (Levine and Feeley 2001: 12227–8 (and cites therein)).

In discretionary jurisdictions, filing is not the only form of discretionary decision-making by prosecutors. Prosecutors also exercise significant discretion when making a plea bargain offer to a defendant, a process that involves asking the defendant to waive his right to trial, plead guilty to certain charges in the indictment, and in return receive a reduced punishment. The prosecutor's discretionary choice at the plea offer stage is twofold: she must first decide what sort of punishment reduction is appropriate for the defendant in light of the facts, the defendant's background, and other relevant circumstances, and secondly, she must decide which of the filed charges the defendant must admit in order to receive this reduced sentence. (The defendant can accept the deal, decline the prosecutor's offer, or make a counteroffer, which the prosecutor may then accept, decline, or counter, pursuant to her discretion.)

In both the filing and plea offer contexts, prosecutors tend to be guided by instrumental objectives. They determine how much the case is "worth" in terms of penalty and then file charges (or make plea offers) to achieve that result. The penal codes of most jurisdictions offer a wide menu of options for prosecutors to choose from, because a single behavior can be characterized as any number of different crimes, each of which carries its own set of penalties, and the prosecutor is not legally obligated to choose either the least or the most serious alternative. For that reason, the prosecutor deciding whether and how to charge a case, or whether and how much to deal a case, pays as much attention to his intuitions about the "right" outcome for the defendant as to the provisions of the substantive criminal law. The relationship between justice and the "right" outcome is not always clear or consistent; the two might be in tension with each other, or justice might be viewed as an integral component of the "right" result.

Given the extraordinary ability of the prosecutor to shape the outcome of a criminal case through his discretionary decisions, one naturally wonders about the ability of other criminal justice institutions to constrain this power. That is the subject of the next section of this entry.

External Mechanisms That Influence Prosecutorial Discretion

This section offers a quick assessment of the external sources of regulation on prosecutorial discretion – legislatures, judges, juries, state bar authorities, and voters. As the literature has documented, these outside institutions are remarkably ill-equipped or unwilling to constrain prosecutorial discretion in state criminal justice systems. Formal legal controls over the institution of prosecution are relatively weak, and voters are able to exert only muted control over prosecutors due to information deficits and the relative absence of contested elections.

The first place to look for regulations on prosecutorial behavior is the criminal code, crafted by the state legislature. By defining crimes narrowly and setting penalties at modest levels, legislators can confine the discretion of prosecutors in the jurisdiction. When it comes to criminal regulatory approaches in the United States, though, parsimony does not flourish. Voters expect prosecutors to take the lead in addressing crime, and they expect legislators to give them the legal tools to do the job. Legislatures do exactly that. Over time they tend to multiply – not reduce – the legal tools available to prosecutors, amending criminal codes to cover more behavior, to increase the range of punishments that apply to criminal behavior, and to intensify the overlap between criminal code provisions (Stuntz 2001). Legislatures thus augment the discretionary authority of prosecutors at both the filing and plea offer stages by providing them with a dizzying array of choices and few requirements.

Though legislators do not regulate prosecutorial discretion through the terms of the substantive criminal law, they might motivate or restrict prosecutors through a combination of carrots and sticks, such as grant programs or direct instructions for how to perform their work. Such techniques gain popularity with legislatures who want to appear responsive to victim complaints and press reports of under-prosecution for certain crimes, as these programs tend to raise the priority status of the targeted crimes vis-à-vis others that occur in the community. For example, the state budget might include funding for local offices to hire extra prosecutors to pursue designated crimes that offices might otherwise choose to ignore. Alternatively, legislatures might instruct local prosecutors to file more charges for specified crimes or to reduce the percentage of dismissals in previously filed cases that allege certain law violations.

While these legislative directives have the potential to be meaningful regulatory devices, their current impact is small due to their exceptional and tentative nature. Budgetary line items that direct prosecutors to devote resources to one type of crime rather than another are unusual, and they represent only a small fraction of an office's annual budget. Most of the money that arrives in the local prosecutor's office each year does not have strings attached, meaning the chief prosecutor can allocate his funds to meet locally identified priorities without having to explain his decisions to state lawmakers (for a discussion of how local priorities produce variation among federal prosecution offices, see O'Neill 2004:1486). As for the crime-specific "no drop" laws, which purport to be hard and fast rules limiting prosecutorial discretion, they leave plenty of room for the individual prosecutor to exercise judgment and to manage her caseload. For example, before filing a "no drop" case the individual prosecutor must still determine whether there is a minimum factual basis for the charge, and she is likely to have little trouble fitting cases into exceptions when she wants to reduce or dismiss a case that has already been filed.

Like the legislature, the judiciary has assumed a muted role in monitoring and controlling the discretion of criminal prosecutors. When judges are asked to override prosecutor choices about the selection or pretrial disposition of charges, they apply separation of powers doctrine and conclude that such decisions are executive choices. Applying the formal law of due process, the judge considers only whether the charges have some minimal factual support in the available evidence. Courts will, however, overturn a prosecutorial decision that is based on race, gender, or some other prohibited ground (Oyler v. Boyles 1962).

Judges do have the statutory authority to accept or reject plea agreements that the parties present to them, and judges concerned about inappropriate deals will question the advocates about their terms. But these judicial powers operate within a system of mass justice where institutional competencies differ and power arrangements shift over time. With respect to competency, the parties typically know more than the judge about both the alleged crime and the defendant's background; for that reason, it is rare for the judge to override a plea deal that both parties support. On the power front, the introduction of mandatory minimum sentence requirements and sentencing guideline schemes has led to a decrease in judicial authority relative to prosecutorial authority (Miethe 1987; Engen and Steen 2000). Legislative innovations intended to thwart judicial leniency thus have merely shifted the critical decision point and the power balance in the criminal court, as prosecutorial charge determinations have become squarely determinative of sentence outcomes in a wide range of cases. This has led scholars to describe the current framework as an "administrative" rather than adjudicatory, criminal justice system (Lynch 1998).

While judges have lost some of their ability to rein in prosecutors, juries have retained their theoretical role as a check on prosecutorial discretion through their power to nullify. Jury nullification denotes the power of the jury to return not guilty verdicts despite strong evidentiary support for the crimes charged. By exercising this power, juries can signal to prosecutors that the charges brought against a particular defendant ought not to have been filed or that the criminal code provision is at odds with community values or priorities. But the jury's nullification power is rarely more than theoretical in light of courthouse realities. Fewer than 5 % of criminal cases are heard by juries (most are plea bargained out of the system at the pretrial stage), and most judges do not allow juries to learn of their power to nullify – either through court-authored jury instructions or attorney argument. As a result, few criminal defendants can count on being saved from prosecutorial excess by a jury with a conscience (or an ax to grind).

Prosecutors as attorneys are also subject to the rules of the legal profession, which instructs and regulates its own members pursuant to disciplinary codes and bar tribunals. But state bar organizations have brought relatively few disciplinary proceedings against prosecutors, and those that have been brought tend to result in only light punishment. Moreover, the courts have routinely found that prosecutors are entitled to absolute immunity from civil damages for all professional decisions made in the course of prosecuting a case, so a criminal defendant who challenges the prosecutor's discretionary filing or bargaining strategy in his case would face an absolute bar to recovery in civil court.

In the absence of robust standards stemming from the legislature, judiciary, jury, or state bar, perhaps state-level elections keep the chief prosecutor's discretion within acceptable boundaries. In contrast to the 93 appointed chief prosecutors who populate the federal criminal justice system (aka United States Attorneys), the more than 2,300 chief prosecutors in the much higher-volume state systems must run for office. Many chief prosecutors are elected on a countywide or citywide basis and must live in the community that elects them. (Occasionally a chief prosecutor is appointed by the governor to fill a recently vacated post in between electoral periods.) For that reason, the pressures of the ballot might subject the elected prosecutor to the wishes of the population she serves or at least force her to pay attention to those wishes when exercising her discretion.

Yet elections of prosecutors deliver less than they promise by way of accountability due to incumbency advantage and the content of electoral discourse. Incumbents enjoy reelection rates of 95 % or higher in most jurisdictions, and about 85 % of them run unopposed (Wright 2009). Aside from the benefit that arises from their position, incumbents in contested prosecutorial elections rarely encounter meaningful public scrutiny of their policies or priorities for the office. Instead, elections turn on generic claims about "competence," familiar but unhelpful measures (like the "conviction rate" of the office), and – most common of all – claims about high-profile cases (both successes and failures). Election rhetoric does not highlight ideological or policy differences between candidates nor does it describe the nature of discretionary decision-making by either the chief or her assistants.

Taken together, these external institutions are sure to have some cumulative regulatory effects on prosecutorial discretion. They do part of the work to ensure that prosecutor choices comply with the law and with current public priorities. They do not, however, explain why prosecutors make the decisions they make in individual cases. To fully understand prosecutorial discretion, one should consider practices that originate from inside the prosecutor's office as well.

Internal Mechanisms That Influence Prosecutorial Discretion

In light of the gaps left by external regulatory approaches, what are the prospects for *internal* regulation of prosecutorial discretion? Some legal commentators considering the sources of internal regulation have focused on the value of one's internal moral compass, concluding that a prosecutor's professional conscience keeps her individually committed to the ideal of responsible behavior in the exercise of her discretion (Cassidy 2006). But this portrayal of the prosecutor as a self-determined island is vastly incomplete. For one thing, the professionals who work together routinely in a criminal courtroom – the prosecutor, the defense attorney, the judge, the clerks, and so forth – influence one another in predictable ways. Some prominent scholarship has explored the impact of these "working groups" of courtroom actors, noting that the members of such groups tend to prioritize the maintenance of their relationships over individual goals and that these relationships affect prosecutorial choices in given cases (Nardulli et al. 1988).

Working groups within the courtroom are not the only relevant group in a prosecutor's world: the home office can also significantly shape a prosecutor's understanding of the justice system, public priorities, and even what qualifies as a crime. Sometimes this office's influence is explicit, as when the chief prosecutor announces office policies that restrict the discretion individual line prosecutors may exercise for certain crimes (like the imposition of compulsory prosecution for crimes involving firearms) or at certain times (like the imposition of limits on how much plea bargaining will be tolerated after filing). The leadership of an office can also create monitoring and enforcement mechanisms within the office to learn about departures from the announced policies and to discourage them. These features are commonplace in federal prosecution offices (called United States Attorneys' Offices), which are all organized under the US Department of Justice. Such formal bureaucratic controls are also a routine part of the prosecutorial services in many other countries (Wright and Miller 2010; Johnson 1998).

Beyond the explicit instructions or direct oversight received from the elected prosecutor or her chief assistant, line prosecutors take their cues from the unarticulated values at work in the office. These often unspoken principles can affect prosecutorial discretion in a variety of ways. For example, they might address the best treatment of a particular type of offense or offender, or they might involve general attitudes about the importance of consistency in handling all types of cases. Like the official policies announced by the chief, these unofficial, word-of-mouth standards have the capacity to both guide and constrain discretionary choices by prosecutors in their individual caseloads.

Finally, structural aspects of the home office may guide prosecutorial decision-making. Various organizational features of the prosecutor's office – size of the workforce, status hierarchies, hiring strategies, job assignments, promotion ladders, physical arrangement of offices, access to the boss, the existence of vertical prosecution units, and the like – structure the professional identities and work lives of the attorneys in the office (see Levine and Wright 2012). These aspects of the social architecture inside the office combine with aspects of the office's external professional environment – such as the proximity to the courthouse, relationships with the defense bar, relationships with the judiciary, relationships with local law enforcement, stability of courtroom personnel, and docket size and diversity (Utz 1978; Jacoby 1977) – to produce the overall institutional environment in which the individual prosecutor works. While the prosecutor may not explicitly recognize environmental factors as controlling when he is considering whether to file charges or to offer a plea deal, their influence is nonetheless observable. For example, scholars have found that offices display certain overall tendencies that distinguish them from other offices in terms of willingness to bargain with the defense bar or to challenge the local bench. Moreover, in most jurisdictions and with respect to most crimes, local law enforcement officers retain significant discretion about which cases to forward to the prosecutor's office in the first place, thereby affecting the diet of potential cases that prosecutors even see. Hence, prosecutorial willingness and ability to press forward certain kinds of cases may depend significantly on law enforcement willingness and ability to properly investigate those cases.

In sum, while external institutions have yielded a lot of ground to prosecutors in the battle over the need for limits on filing and plea strategies, forces inside the prosecutor's own office – explicit policies, behavioral norms, and structural arrangements – tend to keep most individual prosecutors within reasonable (or at least fairly predictable) bounds when it comes to exercising their individual case management choices. Of course, if an office's internal constraints are inadequate, misguided, or corrupt, as when an office fails to properly train its employees regarding their Constitutional disclosure obligations, uses of discretion become less predictable and more risky in terms of legality.

The final section of this entry moves away from the structural perspective to address case- and offender-level characteristics that seem to influence prosecutorial decisions. It also considers scholarly treatment of the risks that such decisions will discriminate against, or further stereotypes about, crimes, offenders, and victims.

Case and Offender Traits That Influence Prosecutorial Discretion

Prosecutors in the USA are under no legal imperative to achieve (or to prioritize) uniformity in case processing; unless internal office policy demands otherwise, they need not worry about trading consistency for individualized treatment of suspects accused of similar crimes (Remington 1979; cf. Johnson 1998, discussing the consistency imperative in Japan). The backstop is the Equal Protection Clause of the Constitution, which prohibits filing or plea strategies based on the offender's membership in a protected class (Oyler v. Boyles 1962). Because the Constitution can tolerate variation that falls short of this kind of intentional discrimination (and because intentional discrimination is exceptionally difficult to prove), empirical work on prosecutorial discretion has centered on identifying the components of individualized treatment, with a normative inquiry into whether certain factors are legally appropriate to include in the filing or punishment calculus. Accordingly, work in this area tends to compare the impact of legally relevant variables with that of legally irrelevant variables on prosecutorial decision-making and case outcomes (see, e.g., Adams and Cutshall 1987; Williams et al. 2007).

Most studies, whether based on qualitative or quantitative data, find that legally relevant variables strongly correlate with both filing decisions and case outcomes. For example, prosecutors assert (and independent review of case files demonstrates) that offenders with significant criminal histories are more likely to suffer adverse consequences in the criminal justice system at every level – to have charges filed against them, to have serious charges filed against them, to have higher bail amounts requested and granted, to be convicted of at least one crime charged in the indictment, and to receive sentences involving incarceration. There is also a positive correlation between these outcomes and evidence strength or crime seriousness (judged by witness number and credibility, level of injury, quantity of drugs, amount of dollar loss, availability of forensic reports, and the like).

For many scholars of prosecutorial discretion, the influence of these factors is expected and defensible; after all, the legally relevant components of a crime and of the offender's background should affect professionals' judgment about the need for criminal justice intervention, particularly when resources are scarce and trial outcomes are uncertain. For others, facially neutral charging and case-handling strategies mask stereotypes about crimes, criminals, and victims that lead criminal justice officials "to focus on some offenses and offenders more than others" (Dawson 2004:106), which in turn causes them to reproduce and reinforce societal biases in the courtroom (Frohmann 1997; see also Spears and Spohn 1997). It may also cause them to underenforce certain crimes, as they implicitly read into the statute extra requirements (elements that the legislature did not explicitly include) in order to conserve enforcement resources or to avoid presenting juries with ambiguous cases (McPhail and Jenness 2005; Levine 2006).

Likewise, the empirical salience of legally irrelevant, or "extralegal," factors in determining case outcomes gives rise to concerns about the exercise of official discretion in the absence of meaningful external controls. Criminal justice scholars have long questioned whether prosecutors exercise their discretion – file charges, request high bail amounts, recommend longer sentences – in ways that disadvantage men, people of color, the poor, nontraditional victims, and other minorities. For example, numerous studies have shown that race is a significant variable in cases involving interpersonal violence (see, e.g., Walsh 1987), although sometimes it is the race of the victim, rather than the race of the defendant, that produces a statistically significant effect (see, e.g., Kingsworth et al. 2002: 562). Findings regarding the impact of offender race on prosecutorial treatment of nonviolent offenses have been more mixed (cf. Engen et al. 1999 with Steffensmeier and Demuth 2000).

Geographic variation within districts that are all subject to the same formal law has also come under scrutiny, with scholars asking whether offenders receive different treatment based on which office files the case against them. Intra-district variation is troubling but not unexpected, given the chief prosecutor's ties to his or her electoral community and the dimensions on which communities vary. Scholars have found a correlation between community poverty levels, community political conservatism, and prosecutorial dismissals (Franklin 2010) and between community demographics and prosecutorial willingness to file charges with mandatory minimum sentences (Ulmer et al. 2007). Geography and defendant characteristics also may not be mutually exclusive influences when it comes to the filing decision. For example, Franklin found that prosecutors in different counties did not use traits like age, race, sex, and prior criminal history in the same way; rather, "the degree to which these factors influenced prosecutorial decision-making (in the initial filing decision) varied depending on the jurisdiction" (Franklin 2010: 697).

The problems with treating similarly situated defendants in a disparate manner become particularly acute in the death penalty context. There has been quite a bit of scholarly interest in the prosecutor's decision to file a murder case as a capital murder case, given that most state statutes authorize capital murder prosecutions in a variety of settings but do not require even the most heinous murders to be pursued in this fashion. For example, scholars have documented significant disparities between counties located in the same state, applying the same formal law, when it comes to their rate of death penalty filings per "death eligible" murder case (American Bar Association 2006), leading to policy calls for more transparency and consistency in the process in order to assure that one's chances of ending up on death row do not arbitrarily depend on county boundaries. Others have found that, irrespective of jurisdiction, the race of the victim has a strong influence on whether a homicide is pursued as capital murder as opposed to something less (Williams et al. 2007). Because those who kill whites are statistically more likely to be prosecuted for capital murder than those who kill African-Americans, prosecutors have been accused of unfairly devaluing the lives of minorities relative to whites. So far, courts have refused to consider these sorts of statistical disparities as legally actionable under the Equal Protection Clause, given the absence of proof of intent to discriminate.

Conclusion

The discretionary decision to charge a suspect with a crime or to offer a defendant a deal prior to the start of trial results from a complex network of factors, some explicit, some implicit in the mind of the prosecutor. The relative absence of external controls on the prosecutor's decision-making process has led to calls for more oversight and accountability, particularly in light of the decrease in judicial authority that has resulted from sentencing guideline schemes and mandatory minimum requirements. While a certain amount of variation is perhaps inevitable given disparities in local needs, resources, priorities, and personalities, institutional mechanisms are necessary to ensure that prosecutorial choices are thoughtfully made, wisely and consistently implemented, and subject to evaluation. Without such efforts, the power of the prosecutor is likely to grow stronger, fed by the public's fear about rising crime rates, politicians' inclination to expand rather than contract the web of criminal statutes, and courts' reluctance to impose doctrinal limits on prosecutorial behavior that falls short of intentional discrimination.

Prostitution

Ronald Weitzer
Department of Sociology, George Washington University, Washington, DC, USA

Overview

Most research focuses on street prostitution and female sex workers, with much less attention devoted to indoor prostitution, male and transgender workers, clients, and third parties including managers. Furthermore, most of the literature examines prostitution where it is illegal, neglecting nations where it is legal and regulated by the government. This entry summarizes theory and research and argues that research on neglected topics will enrich our understanding of contemporary prostitution.

Introduction

Prostitution is one of the "vices" that is distinguished by moral ambivalence: It is considered both deviant and enticing or pleasurable at the same time. Unlike predatory crimes with a clear victim, prostitution involves exchanges between willing buyers and sellers, which leads some members of the public to view it with a measure of tolerance even if they hold an otherwise negative view of it. The same moral ambivalence applies to pornography, gambling, and marijuana use.

The research literature on prostitution is sizeable but remains deficient in some important respects. Much more attention has been paid to street prostitution than to indoor prostitution and to female prostitutes much more than other actors (male and transgender workers, clients, managers). This entry highlights key aspects of contemporary prostitution and then draws attention to several under-examined issues. The focus is mostly on Anglo-American societies.

Competing Theories

Three main theoretical perspectives have been applied to sex work. One of these, the *oppression paradigm*, holds that prostitution reflects and reinforces patriarchal gender relations. Advocates of this paradigm argue that exploitation, subjugation, and violence against women are *intrinsic to and ineradicable from* sex work (Barry 1995; Jeffreys 1997), and these advocates typically use dramatic language to highlight the plight of workers ("sexual slavery," "prostituted women," "survivors"). Such terminology is meant to emphasize the notion that prostitutes are victims and that prostitution is not something that can be chosen. Likewise, clients are called "prostitute users" and "sexual predators."

Some of these claims are not amenable to verification or falsification, and the very definition of prostitution as inherently oppressive is one dimensional. Oppression theorists typically describe *only* the worst examples of sex work and treat them as representative, and they tend to ignore counterevidence that challenges the theory. Despite being a fairly extreme paradigm, it remains one of the three main theoretical perspectives on sex work.

The *empowerment paradigm* is radically different. It focuses on the ways in which sexual services qualify as work and may be potentially liberating for workers (Chapkis 1997; Delacoste and Alexander 1987). This paradigm holds that there is nothing inherent in sex work that would prevent it from being organized like any other economic transaction for the mutual gain of buyers and sellers alike. Prostitution can benefit sellers economically and can, under the right circumstances, provide greater control over working conditions than many traditional jobs. Writers who adopt the empowerment model also argue that most of the tenets of the oppression model reflect the way in which *some* sex work manifests itself when it is *criminalized*.

Most empowerment theorists argue that sex work is *potentially* empowering, not that it is necessarily so. They tend to neglect sex workers who labor under harsh conditions and instead highlight success stories in prostitution. It can be liberating for those who are "fleeing from small-town prejudices, dead-end jobs, dangerous streets, and suffocating families" (Agustin 2007, p. 45).

Both of these paradigms are one dimensional. While exploitation and empowerment are certainly present in prostitution, there is sufficient diversity across time, place, and sector to demonstrate that prostitution cannot be reduced to a single phenomenon. An alternative perspective, the *polymorphous* paradigm, holds that there is broad variety of occupational arrangements, power relations, and experiences of those who sell and buy sex. This paradigm is sensitive to complexities and to the structural conditions shaping the uneven distribution of agency, subordination, and job satisfaction (Weitzer 2010). The polymorphous perspective is superior to the other two paradigms because it is supported by a wealth of social science evidence (see Shaver 2005; Vanwesenbeeck 2001; Weitzer 2010).

Types of Prostitution

Prostitution is defined as the exchange of sexual services for material compensation. There is a great deal of *variation* in prostitution within and between societies and across different echelons. Prostitutes differ in their reasons for entry, number and type of clients, freedom to refuse clients, access to resources for protection, relationships with colleagues, dependence on third parties, experiences with the authorities, public visibility, and impact on the surrounding community.

Street Versus Indoor Settings

In street prostitution, the initial transaction occurs in a public place (sidewalk, park, truck stop), and the sex act takes place in either a public or private setting (alley, car, park, hotel, etc.). Indoor prostitution takes place in brothels, massage parlors, bars, hotels, private premises, and other places. In many countries, indoor prostitution is much more prevalent than street prostitution. On many dimensions of prostitution, street and indoor sectors differ substantially. It is not the sheer fact of being indoors that distinguishes indoor from street prostitution; instead, certain features of indoor settings are preconditions for a work environment that can differ substantially from street-level work. Such indoor features include the capacity for better screening of clients, less accessibility to street predators, and greater safety if one works indoors with other prostitutes or with a manager. In addition, prostitutes who work indoors generally come from at least somewhat more advantaged socioeconomic backgrounds than those who work on the streets.

Individuals enter prostitution through different paths. Some are recruited by pimps or otherwise coerced into the trade; others drift into prostitution gradually and tentatively, often at the encouragement of friends. Some initially worked in other branches of the sex industry (e.g., strip clubs, phone sex) and later decided to experiment with prostitution. Many street prostitutes are runaways who end up in a new locale with no resources and little recourse but to engage in some kind of criminal activity. Economic motives predominate throughout the trade, ranging from survival to a desire for financial independence or upward mobility.

A segment of the street population is involved in "survival sex": They sell sex out of dire necessity. Many street workers have a history of childhood abuse (violence, incest, neglect). Many work and live in crime-ridden areas; are socially isolated and disconnected from support services; use addictive drugs; are in poor health; are exploited and abused by pimps; and are vulnerable to being assaulted, robbed, raped, or killed on the streets. Off-street work is less hazardous. Studies that compare street and indoor workers, using well-constructed, purposive samples, find substantial and sometimes huge differences in victimization rates. In addition to street-indoor differences in *ever* being victimized, similar disparities have been documented in the *frequency* and *severity* of victimization.

This does not mean that off-street work is risk-free: Indoor work in the Third World, for example, is typically conducted under harsher conditions than in developed countries. Still, there is no doubt that indoor settings are *generally* safer than the streets: Indoor workers and their managers are in a better position to screen clients prior to contact; they may work in a place with video surveillance and alarm systems and if they work with others, can rely on colleagues to intervene in the event of trouble with a client.

Street and indoor prostitutes also differ in the *services* they provide. Street workers spend little time with customers and conversation is kept to a minimum. Indoor interactions are typically longer and richer and include conversation, foreplay, nonsexual intimacy, and a semblance of romance. Studies also show that escorts and brothel workers are much more likely than street workers to receive a massage, manual stimulation, or oral sex from their clients (Lever and Dolnick 2010; Woodward et al. 2004). Some indoor workers *expect* such conduct from clients as a routine part of the encounter. For them, the experience revolves around *both* party's sexual pleasure.

Like other jobs, prostitution does not have a uniform effect on workers' psyches and self-images. Research indicates, as one would expect, that street prostitutes are much more likely than both nonprostitutes and indoor sex workers to exhibit psychological disorders and low self-esteem. The stress and danger associated with street work contribute to psychological problems.

A comparative study of 75 streetwalkers and 75 call girls in California and 150 legal brothel workers in Nevada found that 97 % of the call girls and 50 % of the brothel workers reported an *increase* in self-esteem after they began working in prostitution, compared only 8 % of the streetwalkers (Prince 1986, p. 454). And an Australian study found that half of the 102 call girls and 103 brothel workers interviewed felt that their work was a "major source of satisfaction" in their lives, while 7 out of 10 said they would "definitely choose" this work if they had it to do over again (Woodward et al. 2004, p. 39). A majority of indoor workers in other studies similarly report that they enjoy the job, feel that their work has at least some positive effect on their lives, or believe that they provide a valuable service. Self-esteem and job satisfaction are higher at the mid and upper levels of prostitution because of workers' higher education, greater income, control over working conditions, and better screening of clients.

Sex workers do not necessarily confine themselves to one type of work for their entire career. There is some occupational mobility. Some strippers and porn performers, male and female, engage in paid sexual encounters with their fans. It is rare, however, for workers to experience substantial upward or downward mobility. Transitioning from street work to the middle and top echelons is quite rare, because most street workers lack the education and social skills associated with upscale work.

The studies reviewed here provide strong evidence contradicting some popular myths as well as the oppression paradigm in academia. While certain factors are universal (minimizing risks, managing client behavior, coping with stigma), other work-related experiences, as well as the harms typically associated with prostitution, vary greatly. The prostitution market is *segmented* between the indoor and street sectors – marked by major differences in working conditions, risk of victimization, and job satisfaction and self-esteem.

Male and Transgender Prostitution

Most theory and research centers on female prostitutes. Transgender prostitutes rarely have been studied, whereas male prostitutes have attracted somewhat more attention from scholars. The limited research points to both similarities and differences between the three types. Like women on the street, young male street prostitutes often enter the trade as runaways or to support a drug habit. Like mid- and high-end female workers, men working at those levels have at least some regular clients and may develop emotional attachments to them. And, like female workers in the mid- and upper-level tiers, similarly situated men are more likely than their street counterparts to view their work positively (Minichiello et al. 2001; West 1993). Uy et al. (2007) found that a sample of male escorts felt desired and validated as a result of being generously paid for sex; their self-confidence and body images improved the longer they sold sex.

Gender makes a difference in the following areas. Compared to women, men:

- Are less likely to be coerced into prostitution, to have pimps, and to experience violence from customers because males are able to exercise greater physical power over customers
- Exercise greater control over their working conditions
- Are less stigmatized within a sector of the population (the gay community) but more stigmatized in the wider society because of the combination of prostitution and homosexual behavior

Too little is known about transgender sex workers to draw even tentative conclusions along these bulleted dimensions. However, transgenders do face greater challenges than both female or male prostitutes: They have higher HIV infection rates, "usually have the least desirable prostitution location, make the least money, and are stigmatized and ridiculed by non-transvestite male and female prostitutes" (Boles and Elifson 1994, p. 85). Transgender sex workers are also more likely than males to be assaulted or raped while at work. Many male transgenders conceal from customers that they are not biological women, increasing the chances of altercations with deceived clients. Other customers expressly seek out transgenders who appear to be women but are anatomically male – something the customer may find "kinky" or thrillingly transgressive and allowing them to have the "best of both worlds" physically and sexually. This dynamic is unique to transgender sex workers and their customers.

A Brazilian study reported that for transgender sex workers, prostitution was the only sphere of life that enhanced their self-image: Prostitution gave them a "sense of personal worth, self-confidence, and self-esteem" (Kulick 1998, p. 136). They sold sex not only for the money but also for emotional and sexual fulfillment. In a San Francisco study, researchers discovered that "sex work involvement provided many young transgender women of color feelings of community and social support, which they often lacked in their family contexts." Another advantage was that sex work gave these individuals a "sense of independence and non-reliance on others (i.e., managers, co-workers) who might express discrimination or harassment" (Sausa et al. 2007, p. 772). Sex work was one of the few arenas in which they could shield themselves from societal rejection.

Customers

A significant number of men have bought sex. The General Social Survey reports, in ten polls from 1991 to 2008, that 3–4 % of American men had paid for sex in the past year and 15–18 % saying they had paid for sex at some time in their life. Similar figures are reported for Australia (16 %) and the average within Europe (15 %) (Rissel 2003). The real numbers are likely higher given the stigma involved in revealing such conduct. The majority of customers appear to have bought sex only once or a few times, while a minority are repeat or frequent clients.

Customers vary demographically (e.g., age, social class, marital status) just like the wider male population: A study comparing a large sample of customers with a nationally representative sample of American men found few differences between them (Monto and McRee 2005). Most clients do not act aggressively or violently: There is "no evidence to suggest that more than a minority of customers assault prostitutes" (Monto 2010, p. 243).

Customers buy sex for very different reasons:

- They desire sex with a person with a certain demeanor or physical appearance (e.g., physique, race, transgender).
- If they have a regular partner, they may be unsatisfied with the sexual dimension of their relationship and seek satisfaction elsewhere.
- They have difficulty finding a partner for a conventional relationship.
- They find this transgressive conduct thrilling.
- They seek to exercise control over or violence against women and act out this desire by targeting prostitutes because of the ease of access and belief that they will not report abuse to the police.
- They want to be free of the obligations of a conventional relationship.
- They seek an emotional connection in addition to sex.

A survey of 1,342 customers in three cities found that 41 % sought "a different kind of sex than my regular partner" wants, 43 % said that they were "excited by the idea of approaching a prostitute," 42 % said they "like to have a -variety of sexual partners," 42 % said they "like to be in control when I'm having sex," and 28 % said they did not want the responsibilities of a conventional relationship (Monto 2010).

Some clients are motivated by the possibility of forming a short- or long-term relationship with a sex worker. This is particularly evident in tourist locations, such as Thailand, the Philippines, and the Caribbean, where Western men meet dancers or bargirls at nightclubs and pay a bar fine to leave the club with a woman. They may spend a night or several days together (perhaps visiting tourist sites) with the man paying for the woman's time or for all expenses. Some of these men become boyfriends and enter into long-term or serial relationships, sending gifts and money from overseas and reuniting on return visits. Many of the women and some of the men are consciously seeking a long-term relationship, and some end up marrying. The women see such associations as a means of securing upward social mobility. A similar dynamic occurs among some gay tourists and male prostitutes, where paid sex can evolve into a protracted boyfriend relationship (Padilla 2007).

Some recent research sheds light on customers' *experiences* during paid-sex encounters. In addition to those Internet websites where workers advertise (sites listing services and prices, biographical sketches, photos, etc.), some websites contain message boards for clients. These sites provide novices with information on what to expect in prices and services, client "reviews" of a specific worker (appearance, behavior), location of establishments, and other useful information and accounts of personal experiences. The sites provide unique insight into customer expectations, justifications, and conduct norms – dimensions addressed only partially in previous interviews and surveys. Derogatory comments about certain providers are made in some online entries but others lavish praise on specific workers. And many of the cyber exchanges among men draw from a code of ethics for consumers: discussing inappropriate behavior toward sex workers, with warnings for misogynists, those seeking underage workers, and other deviants. Internet forums offer a unique window into customers' experiences, the meanings they attach to prostitution, and a new subculture.

Many clients of indoor workers seek more than sex. They also want a provider to be attentive and friendly; to engage in conversation; and to kiss, cuddle, and be otherwise affectionate. This kind of treatment has long been sought by customers of indoor workers, but recently, it has acquired a new label – the "girlfriend experience" (GFE), which borders on what one would expect from a girlfriend or the "boyfriend experience" for clients of male prostitutes. One study found that customers' online entries focused on nonsexual aspects of the GFE to a greater extent than on a sex worker's physical attributes or sexual performances (Sharp and Earle 2003). For some clients, the GFE is more physical and means that the sex is not mechanical but instead is experienced as "making love." Many customers value reciprocity: They are interested not only in satisfying themselves but also in giving a sex worker pleasure. Such clients, as well as those who seek emotional intimacy and companionship, challenge the oppression paradigm's assumption that commercial sex inherently involves objectification. Indoor clients in one study did not view sex workers as "targets of sexual conquest" or "simply as bodies"; instead, these men were paying for a meaningful, personal connection with a woman (Sanders 2008, p. 98).

Research shows that many have had very good paid-sex experiences and feel that their encounters have enhanced their lives. Others, however, have had negative feelings: They fear discovery, feel shame or guilt, or are dissatisfied with a particular encounter because of awkwardness, performance problems, being rushed, or feeling that they did not get what they paid for. Others feel embarrassed about paying for sex, fear contracting a disease, or fear being caught by wives, girlfriends, or the police.

Like any service occupation where workers spend an extended amount of time with clients, indoor sex workers view different clients differently. They like some clients tremendously and despise others and are indifferent to yet others. Some customers are demanding, belligerent, and difficult to handle; this does not appear to be the norm among clients of mid- and upper-echelon providers because they can be more selective. In one study, "most call girls have not had bad experiences, and more often than not, they have positive things to say about their customers" (Perkins and Lovejoy 2007, p. 112). As one call girl stated, "The only way I can sustain regulars is if I actually like them and I may like them for different reasons.... A number of my clients are intelligent men who are well informed and can carry on a stimulating conversation" (quoted in Perkins and Lovejoy 2007, p. 63). Bernstein (2007, p. 103) describes this as "authentic (if fleeting) libidinal and emotional ties with clients, endowing them with a sense of desirability, esteem, or even love." This is certainly not true for all indoor prostitutes, as some maintain strict affective boundaries to avoid developing strong feelings for their clients: They engage in "counterfeit intimacy" – nothing more than a manufactured emotional connection that only *appears* to be a GFE.

It might be assumed that all customers would prefer to buy sex services indoors because these settings are associated with greater safety, hygiene, a more pleasant atmosphere, and a much lower risk of being arrested by the police than what is typical of street-level sex.

Some indoor places, such as brothels and saunas, offer other kinds of recreation in addition to sex, such as a bar, karaoke singing, stripping, and gambling – attractions that clients may value as much as the sex for sale. Many clients indeed feel this way, but others prefer the streets. Streetwalkers may be preferred because of easy access and low prices, and some men get a thrill out of cruising for sex. These men are not seeking a GFE; the brevity of street transactions means that conversation is minimal and an emotional connection either impossible or rather truncated. Other clients would never consider buying sex on the street, because they are seen as dangerous places.

What about female customers? Little is known about this but it is a much smaller market than that catering to male clients. Vacation spots are one setting in which women may buy sex from men. In the Caribbean, for instance, affluent European and North American female tourists meet young local men on the beaches and at clubs (Phillips 1999; Pruitt and LaFont 1995; Taylor 2001). The similarities between male and female sex tourism include the economic inequality between buyer and seller. In both cases, local people may have few other options for earning the kind of money they can get from selling sex, while the foreign client comes from much more advantaged circumstances. Aside from this fundamental structural pattern, it is not known whether female sex tourists differ significantly from the male tourist/female provider type in terms of objectification of the worker, amount or type of exploitation, and the exercise of control over the workers. Finally, almost no research has been done on commercial sex transactions in which both parties are women. What differences, if any, are there between this type of exchange and transactions where both parties are men? Comparative research would help to clarify the ways in which gender differences affect the dynamics of commercial sex exchanges.

Third Parties

Most research focuses on either sex workers or customers, ignoring third parties. Much more research is needed on the dynamics of recruitment, socialization, surveillance, exploitation, coercion, and trafficking. The findings will contribute to a more comprehensive picture of diverse power relations, ranging from those types where workers experience extreme domination to those where they exercise substantial control and are free of mistreatment.

While many prostitutes work independently, others are managed by or involved with third parties. A manager is someone who exercises control over a worker and extracts some or all of the profit. This includes street pimps and those who run brothels, massage parlors, and escort agencies. Some management practices are consistent with those of any other business, while other aspects are unique to a sexually oriented and marginalized business. Workers generally expect managers to screen customers and act as allies, defending them against problem clients. But managers vary in the extent to which they live up to these expectations. Some provide the bare minimum of amenities to their workers, are lax about health and safety, favor certain employees over others, or treat all of their workers very poorly; others have collegial relations with their employees, rigorously screen customers, and generally take pains to ensure safe and healthy working conditions.

These different patterns are illustrated in a small but important body of research, including Heyl's (1977) study of the training of novice workers in one American brothel, Zheng's (2009) ethnography of erotic karaoke bars in a Chinese city, Trotter's (2008) ethnography of bars in the harbor areas of South Africa, where the bar girls cater to foreign sailors, Steinfatt's (2002) analysis of bar prostitution in Thailand, and Perez-y-Perez's (2003) participant observation in three New Zealand massage parlors. Each researcher documents the ways in which managers control, support, or exploit workers, and act as brokers between workers and customers. Like other businesses, the managers also deal with external forces, such as the police, political officials, and local residents when they attempt to intervene in the affairs of the establishment – for example, demanding bribes or free sex, imposing new restrictions on how the business operates, or calling for the place to be shut down. Middlemen are a different and unique third party, connecting sex workers with clients. They offer a vital service where direct client access to workers is hampered. For instance, middlemen in towns along transnational highways get paid by long-distance truck drivers who need interpreters and brokers to find a local prostitute; the middlemen recommend specific women based on the drivers' preferences and protect both the clients and the workers from robbery, assault, or reneging on agreed-upon services. These are some of the ways that third parties organize and manage prostitution.

Legal Systems

The legal context governing prostitution can be considered a critical variable, but most research has been conducted in nations where prostitution is prohibited. This means that what we think we "know" about prostitution may be distorted by the heavy focus on criminalized prostitution. The few existing studies of legal prostitution systems indicate that many of the harms often associated with prostitution are partly due to its illicit status. Where it is illegal, prostitution is set apart from legitimate work, workers are marginalized, and the authorities provide little if any protection. Legalization has the potential of alleviating these problems. And the fact that prostitution is legal and regulated in several nations shows that there are alternative prisms through which a population can view prostitution, perhaps including somewhat different moral universes within which this and other kinds of vice are regarded. It is possible, therefore, for this type of deviance to become at least somewhat normalized, as is true for some other vices, in the aftermath of legalization.

Certain kinds of prostitution are legal and regulated by the government in many more nations than is commonly thought, including the Netherlands, New Zealand, Australia, and Germany. It is technically illegal yet tolerated and even regulated in some other places, such as Belgium and Thailand. Regulations vary from place to place, but a common objective is harm reduction. Depending upon the nation, the law may give workers labor rights and provide for the screening of brothel owners and the licensing and taxing of their businesses; regulations may govern how establishments operate, dictate their size and their signage, and impose safe sex and other health requirements (Weitzer 2012).

The available evidence suggests that prostitution, when legalized and regulated by the government, can pay dividends although this is certainly not guaranteed. Nevada legalized prostitution in 1971 and currently has about 30 brothels scattered around its rural counties (but not in Las Vegas and Reno). These legal brothels "offer the safest environment available for women to sell consensual sex acts for money" (Brents and Hausbeck 2005, p. 289). Research on other legal prostitution regimes finds similarly that they tend to increase sex workers' safety (Weitzer 2012). In most of these cases, brothels have implemented screening procedures, surveillance, panic buttons, or listening devices that reduce the chances of abuse by customers and allow for rapid intervention in case of trouble.

Legalizing prostitution is one thing; implementing and enforcing regulations in accordance with the new law is another, and it has presented serious challenges in many nations post-legalization. Some of the common problems include difficulties in getting prostitutes and business owners to comply with the law, eliminating parasitical third parties such as pimps and traffickers, and dealing with continuing opposition from a segment of the public that wishes to tighten restrictions or repeal the law entirely. We are just beginning to identify regulations that work well and those that are problematic, and policymakers continue to grapple with unforeseen challenges in governing a legal prostitution sector. There are some exceptions to these teething problems, such as Nevada and New Zealand, where the aftermath of legalization has been relatively smooth, but elsewhere (e.g., Germany, Australia, the Netherlands), the implementation of legal arrangements has been buffeted by a host of problems, including the simultaneous growth of illegal prostitution in tandem with the legal sector – a two-tiered situation that has been difficult to resolve (see Weitzer 2012). Such problems are not unique to prostitution post-legalization but apply to other vices as well, as illustrated by the recent challenges posed by legalized medical marijuana in the United States.

Conclusion

The literature is heavily weighted toward studies of street prostitution, female sex workers, and illegal prostitution. To facilitate a more balanced and comprehensive picture, a major shift in research is needed – investigating indoor sex workers of all types, male and transgender providers, managers, and legal prostitution systems. Research in these areas will enhance our understanding of sex work and its polymorphous character.

Overview

Sometimes it is important for legal purposes to determine a decedent's mental state at the time of death. The psychological autopsy was developed in the late 1950s by mental health professionals associated with the Los Angeles Suicide Prevention Center (SPC) to assist with clarifying the mode of death in equivocal cases (Litman et al. 1970; Shneidman 1981; Shneidman and Farberow 1970). An equivocal death is one in which the *cause* of death may be known – but the *mode* of death is unclear (Shneidman 1981). The mode of death is classified by way of the NASH acronym: natural causes, accident, suicide, or homicide. For example, if an individual is found floating in a river, the cause of death may be asphyxiation due to drowning, but the mode of death may be unknown with three possibilities arising: an accidental drowning, a suicide, or even a homicide. Another example would be someone found dead at the base of a building; the cause of death is multiple crushing injuries, but was this an accidental fall, a suicidal jump, or a case of the deceased being pushed? Shneidman (1981), who coined the term *psychological autopsy*, noted that as many as 20 % of all deaths may initially be deemed equivocal. In such deaths, the mode of death cannot be determined by conventional medical or investigative procedures. What is needed is a retrospective evaluation of the decedent's mental state and the surrounding facts in the case to help determine the mode of death. This entry begins with a historical summary of the psychological autopsy and an examination of its relationship with other forms of analysis, its legal admissibility, and its criticisms of the technique. This will be followed by a discussion of guidelines for conducting psychological autopsies, including appropriate qualifications for practitioners, decision-making frameworks, and the reporting of results. Finally, future directions for the psychological autopsy will be outlined.

Historical Foundations

The psychological autopsy was developed when Drs. Edwin Shneidman, Norman Farberow, and Robert Litman from the SPC were invited by then Los Angeles County Coroner, Dr. Theodore Curphey, to assist in cases of equivocal suicide. The coroner named this group the Death Investigation Team. Shneidman and Farberow (1970) reported that the team

> focused primarily on the *personality* elements associated with suicide, such as suicidal intention, subtle communications relating to suicidal intent, reactive or psychotic depression, and schizophrenia... the approach of the team was to reconstruct the life style and personality of the deceased, mainly by interviewing the spouse, grown children, parents, physician, and others who knew him well. On the basis of these psychological data, and any other physical evidence of suicide, accident, homicide, or natural death that might be found, the Death Investigation Team attempted to make informed extrapolations over the last days of the victim's life and then to report these conclusions and recommendations to the coroner for final integration with his other findings (p. 497).

It should be noted that Dr. Avery Weisman subsequently adapted the psychological autopsy for use in helping to understand the precipitating causes related to unequivocal deaths. To this end, Shneidman (1974) wrote that "Dr. Weisman has creatively extended the reach of the psychological autopsy to deaths that are unequivocal as to mode, pursuing such additional piercing questions as: why did this (clearly physically, accidental, or suicidal) death occur at *this* time? What psychological events preceding the dying period might be related to the death itself? How can we understand this death better?" (p. xi). Weisman (1974) described the application of the "Omega Version" of the psychological autopsy within hospitals, which included information obtained from "actual contact with the patient" (p. 35).

In contemporary times, the psychological autopsy is frequently used as an approach to help understand suicides. In fact, a database search of the term psychological autopsy will invariably result in more references referring to the use of the technique in unequivocal cases than the equivocal cases for which it was originally developed. Accordingly, LaFon (1999) sensibly suggested that the equivocal death psychological autopsy be differentiated from the suicide psychological autopsy. The focus of this entry will be on the equivocal death psychological autopsy, although invariably some literature and research pertaining to the suicide psychological autopsy are still relevant to the investigation of equivocal deaths as the two variants of the technique are clearly conceptually and practically related.

It should also be noted that since the introduction of psychological autopsies, a variety of terms have been used to describe the use of the psychological autopsy in equivocal deaths. For example, some authors have used the term *psychiatric autopsy*, although this has usually been used as a synonym for the same technique. Bendheim (1979) attempted to differentiate the psychiatric autopsy from the psychological autopsy based on the differences in training between the two types of mental health professionals. However, Ogloff and Otto (1993) cogently noted that "this distinction appears strained and smacks of guild interests more than significant differences in technique" (p. 608). Accordingly, the broader term, psychological autopsy, seems to have been used by most mental health professionals who research or carry out this type of work.

Equivocal death analysis (EDA) was a term coined by behavioral scientists at the Federal Bureau of Investigation to describe their analyses of equivocal deaths for law enforcement (Ault et al. 1994; Poythress et al. 1993). Canter (1999) noted that an EDA "is carried out by law enforcement officers, usually FBI agents, who only examine the crime scene material and other information directly available to the police inquiry" and suggested that "an EDA is open to many more biases and distortions than a 'full' psychological autopsy" (p. 128). However, recent literature from EDA practitioners suggests that there is perhaps little actual difference between the two terms (Lacks et al. 2008), although assessors may not always conduct the required interviews themselves. Given the variety of terms in use and the various permutations of the technique, Ogloff and Otto (2003) suggested the umbrella term *reconstructive mental state evaluation* to "include techniques or a group of techniques whereby a mental health professional attempts to describe or discern the mental state of a deceased or missing person at some prior point in time" (p. 1186). It should be noted that they stressed this definition and did not suggest that nonmental health professionals were unqualified to conduct such analyses in certain circumstances.

Relationship to Other Forms of Analysis

While seemingly esoteric, psychological autopsies clearly have some parallels with other forms of behavioral and psychological analysis. As the prior mental state of the person is one of the key considerations, clinical assessments for the purposes of an insanity or mental impairment defense are conceptually related. While both techniques involve the retrospective analysis of collateral information, insanity evaluations generally involve knowledge of the behavioral outcome and are concerned with determining the person's mental state and intent at the time of the offense (Ogloff et al. 1993). In comparison, while psychological autopsies also require a retrospective assessment of the individual's mental state and intent, an opinion is also required regarding the person's actions (i.e., to determine the mode of death). Indeed, in the case of the mental state at the time of the offense evaluation, the mode of death is known. Furthermore, the major difference is obviously that for insanity evaluations the person being assessed is available for examination, although his or her mental state may well have changed from what it was at the time of the offense.

Some authors have made a conceptual link between the psychological autopsy and offender profiling, a technique in which the likely characteristics of a person are inferred from their offense behaviors. This link likely reflects the fact that some authors and practitioners have been engaged in both activities (e.g., Ault et al. 1994; Canter 1999). However, these are considerably different techniques. Offender profiling is essentially a form of retro-classification that provides the broad characteristics of an unknown offender. In contrast, the psychological autopsy provides more fine-grained and definitive opinions regarding the intentions of a known individual, right down to classifying their death into one of four nominal categories. Where the two activities do overlap is in regard to their basic rationale. According to Shneidman (1970), psychological autopsies are theoretically based on the principle that dying behaviors are an integral part of the lifestyle of the individual. In this way, a detailed examination of the individual's life will shed light on their death. Similarly, offender profiling is often based on the premise that behavior reflects personality (Douglas et al. 1992), such that aspects of offence behavior will reflect behavior in other aspects of the offender's life. Thus, both activities can be conceptualized as elaborations of routine activity theory (see Canter 2000) but from different directions and with very different levels of focus.

Perhaps the most closely related technique to the psychology autopsy is that of indirect personality assessment. As the name suggests, this involves an assessment of an individual's personality without actually meeting the person. These include "psychiatric profiles" of world leaders used by governments for intelligence purposes, such as the well-known psychiatric analyses of Adolf Hitler conducted in the 1940s (e.g., Langer 1972). A seemingly more common application is in criminal investigations, where evaluations of an individual suspect and their likely reaction to questioning or other investigative approaches are discerned from collateral information (Ault and Hazelwood 1995). This is similar to a psychological autopsy, except for the fact that the person is still alive, although, as with the psychological autopsy, the person conducting the assessment does not have the benefit of directly accessing the subject of the evaluation. The other difference lies again in the focus, which is on likely future behavior rather than likely past behavior (i.e., reason and cause of death).

Legal Admissibility of Psychological Autopsies

Evidence based upon psychological autopsies, or similar reconstructive evaluations, has been admitted by courts in various jurisdictions, although this has primarily been in the civil arena. In the United Kingdom, attempts to admit psychological autopsies in criminal cases have been unsuccessful. For example, in the case of *R v. Gilfoyle*, a man was convicted of murdering his pregnant wife who died from hanging. A psychological autopsy conducted by a professor of psychology suggested that suicide was a likely mode of death, but this was deemed inadmissible (see Canter 2005). However, evidence of a similar nature was admitted in the unpublished Northern Ireland case of Torney (1996, as cited in Gudjonsson and Haward 1998). In this case a police officer was charged with the murders of his wife, son, and daughter. He claimed that his son had gone "berserk" and killed his mother and sister before committing suicide. A psychologist reviewed the case material and testified that the scene was not consistent with this scenario. Rather, they suggested that a carefully planned execution was more likely. This evidence was admitted and the defendant was convicted of all three murders. While this evidence does not appear to have been described as a psychological autopsy, the parallels with this technique are obvious.

In regard to American courts, Ogloff and Otto (1993, 2003) noted that the technique has been chiefly admitted within civil courts, but added that there has been reluctance to permit testimony regarding mode of death. Rather, testimony limited to the decedent's state of mind prior to death is more likely to be allowed. Ogloff and Otto also noted that psychological autopsies have been allowed in cases of insurance and workers compensation, but not in regard to testamentary capacity or intestate succession, which suggests that the courts are uncomfortable with psychological autopsies that opine on the ultimate issue. Ogloff and Otto also found that criminal courts have been less willing to admit such evidence, and on the rare occasions in which they have, the ultimate issue is not directly addressed. Indeed, Ormerod (2001) described the 1996 case of *USA v. Jean* in which a "psychological expert was permitted to testify that none of the indicators of suicide normally associated with a person who commits suicide were present" (p. 22) but was not permitted to state that therefore the deceased was murdered.

Criticisms of Psychological Autopsies: The USS Iowa Controversy

The use of psychological autopsies in equivocal deaths was soundly criticized following the widely publicized and now infamous USS Iowa incident in 1989. This involved an explosion aboard a US naval ship that killed 47 sailors. A Naval Investigative Service (NIS) investigation initially ruled out the possibility of an accidental explosion. The NIS focused their attention on two sailors: one who died in the explosion and a friend who was set to be the beneficiary of the other's life insurance policy. They asked behavioral scientists at the FBI's National Center for the Analysis of Violent Crime to give an opinion, based upon the evidence collected during the investigation, regarding the likelihood of three outcomes:

(a) Mass murder by the surviving sailor
(b) A suicide-homicide attempt by the dead sailor to get revenge on the surviving sailor for getting married
(c) Suicide by the dead sailor due to a variety of personal reasons

The FBI analysts formed the latter opinion. This caused considerable controversy, with some writers critical that the agents had not considered the possibility of an accident (which was later determined to be the cause of the explosion when the case was reopened; see Lacks et al. 2008). This is perhaps an unfair criticism because an accident had been ruled out by the referring agency at the time of the referral. Nevertheless, a "peer review" panel of 14 psychologists and two psychiatrists was somewhat critical overall. The co-chair of the House Armed Services Committee reportedly commented that "the FBI flunked this peer review" (see Poythress et al. 1993, p. 10).

However, a more balanced evaluation of the review panel's conclusions is provided in an empirical study of their reports (Otto et al. 1993). This revealed that the members of the peer review panel were largely in agreement with the FBI agents' inferences regarding the dead sailor's adjustment and psychological functioning, with agreement on 70 % of such information. However, the panel was not in agreement with the agents regarding the dead sailor's culpability and risk for suicide, with the FBI agents providing what were described as more negative and stronger conclusions than those of the panel members. There was also some suggestion that competing hypotheses were ignored. On the basis of this case, some members of the panel recommended that the users of psychological autopsy techniques "should not assert categorical conclusions about the precise mental state or actions of the deceased" (Poythress et al. 1993, p. 12) and should also make appropriate qualifying statements for any opinions rendered. This is a very sound suggestion that should be followed in psychological autopsies and other equivocal death analyses since they force the person or people conducting the review to explicitly consider and weigh evidence both in favor of and against all reasonable alternatives.

Qualifications Necessary for Conducting Psychological Autopsies

Those conducting psychological autopsies would appear to require a high degree of expertise and knowledge from a variety of disciplines and areas. Given the nature of the practice, it is recommended that the assessor be a registered mental health professional (i.e., a psychologist or psychiatrist is most likely), that they have training and experience in the assessment of suicide and risk factors for suicide, and that they have some familiarity with viewing and interpreting death scene materials and photographs. As noted above, a deficit in one of these areas would not necessarily obviate an individual from conducting psychological autopsies, so long as the person benefitted from the expertise of colleagues who have the requisite level of expertise in a complimentary area. Indeed, FBI behavioral analysts and detectives trained in the FBI's methods conduct such analyses without being registered mental health professionals; ideally, however, they have access to psychological or psychiatric experts with whom they can discuss the case and obtain the necessary assistance and support. Regardless, these proposed skills suggest that some degree of specialist multidisciplinary knowledge is required. Similarly, Ritchie and Gelles (2002) suggested that mental health professionals conducting psychological autopsies should receive "basic didactic information" in the areas of crime scene investigation, toxicology, and forensic pathology. This advice would seem particularly necessary for psychologists who need not be medically trained and may not have a background in biology or chemistry.

Lack of Standard Guidelines

Despite the fact that psychological autopsies have been conducted in cases of equivocal death since the late 1950s – and likely long before without being recognized as such – there is a remarkable lack of standard guidelines for the technique. Shneidman (1981), one of the originators of the technique, advocated a flexible procedure but noted that there were 16 areas of information which "might be included" in a psychological autopsy. These were extended and greatly elaborated by Ebert (1987) to 26 categories of applicable information regarding the deceased individual. Ebert's list of information has been deservedly influential, as subsequent guides have essentially modified and slightly extended his initial list. All of these approaches provide useful information for ensuring that data collection is thorough. However, none describe how one should subsequently use the information to make a final conclusion (Otto et al.1993). Ogloff and Otto (1993) argued that without a standard technique, terms such as psychological autopsy "are really describing a goal of an inquiry as much as a particular technique" (p. 611). This is concerning because opinions expressed in psychological autopsies can ultimately form the basis of very important decisions. For example, Jobes et al. (1986) reported that, in an experimental paradigm, the inclusion of brief psychological autopsies had a statistically significant impact on medical examiners' subsequent opinions regarding mode of death.

An attempt at providing an actuarial (i.e., mechanical and algorithmic) approach to one of the decisions involved in psychological autopsies is the *Empirical Criteria for the Determination of Suicide* (ECDS; Jobes et al. 1991). This is a 16-item tool, derived from an earlier 55-item Death Investigation Checklist, which can provide an indication as to whether a death is likely to be a suicide or an accident. The ECDS involves three sections. Section A refers to self-infliction and intention and consists of 13 items (e.g., toxicological evidence indicates self-inflicted death, decedent had suicidal thoughts). Section B refers to self-infliction only and includes two items (i.e., decedent had experienced general instability in immediate family, decedent had recent interpersonal conflict). Section C includes one item relating to intention only (i.e., decedent had history of generally poor physical health). A total self-infliction score is obtained by adding sections A and B, and a total intention score is obtained by adding sections A and C. The case is determined to be a suicide if the score on both totals is three or more. The case is determined to be an accident if at least one of the total scores is two or fewer.

The ECDS was found to correctly classify 100 % of suicides and 83 % of accidents in the cases reviewed, producing an overall level of correspondence with the professional medicolegal judgment of death 92 % of the time. However, and perhaps appropriately, the authors cautioned that "it must be emphasized that the ECDS do not provide absolute and definitive determinations of the manner of death independent of professional medicolegal judgment. Indeed, the ECDS should only be understood (and used) as a tool for investigation which augments professional judgment" (Jobes et al. 1991, p. 254). Similarly, Simon (2002) described the ECDS as "useful as an adjunctive tool to professional clinical judgment" (p. 150). It should also be noted that the ECDS was developed to differentiate between suicide and accident modes of death, so it is not applicable in cases of potential homicide.

A Decision-Making Framework for Psychological Autopsies

As noted above, the various published lists of information required to inform a psychological autopsy vary in the degree and nature of information required, and they do not describe how one should subsequently use the information to make a final conclusion of accident, suicide, homicide, or natural causes. Shneidman (1981) provided a rare example in which a widow revealed to him her late husband's suicide note that she had not shown the police, but such "smoking gun" variables are likely to be very rare in equivocal death cases. Ebert's (1987) pioneering guidelines suggested that practitioners make a chart divided into the four nominal categories (natural causes, accident, suicide, homicide) and record data that supports each mode of death. Analysts were also encouraged to consider the possible reasons why the deceased may have committed suicide and the possible reasons why they may have been murdered. The listing of evidence for and against the four modes of death (or three, as some authors focus only on accident, suicide, and homicide where appropriate) has also been advocated by subsequent authors (e.g., Napier and Baker 2005; Ritchie and Gelles 2002). However, this process should not simply result in an additive procedure wherein the person counts the number of items in each category and chooses the one with the highest frequency count. Rather, Napier and Baker (2005) stated that "the goal is to arrive at a preponderance of factors listed under one of the headings" but added that "from this listing it becomes evident that some factors weight more heavily than others" (p. 624). The final determination is made therefore by the evaluator by some unknown weighting of the various pieces of evidence adduced.

Given the paucity of guidelines for assisting practitioners in making the inferential leap of determining accident, suicide, or homicide in psychological autopsies, Davis (2004, 2010) proposed that a scenario-based hypothesis-testing approach that forms part of a structured decision-making and report-writing framework may be useful. The first section of these guidelines is the *Checklist of Equivocal Death Information*. This brings together more than 30 areas of information included in previous psychological autopsy publications, as well as other potentially useful information, and is loosely divided into six domains: Personal, Health, Family, Relationships, Preceding Months and Days, and Death Scene. The assessor conducting a psychological autopsy is interested in the longitudinal status of information within each of these domains as well as any recent changes. The *Personal* domain covers the deceased's education and employment history, military service, religious beliefs, legal history, victimization, writing, language, reading material, feelings regarding death, familiarity with methods of death, and hobbies and interests. The *Health* domain covers physical health, alcohol and substance use, and mental health (including general psychological history, mood, and personality). The *Family* domain addresses the quality of relationships with family members, any familial history of substance use or mental illness, conflicts within the family, and any history of suicides or recent deaths in the family, along with the deceased's reaction to any such deaths. The *Relationships* domain covers the deceased's history of intimate and non-intimate relationships, as well as the details of any current romantic relationships. The *Preceding Months and Days* domain draws the assessor's attention to psychosocial stressors, any pre-suicidal behavior, recent changes in habits or routine, and any evidence of future life plans. An estimation of the mental status examination prior to death (i.e., orientation, mood, affect, psychotic symptoms, and judgment) is made, and the events of the day prior to death are reconstructed with particular focus on any departures from the deceased's usual routine. The final domain is the *Death Scene*. This involves an examination of the police report, death scene photographs, pathology and other forensic reports, any suicide notes, and the significance of the death scene to the victim. Particular attention is paid to any evidence of other people at the death scene, any signs of a struggle, the possibility of a staged crime scene, or evidence of sexual activity.

There is some unavoidable overlap between these various domains. However, the grouping into six categories facilitates consideration of the deceased's personality, behavior, mental state, and interpersonal environment over time, with the final two domains providing an eventual focus on the preceding days and the death itself. The checklist, like other previously published psychological autopsy checklists, provides an aide-memoire for the assessor to ensure that a comprehensive assessment takes place, thereby reducing errors of omission. However, a thorough assessment will also be sensitive to the idiographic features of the case. For example, if the death potentially involved dangerous autoerotic practices, more information regarding the deceased's history of such behavior would undoubtedly be required. Hazelwood et al. (1981) identified five characteristics of the autoerotic death scene which assessors should consider in such situations: evidence of a physiological mechanism for obtaining sexual arousal that is dependent upon a self-rescue mechanism or the victim's judgment to discontinue its effect, evidence of solo sexual activity, evidence of sexual fantasy aids, evidence of prior dangerous autoerotic practice, and no apparent suicidal intent.

To use this wealth of information to answer the questions required of a psychological autopsy, Davis (2004, 2010) has argued that it is important to adopt a method in which the totality of the data is considered in context. While not a case of equivocal death, Canter (1999) alluded to the use of a hypothesis-testing approach in investigating the cause of a fire. This is not unlike the "scenario"-based approach advocated for the assessment and management of recidivism risk in offenders and sex offenders (Hart et al. 2003), although that approach is used to speculate about the future rather than the past. Nonetheless, such an approach appears relevant to the analysis of equivocal deaths, as it promotes consideration of multiple variables in context, rather than simply adding variables together in an abstract mechanical fashion.

Using the above approach, Davis (2004, 2010) proposed that assessors develop a series of scenarios that may explain the death in each modality (accident, suicide, and homicide). The assessor then lists the evidence for and against each competing scenario. It is important to explicitly list and evaluate evidence that does not support one's preferred scenario, as failing to acknowledge conflicting information may contribute to the bias of the assessor and has been a previous criticism of psychological autopsies (Poythress et al. 1993). In essence, each scenario is conceptualized as a hypothesis that has to be subjected to systematic critical scrutiny and potential falsification.

In evaluating these scenarios, relevant empirical information should be consulted where appropriate. For example, significant changes in routine are an important consideration in suicide cases (Litman et al. 1970). When formulating homicide scenarios, it is important to also consider the deceased's level of risk for murder and to determine how much their lifestyle and activities placed them at risk of being a victim of violence. When formulating accident scenarios, the lethality of the deceased's behavior should be taken into account, such as how likely an accident was to result in death.

At the end of this process, Davis (2004, 2010) proposed that assessors rate the likelihood that each scenario occurred. This can be expressed in probabilistic terms, or perhaps more appropriately, using ordinal ratings of low, moderate, or high. This is important, because as mentioned above, making outright conclusive opinions has previously been questioned in the literature (Poythress et al. 1993). It would be prudent to consider relevant crude base rates where possible (although they will presumably all be quite low) and also to consider which is the most parsimonious explanation out of the competing scenarios. When making their final determination as to likely mode of death, it may also be helpful for the assessor to provide an indication of their confidence in the decision being made. Indeed, Douglas and Ogloff (2003) have found that determinations of future risk made by forensic mental health evaluators when they are confident about their decision are more likely to be accurate than when they are less confident about their determinations of risk for violence. The option of "unclear" should always be available, as the assessor should not feel that a conclusive opinion must be made. It is an inevitable reality of this inexact and complex practice that some cases will simply have to remain equivocal.

Communicating Psychological Autopsy Results

The most detailed and prescriptive report-writing guidelines for psychological autopsies have been provided by the United States military. These guidelines involve numerous subheadings in an attempt to carefully avoid speculation in the report. Part of a proposed peer review process is to determine whether the examiner has followed the prescribed structure when writing their reports (see Ritchie and Gelles 2002). Employing a somewhat different approach, Davis (2004, 2010) suggested that the exact format of the report will likely vary from case to case; however, a useful structure should include the following components: sources of information and caveats, case summary, personal history of the deceased, stressors, evaluation of different scenarios in each modality (the core of the report) and a final opinion of which scenario is most likely, and the assessor's degree of confidence about the opinion.

Future Directions

The psychological autopsy has been in existence for more than 50 years. However, it is still hampered by questions of practically unknown reliability and validity. Indeed, Ogloff and Otto (2003) observed that it is difficult to find another area of psychological expert testimony that has been admitted as evidence with such little empirical foundation. It should be noted that reliability has received some limited research attention in regard to the psychological autopsy of unequivocal suicides. Werlang and Botega (2003) developed a semi-structured interview protocol to assist in conducting such analyses. They found that this resulted in a high level of inter-rater reliability in regard to assessors' final ratings on each scale of precipitators and stressors, motivation, lethality, and intentionality. Similar studies are needed to determine the inter-rater reliability of psychological autopsies in cases of equivocal death, particularly in regard to the various modes of death. Structured guidelines, such as those described above, have the potential to maximize inter-rater reliability over that of more intuitive approaches.

Establishing the validity of psychological autopsies is extremely difficult, which may explain why it has not yet been accomplished or even attempted. By definition, validity is impossible to determine because the focus of the analysis is deceased. The very factors that make a death equivocal and in need of a psychological autopsy also obviate any knowledge of the "true" mode of death by which to compare the outcome of the analysis. However, Ogloff and Otto (1993) suggested almost two decades ago that researchers could identify cases in which the correct answer is known and then remove the most obvious information, such as a suicide note, prior to presenting the case. Analysts using the psychological autopsy could then be compared to the known "true" outcome to provide some measure of predictive validity. However, such studies have not yet been conducted. Accordingly, the psychological autopsy currently remains a promising, yet unavoidably subjective, form of forensic analysis in cases of equivocal death.

Psychology of False Confessions

Jennifer T. Perillo
John Jay College of Criminal Justice and
The Graduate Center, The City University of
New York, New York, NY, USA

Overview

A false confession is an admission by an innocent person to a crime he or she did not commit, often accompanied by a narrative indicating the particulars of how the crime was committed and why. As first noted by Hugo Munsterberg in 1908, innocent people may confess for a variety of reasons, both dispositional and situational. Munsterberg exhibited an understanding of false confessions ahead of his time and discussed different types of false confessions that are prompted in different ways. In the decades since Munsterberg's historical work, research has revealed much about the various motivations, tactics, and issues that may result in false confessions, as well as the consequences of those confessions.

False confessions create serious problems for the criminal justice system, especially when the consequences for wrongful convictions are considered. Confession evidence is enormously powerful in court and has a strong impact on judges and juries. Even when contradicted by other evidence and lacking corroboration, confessions produce high rates of conviction. This is partially because confessions can corrupt other evidence, making exculpatory evidence seem artificially weaker while at the same time making inculpatory evidence seem stronger.

To safeguard the criminal justice system, researchers have proposed a number of reforms to the practices of interrogation – including a ban on tactics that put innocent people at risk and the requirement that all interrogations be recorded in their entirety. Additionally, questions have risen concerning the admissibility of expert testimony to educate jurors on why innocent people would confess and the possible impact of those confessions on other evidence. If the rate of false confessions can be curtailed and if lay jurors can become better informed about the limits of confession evidence, the conviction of innocent people may be significantly reduced.

Fundamentals of False Confessions

Prevalence of False Confessions

Although false confessions pose a problem for the criminal justice system, there is no way to derive or estimate the frequency of false confessions. Often guilt and innocence cannot be known, and many confession cases are never adequately scrutinized. Examples throughout history, however, suggest false confessions are not a rare occurrence. Dating back to the Salem witch trials of 1692, numerous false confessions have been revealed through various means.

In the past, false confessions could only be identified only when the confessed crime was proved to be impossible (e.g., the alleged victim was still alive) or the real perpetrator was apprehended. The advent of DNA testing in recent years has expanded the identification of the wrongfully convicted, predominantly in cases involving rape and murder. In aggregated databases, it appears that 15–25 % of those wrongfully convicted had confessed to their crimes.

Confession experts note that these cases are the tip of the iceberg. Indeed, the databases of wrongful convictions do not include those whose false confessions were discovered before trial, those that were not publicized, those that were not contested by the confessor, or those that resulted in a plea bargain. In addition, there remain numerous inmates protesting their innocence who are barred access to DNA testing, some of whom may be innocent. Finally, these databases concentrate on US populations – despite documentation of false confessions all over the world – and within the criminal justice system, thus excluding false confessions that occurred within the private sector (e.g., loss prevention cases) and in military intelligence settings.

Types of False Confessions

Although it is not possible to determine the overall prevalence of false confessions, it is possible to distinguish among different types of false confessions. Researchers recognized that false confessions occur in different ways and for different reasons and created a taxonomy that distinguishes between three types of false confessions: voluntary, compliant, and internalized (Kassin and Wrightsman 1985).

Voluntary False Confessions

Voluntary false confessions occur when individuals willingly and purposefully claim responsibility for crimes they did not commit. These admissions are made in the absence of police pressure or encouragement. People may volunteer false confessions for any number of reasons: to garner attention, fame, or recognition; to satisfy a need for self-punishment in the face of perceived transgressions and feelings of guilt; the inability to distinguish fact from fantasy, which is a common feature of certain psychological disorders; or to protect someone else. Especially a problem with juveniles, voluntary false confessions often occur to protect a parent, child, or other close relative or friend.

Compliant False Confessions

Compliant false confessions occur in response to police pressure during interrogation. In these cases, a suspect is induced to confess in order to escape the stress of interrogation, to avoid a threatened or implied punishment, or to gain a promised or implied reward. The social pressure acting in the interrogation room serves to convince innocent individuals that the short-term benefit of confession (i.e., escape from the interrogation room) outweighs the long-term costs (i.e., prosecution and possible conviction). As a result of isolation, stress, fatigue, or deprivation of needs, innocent individuals may acquiesce to demands for confession, despite knowing they are innocent, as an act of public compliance.

Internalized False Confessions

Sometimes, innocent suspects actually come to believe they have committed a crime for which they are innocent. Typically internalized false confessions involve suspects whose memories are rendered vulnerable to manipulation and who are presented during interrogation with highly suggestive and misleading "evidence" of their guilt. In these cases, the suspect becomes confused, comes to believe that he or she may have committed the crime, and even, at times, confabulates detailed false accounts of what happened. The innocent suspects' internalized beliefs in their guilt can actually lead to the formation of false memories of what they allegedly did, how they did it, and why.

Risk Factors for False Confession

The risk of false confessions is associated with three sets of factors: (1) dispositional characteristics that make some suspects more vulnerable than others, (2) situational factors associated with the stresses of custody and interrogation, and (3) the phenomenology of innocence, whereby innocents waive their rights.

Dispositional Risk Factors

Dispositional risk factors refer to personal characteristics of suspects that increase their risk of a false confession relative to the general population. Not everyone is equally vulnerable to influence during an interrogation. Instead, factors such as personality, cognitive impairments, psychopathology, and youth can place some individuals at a disproportionate risk of falsely confessing.

Compliance and suggestibility appear to be two important personality risk factors (Gudjonsson 2003). Compliance refers to a desire to please others and avoid confrontation and conflict. Compliant individuals are particularly susceptible to those in a position of authority, with whom confrontation would be much more stressful, putting them at risk in an adversarial interrogation. In contrast, suggestibility concerns the strength and stability of one's memory. Overall, individuals who score high in suggestibility have poorer overall memories, lower self-esteem, high anxiety, and low levels of assertiveness.

The Gudjonsson Suggestibility Scale (GSS) is the typical measure used to assess interrogative suggestibility (Gudjonsson 1984). This measure involves presenting a narrative to a subject who must recall the story immediately and then after a delay. The subject then answers questions about the contents of the paragraph, and some of the questions include misleading information. The test administrator provides negative feedback indicating several answers are incorrect, and then the subject is retested. The scale provides subscale measurements of shift, the tendency to change one's memory over time, as well as yield, the tendency to cede to misleading questions and incorporate misinformation into memory. In studies of crime suspects, those who had confessed and later retracted their confessions scored higher in suggestibility than the general population, whereas resistors, those who maintained their innocence throughout interrogation, obtained lower scores. Sleep deprivation and alcohol withdrawal can also increase an individuals' suggestibility as tested by the GSS.

Individuals suffering from mental retardation or other intellectual deficits are also at risk in an interrogation setting (Gudjonsson 2003). Mental retardation is associated with heightened levels of both compliance and suggestibility. Individuals with mental impairments are also less likely to fully comprehend their *Miranda* rights, more likely to acquiesce to authority figures, and more susceptible to leading questions, misinformation, and other forms of suggestive questioning. Research shows that individuals with mental retardation rely more on authority figures for answers to problems, accept blame for negative outcomes, and have memory deficits.

Research has also identified mental illness as a risk factor (Gudjonsson 2003). Many psychological disorders are associated with distorted perceptions of reality, including difficulty with reality monitoring or separating real life from fantasy. Other common symptoms of psychological disorders include impaired judgment, debilitating anxiety, mood disturbance, and lack of self-control. Each of these factors alone can increase the likelihood of false confession and, in combination, may create a strong risk factor for offering misleading information, including false confessions, during interrogation. Individuals suffering from high anxiety may also be more likely to false confess simply to escape the stress of the interrogation room.

Youth is a particularly strong dispositional risk factor (for a review, see Drizin and Colgan, 2004). Overrepresented in the cases of known false confessors, juveniles aged 18 and younger comprise over 30 % of the sample. Juveniles tend to be more compliant toward authority figures, and they are more likely to trust what those authority figures tell them. Juveniles are more suggestible than adult witnesses, so they are more likely to confabulate details for false accounts under suggestive questioning. Juveniles also have less ability to consider long-term consequences of their actions. This means that juveniles are more likely to confess to obtain the short-term goal of leaving the interrogation room without considering the long-term consequences of such an action. Juveniles also show poorer comprehension of their *Miranda* rights than adults, so they are less likely to invoke their rights. Research also shows that juveniles are overall more likely to confess than adults.

Situational Risk Factors

Situational risk factors refer to aspects of the custodial setting and police interrogation tactics that can lead innocent people to confess. The Reid technique, the leading method for interrogating suspects used by interrogators across the United States and widely used across the world, uses psychological tactics to produce confessions from suspects (Inbau et al. 2013). The basic approach of the Reid technique is to increase the anxiety associated with continued denial of an offense and decrease the anxiety associated with confession to make it easier for a perpetrator to admit involvement in a crime. To that end, the Reid technique uses many tactics to increase the anxiety of the interrogation setting, some of which may increase the vulnerability of innocent suspects. In particular, researchers have focused on three basic aspects of the interrogation process: isolation, confrontation, and minimization.

Interrogators are trained to question suspects in the police station, away from any support system or familiar surroundings. The Reid technique offers specific instructions on the layout of interrogation rooms, recommending that they be sparse and free of any visual distractions to increase feelings of isolation. Basic social psychology research has shown that isolation can have profound effects on people, who are social beings, particularly in times of stress. Isolation reduces feelings of self-control, autonomy, certainty about the future, anxiety, and, in turn, incentive to confess in order to escape the aversive situation.

The anxiety stemming from isolation builds up over time, which highlights the issue of interrogation time as a risk factor. Observational and survey research indicate that the typical interrogation lasts under 2 h. In contrast, interrogations resulting in known false confessions last an average of more than 16 h, with over one-third of false confessions lasting between 12 and 24 h (Drizin and Leo 2004). It stands to reason that these lengthy interrogations are associated with increased anxiety, fatigue, and sleep deprivation, which can impair decision-making and increase the tendency to confess as matter of expediency.

In the second stage of interrogation, interrogators confront suspects with strong assertions of guilt. The goal is to convince suspects that resistance is futile and that confession is their best option. Interrogators are specially trained to overcome suspects' denials, refute their alibis, point to inconsistencies in their stories, and convince them that proof of the suspect's guilt is certain. These claims are often bolstered by the presentation of false evidence. One common method of presenting false evidence is through use of the polygraph. After a suspect takes a polygraph, the interrogator informs the suspect that he or she has failed, irrespective of the actual outcome of the test. This tactic is designed to convince suspects that their guilt is obvious and conviction is certain, so confession is the only reasonable option. The presentation of false evidence serves to make innocent suspects feel trapped by the evidence. In this situation, innocent suspects sometimes feel they have no choice but to confess in order to obtain leniency for a crime for which they do not believe they can prove their innocence. There have been numerous exoneration cases involving the presentation of false evidence, and false evidence has been shown to consistently increase the rate of false confession in laboratory experiments as well.

The third stage of the interrogation process is to minimize the crime. Once suspects feel trapped by the weight of alleged evidence, interrogators provide suspects with moral justifications and face-saving excuses for the crime. Minimization increases the tendency to confess by minimizing suspects' perceptions of the consequences of confession. Interrogators are thus trained to develop elaborate "themes" for why a suspect committed a crime – themes that minimize their moral culpability. Interrogators may suggest that the crime was accidental, for example, provoked by the victim, unplanned, well intended, or the result of a drug or alcohol problem or peer pressure. Although minimization statements do not offer explicit promises of leniency, research shows that they lead people to infer that leniency will be forthcoming following confession.

Innocence as a Risk Factor

By observing that innocent suspects behaved differently from guilty suspects in the interrogation room, Kassin (2005) proposed the provocative theory that innocence itself could be a risk factor for confession. Innocent suspects tend to believe the truth will prevail and their innocence will be obvious to interrogators. As a result, innocent suspects put themselves at risk by waiving their *Miranda* rights to silence and to counsel, agreeing to speak with the police, and cooperating fully (Kassin and Norwick 2004). Believing they have nothing to fear or hide, innocent suspects fully answer questions about a crime, even when the answers include information that could be seen as incriminating. Research suggests that innocent suspects do not use self-presentation "strategies" about their narrative content when talking to police, so their stories do not vary according to the questioning process (e.g., Hartwig et al. 2005). Of course, innocent suspects are often initially unaware that they are suspects, instead believing that they are aiding in the investigation.

Being forthright can have unintended consequences for the innocent suspect who is interrogated. Research shows that police presume guilt when questioning suspects and that this guilt bias can lead them to engage in more aggressive interrogations with innocent suspects who vigorously deny involvement (Kassin et al. 2003). These aggressive interrogations may include more problematic techniques that increase risk of false confession. When interrogators use the false-evidence ploy, for example, innocent suspects may feel trapped and confess as a means of minimizing consequences. Even when interrogators do not use the false-evidence ploy, the practice of increasing the anxiety associated with denial during interrogation can lead innocent, as well as guilty, suspects to search for a way out of interrogation. When police officers bluff about evidence – assert evidence has been found but not yet tested – innocent suspects may still falsely confess to escape the stressful situation, believing the evidence would later exonerate them (Perillo and Kassin 2011).

Empirical Research on False Confessions

False confessions have been studied using a variety of methods: individual and aggregated case studies, naturalistic observations of police interrogations, self-report data from police officers and prison inmates, and laboratory and field experiments.

Two main laboratory paradigms exist in the false confession field. In the first, participants are accused of hitting a forbidden key during a computer-typing task and crashing a computer (Kassin and Kiechel 2004; Kassin and Kiechel 1996). In the original study of this paradigm, researchers also manipulated participant vulnerability by varying the speed in which the participants typed the letters. Some participants were also presented with false evidence in the guise of a confederate who claimed to have seen the participants hit the key they were instructed to avoid. The false-evidence ploy increased rates of false confession, internalization, and confabulation, especially among those when rendered vulnerable with the fast typing speed. This computer-crash paradigm has been used all over the world to replicate and extend these original findings.

A second paradigm tested false confessions by varying guilt and innocence within a cheating scenario (Russano et al. 2005). Participants were paired with a confederate to solve a series of problems, which varied between solo and joint sessions. In the guilty condition, the confederate requested help from the participant during a solo session, which was a violation of the experimental rule. In the innocent condition, the confederate worked silently and did not request help. All participants were later accused of cheating by the experimenter. In a test of the impact of minimization, the experimenter then promised leniency, made minimizing remarks, used both tactics, or used no tactics when asking for a confession. Results showed that minimization substantially increased the rate of false confession, similar to the increase caused by an explicit promise of leniency. This paradigm has also been replicated and extended a number of times and offers the advantage of eliciting from participants true and false confessions to willful actions of consequence.

Current Issues and Controversies

The Identification of Suspects

The Reid technique operates through a two-part structure. Interrogators are trained to first conduct a pre-interrogation interview, during which investigators identify who should be a suspect. After identification of suspects, the second stage begins: the interrogation.

The pre-interrogation interview is designed to be a nonconfrontational information-gathering interaction during which the interrogator establishes rapport, develops an understanding of a suspect's baseline of behavior, and attempts to determine whether the suspect is being deceptive. Using the Behavior Analysis Interview, or BAI, interrogators are trained to ask behavior-provoking questions and then observe the suspect's responses. The responses to the provocative questions are believed to offer indications of innocence or guilt. Interrogators are taught to focus on nonverbal cues (e.g., body language, fidgeting, eye gaze, posture) as well as verbal cues (e.g., qualified denials, pauses) to decide who is lying or telling the truth. If the interrogator is convinced of truthfulness, the individual is dismissed and sent home. If the interrogator is convinced of deception, the suspect is interrogated.

The Reid technique, both in the manual and in actual training sessions, claims that interrogators can be trained to make these judgments of guilt and innocence at a high level of accuracy, yet the research in the field of deception detection is highly contradictory to these claims. Research has consistently shown that laypersons can only detect deception at around chance levels (i.e., 54 % accuracy) and, furthermore, that training does not appreciably improve performance (Bond and DePaulo 2006). Research studies specifically using the BAI have shown similarly dismal rates of accuracy in deception detection and identification of guilty suspects. There is no evidence that the behavior-provoking questions recommended by the Reid technique actually have any diagnostic value. Furthermore, there is no evidence that suggests that the verbal and nonverbal cues upon which interrogators are trained to rely have any diagnostic value. Research on deception detection has consistently shown that there are few valid cues to deception and that those that do exist are often too weak to be used for discriminatory purposes in an interrogation (Hartwig and Bond 2011). Instead of improving performance, training simply increases and often inflates confidence in one's decision.

The pre-interrogation interview sets the stage for interrogations as a guilt-presumptive process. Investigators enter into interrogations with a strong belief in the guilt of their suspects, so the goal of each interrogation is to extract a confession. This guilt-presumptive belief impacts how investigators conduct and perceive their interrogations. Research in basic psychology has long shown that once people form a belief, they seek out information that confirms that belief and ignore or misinterpret evidence that contradicts it. Known as confirmation bias, this tendency means it is difficult for a suspect to convince an interrogator of his or her innocence once a suspicion of guilt has formed. The presumption of guilt can also create a self-fulfilling prophecy, whereby the interrogator's aggressive behavior invokes anxiety in the suspect, which in turn confirms the interrogator's belief in guilt. Research has shown that interviewers who believe a suspect is guilty ask more guilt-presumptive questions and place more pressure on suspects to confess, which increases risk for false confession.

The Consequences of Confession

The criminal justice system is designed to provide safety nets to prevent false confessions from resulting in prosecution and wrongful convictions. For these safety nets to work, attorneys, judges, and juries must be able to distinguish between true and false confessions. The narrative content of confessions, however, as well as their corrupting influence on other evidence makes it difficult for people inside and outside the system to make this distinction.

The Impact on Juries

Confession evidence is considered something of a gold standard for evidence. It is difficult for laypersons to accept the idea that individuals may falsely confess to crimes they did not commit; therefore, juries tend to accept confessions at face value. Research has shown that juries are capable of distinguishing between coercive and noncoercive interrogations, but that distinction does not impact their use of the confession in their verdicts. Juries are just as likely to use highly suspect confessions derived from coercive interrogations to determine verdicts as they are to use one stemming from a noncoercive interview.

Another reason why juries may have a hard time dismissing false confessions is their often-elaborative content. Examination of the narrative content of false confessions has shown that false confessions tend to be highly detailed, often containing accurate nonpublic information about the crime (Garrett 2010). False confessions also tend to include descriptions of motives and feelings during and after the crime (Appleby et al. 2011). Combined with the tendency to rely on the (erroneous) common sense that innocent people do not falsely confess, these crime details may serve to convince jurors that these confessions are true and accurate statements from actual perpetrators.

Corrupting Influence of Confessions

Confessions can also taint the interpretation of other evidence. Once it is known that a suspect confessed, trained professionals as well as laypeople may view other evidence as consistent and indicative of guilt – especially when that evidence is ambiguous. This effect has been observed in judgments made about polygraph charts and eyewitness identifications (Elaad et al. 1994; Hasel and Kassin 2009). Research has also shown that context effects have similarly been observed in judgments made from fingerprints and certain complex DNA evidence (Dror and Charlton 2006; Dror and Hampikian 2011). These findings are bolstered by a recent analysis of DNA exonerations from the Innocence Project, where forensic science errors are found in nearly two-thirds of false confession cases (Kassin et al. 2012).

Reforms

Research has shown that confessions may sometimes improperly influence the investigation, prosecution, and review of cases. To that end, interrogation reform is needed to follow the best practices that have been identified in the literature. Research must also continue to address other potential reforms at other stages in the criminal justice process.

The PEACE Model

Reforms to interrogation practices have been enacted in Great Britain. Beginning with the Police and Criminal Evidence (PACE) Act of

1984, interrogation practices have shifted from a focus on psychologically coercive tactics designed to elicit confessions to a more investigative, fact-finding approach. In 1993, the Royal Commission on Criminal Justice created the PEACE model, which instituted training for police officers and further reduced reliance on psychologically coercive techniques. PEACE refers to the five components of the new interviewing technique: "preparation and planning," "engage and explain," "account," "closure," and "evaluate." Studies show that certain Reid techniques – including minimization and the false-evidence ploy – are now rarely used in Great Britain, yet the rate of confessions has not dropped (for a review, see Kassin et al. 2010). Given the current research findings, it appears investigative interviewing may present a useful alternative to the confrontational methods of the typical American interrogation.

Expert Testimony

Getting false confession experts admitted into court has proven difficult in many jurisdictions. In general, expert testimony on false confessions has been excluded for two reasons: (1) questions about the science behind the study of false confessions and (2) the idea that false confession research is known to jurors as a matter of common sense, rendering expert testimony unnecessary. Research has shown that jurors may be able to distinguish between coercive and noncoercive tactics, but they still do not believe that coercive tactics will produce false confessions. Recent research combined with anecdotal evidence suggests that jurors believe that the ends justify the means, in that it is acceptable to use highly coercive tactics to obtain confessions, strengthening presumptions that highly coerced confessions may be nonetheless accepted as true (Blandón-Gitlin et al. 2011). This recent research has also suggested that expert testimony can successfully educate jurors as to how these coercive tactics can produce false confessions, but much more research on the potential benefits of expert testimony is needed.

Videotaping of Police Interrogations

The most widespread proposed reform, which has recently been adopted in many states and jurisdictions, concerns the videotaping of interrogations in their entirety. Videotaping of interrogation is actually the leading recommendation of the official American-Psychology Law Society White Paper on false confessions (Kassin et al. 2010). The strengths of videotaping benefit both the police and the suspect. With a complete recording of an interrogation, the truth about the use of egregious interrogation tactics is known. This record may serve the suspect by reducing interrogators' reliance on those tactics, as well as providing an accurate record about the use of those tactics for court. This practice may also serve interrogators, however, because that same record could be used to refute illegitimate claims of police intimidation or coercion.

It is a well-known finding in psychology that memory is not perfect. Memories are subject to forgetting and distortions, which impair the accuracy of a suspect's or interrogator's memory of an interrogation. With a videotape of the interrogation, there is no question of who said what and when. It would be possible, for example, to review a tape and see where evidence "only the perpetrator could know" actually came from – the suspect or the interrogator. Anecdotal evidence has shown that police interrogators sometimes make source monitoring errors and remember suspects as first admitting details that they had in fact confronted them with earlier. Review of videotaped interrogations could clarify cases when incriminating accounts by a suspect were based on information first offered by the interrogator and, just as importantly, affirm investigators' accounts when the suspect indeed offered unique information "only the perpetrator could know."

Conclusions

False confessions weaken the integrity of our criminal justice system. Many recent examples have garnered strong media attention and interest, including the Amanda Knox case. Research has identified a number of risk factors that place innocent suspects at risk for falsely confessing, including dispositional and interrogative risk factors as well as innocence itself. Research has also been undertaken to understand the consequences of confession in hopes that the impact of false confessions may one day be mitigated, if not prevented.

Still, more research is needed in the realm of false confessions. Investigative interviewing presents a first step for interrogative reform, but there remains a need to identify interrogation tactics that have genuine diagnostic value – the ability to elicit true confessions without also eliciting false confessions. Research also must further investigate the consequences of confessions – how confessions impact the criminal justice process and how that impact can be minimized – and the extent that expert testimony can serve as a remedy to the consequences of confession. These avenues of research have been largely untouched and need to be explored.

By offering erroneous evidence that a crime has been "solved," false confessions interfere with our justice system's ability to capture the actual perpetrators of crime. Once police have a confession from the person they believe committed the crime, all avenues of evidence toward other suspects – including, in cases of false confessions, the actual perpetrator – are no longer explored, and any further evidence pointing another direction is often either disregarded or misinterpreted to further implicate the innocent confessor. Current practices must be evaluated and reforms undertaken to secure convictions from the actually guilty while avoiding the wrongful convictions of innocent persons.

Overview

The history of psychiatric nosologies has been scattered with a variety of terms used to describe individuals with serious personality pathology that leads them to engage in ways considered repugnant to the social mores of the time. Manie sans delire, moral insanity, moral imbecility, degenerate constitution, congenital delinquency, constitutional inferiority, sociopathy, antisocial personality disorder, and psychopathy are among the many semantic variations of the main theme. While the diagnostic labels have continued to evolve for more than 200 years, the personality characteristics and behaviors that they denote have remained relatively unchanged. The most commonly ascribed characteristics include a pronounced disorder of affective or moral functions, accompanied by irresponsibility, impulsivity, and a propensity to engage in behavior that brings them into conflict with society – and often the law. However, the disorder is typically absent of any appreciable alteration in cognitive functioning, such as perception, judgment, imagination, or memory.

The term psychopathy has been most consistently used in the psychological and psychiatric research and clinical literature; therefore, that is the term that will be used in this entry. The entry begins with a brief overview of the history of psychopathy and its clinical and behavioral implications before turning to a discussion of the relevance of psychopathy for criminology.

What Is Psychopathy?

First and foremost, psychopathy is a serious personality disorder. Personality disorder is defined as "an enduring pattern of inner experience and behavior that deviates markedly from the expectations of the individual's culture, is pervasive and inflexible, has an onset in adolescence…is stable over time, and leads to distress or impairment" (American Psychiatric Association 2000, p. 629). Personality disorders are manifested by difficulties in at least two of the following four areas: cognitions (capacity to think and reason), affectivity (expressed emotion), interpersonal functioning (ability to engage in meaningful and stable relationships), and impulse control (the ability to adapt and control behavior). Psychopathy is a personality disorder that is characterized by deficits in interpersonal functioning, expressed emotion, and behavior. Characteristics of the disorder in the interpersonal domain include an elevated sense of importance, proneness to pathological lying and manipulation, and superficiality. The deficits associated with expressed emotion include having a flat level of affect, limited capacity for empathy, remorse, and feelings of guilt. Low levels of anxiety are also noted. The behavioral manifestations of the disorder include an elevated need for stimulation, proneness to boredom, impulsivity, irresponsibility, and a failure to take responsibility for their own actions. Such individuals tend to lack conventional social values which repeatedly bring them into contact with authority figures and, oftentimes, the law.

Millon and colleagues (1998) noted that "psychopathy was the first personality disorder to be recognized in psychiatry. The concept has a long historical and clinical tradition, and in the last decade a growing body of research has supported its validity…" (p. 28). Early on, the term psychopathy was used to refer to a range of personality disorders ("psychopathic personalities") that were seen to be extreme forms of normal personality. General descriptions of people who share the characteristics found in the modern conceptualization of "psychopathy" (see Cleckley 1941) have been found in ancient writing. Scholars and practitioners alike have debated the merits of conditions such as those characterized by so-called antisocial features for as long as attempts have been made to classify mental disorder. For example, the term "manie sans délire" (i.e., mania without confusion of the mind), which Pinel coined in the 1700s to describe patients whose affective faculties were disordered, was criticized as early as 1866 for only having use in court (Falret 1866). As noted at the outset, over the years, a number of different labels have been used for the condition; all of the terms that have been used are pejorative, and there is little doubt that each would conjure up very negative images for people. The term with the longest clinical tradition is "psychopathy." As such, it has been the subject of considerable research and scholarly writing. While sharing characteristics with psychopathy, the contemporary condition antisocial personality disorder is much broader and is based more on behavioral features than on some of the traditional personality characteristics associated with psychopathy.

In 1941, the American psychiatrist Hervey Cleckley described the condition of psychopathy in his now classic book the *Mask of Sanity*. He identified 16 characteristics of psychopathy which he drew from the literature and his clinical experience:

1. Superficial charm and good intelligence
2. Absences of delusions and other signs of irrational thinking
3. Absence of "nervousness" or psychoneurotic manifestations
4. Unreliability
5. Untruthfulness and insincerity
6. Lack of remorse or shame
7. Inadequately motivated antisocial behavior
8. Poor judgment and failure to learn from experience
9. Pathological egocentricity and incapacity for love
10. General poverty in major affective reactions
11. Specific loss of insight
12. Unresponsiveness in general interpersonal relations
13. Fantastic and uninviting behavior, with drink and sometimes without

14. Suicide rarely carried out
15. Sex life impersonal, trivial, and poorly integrated
16. Failure to follow any life plan

Initially this disorder was known as psychopathy or psychopathic personality; however, by the introduction of the second edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-II 1968), the condition was labeled "Personality Disorder, Antisocial Type," although the diagnostic criteria still closely resembled those described by Cleckley (1941).The term "antisocial personality disorder" was first introduced in 1980 in the DSM-III (American Psychiatric Association 1980) and has remained with the most recent edition of the DSM, published in 2000 (DSM-IV-TR; APA 2000). Beginning with the introduction of DSM-III in 1980, the DSM criteria began to focus almost exclusively on behavioral features. The current criteria for antisocial personality disorder are as follows:

- Evidence of conduct disorder before age 15
- A pervasive pattern of disregard for, and violation of, the rights of others since the age of 15, as indicated by three or more of the following:
  1. Failure to conform to social norms with respect to lawful behaviors, as indicated by repeatedly performing acts that are grounds for arrest
  2. Deceitfulness, as indicated by repeated lying, use of aliases, or conning others for personal profit or pleasure
  3. Impulsivity or failure to plan ahead
  4. Irritability and aggressiveness, as indicated by repeated physical fights or assaults
  5. Reckless disregard for safety of self or others
  6. Consistent irresponsibility, as indicated by repeated failure to sustain consistent work behavior or honor financial obligations
  7. Lack of remorse, as indicated by being indifferent to or rationalizing having hurt, mistreated, or stolen from another

Ogloff (2006) noted that while the current diagnostic conceptualization of antisocial personality disorder is based largely on behaviors, traditionally the focus of psychopathy was on the interpersonal and affective deficits. Regrettably, the disorder has become a diagnostic category for behavioral difficulties pertaining to criminality. Moreover, as will be discussed below under implications, far more people (particularly prisoners) meet the criteria for a diagnosis of antisocial personality disorder than is warranted.

To complicate matters further, the tenth edition of the International Classification of Diseases (ICD-10; World Health Organization 1992) uses both personality traits and behaviors for the diagnosis of dissocial personality disorder, conceptually similar to psychopathy. The criteria for this disorder are:

1. Callous unconcern for the feelings of others and lack of the capacity for empathy
2. Gross and persistent attitude of irresponsibility and disregard for social norms, rules, and obligations
3. Incapacity to maintain enduring relationships
4. Very low tolerance to frustration and a low threshold for discharge of aggression, including violence
5. Incapacity to experience guilt and to profit from experience, particularly punishment
6. Marked proneness to blame others or to offer plausible rationalizations for the behavior bringing the subject into conflict with society
7. Persistent irritability

As compared to antisocial personality disorder, dissocial personality disorder places more emphasis on traditional psychopathic personality features. In particular, dissocial personality disorder emphasizes deficits of affect or expressed emotion, which have traditionally been seen as among the central personality features of psychopathy.

How will antisocial personality disorder and psychopathy fare in the upcoming revision to the DSM, the DSM-5? The proposed changes to the DSM-5 include substantial shifts in how personality disorders are defined and organized (see www.dsm5.org). Included in these changes are significant modifications to the criteria for antisocial personality disorder. The proposed DSM-5 revisions, referred to as antisocial personality disorder/dissocial personality disorder available at the time of writing, shift the diagnostic focus more toward the traditional interpersonal and emotional aspects of psychopathic personality and rely less heavily on the behavioral, or criminal actions of the individual. While the revision process is yet to be completed, clarification and differentiation between antisocial personality disorder and psychopathy are warranted lest the confusion will continue.

The Operationalization of Psychopathy

The Hare Psychopathy Instruments

Although the criteria for antisocial personality disorder have changed with each edition of the DSM, Dr. Robert Hare developed the Psychopathy Checklist (PCL-R; Hare 1980, 2003) to reliably and validly assess the traditional construct of psychopathy described by Cleckley (see Fig. 1).

The PCL-R is a symptom-construct rating scale comprised of interpersonal, affective, lifestyle, and antisocial features. It consists of 20 items, 18 of which comprise a two-factor, four-facet model (the two additional items do not load on either factor but do contribute to the total score). Each of these items is coded on a three-point ordinal scale (0 = does not apply; 1 = partially applies; 2 = definitely applies), such that total scores on the instrument range from 0 to 40. Scores on this instrument measure the extent to which an individual matches the prototypical "psychopath." The PCL-R is a dimensional measure of psychopathic traits, and while it is true that many people may possess some of the characteristics to some extent, very few possess enough of the traits to be considered "psychopathic" (i.e., with scores above 30 on the instrument). Indeed, approximately 15 % of North American male prisoners, 7.5 % of North American female prisoners, 10 % of male forensic psychiatric patients, fewer than 3 % of psychiatric patients, and an estimated 1 % or less of the general community would have PCL-R scores of this magnitude.

The PCL-R is recognized as the "gold standard" in the assessment of psychopathy. It has been adapted to produce a screening version (Psychopathy Checklist: Screening Version, PCL:SV) and a youth version (Psychopathy Checklist: Youth Version, PCL:YV). The PCL-R has been found to be strongly related to re-offending and violence and is widely used in clinical practice and research in forensic settings. It has proven useful in predicting recidivism,

Psychopathy and Antisocial Personality Disorder, Fig. 1 The psychopathy checklist-revised (PCL-R) poor treatment outcome, and as a strong predictor of violence. There are now well over 500 research articles and chapters on the PCL measures.

Despite the widespread use of the PCL-R, there has been heated scholarly debate in regard to the inclusion of the fourth facet – antisocial behavior – as a diagnostic feature of psychopathy. Cooke and Michie (2001) argued on the basis of factor analytic results that a three-factor model for psychopathy, essentially the first three facets of the PCL-R, was appropriate. They argued that the antisocial features of psychopathy were behavioral manifestations or consequences of these core features. Nonetheless, they still emphasized "the necessity of continuing to use the full PCL-R for risk assessment and other applied purposes" (p. 186). The suggestion of a three-factor model was subsequently disputed by Hare and colleagues who developed the four-facet model in addition to the previous two-factor model. Nevertheless, the importance of antisocial behaviors as features of psychopathy continues to be vigorously debated in the literature, often in quite caustic exchanges (e.g., Hare and Neumann 2010; Skeem and Cooke 2010a, b). In any event, the PCL-R currently remains the instrument of choice for the assessment of psychopathic personality features, although other instruments are being developed.

Self-Report Measures of Psychopathy

Some self-report measures have been developed to assess similar factors identified in the PCL-R. Although limited in their utility given the characteristics of manipulation and pathological lying associated with psychopathy, the measures have utility for research and some clinical applications that do not require a comprehensive assessment of the individual.

The Levenson Self-Report Psychopathy Scale (LSRP; Levenson et al. 1995) is a brief, 26-item measure that was designed to assess psychopathic features in subclinical samples. The Self-Report Psychopathy-II Scale (SRP-II) is a 60-item scale that was originally designed to be a self-report version of the PCL-R. In comparing the SPR-II to the PCL-R in forensic settings, Hare (1991) found that the total scores of each measure had a correlation of $r = .54$. In recent years, the SRP-II was revised to form the SRP-III in response to criticisms regarding an excess of anxiety-related items and minimal inclusion of antisocial behavior items within the SRP-II.

The Psychopathic Personality Inventory (PPI; Lilienfeld and Andrews 1996) is a 187-item scale that was developed for use in noncriminal populations. The PPI was originally conceptualized as having eight lower-order factors and a total score. However, subsequent factor analyses suggested that the items formed two factors conceptually related to those on the PCL-R (Lilienfeld and Fowler 2006). A more recent version of the PPI was developed to lower the reading level, decrease cultural bias, and reduce the number of items to 154 (Lilienfeld and Windows 2005). The PPI-R is reported to perform similarly to the original measure, but additional research is warranted.

What Causes Psychopathy?

Despite the long-standing interest in psychopathy, research and knowledge pertaining to the etiology of psychopathy is in its infancy. Some evidence suggests that psychopathy has a genetic influence. Although it is difficult to know precisely how much of the psychopathic personality is attributed to genetics, it is likely to be in the order of 30 % of the variance of personality. This shows that while genetics is an important contributing factor to the etiology of psychopathy, it is not the full story.

Discussions regarding the causes of psychopathy are often tied to speculation and theories about variants or subtypes of psychopathy. Researchers have proposed that psychopathy is not a homogeneous construct, but rather a heterogeneous construct with different etiological factors associated with different subtypes of psychopathy. Most often, these subtypes are referred to as primary and secondary psychopathies (Karpman 1948; Lykken 1995). Each of these subtypes has its own hypothesized etiology and associated characteristics.

Traditionally, the primary psychopath has been described as incapable of experiencing emotions, thus not capable of feelings such as guilt, empathy, or remorse. The primary psychopath is cold and calculating and engages in behavior not hampered by anxiety. In contrast, the secondary psychopath can experience a high level of negative emotions, such as anxiety and guilt, and displays behavior that is more aggressive and impulsive.

It has been suggested that the affective deficit underlying primary psychopathy occurs as a result of nature (e.g., genetics), whereas the affective disruption of the secondary psychopath is the result of nurture (e.g., environmental insults) (Karpman 1948). Environmental factors responsible for the later development of secondary psychopathy have been suggested to include unresolved conflicts resulting from harsh punishment and parental rejection (Karpman 1948), poor and ineffective parenting (Lykken 1995), and early childhood abuse or abandonment (Porter 1996). Not only does the speculated etiology of primary versus secondary psychopathy differ, but so does expectations regarding treatment outcome for the two subtypes. Given the presence of anxiety and learned emotional adaptation to environmental abuses, the secondary psychopath is seen as more amenable to treatment than the primary psychopath (see Ogloff and Wood 2010).

Research from Skeem and colleagues (2007) also lends empirical support to distinct subtypes of psychopathy. Skeem and her colleagues (2007) found support for two homogeneous groups that parallel classic primary and secondary psychopathy formulations. They found that violent psychopaths who scored high on a measure of psychopathy were distinguishable based on their level of anxiety. Skeem and colleagues (2007) noted that "secondary (high-anxious) psychopaths were most drastically distinguished from primary (low-anxious) psychopaths by their (a) emotional disturbance (anxiety, major mental and substance abuse disorders, borderline features, impaired functioning), (b) interpersonal hostility (irritability, paranoid features, indirect aggression), and (c) interpersonal submissiveness (lack of assertiveness, withdrawal, avoidant and dependant features)" (p. 405).

A considerable amount of research has been devoted to the study of emotional, attentional, and cognitive processing in psychopathic personality disorder. This research shows that psychopathy is not readily interpreted in terms of damage to specific areas of the brain; but any brain abnormalities that do exist are subtle and likely more functional than structural. For example, while brain anomalies in psychopaths are largely found in the amygdala and orbital-frontal cortex, individuals with physical damage to these areas show more global deficits than do psychopaths. As such, psychopathy is not apparently the product of structural brain damage or deficits.

While *structural* brain differences of psychopaths compared to non-psychopaths are limited, considerable research exists to show that there are some significant *functional* differences in the brain functioning between psychopaths and others. Generally, the differential processing of attention and emotional information by psychopaths has implicated anomalies in the functioning of the amygdala, the orbital-frontal cortex (OFC), and differences in cerebral asymmetry. For example, the amygdala is considered to modulate sensory processing and the processing of emotional stimuli, as well as influencing goal-directed behavior, all of which appear impaired in psychopathy (Blair et al. 2005). Studies have shown impaired learning from punishment when there is potential for reward (gambling tasks), reduced autonomic response to distress in others, impaired naming of fearful and sad expressions (but not other emotions), and reduced physiological responses to anticipation of fear- or pain-inducing stimuli (see Blair et al. 2005; Hiatt and Newman 2006).

Substantial advancement has been made toward understanding the neurobiological aspects of psychopathic personality, but a coherent picture or etiological model that can explain all aspects of these anomalies or how they may give rise to either the personality or behavioral characteristics of psychopathy is yet to be devised. The most widely inclusive theory is posited by Blair and colleagues (2005), who argue that genetic anomalies disrupt amygdala functioning from an early age, leading to impairment in emotional learning as a core dysfunction of psychopathy. This impaired emotional learning would not necessarily lead to the development of the full psychopathy syndrome (such as antisocial and impulsive behaviors), but increases the probability that an individual will learn to employ antisocial means to achieve goals depending on social environment and learning history (i.e., environmental risk factors). Blair and colleagues argue that instrumental aggression may result from impairment to the amygdala functioning (impaired socialization, affect processing, and empathy), while reactive aggression may be the result of OFC impairment (inability to modify behavior to achieve goals when environmental cues change, leading to frustration and then aggression). However, their theory fails to account for additional brain abnormalities in psychopathy, such as cerebral asymmetry. In addition, the heavy focus of research on male adult prison inmates (where psychopathic personality is likely to be easily available and identifiable) makes it difficult to separate deficits associated with the core personality features (Factor 1) and antisocial behavior more generally. There is a need to examine potential neurological and cognitive abnormalities among "successful" psychopaths in the community, as well as in alternative cultural, ethnic, gender, and age groups.

Criminal Correlates of Psychopathy

As noted previously, less than one percent of people in the general population are thought to be psychopaths. However, research shows that between 15 % and 20 % of people in prisons have high scores on the PCL-R (Hare 2003). Literally hundreds of studies, and at least six meta-analyses, have explored the relationship between psychopathy and recidivism; they have uniformly found that psychopaths are at greater risk for offending and violent offending. While the specific rates of offending differ somewhat across the samples, as compared to non-psychopaths, at 1-year follow-up, psychopaths have been found to be approximately three times as likely to offend and four times as likely to violently re-offend than non-psychopathic offenders. Indeed, Hemphill (2007) reported that across three separate meta-analyses, the unweighted correlation between PCL-R scores and violent recidivism was "in the .20–25 range" and admitted that these were conservative values (i.e., the effect sizes were larger when weighted by sample size). Furthermore, Monahan and colleagues (2001) studied a range of risk factors for violence among civil psychiatric patients in the United States and found that the PCL:SV had the highest correlation with subsequent violence of all of the 134 risk factors ($r = .26$).

While not originally developed to be a risk assessment measure, psychopathy has emerged as a robust risk factor for criminal recidivism, and many have advocated its use in any assessment of risk for offending or violence. For example, Hart (1998) stated that "psychopathy is such a robust and important risk factor for violence that failure to consider it may constitute professional negligence" (p. 133). Accordingly, several formal risk assessment schemes require that one include or consider scores on the PCL-R or the PCL:SV.

Psychopathic offenders differ in many ways from their non-psychopathic criminal counterparts. Compared with other offenders, psychopaths are at greater risk for callous, cold-blooded behavior and crimes, institutional infractions, general recidivism, violent recidivism, and sexual recidivism (Hare 2003). Psychopaths also engage in a greater number and variety of criminal behaviors when compared to other repeat offenders, begin committing crimes at an earlier age than other career criminals, and display a different pattern across the lifespan. While criminal behavior tends to decrease over time, Hare and colleagues found that only about half of the psychopaths studied demonstrated a significant decrease in criminal behaviors beginning around ages 35–40 years. However, this reduction largely applied to nonviolent offences and minimal reduction was seen in violent behavior.

Woodworth and Porter (2002) studied 125 homicide offenders and found that the majority of homicides committed by psychopaths were "instrumental" murders (i.e., cold-hearted murders that are conducted for revenge, thrill seeking, or some material gain) rather than "reactive" (i.e., in the heat of the moment without secondary gain). By contrast, the types of murders committed by non-psychopaths were fairly evenly split between instrumental and reactive. Among sexual homicides, psychopathic perpetrators exhibit significantly higher levels of gratuitous and sadistic violence than non-psychopathic sexual homicide perpetrators (Porter et al. 2003). Overall, violence by psychopaths is more likely to be motivated by material gain, revenge, or thrill seeking (i.e., instrumental aggression) rather than momentary heightened emotional arousal (reactive aggression).That said, psychopaths are likely to engage in violence in response to both motivations, whereas non-psychopath violent offenders typically do not engage in instrumentally motivated violence (Blair et al. 2005).

Psychopathy and Criminal Investigation

Given the prevalence of psychopathic personality features in the criminal justice system, particularly in regard to serious violent offenders, it is perhaps unsurprising that psychopathy is an important construct for behavioral scientists who provide consulting services to law enforcement agencies. Such activities are known variously as criminal investigative analysis, behavioral investigative advice, and offender profiling (Depue, → Criminal Investigative Analysis; Rainbow, Gregory, & Alison, → Behavioural Investigative Advice). These can involve making inferences about an unknown offender's likely characteristics based on the behaviors exhibited during their crimes, as well as recommendations for investigative or interview strategy (Ault and Hazelwood 1995). Impulsivity and sensation-seeking behavior, glibness and superficial charm, conning and manipulative offence behavior, and predation and instrumental violence may all suggest the presence of psychopathic personality features in an unknown offender (see O'Toole 2007). While far from a clinical diagnosis, such hypotheses, when viewed in conjunction with other inferences from the offender's behavior, can assist in the development of appropriate investigative and interview strategies.

The White-Collar Psychopath

While most research on psychopathy has been conducted on criminals, it has long been speculated, therefore, that not all psychopaths engage in criminal or violent behavior resulting in imprisonment and that individuals with psychopathic personality can be found in a variety of successful trades and professions in the general community. Hare (1993) argued that psychopaths are "to be found nearly everywhere – in business, the home, the professions, the military, the arts, the entertainment industry, the news media, academe, and the blue-collar world" (p. 115). It has also been argued that certain psychopathic traits (fearlessness, dominance, superficial charm) may prove valuable in some professions such as law, politics, and leadership positions in business and the military (Lykken 1995). However, the limited research evidence has been based on anecdotal clinical descriptions, with almost no quantitative study (e.g., Babiak 2007). Cleckley's seminal book (1941) described several case studies of people who possessed the "core" personality features observed in criminal psychopaths, but manifested those traits in ways that did not result in frequent criminal activity (or at least, arrest). Nonetheless, the case studies that have been discussed have shown that high psychopathy scores in the business world are associated with manipulation of co-workers and bosses, circumventing human resources, finance, and security systems, and fast-tracked promotion to management ranks and successful careers despite limited experience or professional dedication (Babiak 2007).

Descriptions of psychopaths in the community and business have highlighted terms such as "successful," "sub-clinical," and "white-collar" psychopaths, but conceptual difficulties have been raised in the differentiation between such individuals and their criminal counterparts. For example, Hall and Benning (2006) question whether the etiology of psychopathy among noncriminals is the same as for psychopathic criminals (i.e., do community psychopaths differ in degree or kind from criminal psychopaths?). Should "successful" psychopathy be viewed as dimensionally sub-clinical, as a moderated manifestation of the same level of traits, or as a separate clinical entity with different etiological development? These are questions that will be examined in future research on corporate and other community psychopaths.

Conclusions and Future Directions

Psychopathy is an important clinical diagnosis that has significant implications for the criminal justice system. Although few in number, psychopaths are more likely than others to engage in offending and are more likely than other offenders to re-offend or commit violent offences. The specific terms used to identify this group of people have varied over time – with terms such as antisocial personality disorder, sociopathy, and dissocial personality disorder being used in varying ways to conceptualize this population. As the information presented and discussed in this entry shows, despite the longstanding interest and the burgeoning research on the topic of psychopathy, relatively little is still known about the etiology of this serious personality disorder.

With advanced knowledge of genetics and developing technology in brain imaging, it is known that a portion of the variance in the development of a psychopathic personality can be attributed to genetic factors. Similarly, research shows that functional and even some significant structural brain differences exist among people who are psychopathic that distinguish them from others; however, the differences are relatively small and are not yet diagnostic. With ongoing advances in technology and methodology, however, this area shows considerable promise for research. At present, it appears that the brain differences that do exist pertain to areas of the brain associated with affect and emotions and other areas that relate to behavioral control and impulsivity. Importantly, social development and environmental factors play a significant role in the development of psychopathic personality traits and the type of behavior that manifests. Taken together, psychopathy is best construed as a disorder that is influenced by interactions of genetic, biological, and social factors which are moderated by the environment.

Although psychopathy has been discussed in the broad population and among people who are not necessarily criminals (e.g., Cleckley 1941), the interest surrounding this disorder has been largely driven by the criminal correlates of psychopathy. As noted above, it is not surprising that people who are not influenced by society's rules and laws, who do not have the capacity for affective features like empathy and guilt, and who do not learn from punishment have increased levels of offending and recidivism. Indeed, the prevalence of psychopathy in criminal (15–20 %) and even forensic mental health (10 %) samples is much greater than what is found in the community (less than 1 %). People with high levels of psychopathic personality features have been found to have higher rates of all types of offending and violence. The offences that psychopaths commit are more likely to be instrumental, or for secondary gain, than for other offenders. The violence that they inflict is typically more extreme and callous.

Taken together, psychopathy is an important construct for those who work in criminology and related fields. There is a large and growing body of research that has enabled an enhanced understanding of psychopathy and its correlates. At the time of writing this entry, at least two significant developments were occurring in the field. First, the DSM-5 was in the final stages of development with the Personality Disorders Working Group having finished its work. It is anticipated that the DSM-5 will be published in May 2013 so one will need to wait to see exactly how antisocial personality disorder is defined at that time and whether the traditional personality features of psychopathy will be prominently featured. Second, a new measure of psychopathy, the Comprehensive Assessment of Psychopathic Personality (Cooke et al. 2004) was being developed and validated. This instrument shows promise as a measure of psychopathy that builds upon the literature. It is designed to be comprehensive and dynamic with the ability to assess possible changes in the severity of symptoms over time. Preliminary research has indicated that the CAPP shows comparable predictive validity to the PCL:SV in regard to violent and nonviolent crime (Pedersen et al. 2010). Nonetheless, it will be some time before the research base is developed to know how effective the measure will be in identifying psychopathic personality features or whether it will be best utilized as a stand-alone measure or an adjunct to the PCL-R. It is clear, therefore, that despite the long history and research interest in psychopathy, there is still much to learn.

Overview

Psychopathic personality disorder (PPD) is a form of personality disorder; it influences how an individual typically thinks, feels, and behaves. Those who suffer from this disorder have difficulty forming and maintaining attached relationships with others, they are often suspicious and intolerant, their emotional experiences are impaired, their view of their self is distorted, being grandiose and self-centered, and their behavior is frequently reckless and aggressive.

Historically, PPD has been linked to offending in both preclinical and early clinical writing. In recent years research on PPD has been dominated by the Psychopathy Checklist-Revised (PCL-R), an instrument developed in criminal populations and used to make a lifetime diagnosis of the disorder. Meta-analytic studies using the PCL-R, and its derivatives, suggest a small to moderate relation between the PCL-R and future reoffending. Care must be taken in the interpretation of these results because PCL-R ratings focus, both explicitly and implicitly, on the past criminal behavior of the person being assessed.

The development of new measures of psychopathy suggests that the construct of psychopathy, as distinct from the PCL-R measure, may have predictive utility. In practical contexts, for example, risk management, a clear formulation of an individual's profile of PPD symptoms, and its relevance for future violence and risk management, is likely to have utility. Future research should focus on the relationships among specific facets of PPD and specific facets of offending behavior.

Psychopathic Personality Disorder and Offending

Personality disorders are forms of mental disorder that are chronic in nature, starting in adolescence or early adulthood; they affect how an individual thinks, feels, and behaves, the consequences being chronic disturbance in the individuals relations with self, others, and their environment. This chronic disturbance leads, in turn, to subjective distress and/or a failure to properly fulfil social roles and obligations (American Psychiatric Association 2000). In psychology traits are inferred, "latent," constructs that are hypothesized to be causal entities that underpin behavioral dispositions. Traits are inherently explanatory; they can predict a range of consequential outcomes. The symptoms of personality disorders are regarded as being extreme personality traits that lead to disorder and dysfunction.

Psychopathic personality disorder (PPD) is a specific form of personality disorder that is characterized by dysfunction in six domains of functioning. In terms of the interpersonal features, those who suffer from PPD are generally pathologically dominant in their relationships with others; they are frequently antagonistic, deceitful, and manipulative. They have difficulty forming – and maintaining – attachments to family, friends, and intimate partners; typically, they are detached, uncommitted, and unempathic. Cognitively they are frequently suspicious, intolerant, and inflexible; their emotional function is impaired because they lack appropriate anxiety, emotional depth, and empathy. Those suffering from PPD suffer a distorted view of self – an unusual form of psychological disturbance; in particular, they may display a sense of being invulnerable, unique, or entitled; they are self-centered and engage in self-justification. Behaviorally, they are unreliable, reckless, and aggressive (Cooke et al. 2012).

The concept of psychopathy, and its link to offending, has been the subject of debate and controversy: there are significant conceptual and empirical challenges in understanding the link. In this entry the association between PPD and offending will be considered from its historical roots to recent empirical research. Some of the challenges confronting the clear explicating of both the strength and quality of the association between PPD and offending will be outlined; the practical implications that this association has for the effective risk management of certain offenders will be considered.

Psychopathic Personality Disorder Crime and Antisocial Behavior

Quick reflection will reveal that it would not be surprising if the personality features enshrined in the definition of PPD alluded to above led to criminal behavior; indeed, PPD is frequently associated with diverse types of criminal behavior. Skeem et al. (2011) illustrated this diversity: the corporate psychopath who swindles investors with elaborate Ponzi schemes, the con artist who dupes others with ease and consummate skill, and even the serial killer.

Current empirical evidence suggests that those who suffer from PPD have distinctive criminal careers, starting early in life and desisting much later than other offenders – if at all – and they engage in a diverse range of types of criminal activity (Hart and Hare 1997). Their criminal conduct is often motivated by factors that differ from those which drive other offenders (e.g., the need to dominate and control; instrumental rather than expressive needs); also, the behavioral topography of their criminal acts (e.g., victim type and modus operandi) varies from those who do not suffer from this disorder. For example, those who suffer from PPD are more likely to have male strangers among their victims as compared with those who do not suffer from PPD.

General theories of crime, in terms of psychosocial and cultural factors, may have less traction in terms of explanation for the offending of this group. While PPD is regarded as a mental disorder, within the framework of Anglo-American legal theory, those with PPD are legally sane; they retain both the cognitive ability to appreciate that criminal acts are morally reprehensible and sufficient volitional control to inhibit their antisocial and criminal acts – should they choose to do so (Hart and Hare 1997).

PPD has long been associated with criminal behavior whether in ancient sources including the Bible, Chaucer's Canterbury Tales, and the Icelandic Sagas or in the early clinical descriptions of mental disorder. In the early clinical descriptions, three strands linking personality pathology and offending can be discerned. Clinical writers in the early part of the nineteenth century linked repeated acts of violence to behavioral dyscontrol (e.g., recklessness and impulsivity) in patients who suffered neither psychotic symptoms nor impaired intellectual functioning but rather suffered from inchoate forms of personality pathology (e.g., Pinel, Partridge, Prichard). Early twentieth century nosologists emphasized a second strand, an interpersonal aspect, characterized by persuasiveness and charm, self-confidence, and social assertiveness which was linked to crimes including swindling and fraud (e.g., Cleckley, Kraepelin, Schneider). A third strand that can be discerned in early clinical writings is the emotionally cold, predatory exploitativeness linked to instrumental violence (e.g., Schneider, Pinel, Rush). Thus clinicians identified three distinct aspects of PPD – interpersonal, affective, and behavioral – each of which might be linked to offending.

Moving from clinical conceptualizations to empirical studies, there is little doubt that the dominant approach to measurement of PPD over the last three decades has been the Psychopathy Checklist-Revised (PCL-R; Hare 2003). The measure was developed in the 1970s and was based explicitly on Cleckley's clinical description of psychopathy. Although designed to measure Cleckley's concept of psychopathy, the PCL-R may be regarded as imperfect as it is overly saturated with measures of criminal acts and impulsivity and omits key Clecklian features such as absence of nervousness (Skeem and Cooke 2010). Given its preeminence in the literature, the PCL-R will be considered in some detail.

The Psychopathy Checklist and Offending

The PCL-R is a 20-item scale that is completed by a trained clinician who has reviewed the subject's institutional and criminal records and has carried out a thorough interview concerning the person's history and personality features. The information about the subject is compared to operational definitions in the PCL-R manual, and the clinician decides whether there is evidence that the subject matches these operational definitions. Broadly speaking, the PCL-R items can be grouped into a number of conceptual groups: (1) Interpersonal (e.g., Grandiose Sense of Self-Worth, Glibness/Superficial Charm, Pathological Lying), (2) Affective (e.g., Shallow Affect, Callous/Lack of Empathy, Lack of Remorse or Guilt), and (3) Behavioral (e.g., Impulsivity, Irresponsibility, Need for Stimulation/Proneness to Boredom). These three aspects, which reflect the clinical condition, form the core of the disorder (Cooke and Michie 2001; Cooke et al. 2007). However, in addition, the PCL-R contains aspects that have been termed "Antisocial" (e.g., Criminal Versatility, Revocation of Conditional Release, Juvenile Delinquency); it also includes items pertaining to having many relationships and sexually promiscuity.

There can be little doubt that over the last three decades, the PCL-R has established itself both in the history of personality disorder research and in the armamentarium of applied and research psychologists. It is widely used. Hare (2003) contended that "Perhaps the PCL-R *saves* lives . . . because it helps to keep very dangerous people in prison" (p. 16, emphasis in original). Others have suggested that the application of the PCL-R can have profound prejudicial effects when it is used in certain court proceedings (Bersoff 2002).

What might the PCL-R tell us about the link between psychopathy and offending?

A common paradigm is to assess prisoners using the PCL-R and then, following their release from prison, prospectively assess their rate of reoffending. Meta-analytic studies suggest a low to moderate association between PCL-R scores and future offending including general recidivism, violent recidivism, and sexual reoffending (e.g., Leistico et al. 2008). Yang et al. (2010), looking specifically at violent offending, found that the PCL-R scores were weakly or moderately associated with future offending, but critically, the interpersonal and affective features of the disorder – the core of the disorder – failed to contribute to the prediction, the observed association being due to impulsivity and history of criminal activity. Indeed, empirical measures that quantify the chronicity of criminal behavior or criminal lifestyle appear to perform as well as the PCL-R in the prediction of both general and violent recidivism (Skeem and Cooke 2010).

While the empirical fact of an association between PCL-R scores and risk of reoffending is clear, the meaning of that association is less clear. To understand the meaning it is necessary to consider, in some more detail, what the PCL-R may actually measure.

Psychopathy and Criminal Behavior: Measurement Issues

The latent structure of the PCL-R has been the focus of some debate regarding the relationship between psychopathy and crime and offending (Cooke et al. 2007; Hare 2003; Skeem and Cooke 2010). Cooke and Michie (2001) demonstrated that PCL-R data, and other measures of the psychopathy construct, could be best represented by a three-factor model in which the superordinate construct of psychopathy was underpinned by three distinct latent traits described as: (1) Arrogant and Deceitful Interpersonal Style, (2) Deficient Affective Experience, and (3) Irresponsible Behavioral Style. Hare (2003) proposed a number of "four-factor" models in which he added what he termed an "Antisocial facet" to the Cooke and Michie three-factor model. Although described as antisocial the facet is operationalized, to a considerable degree, by consideration of criminal behavior including convictions (see above).

There are empirical and theoretical reasons why the four-facet model is, in my view, unsustainable: these issues have been considered in detail elsewhere (Cooke et al. 2007; Skeem and Cooke 2010). In brief, the preferred model of Hare (2003 et seq.) appears to be one in which the Cooke and Michie three factors are shown to be correlated with the "Antisocial facet" (Cooke et al. 2007, figure 5). In essence this correlated model merely says that criminal or antisocial behavior is correlated with the three primary traits of PPD, a perhaps unsurprising finding (Cooke et al. 2007). It does not indicate that the four facets are underpinned by a common cause, i.e., psychopathy (see Smith et al. 2003 for a detailed discussion of the important differences between compound traits and multifaceted traits). Attempts to fit an appropriate model to test the assumption that criminal and antisocial behavior are underpinned by a common cause (Cooke et al. 2007, figure 3) have been generally unsuccessful.

Why might this matter? The majority of empirical research concerning the relationship between psychopathy and offending has been carried out using the PCL-R, or its derivatives, to operationalize the construct of PPD. Our understanding about the association between psychopathy and offending – or lack of understanding – is critically linked to the qualities of the PCL-R. Putting to one side the effect of mono-method bias on our understanding of the association, there are other method and conceptual factors that require consideration.

Psychopathy and Offending: Avoiding the Tautology

Clearly, if we wish to properly understand the relationship between PPD and offending, we must begin by measuring the two constructs separately. Blackburn (2007) explained the error of mixing aspects of personality pathology with aspects of criminal and antisocial behavior within one measure. Blackburn noted that such a practice "confounds different conceptual domains because personality deviation and social deviance belong in different universes of discourse. Personality deviation is defined within the framework of interpersonal norms, whereas social deviance represents departures from legal or moral rules. To define the former in terms of the latter precludes any understanding of the relationship" [between the two] (Blackburn 2007, p. 145, citations omitted).

It is perhaps not surprising that the measurement of psychopathy in the PCL-R is confounded with the measurement of criminal behavior. The PCL-R was developed as a research tool for use in correctional populations (Hare 2003): certain items are explicitly founded upon criminal acts (e.g., Criminal Versatility, Juvenile Delinquency, and Revocation of Conditional Release) while others draw heavily upon offenders' discussion of their crimes and victims (e.g., Callous/Lack of Empathy, Parasitic Lifestyle, Failure to Accept Responsibility for Own Actions).

Failure to disaggregate the measurement of the two constructs of interest – PPD and offending – will inevitably lead to tautological thinking, a problem perhaps most eloquently expressed by Ellard (1988); thus, "Why has this man done these terrible things? Because he is a psychopath. And how do you know that he is a psychopath? Because he has done these terrible things" (p. 387).

This is not merely of theoretical importance. Walters et al. (2008) considered whether the interpersonal, affective, and behavioral facets of the PCL-R actually added to the predictive power of the "Antisocial" facet. They found that the first three facets added little incremental predictive power over and above the "Antisocial" facet. As Walters et al. (2008) observed, "If Cooke and his associates are correct in their contention that criminality is not a key component of the psychopathy picture, then the present results have portentous implications for the psychopathy construct and offer serious challenge to Hare's (1998) assertion that psychopathy is the 'single most important clinical construct in the criminal justice system' (p. 99)" (p. 403).

Given the above, should we abandon consideration of the construct of psychopathy in relation to offending or not? It can be argued that such a course would be premature given the historical, theoretical, and empirical links between PPD and offending. Blackburn's (2007) prescription of separating the measurement of personality deviance from the measurement of criminal and antisocial behavior is a first step; clearer theorizing about the risk processes entailed by the disorder is a second step. Both these steps will be considered now.

A New Model of Psychopathy

A new model of psychopath has recently been developed – the Comprehensive Assessment of Psychopathic Personality (CAPP; Cooke et al. 2012). The CAPP model is an attempt to explicate the construct of psychopathy, to describe the conceptual domain of interest. The CAPP model is distinct from measures of psychopathy but informs the development of measures designed to map the conceptual domain. Perhaps, the two signal features of the model are first, it entails symptoms defined in terms of personality pathology – stylistic variations among people – and excludes symptoms that are departures from cultural or moral standards, such as specific criminal or antisocial behaviors. Second, it is dynamic; in keeping with contemporary psychological thinking, traits are not viewed as fixed but rather they are dynamic constructs that can account for both stability and change in a range of behaviors including criminal activity, in particular, the age-crime curve (Blonigen 2010).

The CAPP model was developed by reviewing the extensive literature on the construct of PPD and by consulting subject matter experts in a systematic manner. Information about putative symptoms was subjected to a lexical analysis that led to the identification of 33 symptoms of the disorder. Symptoms are defined in atomistic terms, rather than high-level, complex, or blended terms. On rational grounds these symptoms were allocated to six conceptual domains that are consistent with past research on basic dimensions of personality pathology, namely, *Attachment* (e.g., detached, unempathic, uncaring), *Behavioral* (lacks perseverance, restless, disruptive), *Cognitive* (suspicious, lacks concentration, lacks planfulness), *Dominance* (domineering, deceitful, manipulative), *Emotional* (lacks remorse, lacks anxiety, lacks emotional depth), and *Self* (self-centered, sense of uniqueness, self-aggrandising). These domains where thought to possess heuristic value and have recently been supported by empirical results (Cooke et al. 2012).

Research on the CAPP-IRS (CAPP- Institutional Rating Scale) is still at the preliminary stage; however, results so far suggest grounds for cautious optimism. Specifically, in terms of predictive validity in relation to recidivism, Pedersen et al. (2010) showed that the CAPP-IRS was comparable to the PCL:SV (a short form of the PCL-R), the predictive validity being moderate. Thus, a method which operationalizes the PPD construct without reference to a history of offending performed as well as the PCL:SV. In a post-dictive study, the capacity of the six CAPP domain scores and three primary PCL-R facets scores to predict Facet 4 of the PCL-R, an index of antisocial and criminal behavior, was evaluated. Stepwise regression analyses demonstrated that the CAPP-IRS Behavioral domain score had superior predictive power over any of the three primary PCL-R facet scores; this is particularly interesting given that the CAPP ratings were based on the previous 6 months while the PCL-R ratings were based on lifetime ratings (Cooke et al. 2012).

These results echo results from other measures of psychopathy which do not depend, to any degree, on ratings of criminal behavior, e.g., The Psychopathic Personality Inventory (PPI-R; Lilienfeld et al. 2005). Skeem et al. (2011) noted that the PPI-R has predictive validity in relation to institutional misconduct, violence, and general offending in a range of populations including adults and young offenders, and community and forensic psychiatric residents. These findings are suggestive that even when construct-criterion contamination is removed, it is still possible to demonstrate a link between PPD and offending.

From Groups to Individuals

The fundamental driver for the renaissance of interest in the concept of PPD over the last few decades has been concern about identifying those who may be of risk of committing violence in the future. The irresistible rise of risk assessment has promoted interest in PPD not least because measures such as the PCL-R, and its derivatives, have been shown to be *relatively* strong risk factors – compared with other risk factors – for future violence. Two broad approaches to risk assessment can be discerned; the actuarial, an approach in which scores on instruments like the PCL-R are used to make a numerical prediction about the likelihood of reoffending, and Structured Professional Judgement (SPJ) approaches where comprehensive knowledge of the individual, and their circumstances, are used to plan a risk management plan designed to obviate and perceived risk. The actuarial approach, although popular, is fundamentally misleading. One foundation problem is the assumption that knowledge about an individual's PCL-R score can provide meaningful predictions about that individual's future offending. Cooke and Michie (2010) demonstrated that the prediction interval (i.e., confidence interval associated with a point prediction) associated with predictions of future offending were enormous – typically between 1 % and 99 % – indicating that such predictions have no value when making decisions about individual cases.

From Statistical Thinking to Psychological Thinking

Should we then dismiss and ignore information about PPD, or might such information have some heuristic or clinical value or relevance. A risk factor can be said to have clinical relevance if it either contributes to the understanding of why an individual might go on to offend violently, or because it contributes to our understanding of why the individual might be difficult to engage in risk management through treatment, monitoring, supervision and victim safety planning.

One of the reasons that the PCL-R has been associated with future violence – *at the aggregate level* – is because it taps into many symptoms (and sequelae) of psychopathy that either increase risk of violence or interfere with effective risk management (Cooke 2010). PCL-R scores are silent on cause; their relevance to risk processes in the individual case has to be explicated. In order to understand future risk, the assessor must disaggregate these risk processes and identify those that apply to the particular individual that they are managing. To illustrate, the nature of the risk – and the risk management plan – of an individual who poses a violence risk because he is pathologically dominant possesses a sense of entitlement and construes others as having malevolent intent would be different to the management strategy for someone who is callous, reckless, and impulsive. Each individuals might be risky because of their particular pattern of psychopathic traits; however, the psychological processes underpinning their risk – and thereby the interventions required – could be quite different.

Psychopathy has been described as a "mini-theory" of violence (Hart 1998); indeed, distinct aspects of psychopathy may be conceptualized as *drivers*, *disinhibitors*, or *destabilizers* that act to increase the likelihood of violence (Cooke 2010). The status needs of psychopathic individuals may drive *violence* because these needs frequently lead to suspiciousness and a tendency to construe maleficent motives underpinning the behavior of others. Those with psychopathic personality disorder are often overly sensitive to challenges to their status. Aggression is a common response to the fear of losing face. Specific forms of violence, e.g., sadism, may be founded on the desire to control, demean, and humiliate others which is a consequence of status needs and other forms of self pathology, including possessing a sense of entitlement.

The emotional deficits that characterize PPD including lack of empathy, guilt, and fear have relevance for criminal behavior, in general, and violent behavior, in particular. The lack of emotional depth, remorse, or empathy all may be considered as *disinhibitors* with the absence of these affective responses resulting in the failure to inhibit antisocial cognitions and actions. If you lack anxiety ahead of a violent act, or you lack remorse for a violent act that you have committed, there is neither inhibition nor cost associated with that act. The behavioral features of the disorder including disruptiveness, recklessness, unreliability, and absence of perseverance, together with attachment deficits including being uncaring and uncommitted, can act as *destabilizers*. These features cause the breakdown in reliable social structures, supports, and routines, and this creates the chaotic circumstances in which violent behavior is more likely (Cooke 2010).

In the applied world, the clinician has to take a fundamentally nomothetic approach to the understanding of an individual offender and their particular configuration of symptoms of PPD. As Millon noted recently, "It is only the unique way in which the personality construct is seen in real patients that is ultimately of clinical value." (Millon 2011; p. 296). An individualized formulation has to be developed in which an understanding of the nature and etiology of an individual's difficulties is developed in a precise and systematic manner, communicated to the client, and others, in the form of a narrative written in natural language. Models such as the CAPP model of PPD can be applied to provide a precise and systematic description of how the symptoms of PPD might influence an individual's likelihood of engaging in future offending, but also, his manageability. The clinician's role is to use this, and other, information in order to establish a risk management plan that entails strategies of treatment, supervision, monitoring, and victim safety planning designed to obviate future violence risk and which takes into account the particular pattern of PPD traits displayed by the client.

Looking to the Future

While historically, PPD and offending have been linked; contemporary research leaves many key questions unanswered, are current empirical findings the result of construct-criterion contamination, i.e., tautological thinking, and are particular aspects or facet of PPD of particular relevance to future offending, in general, or violent offending, in particular; what moderating influence do other key variables, e.g., gender, age, and psychiatric status, have on the putative link between PPD and offending?

In order to answer these – and other – questions, it is necessary to improve our measurement of both PPD and of offending; most studies have depended on the PCL-R and on simple recidivism, the latter criterion being an impoverished account of a complex phenomenon. Future research should endeavor to explore the specificity of relationships between aspects of PPD and aspects of offending. This paradigm is common in other areas of quasi-experimental research. The specific role of cigarette smoking in the etiology of lung cancer only became apparent when the relationship between all types of smoking and all disease was refined. Similarly, it could be conjectured that certain aspects of PPD might be linked with certain types of violence, e.g., instrumental versus reactive.

Conclusions

PPD and offending have long been associated. The empirical evidence goes some way to support a link but methodological problems cloud the true nature of the relationship. From a theoretical perspective new approaches to measurement are required to clarify key issues. From a practical perspective detailed studies, including systematic case studies, are required to clarify the why question: why do particular symptoms, or configurations of symptoms, of PPD increase the likelihood of offending?

Overview

The United States Constitution guarantees the right to be represented by attorney to every person accused of a crime whose life or liberty is at stake. When a defendant cannot afford to hire his own attorney, the government is obligated to provide him not merely with token representation but with effective assistance of counsel. In recent years, indigent defense systems have been characterized as overloaded, and the constitutional promise of effective legal representation for the poor in state courts has been perceived as "broken" (Justice Policy Institute 2011; American Bar Association 2004). Among the primary challenges are excessive caseloads and a lack of adequate funding for defense services. In order to function properly, the adversarial system used in American courts relies upon the presence of capable counsel for both the state and the accused. Without appropriate resources, the ability of the defense attorney to provide effective assistance of counsel is compromised, jeopardizing the constitutional rights of the accused and the integrity of the criminal justice system. According to former US Attorney General Janet Reno, "[i]ndigent defense is an equally essential element of the criminal justice process, one which should be appropriately structured and funded and operating with effective standards. When the conviction of a defendant is challenged on the basis of inadequate representation, the very legitimacy of the conviction itself is called into question. Our criminal justice system is interdependent: if one leg of the system is weaker than the others, the whole system will ultimately falter" (American Bar Association 2004). This entry explores the constitutional foundations of the right to counsel, provides an overview of the various means by which states provide indigent defense services, outlines the numerous tasks and functions that public defender attorneys and staff must perform in order to provide effective assistance of counsel, and examines the implications of an underfunded indigent defense system.

The Right to Counsel

The Sixth Amendment of the United States Constitution provides that "[i]n all criminal prosecutions, the accused shall enjoy the right . . . to have the Assistance of Counsel for his defence." Until the middle of the twentieth century, the Sixth Amendment was held to apply only to the federal government, not to the states, and was interpreted to require the government only to allow the defendant to hire his own lawyer, not to appoint one for him. A number of states did provide counsel in certain cases, either by statute or by virtue of a right created under the state constitution, but the appointment of counsel was typically limited to capital cases (Wice 2005).

In 1932, the Supreme Court held for the first time that a state government was obligated to provide the defendant with counsel in a capital case. Basing its decision upon the Fourteenth Amendment right to due process of law rather than the right to counsel enumerated in the Sixth Amendment, the Court explained that

> The right to be heard would be, in many cases, of little avail if it did not comprehend the right to be heard by counsel. Even the intelligent and educated layman has small and sometimes no skill in the science of law. He lacks both the skill and knowledge adequately to prepare his defense, even though he had a perfect one. He requires the guiding hand of counsel at every step in the proceedings against him. Without it, though he be not guilty, he faces the danger of conviction because he does not know how to establish his innocence. (Powell v. Alabama 1932)

The Powell v. Alabama decision recognized a defendant's right to appointed counsel only in capital cases tried in state courts. In 1938, the Supreme Court held that the Sixth Amendment required the federal government to provide counsel for a defendant facing federal noncapital felony charges who was unable to obtain counsel on his own, unless the defendant had "intelligently waived" the right to counsel (Johnson v. Zerbst 1938). Just four years later, however, the court in Betts v. Brady declined to require states to appoint counsel in all noncapital felony cases, finding that the Sixth Amendment right to counsel was not a "fundamental right" that applied against the states through the due process clause of the Fourteenth Amendment (Betts v. Brady 1942).

In 1963, the Supreme Court overturned Betts v. Brady in the case of Gideon v. Wainwright, finally recognizing a right to appointed counsel in all felony cases prosecuted in state courts. The state of Florida had charged Clarence Earl Gideon with the felony offense of breaking and entering a poolroom with intent to commit a misdemeanor. Unable to afford an attorney, Gideon asked the trial court to appoint one for him. The court denied his request, and after representing himself at trial, Gideon was convicted and sentenced to five years in prison. Gideon petitioned the Florida Supreme Court for a writ of habeas corpus, claiming that his conviction violated his rights under the US Constitution. After the Florida Supreme Court denied relief, Gideon appealed to the Supreme Court of the United States, which agreed to hear his claim and appointed a prominent attorney to represent him on the appeal. The Court went on to hold that the Sixth Amendment right to appointed counsel was indeed fundamental in nature and thus applied against the states under the Fourteenth Amendment's due process clause, declaring it an "obvious truth" that "in our adversary system of criminal justice, any person haled into court, who is too poor to hire a lawyer, cannot be assured a fair trial unless counsel is provided for him" (Gideon v. Wainwright 1963).

Following its decision in Gideon, the Supreme Court interpreted the right to appointed counsel to apply in juvenile delinquency proceedings (In re Gault 1967) and in misdemeanor cases in which a sentence of incarceration is actually imposed (Argersinger v. Hamlin 1972). The Sixth Amendment right to counsel attaches at "a criminal defendant's initial appearance before a judicial officer, where he learns the charges against him and his liberty is subject to restriction," and counsel must be provided "during any 'critical stage' of the post-attachment proceedings" Rothgery v. Gillespie County (2008). The Supreme Court has also interpreted the Fourteenth Amendment to require the appointment of counsel for a defendant's first appeal as of right, as well as for a discretionary appeal by a defendant who has pled guilty (Douglas v. California 1963; Halbert v. Michigan 2005). Finally, the court has held that the due process and equal protection clauses of the Fourteenth Amendment require the state to furnish an indigent defendant with expert witnesses relevant to material issues (Ake v. Oklahoma 1985).

The mere fact that an attorney appears on behalf of the defendant is not sufficient to fulfill the Sixth Amendment right to counsel. When a defendant cannot afford to hire his own attorney, the government is obligated to provide him not just with counsel but with effective assistance of counsel. Effective assistance of counsel requires that the attorney exercise reasonable professional judgment under the circumstances of the case (Strickland v. Washington 1984). Attorneys in every state are also bound to abide by the state's rules of professional conduct. Many states pattern their ethical rules for attorneys on the American Bar Association's Model Rules of Professional Conduct, which require the attorney to provide "competent" and "diligent" representation to every client. These requirements include a responsibility to control the lawyer's workload "so that each matter can be handled competently." The attorney must also promptly communicate with the client regarding significant developments in the case, such as the prosecution's offer of a plea bargain, and meaningfully involve the client in decision-making regarding the case (American Bar Association 2007). The American Bar Association's Standards For Criminal Justice: Defense Function, although not binding upon attorneys, also establish norms for the performance of defense attorneys. Standard 4-1.3(e) specifies that "[d]efense counsel should not carry a workload that, by reason of excessive size, interferes with the rendering of quality representation, endangers the client's interest in the speedy disposition of charges, or may lead to the breach of professional obligations." The standards also set expectations for the defense attorney's performance in specific activities such as investigating the facts of the case and exploring the possibility of disposition without trial.

Indigent Defense Systems

An indigent defendant may be represented by an attorney from a public defender's office, assigned counsel, or a contract attorney. In a public defender program, salaried attorneys represent the majority of indigent defendants within a jurisdiction. Public defender offices exist primarily in larger communities, and public defender attorneys typically work together in a central office that is headed by a director and supported by additional staff (Wice 2005). Public defenders may be government employees, and the public defender office may be an independent nonprofit agency such as the Legal Aid Society of New York. In smaller jurisdictions, a system of assigned counsel is typically used. Under this model, private attorneys are selected from a list, either formal or informal, to take cases and are paid either by the case or by the hour (Lefstein and Spangenberg 2009). Many states cap the fees or hours an attorney may bill per case; some states allow judges to waive these caps upon request, but others do not. Roughly 2,800 out of 3,100 counties in the United States rely exclusively on assigned counsel to provide indigent defense services (Wice). Jurisdictions with public defender offices also use assigned counsel in cases involving conflicts of interest, such as those with multiple defendants. Finally, under the contract model, private attorneys bid to provide representation for all or a percentage of indigent defendants in a particular jurisdiction. Contract attorneys may be paid a flat fee to accept all assigned defendants or may be paid according to their caseload.

Indigent defense systems are paid for by state governments, local governments, or a combination of both. As of fiscal year 2008, indigent defense services in 30 states were supported primarily or entirely through state funds; these states include Florida, Maryland, Missouri, New Hampshire, New Mexico, and Virginia. Indigent defense systems in 18 states (including Alabama, California, Georgia, Michigan, Nevada, New York, and Texas) rely on counties for more than half of their funding; in Utah and Pennsylvania, indigent defense services are funded entirely by county governments (Lefstein and Spangenberg 2009). County-funded systems have been criticized because they create the potential for varying levels of funding, access, and quality depending upon where a defendant lives (Justice Policy Institute 2011).

Public Defender Tasks and Functions

The popular image of a criminal attorney centers upon the exchange of evidence and arguments in the confines of the courtroom. On one side is the prosecution; on the other, the defense. Each attorney calls witnesses, presents evidence to the judge and jury, and summarizes the case in closing arguments. For attorneys who represent indigent defendants, however, the popular view of the role of a criminal attorney is extremely myopic. Instead, the work of the defense team extends well beyond the courtroom, with defenders alternately wearing the hats of investigator, social worker, appellate attorney, and litigator.

Recent work by the National Center for State Courts highlights the diverse set of case-related and non-case-related tasks and functions that indigent defense attorneys and their support staff perform (Kleiman and Lee 2010; Steelman et al. 2007; Ostrom et al. 2005). Case-related activities include all tasks and functions directly associated with the handling of individual cases, from the time of appointment through posttrial and appellate activity. Both attorneys and staff must also devote time to certain core activities that are not directly related to a particular case, such as continuing legal education, attending training and conferences, and handling administrative matters such as budgets and personnel issues, community outreach, and staff meetings.

Attorney Activities

The basic case-related duties and responsibilities of defense attorneys can be sorted into a series of complementary functional areas. The first function is pretrial activities and hearings. This function encompasses all of the in-court and out-of-court work associated with pretrial proceedings, including legal research, preparation, participation in pretrial hearings, and drafting and arguing pretrial motions. Attorneys prepare for and participate in a host of bond and detention hearings, arraignments, pretrial conferences, status conferences, competency hearings, motion hearings, and other pretrial hearings. Additionally, defense attorneys are responsible for preparing and arguing motions regarding the evidence to be used at trial (e.g., motions to suppress, motions in limine) and motions for funds to secure expert witnesses. A second critical function of the defense attorney is negotiating plea alternatives with the prosecution. More than 90 % of criminal cases are resolved without trial through plea bargaining. In most cases, the defendant agrees to plead guilty in exchange for a reduction of the charges or sentence; other cases are resolved without a conviction through programs such as diversion.

A crucial – and often time-consuming – function for defense attorneys is client contact. The American Bar Association's Ten Principles of a Public Defense Delivery Service assert that high-quality delivery of public defense necessitates that "counsel is provided sufficient time and a confidential space within which to meet with the client." The defense attorney is obligated to inform the client of his or her rights at the earliest opportunity, build a rapport with the client that instills trust and confidence, and interview the client about the events associated with the charges. Attorneys are also responsible for keeping the client informed of case developments, responding to all client correspondence and inquiries, promptly explaining proposed plea bargains, and engaging the client in meaningful plea discussions. It is not unusual for an attorney to spend part of each day responding to numerous messages from clients calling to inquire about hearing dates and case status. Meeting with in-custody clients can be especially time-consuming, as the attorney must travel to the jail, contend with security procedures, and wait for the client to be produced.

In order to provide an effective defense, public defenders must perform investigative and discovery activities. Attorneys are responsible for directing the activities of investigative staff, visiting the crime scene, and, when necessary, conferring with social workers and independent experts (e.g., forensic experts). Attorneys are also responsible for interacting with the prosecution regarding discovery and for preparing and submitting discovery requests. In short-staffed offices, attorneys often perform duties that could otherwise be handled by non-attorney investigative staff. These include reviewing audio and video recordings of hearings and interviews, interviewing prosecution and defense witnesses, visiting the crime scene to take measurements and photographs, preparing summary reports of investigations, and serving witness subpoenas.

A more "traditional" function of the defense attorney is participating in bench and jury trials. In addition to in-court work, trials may require a substantial amount of out-of-court preparation. Trial-related activities include preparing for and participating in jury selection, drafting proposed jury instructions, preparing and presenting the opening statement, cross-examining prosecution witnesses, and preparing and presenting the defense case and closing argument. Following a guilty verdict at trial, the defense attorney is responsible for sentencing and posttrial activities, including activities related to sentencing, posttrial motions, probation violations, appeals, and collateral proceedings such as petitions for habeas corpus. Specific post-conviction tasks include researching and preparing posttrial motions (e.g., motion for new trial), reviewing presentence reports, sentencing memoranda and the defendant's social history, addressing the admissibility of the prosecution's sentencing evidence, preparing for sentencing hearings, reviewing and correcting sentencing orders, investigating the circumstances surrounding probation violations, and preparing for probation revocation hearings. Tasks related to appeals and collateral proceedings include preparing petitions and briefs, reviewing the trial record, legal research, and preparing for oral arguments. Appeals and collateral proceedings may be handled by the attorney or office that originally represented the defendant at trial or by an attorney or office specializing in appellate work.

Finally, some attorneys are responsible for social work/sentencing advocacy tasks. Such tasks include identifying alternative sanction options; finding program placements; compiling the defendant's medical, educational, and family history; and coordinating mental health evaluations and reviews.

Staff Activities

Effective assistance of counsel depends on the combined work of a defense team comprising both attorneys and non-attorney support staff. Public defender staff efficiently and cost-effectively perform many functions integral to the effective assistance of counsel, from investigating the facts of the case to locating alternative placement options to maintaining complete and accurate case files. Without sufficient support staff resources, public defenders' ability to provide competent and diligent representation to indigent clients may be seriously compromised. Inadequate staff support also reduces the efficiency of the public defender office, as attorneys are forced to take time away from legal work to answer telephones, type documents, and maintain case files themselves.

Support staff tasks can be classified into two broad categories. The first set of staff functions is administrative in nature and includes activities such as client intake, records management, and secretarial services. Client intake includes tasks such preparing file folders, verifying claims of indigency, handling intake paperwork, scheduling initial client appointments, identifying potential conflicts of interest, and obtaining charging documents from court files. Records management includes entering data into case management systems, archiving and retrieving files, and handling billing for contract attorneys. Finally, secretarial services include tasks such as taking telephone messages, managing attorneys' calendars, typing documents such as motions and subpoenas, and transcribing witness interviews.

The second category of support staff functions consists of professional and paraprofessional tasks directly associated with the facilitation of legal representation, including investigative services, legal research, direct attorney support, and social work/sentencing advocacy. Investigative services are typically performed by an investigator who is responsible for locating and interviewing defense and prosecution witnesses, reviewing the offense report and discovery package, visiting the crime scene to take measurements and photos, viewing and obtaining evidence, preparing summary reports of investigations, and testifying in court when necessary. Legal research is a function typically handled by a legally trained staff member, such as a paralegal, who reviews case files to identify legal issues, prepares legal memoranda, and performs legal research related to procedural and evidentiary issues. Direct attorney support includes in-court and out-of-court activities that provide the attorney with logistical support. Out of court, staff locate clients (e.g., identifying the jail in which a defendant is being held) and determine whether a client is a defendant in other criminal proceedings in the current jurisdiction or in other jurisdictions. Staff members also provide direct support to attorneys in the courtroom during all types of court proceedings, such as arraignments, bail reviews, preliminary hearings, motion hearings, trials, and sentencing hearings.

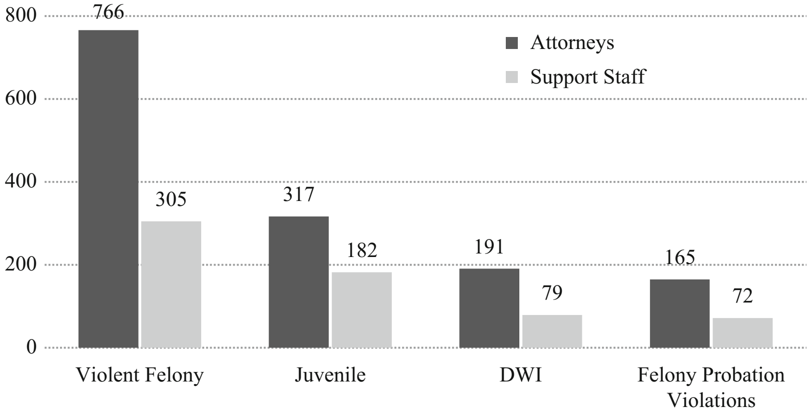
Finally, a specialized group of support staff provide defense attorneys with information related to a client's medical, psychiatric, educational, and family history. Social work/sentencing advocacy staff develop mitigating information for sentencing, match defendants with appropriate drug treatment programs and other alternatives to incarceration, investigate the facts surrounding probation violations, coordinate witness appearances, and directly assist defendants with matters such as jail issues and obtaining legal identification.

Caseload Standards

To ensure that public defenders are able to fulfill their constitutional obligation to provide effective assistance of counsel, a set of national caseload standards were developed in 1973. Caseload standards are important because public defenders do not exercise direct control over the number of defendants they are assigned to represent and therefore the amount of work for which they are responsible. The National Legal Aid & Defender Association (NLADA) points out that public defender workloads "rise or fall due to a convergence of societal trends and decisions made by legislatures, police departments and prosecutors which are completely beyond the control of indigent defense providers" (NLADA 2008). ABA Principle 5 proclaims that national caseload standards should not be exceeded, and the workload of an attorney "should never be so large as to interfere with the rendering of quality representation or lead to the breach of ethical obligations, and counsel is obligated to decline appointments above such levels."

Developed in 1973 by the National Advisory Commission on Criminal Justice Standards and Goals, the existing national caseload standards represent the maximum number of cases that a defense attorney should handle in a year, assuming that the attorney handles only a single case type. The commission recommended that caseloads should not exceed 150 felonies, 400 misdemeanors (excluding traffic), 200 juvenile court cases, 200 Mental Health Act cases, or 25 appeals per attorney per year. In recent years, several states, including Virginia, Maryland, and New Mexico, have developed their own state-specific caseload standards for attorneys and support staff in public defender offices. These efforts have been undertaken in response to the perceived limitations of the 1973 national caseload standards. Criticisms of the existing standards include the facts that the standards were not founded upon empirical research, do not allow for the varying complexity of different felony case types (e.g., homicide, violent felonies, and nonviolent felonies), do not capture the variability between states in criminal justice procedures and practices, and predate the introduction of information technology resources commonly used by today's attorneys and support staff. Furthermore, the standards are silent on the level of staff support attorneys require in order to provide effective representation.

The new state-specific standards are expressed as case weights, which represent the average amount of time needed for an attorney or staff member to handle effectively each case of a particular type, from appointment through post-disposition activity. Separate case weights are calculated for different types of cases of varying levels of complexity (e.g., homicide, violent felony, misdemeanor, driving under the influence of alcohol, juvenile delinquency). For example,



Public Defenders, Fig. 1 Attorney and support staff case weights (minutes) in Virginia

in Virginia, a violent felony case requires, on average, 766 minutes (12.8 hours) of hands-on attorney time and 305 minutes (5.1 hours) of staff time from appointment through post-disposition activity. In comparison, a nonviolent felony case in Virginia requires, on average, 433 minutes (7.2 hours) of attorney time. Case weights are typically constructed from empirical data collected during a "time study" that measures current practice, then reviewed by panels of expert attorneys and support staff to ensure that the weights allow sufficient time to provide effective representation. The case weights can be used in combination with caseload data to calculate total attorney and staff workload for a public defender's office, along with the number of attorneys and support staff members needed to handle this workload effectively.

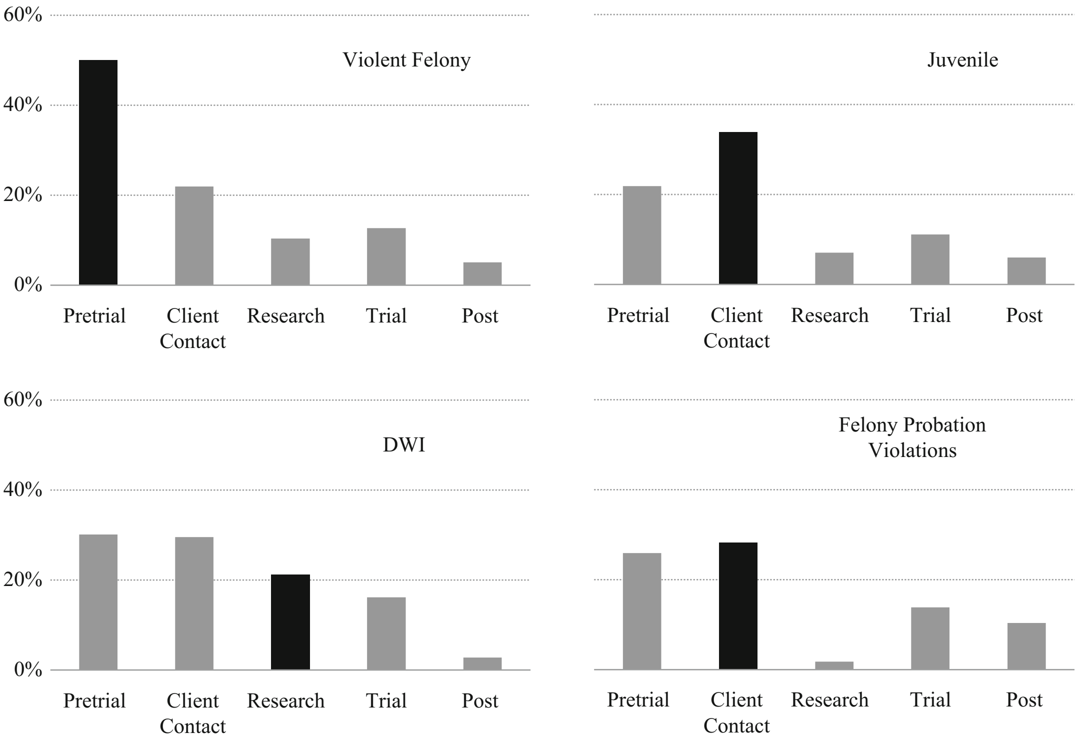
An Example from Virginia

Figure 1 displays a subset of the case weights developed for public defender offices in Virginia in 2010. Each case weight represents the average number of minutes of attorney or staff time required to defend one case of the specified type. Figure 1 illustrates two important concepts about the nature of public defense cases. First, cases handled by public defenders vary in complexity, as measured by the amount of attorney and staff time needed to provide effective assistance of counsel. For example, an average violent felony case requires twice as much attorney time as a juvenile case and four times as much as a DWI case or a felony probation violation. Second, effective assistance of counsel requires the combined efforts of attorneys and support staff. For example, a typical juvenile case requires approximately 5 h of attorney time and 3 h of staff time.

Figure 2 illustrates a third important concept: the relative amount of time attorneys (and staff) devote to different tasks and functions varies dramatically among case types. For example, in Virginia, approximately one-half of the attorney work required to defend violent felony cases is expended on pretrial proceedings, investigation, discovery, and plea negotiations. This results from factors such as the large amount of evidence typically associated with violent crimes and the complexity of plea negotiations in these high-stake cases. In felony probation violation cases, the largest share of attorney time is devoted to contact with the client and the client's family. In DWI cases, on the other hand, a larger proportion of time is spent on legal research.

Implications of Excessive Caseloads

The Washington Public Defender Association asserts that "caseload levels are the single biggest predictor of the quality of public defense representation. Not even the most able and industrious lawyers can provide effective representation when their workloads are unmanageable. A warm body with a law degree, able to affix his or her name to a plea agreement, is not an acceptable substitute for the effective advocate



Public Defenders, Fig. 2 Proportion of Virginia public defender attorney time spent on tasks and functions by case type

envisioned when the Supreme Court extended the right to counsel to all persons facing incarceration." Similarly, a recent report by the Justice Policy Institute argues that "[p]roper resources and adequate time may not guarantee that every public defender will provide quality representation, but high caseloads and limited resources almost guarantee that this will not happen for all clients" (Justice Policy Institute 2011). In many jurisdictions across the nation, excessive caseloads currently jeopardize the quality of indigent defense services (Lefstein 2011). For example, in 2006, public defenders in Clark County, Nevada, had average per-attorney caseloads of 364 felony and gross misdemeanor cases (Lefstein and Spangenberg 2009). Although this figure includes felonies and excludes less serious misdemeanor cases, it is much closer to the 1973 recommendation for misdemeanor-only caseloads (400 per attorney per year) than the corresponding recommendation for felony caseloads (150 per attorney per year). Similarly, a recent census of public defender offices by the Bureau of Justice Statistics found that 15 state programs exceeded the 1973 recommendations for the maximum numbers of felony and misdemeanor cases per attorney (Langton and Farole 2010). Resource constraints have been exacerbated by the recent fiscal crisis, which has resulted in attorney and staff reductions for many public defender systems. For example, the Minnesota Board of Public Defense cut 15 % of its attorney positions in 2008 in response to budget shortfalls. Similarly, the Maryland Office of the Public Defender has recently reduced its workforce by nearly 20 % due to budget cuts (DeWolfe 2011).

Faced with excessive caseloads, public defenders are often forced to adopt a "triage" approach, rationing their time and focusing scarce resources on the most serious or urgent matters. Under such conditions, attorneys may not have sufficient time or opportunity to enter an appearance promptly during the critical early stages of the case, prepare thoroughly for all proceedings, communicate directly and in a timely manner with the accused, fully interview the accused and other witnesses to explore pertinent facts in a case, conduct a thorough investigation of all relevant facts and circumstances in each case, duly focus on each case and provide effective representation at trial, and prepare for and meaningfully participate in the sentencing process (Ostrom, Kleiman, Ryan).

ABA Principle 8 articulates the need for "parity between defense counsel and the prosecution with respect to resources." Without sufficient resources to effectively handle indigent defense caseloads, guarantees of a fair and balanced adversarial process are compromised, with significant costs for individuals, the criminal justice system, and society as a whole. First, the failure to provide effective assistance of counsel can result in the unnecessary imprisonment of innocent defendants or in the imposition of unduly long prison sentences due to errors in scoring sentencing guidelines or failure to present mitigating evidence. The Justice Policy Institute proclaims that "[w]ithout a functioning adversarial justice system, everyday human error is more likely to go undiscovered and result in the tragedy of innocent people being tried, convicted and imprisoned" (American Bar Association 2004). Erroneous convictions and excessive sentences impose extra costs on taxpayers and the criminal justice system in terms of additional jail and prison bed days. Unnecessary incarceration is profoundly disruptive not only to the defendant himself but to his family and employer as well. A wrongful conviction also leaves the true perpetrator free to commit additional crimes, with corresponding societal costs. Second, ineffective assistance of counsel can lead to an increase in the number of appeals and post-judgment challenges to convictions, resulting in increased costs to the criminal justice system (Williams and Bost 1971). Third, when the defense attorney has insufficient time to prepare for and appear at court proceedings early in the life of a case (e.g., bail review hearing, arraignment), the defendant may remain in pretrial detention longer than necessary, or the opportunity for an early resolution of the case may be lost, resulting in increased jail, attorney, and court system expenditures. Finally, a lack of quality representation for indigent defendants can adversely impact perceptions of fairness and public trust and confidence in the criminal justice system. The National Legal Aid & Defender Association states that "public confidence in the integrity of the system is lost when the community perceives that inadequate representation creates a system that metes out justice differently to the rich and the poor" (NLADA 2004). It is not only high-profile reversals of wrongful convictions that can undermine public opinion regarding the quality of indigent defense; damage is also done when defendants, their families, jurors, and other participants in the criminal justice process perceive indigent defense attorneys to be overworked, ill prepared, or unresponsive to the needs and concerns of individual defendants.

Conclusion

Public defenders and other attorneys who represent indigent criminal defendants are essential to the due process of law in our nation's criminal courts. The effective delivery of indigent defense services requires the joint effort of attorneys and support staff, whose work extends well beyond the confines of the courtroom. Recent studies have echoed a growing concern that "[t]he defender systems that people must turn to are too often completely overwhelmed; many dedicated defenders simply have too many cases, too little time and too few resources to provide quality or even adequate legal representation" (Justice Policy Institute 2011). In his 2005 State of the Judiciary address, former New Mexico Chief Justice Richard Bosson observed that "the fiscal needs of the [New Mexico] Public Defender are so dire, their situation seems so hopeless, that many times prosecutions cannot go forward due to lack of sufficient personnel." Chief Justice Bosson went on to describe the criminal justice system with the oft-used metaphor of the "three-legged stool" supported by the prosecution, the defense, and the court: "When one leg is weakened, you know what happens; you end up on the floor. Well, we are not on the floor yet, but we are not far off." As the current fiscal crisis threatens further reductions to already strained budgets for indigent defense services, the three-legged stool is wobbling more visibly in many states across the nation. Empirically based workload standards for public defenders can help to ensure that caseloads are manageable, enabling attorneys to make good on the constitutional guarantee of effective assistance of counsel and helping to preserve the integrity of the criminal justice system.

Subsidized housing

Overview

Since the Department of Housing and Urban Development (HUD) initiated programs to address the shortage of low-income housing in the *U.S. Housing Act of 1937*, the provision of housing assistance to the needy has taken a variety of forms from high-density project-based developments to smaller scale scattered-site complexes and tenant-based voucher assistance. Regardless of form, central concerns around the association between low-income, subsidized housing and local patterns and trends in crime tend to dominate the public imagination. The extant research shows a moderately strong positive relationship between the location of public housing projects and crime hotspots in urban centers. Some studies identify a distance-decay effect whereby rates of delinquency, crime, and violence diminish with distance from the housing complex whereas other research finds crime and violence to be high but relatively contained within the project. There is additional evidence suggesting that residence in public housing can elevate both levels of offending for young male inhabitants and risk of criminal victimization for all tenants. To remediate the concentration of poverty and elevated crime risks associated with large-scale public housing projects located in major American cities, various federal initiatives, including Section 8, MTO, and HOPE VI programs, have gained support in recent decades. Current controversies over the importation of crime into destination communities, ostensibly at the hands of former project residents, serves as a new and promising avenue of scholarly research.

Crime and Public Housing

Scholarly literature investigating the relationship between densely concentrated public housing and crime provides considerable evidence of at least some positive association at both the neighborhood and individual levels-of-analyses. First, there is a moderately strong relationship between the location of public housing developments and crime hotspots in urban areas, although the size of the effect varies by the scale of housing and the number and type of control variables included in the analysis (Galster et al. 2002; McNulty and Holloway 2000; Suresh and Vito 2007). Second, opportunities for involvement in gang violence and drug sales, among other kinds of offending, have been found to be more readily available to youth who reside in public housing developments, compared to those who live outside (Popkin et al. 2000; Venkatesh 2000). In fact, the *same* youth report reductions in criminal involvement after leaving public housing; for example, arrests for violent crime and, in particular, robbery decline by half after juveniles move from project-based public housing into low-poverty neighborhoods (Ludwig et al. 2001; see also Kling et al. 2005a). Finally, public housing residents experience elevated levels of criminal victimization relative to their nonpublic housing counterparts, prompting significant and credible fear of crime (Griffiths and Tita 2009; Holzman et al. 2001; Kling et al. 2005b). Taken together, these findings suggest that twentieth century federal housing policy effectively anchored the poor in highly dangerous environments and isolated them from the economic opportunities that traditionally serve as the building blocks of social and residential mobility.

Part of the rationale for recent shifts away from project-based toward scattered-site and especially tenant-based housing assistance is founded on the premise that the dispersion of public housing tenants across city neighborhoods will deconcentrate urban poverty and dilute the negative effects of related social and economic disadvantages. The logic inspiring the construction of new mixed-income communities on the sites of demolished developments is reflected more broadly in tenant-based housing policies. According to the tenant-based narrative, dispersing public housing tenants across more advantaged neighborhoods and attracting market-rate owners and renters to newly constructed units on the sites of former distressed developments should both deconcentrate poverty and reshape cities to reflect a patchwork of thriving mixed-income communities. The resulting redistribution of low-income families is expected to alleviate the deleterious causes and consequences of concentrated poverty (Massey and Kanaiaupuni 1993). As yet, however, little is known about whether and how tenant-based housing assistance affects the redistribution of crime across the city.

A Brief History of Federal Housing Policy

Federal policies on housing for low-income families in the United States can be distinguished into three distinct eras, each associated with a different ideology and approach to the provision of subsidized housing. Beginning in the 1930s, the first phase "mainly helped two-parent families displaced temporarily by the Depression or in need of housing following the end of World War II" (Wilson 2000, p. ix). More specifically, the *U.S. Housing Act of 1937* integrated housing subsidies into the social welfare system and the *Servicemen's Readjustment Act of 1944* (commonly known as the G.I. Bill) made homeownership loans and access to subsidized rental housing available to returning veterans. Families resided in public housing units for brief periods as a temporary respite and the mix of tenants varied considerably in economic circumstance as a consequence of flexible income ceilings. In this stage, public housing was conceived of, and operated as, "transitional" housing.

The second era of housing policy, targeting slum clearance and urban renewal, can be traced to the passage of the *Housing Act of 1949* supported by President Truman. In this stage, extremely low-income families, many of whom were headed by single mothers, were dislocated from economically disadvantaged crime-ridden neighborhoods marked for slum clearance to high-density public housing developments. In light of the growing population in need of low-income housing, local Housing Authorities in major US cities lowered income ceilings to meet housing demand for the most economically destitute. Thus, eligibility requirements for, and accessibility to, project-based housing tightened considerably. Critics of this second stage of housing policy contend that project-based public housing contributed to a host of urban problems including the concentration of extreme poverty in neighborhoods with public housing, the social and physical isolation of public housing tenants, ineffective and inefficient management of funds for regular maintenance of existing public housing structures, vulnerability to the infiltration of gangs in developments, and elevated levels of crime and violence in public housing communities (Fagan and Davies 2000; Griffiths and Tita 2009; Popkin et al. 2000; Venkatesh 2000). These developments no longer served as a temporary or transitional stopgap, but instead stranded extremely poor residents in rapidly deteriorating social and physical environs. According to critics, the strict eligibility requirements likewise served as disincentives toward self-sufficiency and indirectly encouraged intergenerational tenancy.

Opposition to the siting of these developments was vociferous in well-organized communities of homeowners who feared erosion in property values and the influx of crime (Galster et al. 2002; Santiago et al. 2003). As such, large-scale, high-density public housing developments tended to be clustered within less desirable areas of major cities, where opposition was weak or nonexistent. Indeed, various court decisions over the past few decades, including *Thompson v HUD* (1994), confirm that cities like Baltimore, "with the approval of HUD, acted in concert over many decades to create a deeply segregated system of public housing, with project siting decisions largely driven by community opposition in white neighborhoods, in the context of a central city housing authority with limited jurisdiction over housing outside its own city limits" (Poverty & Race Research Action Council 2005, p. 1). In locating projects in close proximity to one another, tenants were physically isolated from basic amenities by major thoroughfares, were racially and economically segregated, and were socially marginalized from their nonsubsidized counterparts.

Amid mounting concerns over the physical deterioration of buildings and infrastructure, substantial health and safety concerns surrounding the disrepair of tenant units and semipublic spaces (especially hallways, stairwells, and elevator shafts), security concerns cultivated by gangs and gang-related violence, police "sweeps" and "swarms" that represented civil liberties violations, the mismanagement of resources that undermined public trust, and intense fear of crime among residents that thwarted collective efforts at informal social control, a new era of federal public housing policy has once again transformed the administration of housing assistance in the United States (Popkin et al. 2000; Venkatesh 2000). Beginning in 1961, an addition of Section 23 to the *Housing Act* (entitled the Leased Housing Program) allowed qualified low-income renters to reside in privately owned apartment buildings maintained by their local Housing Authority. The building's owner would receive some portion of the market rent from the tenant and the remainder from the Housing Authority itself. In the past 20 years, the shift away from project-based assistance toward tenant-based assistance in the form of alternative programs like Section 8 housing (or, more recently, Housing Choice Vouchers) has grown markedly with the introduction of programs like Housing Opportunities for People Everywhere (HOPE VI) and Moving to Opportunity (MTO).

In 1992, HUD unveiled its HOPE VI vision, originally known as the Urban Revitalization Demonstration (Katz 2009). The blueprint for revitalizing public housing communities under this program would center on a series of major reforms suggested in *The Final Report of the National Commission on Severely Distressed Public Housing*. First, the Commission recognized the need for capital investment in rehabilitating and modernizing public housing stock that had fallen into disrepair, but was not beyond salvaging. Second, the Commission recommended demolishing the 86,000 "severely distressed" public housing units in which residents: (a) lack ready access to social services, support programs, and employment opportunities; (b) live in physically deteriorated buildings; (c) suffer from formal and informal mismanagement of the environment; and (d) reside in developments and neighborhoods marked by excessive crime, drug crime, and violent crime rates relative to the citywide averages. Finally, the Committee emphasized the necessity of access to social services, employment opportunities, and relocation support for those displaced from distressed public housing projects slated for demolition.

Cities such as Atlanta, Baltimore, Boston, Chicago, Los Angeles, and New York – areas in which some of the most distressed public housing developments are located – have been extremely active in realizing the most recent re-visioning of federal housing assistance policy. In various ways, local Housing Authorities in these and other urban centers have aggressively pursued HOPE VI revitalization grants to demolish severely distressed public housing developments, participated in the Moving to Opportunity program which offered Section 8 housing vouchers and housing counseling to 4,600 families who volunteered to relocate to neighborhoods with less than 10 % in poverty (Briggs et al. 2010), and explored ways to expand access to Housing Choice Voucher programs. This movement away from project-based assistance toward tenant-based assistance is intended to benefit public housing residents by offering mobility out of highly disadvantaged crime-ridden communities while, at the same time, serving to deconcentrate poverty, "cool" crime hotspots in urban areas, and encourage the establishment of mixed-income communities.

Crime and Project-Based Developments

Both qualitative and quantitative studies on crime in and around large and densely populated public housing projects have shown elevated levels of property crimes, violent crimes, and drug-related offenses, even compared to surrounding and generally disadvantaged neighborhoods (Griffiths and Tita 2009; Kling et al. 2005b; Popkin et al. 2000; Venkatesh 2000; Weatherburn et al. 1999). Griffiths and Tita (2009) demonstrate, for example, that distressed public housing complexes in Southeast Los Angeles neighborhoods such as

Watts have markedly higher homicide rates relative to surrounding disadvantaged neighborhoods. In some cases, the high concentrations of crime on public housing properties have been shown to diffuse outward from those developments; McNulty and Holloway (2000) find evidence of distance-decay "spread effects" of crime from public housing developments in Atlanta, GA, to the surrounding neighborhoods and Fagan and Davies (2000) report a significant concentration of violent crimes within a 200 yard radius of public housing in Brooklyn, NY. From these patterns, it is clear that crime is concentrated in and around the sites of high-density public housing in major cities. Even when distance-decay effects are identified, however, researchers cannot conclude that public housing residents are necessarily responsible for the elevated crime in the neighborhoods surrounding their developments (Griffiths and Tita 2009).

Although some studies show disparities in offending behavior between public housing residents and their nonpublic housing counterparts, these differences are generally not large. For example, Ireland and colleagues (2003) find that offending rates for youth in public housing in Rochester, NY, are not statistically different from the offending rates of their counterparts outside of public housing, yet public housing youth in Pittsburgh exhibit somewhat higher rates of violent offending. Kids who moved from public housing developments to low-poverty neighborhoods as part of the Moving to Opportunity program were shown to reduce their offending behavior (Ludwig et al. 2001). Nevertheless, scholars have difficulty distinguishing selection effects from causal effects when differences arise (Sampson 2008). That is, it is not clear whether crime-prone individuals are allocated to public housing (Weatherburn et al. 1999) akin to a selection effect or whether the architectural and design features of public housing projects, including physical size and the number of apartments sharing common entries, simply create more opportunities to offend for both local and nonlocal residents (Newman 1972).

On the whole, research suggests that levels of crime in public housing can be explained less by the criminality of tenants and more by the criminogenic opportunities inherent in the design and management of these developments. Public housing is a "crime attractor" such that it provides access to a "mass of prospective victims and/or erode[s] the collective efficacy of the neighborhood" (Galster et al. 2002, p. 291). Indeed, the literature has clearly established that victimization risk is significantly higher for residents of public housing relative to those who reside in private market housing and, therefore, neighborhood crime problems differentially burden public housing tenants (Dunworth and Saiger 1994; Griffiths and Tita 2009; Raphael 2001). Combined, the extreme concentration of poverty as a consequence of the spatially proximate siting of developments, the physical and social isolation of residents, and low levels of formal and informal social control are significant contributors to the elevated rates of crime and violence in housing developments.

Crime and Scattered-Site Developments

Scattered-site supportive housing, which is term typically used to describe developments with fewer than 15 units, can take the form of small apartment buildings purchased by a local Housing Authority, group homes, homeless shelters, or other small-scale subsidized housing for special needs populations such as the elderly, the infirm, substance abusers, or those suffering from mental disease or defect. Such housing has little effect on property values in the surrounding neighborhoods (Hogan, 1996). Moreover, residents in scattered-site housing report similar neighborly interactions, willingness to give and receive aid from neighbors, and embeddedness in the local community as do residents of clustered public housing (Kleit 2001). In the very few studies that have specifically examined the effects of scattered-site supportive housing on neighborhood crime trends, the authors find virtually no evidence of an increase in neighborhood crime after the opening of these small-scale subsidized developments (Galster et al. 2002, 2003; Santiago et al. 2003). The single exception is the finding of a statistically significant increase in total crime and violent crime within 500 ft of supportive housing sites in Denver, CO, but only for slightly larger developments that housed more than 53 residents (Galster et al. 2002). Therefore, the introduction of scattered-site developments into neighborhoods does not appear to increase proximate crime rates, particularly when these buildings are less dense and located in low-poverty areas with pre-construction levels of crime that approximate citywide averages.

Crime and Tenant-Based Housing

Current literature on tenant-based housing assistance suggests that relocating from densely populated high-rise public housing to voucher-subsidized private rentals has null or positive individual-level effects on children and adults, particularly among those who participated in the MTO Demonstration. For example, adolescent involvement in violent offending tends to decline after a move (Kling et al. 2005a), MTO children attend schools with higher test scores and pass rates, MTO parents report improvements in physical and mental health as well as reduction in stress, and adults perceive their new neighborhoods as safer (Goering et al. 2003).

Outcomes for HOPE VI families are more mixed. For example, Clampet-Lundquist (2010) finds that concerns over crime and perceptions of neighborhood safety change, but do not necessarily diminish, among families relocated from distressed public housing developments. More specifically, even those voucher recipients taking up residence in lower crime neighborhoods report fear as a consequence of the loss of social ties and lack of "physical and social protections" that had been available in their previous public housing projects. Indeed, residents perceive themselves to have been more physically secure from violent crime when they resided in upper-floor apartments of high-rises compared to the single-family homes in their new neighborhoods (Clampet-Lundquist 2010). Residents who personally observed offending in the previous development also tended to know the perpetrators. Consequently, the anonymity of destination neighborhoods increases residents' insecurities and perceptions of risk.

Some research illustrates that short-term gains in educational benefits for children of voucher recipients are not borne out in the long term (DeLuca and Dayton 2009) and others find few positive *or* negative effects of mobility on student achievement (Jacob 2004). Part of the explanation for these null effects is related to the characteristics of receiving neighborhoods. According to Jacob (2004, p. 251), "a large proportion of families did not take advantage of the relocation opportunity provided by public housing closings to move to a substantially different neighborhood, and even those children who did move to substantially better neighborhoods did not end up in significantly better schools."

The move to tenant-based assistance and related housing mobility programs has triggered much research on the welfare of and outcomes for affected families, but less attention is focused on how the in-migration of voucher recipients affects conditions in the receiving neighborhoods. In one of the few studies on this topic, Suresh and Vito (2007) suggest that the high assault rates characteristic of densely populated neighborhoods comprised of large-scale public housing developments in Louisville, KY, are gradually displaced into the destination neighborhoods of housing voucher recipients over time. The authors intimate that assault hotspots shift in a pattern consistent with the relocation of residents, particularly when the destination neighborhoods are low-income areas. Based on their study, however, Suresh and Vito (2007) cannot determine whether the victims and offenders involved in assaults in destination communities are actually voucher recipients. In a more recent attempt to disentangle how the in-migration of voucher recipients affects neighborhood crime rates, Van Zandt and Mhatre (2009) arrive at a different conclusion. They suggest that rather than bringing crime with them, voucher families' residential choices are constrained to higher crime neighborhoods in Dallas, TX. Consequently, any relationship between the presence of voucher recipients and neighborhood crime rates is driven by inadequate options for the use of vouchers in safer and more affluent neighborhoods.

Key Controversies

Two controversies presently dominate the literature on public housing and neighborhood crime patterns. The first is a theoretical question that situates researchers into one of two camps – those who subscribe to "types of people" explanations for aggregate levels and patterns in crime and those who subscribe to "types of places" explanations. Whether one views changes in crime rates as a function of changes in the residential population or the characteristics of place that attract offenders to the environs influences how such changes are interpreted. Second, the move to tenant-based housing assistance has spawned questions and concerns over both the consequences for destination neighborhoods and the restrictions on residential opportunities for Housing Choice voucher recipients. These respective controversies are discussed in turn below.

For those who subscribe to the types of people model, changes in crime rates that coincide with shifts in the demographic and socioeconomic composition of neighborhoods can be attributed to the criminality of newcomers. More specifically, when dangerous people move into a new area, law-abiding residents become easy targets for victimization. Rosin's (2008; but see Briggs and Drier 2008) controversial *Atlantic Monthly* article, suggesting that increases in neighborhood crime rates were associated with the movement of subsidized families (i.e., Housing Choice Voucher recipients) into the community, intimated that former public housing residents were "criminals. . .penetrating once-safe suburban neighborhoods" in Memphis, Tennessee (Van Zandt and Mhatre 2009, p. 1). Were it accurate, the speculation that those receiving tenant-based housing assistance are somehow more prone toward criminal activity than are market-rate tenants could be said to represent a "direct link" between subsidized housing and crime (Galster et al. 2002).

By contrast, "types of places" explanations for neighborhood crime trends focus on how neighborhood conditions undermine collective efforts to control public space and provide opportunities for offending. These socially disorganized and "criminogenic" environments are vulnerable to crime because there is little formal guardianship, efforts to generate social control are ineffective, and the communities lack collective efficacy. Importantly, offenders need not be local residents. In this case, scholars treat changes in levels and patterns of crime as contextual effects, in lieu of assuming that residents in high crime neighborhoods are responsible for the offenses that occur there. Here, the link between subsidized housing and neighborhood crime rates is "indirect" and public housing residents "may [simply] be more difficult for the community to enlist as. . . instruments of collective efficacy" (Galster et al. 2002, p. 293).

The second controversy presently unresolved in the literature involves the freedom with which Housing Choice voucher recipients can select destination neighborhoods. Under the logic of tenant-based assistance programs, residents ostensibly experience expanded choice in residential location such that they can choose affordable private rental units in lower poverty neighborhoods, all across the city. The Department of Housing and Urban Development requires that voucher recipients reside in rental units that are at or below HUD-determined Fair Market Rents. One of the standard performance indicators for local Housing Authorities is related to their implementation of "policies to encourage voucher holders to search outside of areas of poverty and minority concentration and to encourage owners of units in lower poverty or minority areas to rent to voucher holders" (Devine et al. 2003, p. 25). Voucher recipients' choices are restricted, however, by the preferences of private landlords to participate in the Housing Choice Voucher (HCV) program. And, unfortunately, landlord participation itself may be conditioned by the characteristics of the neighborhood and its desirability for market-rate renters and homeowners. For example, Wyly and DeFilippis (2010, p. 65) maintain that

> landlords participate only if the mix of benefits and drawbacks (stability of occupancy and rental income, vs. rules and paperwork) is better than the private rental market in the neighborhood; there has always been concern that the shift to vouchers will simply reconcentrate assisted households into a new set of bad neighborhoods.

Unlike the Moving to Opportunity Demonstration, which relocated public housing families into very specific and advantaged neighborhood contexts, the HCV program relies on a looser set of conditions, dependent on private landlords' willingness to rent to HCV holders and inclusionary zoning policies (where these county and municipal zoning ordinances exist).

On the whole, voucher recipients make short-distance moves to neighborhoods in which concentrated poverty and residential racial segregation are only slightly lower than their previous housing project (Wang and Varady 2005), although the long-term outcomes are far superior when families receive substantial housing relocation counseling and are placed in socio-economically prosperous neighborhoods (as was the case for those who participated in the Gatreaux and MTO programs; see Keels et al. 2005). Indeed, the deconcentration of poverty expected to result from tenant-based housing assistance policies that disperse low-income residents to subsidized private rental units will be undermined if voucher recipients tend to reconcentrate in new neighborhoods. In one of few studies examining this issue, spatial econometric models of HCV recipients' destination neighborhoods in New York City show

> no support for the claim that tenant-based vouchers promote poverty deconcentration. Even after accounting for racial segregation and spatial autocorrelation, vouchers have a stronger link to local poverty rates than all other types of federal low-income housing assistance – including the much-aligned category of traditional public housing (Wyly and DeFilippis 2010, p. 82).

If crime rates are already higher and socioeconomic conditions are already disadvantaged in the destination neighborhoods of HCV recipients, it would be fallacious to assume that an influx of HCV families is responsible for changes in neighborhood crime.

There is undoubtedly a complex relationship between public housing and crime that defies easy explanation. Historically, crime and violence rates tended to be exceptionally high in densely concentrated high-rise and garden-style developments, spawning NIMBY (Not In My Backyard) opposition to siting decisions. From this relatively consistent empirical relationship between crime and the location of public housing developments in American cities, however, scholars cannot conclude that public housing residents are necessarily more dangerous or inherently more likely to be involved in offending than their nonpublic housing counterparts. Instead, the physical architecture of these developments and the failure of local housing authorities to adequately maintain the units, buildings, and premises helped to undermine collective efficacy, social control, and social capital that is necessary to forestall crime and protect the public space. With the transformation in housing policy from largely project-based to predominantly tenant-based assistance, new questions about the fate of former residents' destination neighborhoods are expected to gain attention in the criminological literature.

Public Opinion About Sentencing

Karen Gelb
Sentencing Advisory Council, Melbourne,
Victoria, Australia

Overview

Confidence in the courts is critical to the legitimacy and effective functioning of the criminal justice system. However, surveys measuring levels of public confidence in the system have found that public trust and confidence are at critically low levels around the world. This is especially so for the courts and sentencing.

Low levels of confidence in the courts have been of major concern for governments around the world. Within this context, a substantial body of literature has developed that attempts to understand the drivers of public confidence. There are five main themes to this body of research:

- People have little confidence in the courts.
- In the abstract, people believe that sentences are too lenient.
- People have little accurate knowledge of crime and the criminal justice system.
- The mass media is the primary source of information on crime and justice issues.
- When given more information, people become less punitive.

While there is widespread agreement in the literature that people's knowledge of crime and justice is a primary driver of their attitudes to the courts and sentencing, there is less agreement about the practical implications of this finding in terms of improving public confidence. That is, if lack of knowledge about crime and justice is closely related to lack of confidence in the courts, can public confidence be improved by increasing public understanding?

Some researchers believe that the answer to improving public confidence lies in informing and educating the public, often via bodies such as sentencing councils. Others, however, see this approach as doomed to fail in the absence of more widespread opportunities for public deliberation, debate and discussion. While informing and educating is aimed squarely at the intellectual aspect of public attitudes, it is often more emotive factors that drive attitudes. Ignoring the affective to focus on the effective thus only addresses part of the story of the relationship among attitudes, knowledge and confidence in the courts.

Introduction

Confidence in the courts is critical to the legitimacy and effective functioning of the criminal justice system. All government institutions require some level of support from the community, but confidence in the courts is arguably one of the most important for society. The public is central to the legitimacy and function of the criminal justice system: without confidence, people may be less willing to report crimes or to participate in the system as jurors or witnesses.

Surveys measuring levels of public confidence in the criminal justice system have found that public trust and confidence are at critically low levels around the world (Roberts and Hough 2005). In particular, research comparing confidence across agencies within the criminal justice system has consistently found that people have high confidence in the police but low confidence in the courts and prisons (Hough and Roberts 2004). When asked why they have little confidence in the courts, people typically cite lenient sentencing.

Some researchers have described this as a crisis of confidence in the courts. While it is difficult to determine if any given level of public confidence is objectively acceptable, there is consensus among researchers and policymakers in many countries that this lack of public confidence is a cause for some concern. The potential implications of this crisis have led to varied attempts to promote public confidence in the system as a whole, but particularly in the courts.

Background

Public opinion polls have become staple fare for governments wishing to measure community attitudes, and the area of criminal justice is no different. Along with the increased use of such polls since the 1970s has come a heightened sensitivity to the views of the public, as well as an increased role for public perceptions in the development of government policy. This is clearly seen in the rise of the public voice in criminal justice policy. That is, criminal justice systems administered by experts, independent of democratic pressures, have been replaced by systems that are more populist in style and punitive in substance. Public discourse on crime has become more emotive and emotional, with governments responding to public anxieties by seeking to give greater voice and effect to public demands.

To some extent, this more prominent public role reflects an element of penal populism: the development of penal policies that are based on their appeal to the public (and thus their ability to win votes) with little regard for their effectiveness in reducing crime or promoting justice (Roberts et al. 2003).

A penal populist approach is based upon the idea that the public is fed up with crime and with the perceived leniency of the criminal justice system. In an era of penal populism, where the vast majority of people learn about crime and the criminal justice system from the media, a combination of sensationalist reporting practices in the media and populist political responses to moral panics has resulted in widespread myths and misconceptions about sentencing in many Western countries.

Based on the perceived public concerns, penal populists take a firm “tough-on-crime” stance, using imprisonment as a central tool. Penal populism thus provides a framework within which to understand increasing imprisonment rates around the world as well as the proliferation of punitive sentencing policies such as three-strikes legislation, mandatory minimum sentences and sex offender notification laws.

Belief in a punitive public is driven primarily by the results of decades of opinion polls that show that the public believes the criminal justice system, and courts in particular, to be overly lenient. But while governments and the mass media continue to place high credence in the basic opinion poll question of whether sentencing is “too tough, about right, or too lenient” as a way to justify calls for punitive penal policy, academic researchers have repeatedly shown that public opinion on crime and justice issues, and on sentencing in particular, is far more nuanced and complex than such surveys show.

International Perspectives on Public Opinion

Regardless of the methodologies employed, research has consistently shown that public trust and confidence in the courts are especially low and are lower than public confidence in the police. While it may be unreasonable to expect levels of confidence in justice to match those of other institutions such as health care and education, especially given the different (and complex) mandate that the justice system has, the differential in levels of confidence has nonetheless been of major concern for governments around the world.

Within this context, a substantial body of literature has developed that attempts to understand the drivers of public confidence in the courts. There are five main themes to this body of research, each discussed in brief below.

People Have Little Confidence in the Courts

It is clear from the research literature that levels of confidence in the courts should not be expected to be high: one of the most consistent findings in this area is that ratings of satisfaction with, and confidence in, the courts are consistently lower than ratings for police and are objectively rather poor. The main reason for this low rating seems to be twofold: people believe that the courts are too lenient in sentencing offenders, and this perceived lenient sentencing is then held to blame for high rates of crime.

Studies that examine the correlates and causes of confidence in the courts have found few consistent results. One of the findings that does emerge consistently is that people who believe that crime is increasing are likely to be less confident in the courts. This has been linked in the literature with the role of the media in shaping people's understanding of the nature and prevalence of crime.

In their analysis of data from the 1996 British Crime Survey, Hough and Roberts (1998) found that people who thought that sentences were too lenient were more likely to believe that judges were out of touch with society and were doing a poor job. Further analysis showed that people who believed that sentences were too lenient were also those who were particularly inaccurate in their perceptions of crime. The authors concluded that public dissatisfaction with the courts and sentencing is grounded, at least in part, by a lack of knowledge of both sentencing practice and trends in crime. Subsequent sweeps of the British Crime Survey have found identical results, consistently revealing a clear relationship between attitudes to sentencing and confidence in the courts.

More recent studies from other countries have found similar results. For example, in an analysis of survey responses of 1,200 randomly selected people in Victoria, Australia, Gelb (2011) found that the strongest single predictor of confidence in the courts and sentencing was people's levels of punitiveness: the more punitive people were, the less confident they were in sentencing. As with the British Crime Survey data, perceptions of crime played a critical role, with lower confidence in the courts among people who believed that crime had been increasing. Perceptions of crime played both a direct role in predicting confidence, but also an indirect one, with perceptions of increasing crime leading to increased punitiveness, which in turn led to decreased confidence. People who relied on commercial or tabloid media were more likely to have perceived that crime had increased, demonstrating the link between confidence in the courts and the role of the media in shaping people's perceptions of crime.

In the Abstract, People Believe Sentences Are Too Lenient

When representative surveys first came into widespread use, the most common way of measuring public opinion on sentencing was to use the general question of whether sentences are "too tough, about right, or too lenient." This question, in some variant or another, has been used in opinion polls across the world for the last 40 years. And across a variety of Western countries, between 70 % and 80 % of respondents have consistently reported that sentences are too lenient.

On the basis of these survey findings alone, politicians, policy-makers, and the media have concluded that the public is substantially punitive and will therefore support increasingly punitive penal policies. It is from this conclusion that penal populism has developed.

In more recent years, however, this conclusion has been called into question. In particular, researchers have suggested that the finding of a highly punitive public is a methodological artifact – a result of the way in which public opinion has been measured, rather than an accurate representation of what people really think.

Researchers have begun to differentiate between mass public opinion and informed public judgment – between top-of-the-head, immediate public opinion and the kind of reflective, informed public judgment that can develop once people have engaged with an issue, considered it from a number of perspectives, understood the choices that each perspective leads to, and accepted the consequences of those choices. Top-of-the-head responses to simple polling questions represent mass public opinion, as opposed to informed public judgment. While public opinion tends to be volatile and have little internal consistency with other views and beliefs held by the respondent, public judgment is characterized by firmness of opinion (changing little over time) and by the degree of consistency between this view and others held by the respondent.

In order to measure informed public judgment, since the 1980s researchers have gone beyond the single question opinion poll to include additional questions that can clarify and further explain the apparent harshness of public attitudes. In particular, researchers have given respondents more detailed case studies or vignettes to consider and have provided relevant contextual information (such as the cost of imprisonment or re-offending rates) to help respondents frame their answers. This approach aims to measure informed, thoughtful public judgment, rather than the top-of-the-head mass public opinion that is derived from the abstract "too tough-too lenient" question (Green 2006).

In this way the research has attempted to address the methodological limitations of using a single abstract question to measure complex and nuanced public attitudes.

People Have Little Accurate Knowledge of Crime and the Criminal Justice System

Large-scale surveys of public opinion about crime and punishment in the United States, United Kingdom, Canada, Australia, and New Zealand have all shown that the public has very little accurate knowledge about crime and the criminal justice system. Of particular relevance to attitudes about sentencing are findings that show that people have extensive misperceptions about the nature and extent of crime and about court outcomes.

Consistent results from many of the studies in this field show that people tend to:

- Perceive crime to be constantly increasing, particularly crimes of violence, regardless of actual trends in crime
- Overestimate the proportion of recorded crime that involves violence
- Overestimate the percentage of offenders who re-offend
- Underestimate the severity of sentencing practices (e.g., the incarceration rate)

Despite this lack of knowledge, people nonetheless have strongly held opinions about crime and justice issues. In fact, representative surveys have shown that it is those who have the lowest levels of knowledge who also hold the most punitive views. For example, Doob and Roberts (1983) found that those who think that sentences are too lenient are more likely to think that crime overall is violent and to underestimate the proportion of offenders convicted of robbery and assault who are sent to prison. Studies of this kind have provided strong evidence that dissatisfaction with perceived sentencing practice is due at least in part to public misperception and misinformation. But these misperceptions are neither random nor unrelated; they reflect a systematic and cohesive view of crime and criminal justice.

The combination of underestimates of the severity of sentencing and overestimates of the severity of offending builds a grossly inaccurate picture that has serious implications for levels of public confidence in the criminal justice system. People who have the least accurate perceptions of the nature and prevalence of crime are also those who are least likely to have a positive view of sentencers. Knowledge of crime is thus intimately linked to confidence in the courts and the criminal justice system in general. Such public misconceptions have led some researchers to conclude that the answer to low levels of public confidence lies in addressing the gaps in public knowledge of the criminal justice system.

The Mass Media Is the Primary Source of Information on Crime and Justice Issues

Most people do not have direct access to first-hand information about the criminal justice system, either through personal experience or from the experience of family and friends. Instead, people tend to learn about crime and the criminal justice system through the mass media, in particular via newspapers. Given the ubiquity and popularity of the mass media (tabloid newspapers in particular), they play an integral role in the construction of both public opinion and the public "reality" of crime.

Different media provide significantly different views of the world. Broadsheet papers tend to focus on government, quoting experts, elites, and interest group representatives. Tabloid newspapers focus instead on crime victims and their families, offering dramatic and personal testimonials as counterpoint to the more professionalized discourse of the broadsheets.

Green (2006) suggests that complex public policy debates are represented by the media in increasingly constricted and emotive terms. Newspaper portrayals of crime stories do not provide a complete and accurate picture of the issue. Papers report selectively, choosing stories, and aspects of stories, with the aim of entertaining more than informing. Tabloid newspapers in particular tend to focus on unusual, dramatic and violent crime stories, in the process painting a picture of crime for the community that overestimates the prevalence of crime in general and of violent crime in particular. Analysis of British Crime Survey data has shown that tabloid readers tend to be more punitive and less knowledgeable about crime and justice than are broadsheet newspaper readers. In addition, the media provide little systematic information about the sentencing process or its underlying principles. Media emphasis on violent crime, a lack of coverage of statistical trends to place incidents in context and a focus on street crime and failures of the system all encourage a public perception that both the volume and seriousness of crime are getting worse. This perception, in turn, undermines confidence in the criminal justice system.

As people are overly influenced by single-case information, people falsely generalize that leniency characterizes the entire sentencing process. The media's focus on violent crime leads to a perception that this type of event is typical, which affects both people's knowledge of the facts about crime as well as their general levels of fear of crime. Both of these in turn have been shown to influence perceptions of leniency in sentencing.

But tabloid journalism alone cannot be responsible for the gap between the practices of the courts and the public's perceptions of sentencing. In addition to media influence, people may be responding to messages about crime and social order (either implicit or explicit) that are conveyed in tandem by law-and-order political rhetoric and the news media. That is, it is the combination of reporting practices and populist political responses to moral panics that has resulted in widespread myths and misconceptions about crime and justice in general and about sentencing in particular.

Thus, public concerns about crime typically reflect crime as depicted in the media, rather than trends in the actual crime rate. This distorted view is then used to support one particular anticrime policy approach – an expanded and enhanced punitive criminal justice system.

When Given More Information, People Become Less Punitive

There is substantial evidence that the public's lack of knowledge about crime and justice is related to the high levels of punitiveness reported as a response to a general, abstract question about sentencing. Based upon the conclusion that increasing the provision of information will decrease levels of punitiveness, many researchers have moved away from simplistic, abstract survey questions to those which provide much more information and detail to people before asking for a response. The crime vignette approach has been used in representative surveys to provide more information about the offence, the offender and the impact on the victim in order to elicit informed public judgment.

In their groundbreaking work, Doob and Roberts (1983) were the first who demonstrated the powerful effect of providing more information on respondents' attitudes. Of respondents who received a brief description of a manslaughter case (akin to the type of information provided in media accounts), 80 % rated the sentence as too lenient, while only 7 % rated the sentence as about right. In comparison, of those who received a more detailed description with information on incident and offender characteristics, only 15 % rated the sentence as too lenient and 30 % said it was about right. Fully 45 % of this group described the sentence as too harsh. Doob and Roberts concluded that, were the public to form opinions from court-based information instead of through the lens of the mass media, there would be fewer calls for harsher sentences.

To extend this analysis, the authors then turned to comparisons of newspaper accounts with court records of sentencing hearings (such as transcripts) to determine if judgments about a case differed based on the different account given. Newspaper accounts led to perceptions that sentences were too lenient, but when given more complete information, people were more content with decisions made by trial judges.

These seminal studies show that sentences described in the media are perceived by most people as being too lenient, while those described in detail in court transcripts are mostly seen as appropriate. Doob and Roberts concluded that caution should be exercised in responding to calls for harsher penalties as a fully informed public could well be quite content with the current level of severity of penalties.

Diamond and Stalans (1989) adopted a similar approach in their comparison of lay and judicial responses to case study vignettes, in which respondents were asked to impose sentences on the same four moderately severe cases in which prison was a possible, but not inevitable sentencing outcome.

Respondents were presented with detailed information about each of the four cases, including information on the nature of the offence and on the offender's background, as well as a video of the sentencing hearing. They were told the range of possible sentencing options legally available for that case and then completed a questionnaire indicating sentencing preferences.

There was no evidence in any of the four cases that judicial sentences were more lenient than the sentences of the lay respondents: judges' sentences in the study were as severe or more severe than those of the lay respondents. Diamond and Stalans concluded that the perception that judges are more lenient than the public is simply a myth.

These findings have been replicated time and again in the decades since, with a large body of research showing that more detailed information is needed in order to measure informed public judgment rather than mass public opinion.

Key Issues in the Field

There is widespread agreement in the field, based on the large body of research that has now accumulated, that a lack of knowledge about crime and the criminal justice system is a significant factor in perpetuating public misperceptions and misunderstanding – that people's knowledge of crime and justice is a primary driver of their attitudes to the courts and sentencing.

There is less agreement, however, about other factors that may underlie levels of confidence. Do demographic factors influence people's attitudes? What about experience with the criminal justice system or previous victimization? How do other criminal justice attitudes relate to people's confidence in the courts?

There is also debate about the practical implications of inaccurate knowledge about crime and justice in terms of improving public confidence. In other words, if lack of knowledge about crime and justice is closely related to lack of confidence in the courts, can public confidence be improved by increasing public understanding?

What Underlies Low Levels of Confidence in the Courts?

Studies that examine the correlates and causes of confidence in the courts have found few consistent results. One of the findings that does emerge consistently is that people who believe that crime is increasing are likely to report that sentencing is too lenient and to be less confident in the courts. This has been linked in the literature with the role of the media in shaping people's understanding of the nature and prevalence of crime. In particular, people who use commercial or tabloid media as their main source of information about crime and justice issues are more likely to have inaccurate knowledge of the nature and prevalence of crime and of the severity of sentencing outcomes. These same people are also more likely to hold punitive views toward offenders and to report lower levels of confidence in the courts.

The prominence of this constellation of factors – confidence in the courts and sentencing, punitiveness, and perceptions of crime – is found throughout the research literature, highlighting the interconnections among knowledge of crime, media use, confidence in sentencing and punitiveness.

Of the demographic factors examined in the research literature, the main consistent finding seems to be that younger people have higher levels of confidence in the courts than older people. This disparity has been found in studies from a variety of countries that measure confidence in different ways.

The role of other demographic factors is far less clear and has been the source of much study. In particular, factors such as gender, income and education have been included in many studies of the drivers of confidence in the courts but with inconsistent results.

For the most part, research on the demographic drivers of confidence has found no gender differences but has found that people with higher incomes and more education report greater confidence in the courts and indeed in other institutions as well. This finding, however, has not remained uncontested, with some studies finding no statistically significant relationship between these demographic factors and confidence, once factors such as knowledge of crime or fear of crime have been considered. The uncertainty of the role of these demographic factors may thus be a methodological issue rather than a substantive one – it may well be that demographic factors have an indirect rather than a direct effect on confidence, acting via more proximal factors such as knowledge of crime. The use of statistically sophisticated methodologies and analyses is required to address this question definitively.

Another factor that has presented inconsistent results in the literature is experience with the courts and its effect on levels of confidence. While earlier research showed that contact with the courts was related to lower levels of confidence, more recent research has resulted in a more sophisticated understanding: the nature of the experience will determine levels of confidence. That is, a person who has been treated with respect and sensitivity – regardless of whether appearing as a witness or serving as a juror – will be more confident in the justice system. It is thus the nature of the contact, rather than the fact of the contact per se, that influences ratings of confidence.

This finding has also been expressed in terms of procedural fairness: people who perceive that their treatment by the court was fair (regardless of actual outcome) are more likely to express confidence in the courts.

How Can Public Confidence in the Courts and Sentencing Be Improved?

Given the consistent and strong relationship that has been demonstrated between lack of knowledge about crime and justice and lack of confidence in the courts and sentencing, an implicit assumption has arisen in the research literature that educating the public is the solution to address low levels of confidence.

To this end, governments and courts concerned with improving public confidence have undertaken a range of strategies aimed at educating the public. Public education and information campaigns, court media liaison officers, accessible websites, large national conferences and public surveys have all contributed to efforts to promote confidence in the administration of justice by engaging more closely with the community.

One of the more formal responses to the desire to engage and inform the community has been the proliferation of sentencing councils and commissions around the world. Such bodies are being used as conduits to improve the exchange of information among governments, the courts and the public.

The Rise of the Sentencing Council

Sentencing councils that have developed over the last decade have arisen within the context of a somewhat paradoxical political and social environment. At the same time as overall crime rates have fallen in many Western countries, the judiciary has been coming under increasing pressure as the public claims a greater voice in sentencing and law-and-order auctions continue to feature in political campaigns. The status of judges and the courts more generally has been eroded over time by media polls and reports that the courts are “soft on crime” and that judges are “out of touch” with their communities.

Within this complex environment, sentencing councils have arisen as a way of engaging with the public and balancing the interests of the judiciary, the public, politicians and the media. Many of today’s councils have remits that include both providing a mechanism for incorporating community views into sentencing policy and educating and informing the public about sentencing issues. Both of these functions – providing information and allowing the community a voice in sentencing policy – build on the assumption that a better informed and more engaged public will have greater confidence in the courts and sentencing.

Some researchers, however, have questioned whether such councils can really effect any change in perceptions of either the legitimacy of the criminal justice system or the adequacy of sentencing policy and practice. In particular, it has been argued that sentencing councils cannot create more than a symbolic exercise in participation, without substantive effect. Some have argued that “public education” is a euphemism for bringing the public around to the “correct” way of thinking, rather than providing a genuine opportunity for deliberation, discussion and debate (Indermaur 2008).

This view is rather controversial. If education, information and participation are not the answers to improving public confidence, what more can be done to address the public’s lack of accurate knowledge about crime and criminal justice and thus to improve levels of confidence?

The additional component missing from the education approach is emotion. Education and information can only go so far in changing people’s perceptions of, and attitudes toward, the courts and sentencing. Education taps into the intellectual aspects of people’s attitudes. It provides people with information about the effective elements of the criminal justice system: the nature and prevalence of crime, how and why sentencing operates as it does, and the outcomes of court processes. But education cannot tap into the emotional aspects of people’s perceptions. It is often these affective components that play the more important role in shaping people’s attitudes. Indeed, research has shown the (often circular) interconnections among attitudes, beliefs, emotions and experiences.

The Tasmanian Jury Sentencing Study (Warner et al. 2011) provides an indication of this disparity between people’s effective and affective responses to crime. Comparing jurors’ sentences with those actually imposed in the real cases upon which the jurors had deliberated, the researchers showed that the majority of jurors believed that the judge had imposed an appropriate sentence in the case. However, when asked an abstract question about sentencing in general for sex offences, violent offences, drug offences, and property offences, the majority of the jurors believed that sentences were too lenient. This “perception gap” – the lack of consistency between jurors’ views of the specific offence on which they deliberated and their general attitudes toward sentencing – was most pronounced for sex offences and violent offences. Given the highly emotive nature of these types of crimes, it is arguable that this finding nicely illustrates the difference between the effective and affective components that shape people’s attitudes. Although jurors were satisfied with the sentence imposed for the case in which they had heard all the relevant information, they remained dissatisfied with sentencing in general.

As attitudes to crime and punishment are often driven by emotive rather than instrumental concerns, public education must also address the symbolic and emotional issues that punitive attitudes reflect. For example, rather than attempting to improve public confidence in and support for alternatives to prison using only arguments based purely on economic grounds, policy-makers and governments could tap the affective component of public attitudes with the idea that people can change if given the chance through treatment and rehabilitation programs.

While informing and educating is typically aimed squarely at the intellectual aspect of public attitudes, ignoring the affective to focus solely on the effective addresses only part of the story of the relationship among attitudes, knowledge and confidence in the courts.

Unanswered Questions

With the general consensus in the field that improving public knowledge is a key strategy in improving public confidence, it is perhaps somewhat surprising that the issue of the effectiveness of education and information efforts has not been tackled. There are two components to this question: can education and information genuinely change people's underlying attitudes? That is, is the provision of education and information an effective way of addressing the public's lack of confidence? And if so, is this change durable and lasting?

The research is clear that when people are provided with more information, they become less punitive in their responses to survey questions. But it remains unclear whether this change reflects a change in people's opinions – responses formed only when asked about a specific issue – or a change to people's deeper underlying attitudes, their global, enduring orientation in general.

Some researchers have attempted to explain people's punitiveness based on psychological theories of attitude formation. For example, Maruna and King (2004) identified factors that predicted support for community penalties. In their model, expressive predictors (measures of collective efficacy and trust, anxiety about youth, economic pressure and global crime salience) and core beliefs and values (measures of a belief that crime is a choice that people make rather than a product of their circumstances and a belief in people's ability to change) had a strong effect on support for community sanctions, over and above the effect of both socio-demographics and instrumental factors (measures of direct victimization, local crime salience and fear of crime). A belief in people's ability to change was the strongest predictor of support for community sanctions.

But unique and valuable as this research is, it does not address the issue of whether education and information genuinely changes people's underlying attitudes. Indeed, this is a question that remains both unexamined and unanswered in the literature.

The same holds true for the issue of whether change in responses to survey questions represents durable change. It is clear that the provision of information changes responses in the immediate context of the survey, but is this change durable over time? This issue, too, remains both unexamined and unanswered in the literature. It is likely, however, that researchers will need to draw more heavily from the field of psychology in order to address this issue, as it is within that field, not the field of criminology, where substantial work has been undertaken examining the mutability and durability of attitudes. And it is likely that measures from the psychological literature, such as the strength of people's attitudes, will need to be imported into the criminological literature in order to understand the effects of people's attitudes on their behavior (strong attitudes will have significant effects and will resist even the strongest pressure to change, while weak attitudes will have little impact on a person's thinking or actions and will be vulnerable to situational pressures). This kind of approach remains untried in criminology, leaving no evidence as to whether education and information can bring about real, enduring change.

Emerging Directions in the Field

Although the study of public opinion about sentencing has been of substantial interest to researchers for at least several decades now, the field continues to develop, with new directions emerging in both research and policy.

Emerging Directions in Research

Based on the well-documented methodological concerns with asking for top-of-the-head public opinion, in recent years some researchers have opted for a more deliberative style of discussion with respondents. The primary aim in such studies is to provide respondents with the information they might need in order to come to a reasoned, considered and thoughtful decision.

Deliberative polls are based on the kind of detailed dialogue that is critical to the generation of durable and informed preferences. By spending an extended period with respondents (such as a weekend) providing information, discussing the issues and allowing time for deliberation and debate, the deliberative poll aims to measure a kind of public opinion that is informed, nuanced and stable.

In a similar vein, but within the context of real criminal cases, is the kind of study undertaken by Warner and colleagues. Respondents in the Tasmanian Jury Sentencing Survey were actual jurors, who had been in the courtroom all the through the trial, hearing the same information the judges were hearing. With that first-hand knowledge, and with additional information on crime and justice supplied by the researchers, respondents were able to give detailed, thoughtful and nuanced responses to the survey questions. While this study did not include measures of all the expressive factors, instrumental factors, and beliefs and values that may have affected respondents' attitudes, it clearly presents a model for the future of research in the field. It is a methodologically strong and fascinating approach to the study of public opinion about the courts and may well represent a new approach in criminological research in this field.

Emerging Directions in Policy

Given the prominence of the media as people's main source of information about sentencing, one of the ways in which courts have been working to improve public confidence is by working more closely with the media to increase the flow of information. Court websites now include access to judges' sentencing remarks, allowing both the media and the public access to the full reasons behind an individual sentence. Courts are employing liaison officers who can explain sentences to the media in lay language and can create accessible summaries of complex cases. Information and education campaigns, organized by the courts themselves or by governments via the establishment of sentencing advisory councils, aim to inform and educate both the media and the community more generally.

It remains to be seen how courts, governments and bodies such as sentencing councils can address the affective as a way of improving confidence in the courts.

Public Representations of the Police

Haia Shpayer-Makov
Department of History, University of Haifa,
Haifa, Israel

Overview

Ever since the introduction of organized and systematic police forces in the Western nation-states in the early and middle decades of the nineteenth century, they generated great interest in the media. As a prominent institution which evolved in tandem with the rising weight of public opinion in the political arena, the modern police, especially in democratically inclined societies, aimed at cultivating a favorable reputation on the premise that a positive image constituted a key factor in attaining or maintaining their legitimacy, social standing, and efficiency. The interaction between the media and the police, and hence the dominant public representations of the police, changed over time and from country to another. This entry focuses on England, which, while not necessarily typical as a case study, offers an analysis of a society where the issue of police images was crucial. Although the English police did not refrain from coercive methods, whether overt or subtle, they consistently displayed a marked sensitivity to their public image, and many of their operative decisions were made in this light. Further, the English media, in its various forms, devoted exceptional attention to police activity and personnel, providing a vibrant forum for diverse and contesting views on the topic. Although media coverage contained criticism – at times vehement – of the police and its agents, and relations between journalists and the police were not without tension, current research reveals that on the whole, the portrayals of the police were supportive and thereby also enhanced the power of the state. The uncomplimentary opinion of some sectors of the public, particularly those who were the object of police heavy-handedness and control, tended to be played down in public discourse. Since a sizable portion of the population derived their perceptions from the media and not from direct contact with the police, media images had an important impact on hegemonic public attitudes.

The first section of this entry explains the focus on England. The second section traces attitudes in the major conveyors of police representations – the press and fiction – from the early nineteenth century to the First World War. At its core is the finding that despite continued criticism and varied messages in each media format, by the late nineteenth century, the media had shifted from wide criticism and rejection of the notion of a strong public police to an acceptance of its beneficial role. The third and fourth sections explore the interwar and post-Second World War periods, respectively, including, in addition to print culture, also an examination of cinema films and television, pointing to the continued largely supportive attitude in the twentieth century. Despite rising dissatisfaction with the police in the media of the turn of the twenty-first century, the English police maintained their elevated position as a national icon.

Introduction

Ever since their emergence in the early and middle decades of the nineteenth century, modern police institutions in Western nation-states have systematically attracted considerable public notice and have become recurring objects of commentary and publicity.

The fact that the evolution of professional bureaucratic policing systems coincided with the accelerated growth of literacy, mass readership, and the publishing industry intensified this phenomenon. Interest in policing was manifested in a variety of formats, including official documents, parliamentary reports, court proceedings, printed and handwritten correspondences, and public speeches, but what brought the police to the forefront of public attention were the mass media, which in some countries, particularly Britain, France, and the USA, became almost obsessed with the topic. The dramatic changes in media technologies in the twentieth century magnified this preoccupation even further. If in the nineteenth century the press in all its forms, along with published fiction and nonfiction, featured substantial amounts of material about the police, this was supplemented, from the beginning of the twentieth century, by the cinema and, after the First World War, by radio and then television, which dominated the media scene in the latter part of the century. Naturally, the extent and content of the coverage depended inter alia on the freedom of communication in each country. Wherever the media enjoyed a relative absence of interference, the more likely they were to report and convey a range of opinions on the vocation and its personnel.

The interest in policing exhibited by the media is not surprising. Narratives about transgressions, breach of the law, deviant behavior, and the responses they engendered have riveted the human imagination ever since the dawn of civilization, as exemplified in the first chapters of the Bible. As a pivotal social institution designed to detect and prevent crime and maintain order, the modern police shared this intrinsic appeal. Moreover, the mass media, which since the nineteenth century were driven by economic interests and the desire to maximize circulation, were determined to satisfy the boundless curiosity of the public in police matters.

This created an acute dependence on the police for stories, information, and insights, whether for news and entertainment or sober appraisal – a dependence that was symbiotic, since the police in turn needed the media as a channel to the public. The introduction of uniformed patrols in the public sphere made police officers ubiquitously present and highly visible. Their performance, priorities, and conduct therefore informed public perceptions on public policing. Nonetheless, whether or not people had some first-hand experience with the police, many relied on the media to fashion their opinion of the police.

Needless to say, what the police sought was positive publicity, as media attention could both benefit and harm them. In fact, few occupations so badly required favorable exposure as public policing. More and more countries in the nineteenth century witnessed the growth of civil society and democratic values. With public opinion acquiring greater influence on government policies and performance, and on the fate of the body politic, it was crucial for the sovereign state to win as much support as possible. The police, seen as the arm of government, needed to be widely perceived as impartial instruments of the law and as functioning for the good of society. This was vital especially against the background of intense opposition both to traditional policing bodies and to the establishment of new forms of law enforcement, sentiments that were pervasive in large parts of the Western world. There was a need, primarily in democratically inclined societies – typically, the French Third Republic – to demonstrate that the new police were utterly necessary and that their presence was poles apart from the dominant public fearsome image (Berlière 2007). While the police could not expect entirely uncritical backing on the part of the governed, they aimed for sustained control and gaining the confidence of the public generally.

Heightened sensitivity to the reputation of the police continued to guide the thinking of political authorities in the twentieth century even in countries where the police had managed to improve their initially uncomplimentary image. Demonstrating that the police adhered to the letter of the law was of the highest significance in parliamentary democracies, including Weimar Germany in the 1920s and Spain in the early 1930s, but a degree of consent was critical in every society. Even a totalitarian regime such as fascist Italy, which greatly relied on the coercive and arbitrary power of its police, favored good relations with the population over sheer reliance on terror (Dunnage 2007). The drive to maintain a positive police image strengthened in the liberal democracies during the second half of the twentieth century, according special importance to public approval. This did not mean that, in practice, the police always kept to the letter of the law but that throughout the period, the police and the governments they served felt constantly obliged to reinforce their standing.

The police impulse for sympathetic representation also had prosaic reasons. Their success rate, and hence their aura of proficiency and effectiveness, was markedly contingent on active public cooperation, for example, in providing evidence. Not only was it widely contended that a good reputation prompted people to come forward to aid the police (Johansen 2007) but also that a good reputation made people more tolerant of police violence and the use of other contentious means which in turn helped the police attain good results. Again, the media could contribute greatly toward the establishment of a professional image of the police both by underscoring successes and acting as sources of essential information.

The numerous points of contact and reciprocal relationships between the media and the police were manifested in a variety of forms, changing over time and diverging from country to country in light of particular national norms. As a by-product, public representations of the police, too, showed considerable variety in each national context. Space constraints dictate limiting the survey of the evolution of the police image during the nineteenth and twentieth centuries to a single case study – arguably, the most famous police force in the world – the English police. The reasons for this choice are many.

Why the Focus on England

A consciousness of the fundamental importance of good repute was deeply entrenched in the policing system in Britain. Its core structure, based on all-encompassing patrol networks, entailed constant interaction with the policed population. The underlying premise was that the success of law and order enforcement hinged on mutually respectful, or at least mutually tolerant, relations between the police and the public. While some historians stress the willingness of the new police to serve as agents of middle class control of the social and moral behavior of the lower orders, with little heed to the latter's sensibilities, others highlight the determination of senior police management to avoid public hostility and defiance in order to facilitate the constable's work (Inwood 1990). In his comparison between the ascent of police forces in London and New York in 1830–1870, Wilbur Miller quotes Commissioner Richard Mayne, one of the first commissioners of the Metropolitan Police of London, as emphasizing that "the real efficiency of the police depends upon the estimation in which it is held by the public" (Miller 1977). To promote this objective, the first instruction book of the Metropolitan Police, published in 1829 (when the force was established) and in many editions thereafter, commanded police officers to be courteous and considerate as part of a general strategy of inculcating habits of moderation, restraint, and cool-headed response. The spirit of these directives was echoed in the instruction books of the other police forces which subsequently spread throughout the country (Klein 2012).

This embedded sensitivity was a reaction, initially, to the particularly powerful and wide-ranging objections to the notion of a highly organized and systematic police – objections which preceded and accompanied the establishment of police forces in the British Isles. Different social sectors across geography, class, and political boundaries, ranging from Tory gentry to working-class radicals, were motivated by varied fears, namely, that the proposed police would undermine their own particular interests, behave as a standing army, strengthen the central state excessively, become a political tool, intervene in private life, curtail the famous British liberties, or become a financial burden on the ratepayers (Storch 1975). The source of animosity of local elites both in London and in the provinces lay in their desire to retain local control of policing. A recurrent concern equated the new policeman with the figure of the spy, associated closely with despotic governments on the continent and with unlawful and corrupt behavior. The guiding apprehension assumed that under disguise, and therefore unnoticed and unsuspected, undercover police constituted a powerful threat to the norms and habits of life dear to British subjects (Shpayer-Makov 2011).

To overcome opposition, the reformers who backed the creation of the new police molded the concept of a force that simultaneously allayed such fears while meeting the needs of the social and political elite to govern. Officers wore a uniform, but of a blue color, with top hats, to distinguish them from the military, and most were armed with a wooden truncheon only. The uniform made the policeman visible – hence easily identifiable – and approachable when help was sought by the public, thus fortifying the image of policing as a public service. Some policemen occasionally removed their uniform to perform detective tasks, but the scepter of the fearful figure of the spy had the effect of postponing the formation of a fully fledged detective branch in the Metropolitan Police for 13 years. Ultimately, this famous detective branch (popularly referred to as Scotland Yard) and the few other such branches erected subsequently, mainly in urban police forces, formed only a fraction of the entire police workforce. Additionally, apart from the Metropolitan Police of London, all other police forces were accountable not to the Home Office but to their local authorities.

Even after the institution of the police force in England gained wide acceptance in the latter part of the nineteenth century, suspicions of the potential harmful powers of the police lingered and loomed over their evolution, as in other countries. Yet, perhaps more prominently than other police forces, the English police had come to constitute an established national institution and a source of pride to its citizens, even if not unequivocally, as will be seen below. Moreover, it appears that British policy makers made special efforts to attain this consensus. So ingrained was the recognition of the weight of public opinion, that even minor police policies and ad hoc decisions were often colored by the notion of how these would be interpreted outside the police (Inwood 1990). Indeed, a focus on England in the nineteenth and twentieth centuries reveals a culture in which individuals could discuss societal issues and exchange views openly, with the media serving as primary venues for airing a variety of ideas regarding the criminal justice system. In fact, the English media evinced an exceptional and persistent preoccupation with law enforcement, a tradition which reached new heights in the latter part of the twentieth century (Allen et al. 1998). As such, the media facilitated an awareness by the police leadership and state officials of the sentiments and expectations of the public, thereby affecting the evolution of the English police importantly. Notably, research on representations of the police in England is singularly extensive. Although most studies focus on the second half of the twentieth century, quite a few deal with the history of the police image prior to the Second World War. Even if this period does not occupy entire book-length texts, it features in a host of articles and book chapters, particularly regarding the pre-1914 period, and is otherwise interwoven in any number of scholarly texts about the English police or detective fiction.

The rest of this entry will trace dominant representations of the police in the media between the inception of the first modern police force in London in 1829 and the late twentieth century, focusing on two types of cultural texts which were the principal conveyors of police images in the nineteenth century – the press and fiction, extending to include the emerging electronic media – cinema and television, in the twentieth century.

Key Issues

The Long Nineteenth Century

Against the backdrop of economic and social tensions in the 1830s and 1840s, interspersed by overt manifestations of class struggle resulting in brutal incidents of police crowd control and other constricting interventions in working-class life, many contemporary critics concluded that their worst fears regarding the inauguration of the new police had been realized. Hostility to the reformed police was so profound and widespread that their appearance in the streets of the communities which opted for the new arrangement was commonly met with such appellations as "blue devils," "blue plagues," "blue idlers," "hired mercenaries," and "unconstitutional bravoes," as reported in the press (Storch 1975). They were also called "Jenny Darbies," a misnomer for the much reviled continental gendarmes (Miller 1977). Not only did many articles disparage police actions, but their very existence and function were often described as redundant, and they themselves as "unproductive parasites" (Storch 1975). While responses were not monolithic – the press contained articles upholding the current restructuring of the old police alongside radical demands for the abolition of the new body – on the whole public debate during this period was pervaded by suspicion and distrust of the police.

In parallel with concerns about the potential or actual oppressive or intrusive nature of the police, press rhetoric criticized the reformed police as lacking the capacity to suppress crime or cope effectively with other designated duties. In as much as police manpower was recruited mainly from the laboring classes, the policeman appeared to many to be ignorant, simple minded, and limited, with his power attributable to his imposing physiology rather than his mental abilities. "Punch" mocked constables for their fondness for servant girls and cooks and their partiality for beer and food while on duty (Pulling 1964). These themes were aired time and again in ballads and songs performed in music halls. Yet, if such references indicated disrespect for the new police, they also suggested that fear was not necessarily the predominant sentiment and that even during the founding years of the modern police, some viewed constables with a touch of affability.

Predictably, the many working people who habitually found themselves at the wrong end of the policeman's truncheon and were subject to orders to "move on," close supervision, arbitrary arrest, or police violence perceived the police as unwelcome intruders in the community and agents of the political and economic elite. Those with access to the media sometimes expressed their resentment in writing, but many others resorted to physical confrontations not only while resisting arrest but also in taking the initiative and attacking police officers, sometimes unprovoked (Storch 1975). Members of the working class also demonstrated their antipathy by defying new laws and regulations enforced by the new police or simply by refusing to collaborate with them when help was required.

Before long, however, the social classes with a stake in the pacification of political radicalism and in the protection of property gravitated toward staunch support of the police institution. No doubt, the way the new police handled radical protest and public disorders in the 1830s and 1840s, especially in comparison with police on the continent, convinced the propertied classes of the utility of police functioning as being in their interests (Emsley 1991). The many journalists who served as their mouthpiece echoed their satisfaction that the police acted with effectiveness coupled with measured force (Miller 1977), implicitly suggesting that the police were their trusted protectors against the "dangerous classes" (Emsley 1983).

The process was not linear. Miller identifies the 1850s as the decade in which the image of the police improved considerably but regards the 1860s as "a crisis period in police-public relations" (Miller 1977) in light of garroting (a form of violent street robbery) panics in the early 1860s; a well-publicized demonstration in Hyde Park in 1866 which ended in riots and violence; and the rise of Fenian terrorism in the latter part of the decade. However, by the mid-1870s, even though members of the privileged classes here and there questioned certain facets of police behavior, overall, the notion that the police were indispensable for the preservation of the social order reigned supreme in these classes, as is evident in the content of the mainstream press.

Existing studies of police-public relations in the nineteenth century show that it took longer for the working classes to acquiesce in the police presence. The "rougher" elements in the working classes, who continued to be the target of police heavy-handedness during the second half of the century, still regarded the police as their enemy (Miller 1977). But the expanding "respectable" sections of the lower orders, who were victims of criminal offenses no less than their social superiors, grew accustomed to turn to the police as the legitimate representatives of the law and benefit by the services provided irrespective of class, even if they were not particularly fond of the police (Reiner 1985). That a high proportion of working-class adult males were enfranchised in the electoral reforms of 1867 and 1884, thus gaining a certain foothold in the established order, and that the messages of restraint and moderation permeated the police ranks, may have also mitigated the attitude of the respectable working classes toward the police. However, their support was tentative and not deep-rooted. The many instances of police class bias toward individuals in the streets, and their aggressive behavior in working-class demonstrations and strikes which flared up in the late nineteenth century and on the eve of the First World War, kept reviving suspicions of police partiality.

Throughout the period, the size of the press and its readership spiraled numerically, and with it public awareness of various aspects of police existence. The coverage contained a mosaic of approaches and outlooks, depending on the ideological stance of the paper. Broadly, while the Tory press became the most loyal defender of the police, liberal, and to a much greater extent radical newspapers and journals more readily adopted an offensive position vis-à-vis the police (Curtis 2001). Not surprisingly, socialist papers posited the police as the enemy of the people. However, on balance, from the early days of the police until the First World War, the press, which was not equally accessible to everyone, had undergone a metamorphosis from wide rejection of the notion of the public police to a largely consensual endorsement of it, a change which tended to downplay the nuanced, often inimical attitude in the lower social strata (Shpayer-Makov 2011).

Not that relations between the press and the police were consistently harmonious. Despite the rise in the status of journalists, and the mutual and mounting dependence between the police and the press, contacts between them were typified by reciprocal mistrust (Shpayer-Makov 2011). In varied degrees, police authorities in every community supplied newspapers and journals with the material the press needed to meet the insatiable demands of their readers for stories and reports about the criminal justice system, but they did so sparingly and often kept important information to themselves, especially when it reflected badly on the police. In such cases, journalists were forced to rely either on their own detective skills or on informal contacts within the police, particularly detectives who could provide disclosures about ongoing inquiries and who were willing to divulge inside information, sometimes for payment (Shpayer-Makov 2011). For its part, the press, which progressively saw itself as a watchdog of democratic values, monitored police and state authority and, at times, exposed unwholesome aspects of police work, which, as expected, fuelled further suspicion and even hostility between the two sides.

Notwithstanding the respective displeasure between the police and the press, and the occasional censorious account, journalists played a major role in constructing a predominantly flattering image of the English police, even if not always wittingly or actively. In addition to upholding viewpoints favorable to the police, many journalists promoted such an image in the belief that it contributed to the good of society, while undermining the police had the opposite effect (Shpayer-Makov 2011). Others refrained from judgmental commentary in order to maintain fraternal relations with the police. Moreover, the police had learnt to manipulate the mass media by providing selective material and hiding incriminating information. The outcome was partial and beautified accounts of police reality. Surely, some readers, whose number cannot be estimated, were aware of the bias implanted in the press coverage and did not adopt the perspectives expressed in it. Yet, the period was marked by rising public confidence in the press as the authoritative repository of news and hard facts in society; hence, it can safely be deduced that a great many readers accepted the favorable reports they read as mirroring authentic police life.

So beneficial did the police organization, as well as individual officers, appear that more and more columnists complained not about the police presence but about the shortage of police personnel. Admittedly, the institution of the foot patrol constituted a powerful reminder of the authority of the police and the state, but with time, the constable came to epitomize dispassionate and impartial law enforcement. Although he was often sketched as slowly trudging the streets or country lanes, these descriptions became amicable, if on occasion condescending, especially when referring to the rural constables as plods. Newspapers, including those with a conservative leaning, continued to condemn the police as inefficient when they failed to solve a case which gained headlines, such as the brutal murder of five prostitutes in the East End in late 1888 when the London police proved unable to even identify the perpetrator (popularly called Jack the Ripper) (Curtis 2001), but otherwise, the press treated the police officer as reasonably effective. The radical and liberal press vilified the police as undermining civil liberties when they dealt brutally with demonstrations and strikes, but such cases, as well as publicized instances of police corruption and the employment of spies and agents provocateurs, were increasingly posited as exceptional rather than the rule.

Significantly, as the image of the English constable was consolidated in the latter part of the nineteenth century, it became further removed from the initial adverse portrayal of the policeman as a walking panopticon, the personification of a ubiquitous and oppressive technique of surveillance. Instead, the mainstream press, which was increasingly read by the lower strata as well, was packed with stories depicting police officers sacrificing themselves when needed, for example, to save civilians' lives. The visual media, which expanded in the second half of the century, used mass-reproduced images to reinforce the verbal texts, transmitting and circulating illustrations of gallant officers, both uniformed and not, for example, in the midst of catching violent criminals. The policemen in all these images conformed to hegemonic assumptions about the ideal model of working-class masculinity (Shpayer-Makov 2012).

Time and again, the English police were compared to their counterparts on the continent and were found superior if not in efficiency than in ethical standing and respect for the law and individual rights (Shpayer-Makov 2011). The press reiterated the fact that the English police, and above all the Metropolitan Police force, became a model of imitation worldwide, inter alia, because of the bobby's deep-rooted local popularity (Johansen 2007). Further, while in Paris and Berlin the image of the policeman remained that of an agent of the state, the frame of reference in London and in the rest of the country became one of assistance to the community (Emsley 1983).

Even detectives, who initially were identified with the figure of the spy, gained acceptance. At first, journals did not distinguish between uniformed and plainclothes policemen, but before long, even though detectives constituted a small percentage of the police labor force, they drew disproportionate press attention, clearly by virtue of their more intimate connection with crime and hard-core criminals. One of the first opinion leaders to develop an inquisitive curiosity about detectives and their activities was the author and journalist Charles Dickens, who made a point of listening to their stories and accompanying them on their tours of duty, later publishing his impressions in several articles in his journal *Household Words* in the early 1850s. Partly under his influence and the growing interest shown by many other journalists thereafter, the figure of the detective assumed the role of an urban explorer probing the seamy side of life, where he commanded fear bound up with respect. If uniformed policemen attracted sympathy and even esteem, detectives, most of whom generally followed a mundane and unexciting routine, gained a romantic and heroic aura, depicted not only as adventurous and fearless but also as highly able, sharp, and enterprising. By the end of the nineteenth century, some detectives, particularly those serving in the central squad located at Scotland Yard (the headquarters of the Metropolitan Police), found themselves in the limelight and attained the status of celebrities. At the beginning of the twentieth century, with the adoption of fingerprinting as a standardized forensic practice, they gained the added luster of expert knowledge and scientific rigor.

The combined figures of the helpful and supportive community policeman and the indefatigable and clever detective operating in dangerous venues to restore order to society forged the impression, explicitly reiterated in the press, that they constituted the best police service in the world (Emsley 1991).

This was not the case in the literary world. While fictional texts portrayed police officers as moral, honest, and dedicated to their work, on the whole, these books were also more critical of the capabilities of the police and accorded them much less respect than the press. Yet, similarly to the press, though far more emphatically, literary works demonstrated greater interest in detectives than in uniformed policemen. Indeed, so compelling was the figure of the detective that, by the First World War, a whole genre had evolved around it. However, in contrast to the press, the typical fictional police detective emerged as neither highly competent nor a great achiever, and certainly not heroic. What he particularly lacked was a creative imagination and an elevated facility in reasoning. There were impressive and efficient police detectives in the growing body of books and stories featuring detectives, such as Inspector Bucket in Charles Dickens's *Bleak House* (1853) and Sergeant Cuff in Wilkie Collins's *The Moonstone* (1868). Such characters also appeared in seemingly factual accounts of crime fighters written in the first person, which flourished in the third quarter of the nineteenth century. However, with the exception of the pseudo-memoirs and certain imports, such as the translated works of Émile Gaboriau, centered on the French police officer M. Lecoq, the police detective was seldom the protagonist of the plot and not even the principal enforcer of the law.

The character who gained the admiration of contemporary authors and became the focus of numerous narratives, whether canonical or lowbrow, was the private detective, both amateur and professional, who was commonly posited as charismatic, brilliant, and effective. Sometimes he operated by himself, without the involvement of official law forces, but as the nineteenth century wore on, private and public detectives were progressively juxtaposed in the same narrative. The pervasive motif in these narratives, which contrasted starkly with the reality of criminal investigation, featured the private detective as the person who conducted the investigation and was decisive in the successful unveiling of the mystery at the root of the plot. Frequently, he/she gave the police instructions, which they followed as a matter of course, even enthusiastically. Sometimes it seems as if the mediocrity of the policeman only served to highlight the outstanding abilities of the private sleuth. This theme – the superiority of the private over the official detective – had been interwoven in stories by the American author Edgar Allan Poe, first published in England in the middle decades of the nineteenth century, and in books by English authors which appeared at that time, but with the unsurpassed popularity of Arthur Conan Doyle's Sherlock Holmes (first published in 1887), it spread like wildfire in popular literature.

Conceivably, the recurrent fictional formula implying that Holmes-like figures (rather than the official variety) were the quintessential detectives was adopted by many authors, as they viewed it as a key to success. Yet, the repetition of this theme may have also had its roots in class-based doubts of the image projected in the press that the police, originating mainly in the working class, could contend by themselves with the many dangers prevalent in the increasingly industrialized urban environment (Shpayer-Makov 2011). Indeed, most of the fictitious private detectives originated from the middle or upper classes, a lineage which apparently lent itself more readily to a heroic stature. At the same time, a subtle message was conveyed that the police, undeniably essential in modern society, should raise the social and professional quality of its manpower, as well as cooperate and consult with the private sector of the privileged classes more closely.

The Interwar Period

Despite changes in various aspects of police culture during and after the First World War, the attitude of the press and the literary world toward the police remained essentially the same as in the prewar period. The press, and not only in its radical periphery, may have felt more disposed to attack the police for misconduct and malpractice, especially in the metropolis. Newspapers embarked on campaigns exposing details of police corruption, such as the Sergeant Goddard case of 1928 (which led to a royal commission examining the police a year later) and several other scandals concerning dubious police methods, which gained headlines in the 1920s (John Carter 2010). The police handling of both fascist and left-wing demonstrations in the 1930s gave rise to critical accounts representing different political camps. The language used may have been more outspoken than before. However, seen in the aggregate, the press continued to present the police as law-abiding servants of the people, treating reports of the abuse of police power as isolated incidents. Viewed against the background of the rise of the Soviet Union and the spread of authoritarian and fascist regimes in Europe, characterized by intolerance and the use of unlawful means and the secret police to suppress dissidence, the English police shone as representing democratic values and the rule of law.

Antagonistic relationships between the police and the populations who were routinely singled out by the police for stringent control, such as slum inhabitants, working-class adolescents, street sellers, and the unemployed who lived on the margins of illegality (White 1983), was not the stuff that attracted press notice. Moreover, the masculine image of the police was not affected by the entrance of a small number of women into their uniformed ranks. Entrusted with the new tasks of directing traffic and regulating the speed of motor cars, the interwar policeman came into close contact for the first time with members of the middle and upper classes, who resented this new role and complained that he should ignore minor traffic infractions and instead spend his time catching criminals (Klein 2007). However, this did not dampen the oft-articulated conviction that the English police were the best in the world (John Carter 2010).

The reasons for the strained relations between the press and the police, and with Scotland Yard in particular, did not disappear. Notably, however, Scotland Yard manifested an increased appreciation of the importance of maintaining a good rapport with the press when in 1919 it set up a press bureau, albeit consisting of a single civil servant whose function was to issue twice-daily bulletins to journalists (Chibnall 1977). This appreciation intensified as the century wore on.

Fiction writers still found the private detective more suitable for a commendable profile than the policeman, and although a more agreeable approach to policemen in detective fiction is detectable, they were still portrayed as inferior in intellectual acumen as well as powers of observation and detection. Only infrequently was a police detective the protagonist in the narrative. The most famous author associated with this tradition in this period was Agatha Christie, who invented two private detectives – Hercule Poirot and Miss Marple – both of whom were consistently responsible for ingenious breakthroughs in investigations and for revealing the true story.

The cinematic screen, which since its pioneering days at the turn of the twentieth century featured crime films, more or less replicated printed fictional works in presenting the private detective as more accomplished than police officers. Not only were the officers not cast as heroes, but occasionally, they were depicted as corrupt, unfair, or ridiculous (Reiner 2008).

Notably, a number of real-life policemen, and not only from the highest echelons, took an active part in molding the police image in the media. Starting in the late Victorian period, several police officers, primarily retired detectives from Scotland Yard, managed to publish their memoirs, a commendable achievement given their humble origins (Shpayer-Makov 2011). This trend continued and accelerated in the interwar period (Lawrence 2003). Insulted by the belittling portraits of police officers in fictional works, they took advantage of the growing interest in their life stories as crime fighters to contest this image as unreliable and distorted. Whether consciously or not, the representational strategy adopted by these police authors succeeded in crafting an image of themselves as professional and talented policemen, possessed with a remarkable memory and cerebral acumen (Shpayer-Makov 2011). No private detective was on the scene to advance investigations and protect society. Success was theirs only and many times over.

The Post–Second World War Period

The war and its aftermath promoted greater state regulation in Britain, and with it, the expansion of the public sector, a process that was manifested inter alia in the extension of the welfare state, the democratization of the educational system, and enhanced police powers. Significantly, economic recovery in the late 1940s was accompanied by a rise in crime statistics. Although it is difficult to establish a definitive correspondence between real events and media representations, the convergence of these social and political factors undoubtedly provided the context for major shifts in the portrayal of police officers in fiction and cinema in the postwar period.

The press had long exhibited little concern for private detection, while putting faith in the police as the upholders of law and order. It also maintained a tradition of showing a certain interest in the everyday life of the constable on the beat and in the inner world of police stations, although typically, its preference was a focus on the dramatic and the sensational or at least on what was newsworthy. A new development was that fictional works, whether in print or in film, now followed a similar pattern, shifting away from placing private detection in the foreground of law enforcement and instead highlighting authentic police work. While talented private sleuths still enjoyed a lingering appeal, significantly, a novel literary sub-genre emerged in the late 1940s – the police procedural – which soon acquired popularity on both sides of the Atlantic. The title derived from a conventional plotline in which ordinary police detectives, shown as true professionals, deciphered crimes by employing real-life police procedures and methods, which were at variance with the more fanciful means used by the classic private investigator (Dove 1982). In line with the collective spirit of the age, the resolution of an investigated crime was not the product of the mind and exertions of the individual detective, as formerly, but of the collaborative efforts of a police team headed by a central figure who was invariably a policeman. In the same realistic vein, the principal investigator was not an outstanding individual or from a pedigreed background.

Until the mid-1960s, the police typically played a minor role in cinema films, as in the prewar crime fiction (Allen et al. 1998). Still, in the immediate postwar period, an invented cinematic police figure struck a special chord with contemporary audiences and left an indelible imprint on public consciousness thereafter – George Dixon from the East End of London, appearing in the film *The Blue Lamp*, released in 1950. Halfway through the film, he is killed by a criminal (played by the young Dirk Bogarde), but television, which since its inception opted for police protagonists in its crime series, resurrected him in the mid-1950s as the central figure (played by Jack Warner) in a series entitled *Dixon of Dock Green*, which ran until 1976. Dixon, depicted as an honest, kind-hearted, fair-minded, and dedicated patrol officer, respected by all in his neighborhood, fitted in perfectly with the evocation of society in postwar crime cinema "as largely based on shared values and a clear but accepted and just hierarchy of status and authority," where "criminals were normally brought to justice" (Allen et al. 1998). So idealized was this personification of the English bobby (Emsley 1991) that years later people would nostalgically refer to the period it described as the golden age of English policing.

Although Dixon continued to enjoy public adulation, changes in the police and in society at large during the 1960s and 1970s introduced new police images in the media. The police, and not private civilians, continued to be perceived as the ultimate law enforcers, but the increasing use of cars in policing resulted in a decreased role for the beat officer and a distancing of policemen from the community. This development was reflected in the acclaimed TV series *Z Cars*, shown during 1962–1965 and 1967–1978, revolving around a mobile team of policemen in the north of England.

Moreover, the general climate of police culture in film and TV no longer connoted fair play and strict adherence to the law, as in the Dixon series. Against a backdrop of student protest, growing permissiveness, the advent of a rebellious youth culture and other challenges to the established order and, more broadly, to the concept of authority, policemen were increasingly featured as callous and manipulative crime fighters who did not hesitate to bend the law and use violence yet were better able to combat hardened criminals and other grave dangers to society. Political terrorism by the IRA and the Angry Brigade in the early 1970s certainly lent force to the notion that policemen needed to be tough and, if necessary, resort to shady practices (Chibnall 1977). A number of reported scandals pointing to abuse of power within the police, while slurring the reputation of the police also reinforced the understanding that the imperfect fictional police characters in the entertainment media were true to life. Here and there, films and TV series depicted police officers as good-natured fools (Allen et al. 1998), but a more typical presentation, even if it focused on their weaknesses, still conveyed the point that they were skillful and hard workers who gave their all to serve the community and obtain just ends (Leishman and Mason 2003). Such police characters appeared in various TV series and films, the most famous of which was television's Detective Inspector Jack Regan, the protagonist in *The Sweeney* (1975–1978), which centered on Scotland Yard's elite squad. Disrespectful of hierarchy, bureaucratic rules, and genteel norms, Detective Regan was the symbol of a relentless urban fighter against threats to the community who utilized unconventional means but was incorruptible.

The late twentieth century is regarded by many scholars as a dramatic milestone period in police exposure in the media, when "the police were rarely out of the news, and very little of the police news was good news" even though police authorities were investing far more in image promotion than previously (Stead 1999; Reiner 1985). Diverse factors may account for this exposure, including controversial police conduct in various circumstances, external and internal investigations of the police which gained considerable publicity, mounting media interest in policing matters, the diminishing role of public policing due to privatization, and the use of more advanced technological means to disseminate information (Leishman and Mason 2003). Still, as Robert Reiner has pointed out, the police remained "a powerful political and cultural force" (Reiner 2008).

Conclusion and Future Research

Clearly, from the rise of the reformed police in the third decade of the nineteenth century until the close of the twentieth century, the figure of the policeman was multifaceted, with each media format recording its own version of police representations. However, viewing the media as a whole, researchers are almost unanimous in concluding that despite twists and turns and periodic sharp criticism, they painted the police in a favorable light (Reiner 2008), generally downplaying the less salubrious features of police life, such as levels of corruption and rule-breaking, embedded prejudices and recurrent failures. Admittedly, readers did not necessarily internalize the mediated messages. Media research has long affirmed that audiences are not passive recipients of the material they read or see but rather interpret and make sense of this information, largely according to how it relates to various aspects of their lives (Reiner 2008). Nonetheless, no doubt the media played a critical role in elevating the English police to a prominent and respectful place in the national psyche.

Despite the extensive body of literature on texts related to the police, whether written by or about them, there is still considerable scope for further research of such texts. Undoubtedly, each country merits an overview of its own police representations, including comparisons between the content and impact of the various popular media locally and across national boundaries, exploiting new directions and the interdisciplinary emphasis in historical research. The diverse portrayals of the English police in written texts and on the screen have drawn wide scholarly interest, particularly since the cultural turn in the 1970s, but large gaps in our knowledge remain, for example, in visual representations in print and dominant perceptions on stage. Furthermore, various themes relating to the press in the pre–Second World War period might be explored, including police-press relations, their mutual influence, the role played by journalists in this context, and the self-management of the police image. In addition, little research has been devoted to rival representations of the police in the press of the interwar period.

With the spread of academic scholarship into the area of popular culture in the 1970s, detective fiction assumed primary importance in the reappraisal of popular texts. For example, best-selling detective narratives of the Victorian and Edwardian periods, which did not enter the canon and were forgotten with the passage of time, began to be the objects of academic study, but further examination of these little-known texts is called for as a way of revealing underlying popular sentiments of the time. Similarly, further critical scrutiny of police images on the screen in the early days of cinema is merited. Such studies should focus on the cultural meanings of texts and might well utilize the more traditional approaches in historical analysis. This research would add to our understanding of social experience as well as the collective mental world of the period.

Overview

Pulling levers focused deterrence strategies are increasingly being implemented in the United States to reduce serious violent crime committed by gangs and other criminally active groups, recurring offending by highly active individual offenders, and crime and disorder problems generated by overt street-level drug markets. These new approaches share many of the same basic elements of third-party policing, problem-oriented policing, and situational crime prevention strategies. Briefly, pulling levers focused deterrence strategies seek to change offender behavior by understanding underlying crime-producing dynamics and conditions that sustain recurring crime problems and implementing an appropriately focused blended strategy of law enforcement, community mobilization, and social service actions. Direct communications of increased enforcement risks and the availability of social service assistance to target groups and individuals are a defining characteristic of pulling levers strategies. The available evaluation evidence suggests these new approaches generate noteworthy crime reduction gains. Unfortunately, little systematic research exists to explain why these strategies seem to work in practice.

Introduction

A number of US jurisdictions have been experimenting with new problem-oriented policing frameworks, generally known as “pulling levers” focused deterrence strategies, to understand and respond to serious crime problems generated by chronically offending groups, such as gun violence among gang-involved offenders. These new initiatives generally follow a core set of activities to reduce violence: the convening of an interagency working group representing a wide range of criminal justice and social service capabilities; more or less real-time partnerships with academic researchers to develop jurisdiction-specific assessments of violence dynamics, perpetrator and victim characteristics, and related issues such as drug market characteristics and patterns of weapons use and acquisition; the design and implementation of a focused law enforcement, community mobilization, and social service/opportunity provision strategy; and the direct communication of enforcement risks and offers of help to the criminally active groups and chronic offenders.

Many of the key ideas of pulling levers focused deterrence strategies fit well within the developing discipline of third-party policing (Mazerolle and Ransley 2005). This perspective suggests that the resources of the police should be expanded to “third parties” that are believed to offer significant new resources for doing something about crime and disorder. Third-party policing asserts that the police cannot successfully deal with many problems on their own and thus that the failures of traditional policing models may be found in the limits of police powers. Using civil ordinances and civil courts or the resources of private agencies, third-party policing recognizes that much social control is exercised by institutions other than the police and that crime can be managed through agencies other than the criminal law.

The developing evaluation evidence suggests that pulling levers focused deterrence strategies generate noteworthy violence reduction benefits (Braga and Weisburd 2012). However, the varied crime prevention mechanisms that generate the observed effects are not well understood. Pulling levers strategies follow the iterative steps of problem-oriented policing (problem identification, problem analysis, development of appropriate prevention responses, and assessment; Goldstein 1990); honor core situational crime prevention ideas (Clarke 1997), such as increasing risks faced by offenders, while finding new and creative ways of deploying traditional and nontraditional law enforcement tools to do so; and are illustrative of the regulatory shift in policing that is articulated within third-party policing such that some of the “pulling lever” tools are the same interventions used in third-party policing programs that seek to engage others, either voluntarily or coercively, to do something more about crime and disorder problems than they are currently doing (Mazerolle and Ransley 2005).

Pulling levers focused deterrence strategies can be seen as a generally applicable framework for acting on the core set of situational crime prevention ideas (Braga and Kennedy 2012; Skubak Tillyer and Kennedy 2008). Mapping focused deterrence actions onto the base situational prevention ideas of increasing the effort, increasing the risks, reducing rewards, reducing provocations, and removing excuses is helpful in understanding the crime prevention mechanisms that generate the observed crime reduction results. In this entry, the emergence of pulling levers focused deterrence strategies to control gang violence and the application of these approaches to individual chronic offenders and overt drug markets is discussed within the context of third-party policing. The crime control mechanisms that seem to be associated with puller levers programs are discussed within the situational crime prevention framework.

The Emergence of Pulling Levers Focused Deterrence Strategies

Pioneered in Boston to halt youth violence, the focused deterrence framework has been applied in many American cities, in part through federally sponsored violence prevention programs such as the Strategic Alternatives to Community Safety Initiative, Project Safe Neighborhoods, and the Drug Market Initiative. In its simplest form, the approach consists of selecting a particular crime problem, such as youth homicide; convening an interagency working group of law enforcement practitioners; conducting research to identify key offenders, groups, and behavior patterns; framing a response to offenders and groups of offenders that uses a varied menu of sanctions (known as "pulling levers") to stop them from continuing their violent behavior; focusing social services and community resources on targeted offenders and groups to match law enforcement prevention efforts; focusing community normative expressions on targeted offenders and groups; and directly and repeatedly communicating with offenders to make them understand why they are receiving this special attention and what the special attention comprises (Kennedy 1997).

The Boston Gun Project was a problem-oriented policing enterprise expressly aimed at taking on a serious, large-scale crime problem – homicide victimization among young people in Boston in the 1990s. The trajectory of the Boston Gun Project, and the resulting Operation Ceasefire intervention, is by now well known and extensively documented (see, e.g., Kennedy et al. 1996; Braga et al. 2001). Briefly, a working group of law enforcement personnel, youth workers, and Harvard researchers diagnosed the youth violence problem in Boston as one of patterned, largely vendetta-like hostility among a small population of chronic offenders and particularly among those involved in 61 loose, informal, mostly neighborhood-based "gangs." These 61 gangs consisted of some 1,300 members, representing less than 1 % of the city's youth between the ages of 14 and 24. Although small in number, these gangs were responsible for more than 60 % of youth homicide in Boston.

The ability of the City of Boston to deliver a meaningful violence prevention intervention was created by convening an interagency working group of line-level personnel with decision-making power that could assemble a wide range of incentives and disincentives (Braga et al. 2002). In addition to the Harvard research team, the Ceasefire Working Group was specifically comprised of members from the Boston Police Department's Youth Violence Strike Force; US Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF); US Attorney's Office (federal prosecutors), Suffolk County District Attorney's Office (local prosecutors), Massachusetts Department of Probation, Massachusetts Department of Parole, Massachusetts Department of Youth Services (juvenile corrections), Boston School Police, City of Boston youth outreach workers, and Boston TenPoint Coalition activist black clergy. As needed, Massachusetts State Police, US Drug Enforcement Administration, Youth Service Providers Network, Boston Public Schools, and other agencies were also involved in particular interventions. It was also important to place on the group a locus of responsibility for reducing violence. Prior to the creation of the Ceasefire Working Group, no one in Boston was directly responsible for developing and implementing a comprehensive strategy for reducing violence (Braga et al. 2002).

The Operation Ceasefire focused deterrence strategy was designed to prevent violence by reaching out directly to gangs, saying explicitly that violence would no longer be tolerated, and backing up that message by "pulling every lever" legally available when violence occurred (Kennedy 1997). The chronic involvement of gang members in a wide variety of offenses made them, and the gangs they formed, vulnerable to a coordinated criminal justice response. The authorities could disrupt street drug activity, focus police attention on low-level street crimes such as trespassing and public drinking, serve outstanding warrants, cultivate confidential informants for medium- and long-term investigations of gang activities, deliver strict probation and parole enforcement, seize drug proceeds and other assets, ensure stiffer plea bargains and sterner prosecutorial attention, request stronger bail terms (and enforce them), and bring potentially severe federal investigative and prosecutorial attention to gang-related drug and gun activity.

Simultaneously, youth workers, probation and parole officers, and later churches and other community groups offered gang members services and other kinds of help. These partners also delivered an explicit message that violence was unacceptable to the community and that "street" justifications for violence were mistaken. The Ceasefire Working Group delivered this message in formal meetings with gang members (known as "forums" or "call-ins"), through individual police and probation contacts with gang members, through meetings with inmates at secure juvenile facilities in the city, and through gang outreach workers. The deterrence message was not a deal with gang members to stop violence. Rather, it was a promise to gang members that violent behavior would evoke an immediate and intense response. If gangs committed other crimes but refrained from violence, the normal workings of police, prosecutors, and the rest of the criminal justice system dealt with these matters. But if gang members hurt people, the working group concentrated its enforcement actions on their gangs.

The Ceasefire "crackdowns" were not designed to eliminate gangs or stop every aspect of gang activity but to control and deter serious violence. To do this, the working group explained its actions against targeted gangs to other gangs, as in "this gang did violence, we responded with the following actions, and here is how to prevent anything similar from happening to you." The ongoing working group process regularly watched the city for outbreaks of gang violence and framed any necessary responses in accord with the Ceasefire strategy. As the strategy unfolded, the working group continued communication with gangs and gang members to convey its determination to stop violence, to explain its actions to the target population, and to maximize both voluntary compliance and the strategy's deterrent power.

A large reduction in the yearly number of Boston youth homicides followed immediately after Operation Ceasefire was implemented in mid-1996. A US Department of Justice (DOJ)-sponsored evaluation of Operation Ceasefire revealed that the intervention was associated with a 63 % decrease in the monthly number of Boston youth homicides, a 32 % decrease in the monthly number of shots-fired calls, a 25 % decrease in the monthly number of gun assaults, and, in one high-risk police district given special attention in the evaluation, a 44 % decrease in the monthly number of youth gun assault incidents (Braga et al. 2001). The evaluation also suggested that Boston's significant youth homicide reduction associated with Operation Ceasefire was distinct when compared to youth homicide trends in most major US and New England cities (Braga et al. 2001).

The assertion that pulling levers focused deterrence strategies generate noteworthy violence prevention gains has been strengthened by subsequent replications of the Boston experience. A number of cities have experimented with the pulling levers framework to control gang violence and experienced some very encouraging results. Consistent with the problem-oriented policing approach, these cities have tailored the approach to fit their violence problems and operating environments. Quasi-experimental research designs have revealed noteworthy violence prevention gains in East Los Angeles, California (Tita et al. 2004); Indianapolis, Indiana (McGarrell et al. 2006); Lowell, Massachusetts (Braga et al. 2008); and Stockton, California (Braga 2008).

The emergence of the pulling levers focused deterrence approach to controlling violent gangs and other criminally active groups can be most directly traced to the increasing use of problem-oriented policing and situational crime prevention techniques by police departments over the course of the 1990s to address violent crime problems. The devastating harms generated by the 1990s youth violence epidemic helped to push criminal justice agencies, especially police departments, toward developing innovative violence prevention strategies (Weisburd and Braga 2006). However, like third-party policing more broadly, it is important to recognize that the development of pulling levers strategies can also be placed in the context of a regulatory shift in policing that occurred during the 1990s which flowed from a changing climate of governance and regulation as well as a blurring of civil and criminal laws (Mazerolle and Ransley 2005). As will be discussed further below, the formation of interagency working groups that seek to regulate the behavior of high-risk groups through the routine application of enforcement levers mirrors the creation of an actuarial system, where the public police are one node in a network, responsible for identifying and managing risks.

Applying Pulling Levers Focused Deterrence to Individual Offenders

A variation of the Boston model was applied to individual offenders in Chicago, Illinois as part of the US Department of Justice-sponsored Project Safe Neighborhoods (PSN) initiative (Papachristos et al. 2007). Gun- and gang-involved parolees returning to selected highly dangerous Chicago neighborhoods went through "call-ins" where they were informed of their vulnerability as felons to federal firearms laws, with stiff mandatory minimum sentences; offered social services; and addressed by community members and ex-offenders. A quasi-experimental evaluation showed a neighborhood-level homicide reduction impact of 37 % (Papachristos et al. 2007). Individual-level effects were remarkable. For offenders with gun priors but no evidence of gang involvement, for example, attendance at a call-in reduced return to prison at around 5 years from release from about half to about 10 % (Fagan et al. 2008).

Applying Pulling Levers Focused Deterrence to Overt Drug Markets

There is less experience in applying the focused deterrence approach to other crime and disorder problems. In High Point, North Carolina, a focused deterrence strategy was aimed at eliminating public forms of drug dealing such as street markets and crack houses by warning dealers, buyers, and their families that enforcement is imminent (Kennedy 2009). With individual "overt" drug markets as the unit of work, the project employed a joint police-community partnership to identify individual offenders, notify them of the consequences of continued dealing, provide supportive services through a community-based resource coordinator, and convey an uncompromising community norm against drug dealing. This application of focused deterrence is generally referred to as the "Drug Market Intervention" (DMI) strategy.

The DMI seeks to shut down overt drug markets entirely (Kennedy 2009). Enforcement powers are used strategically and sparingly, employing arrest and prosecution only against violent offenders and when nonviolent offenders have resisted all efforts to get them to desist and to provide them with help. Through the use of "banked" cases, the strategy makes the promise of law enforcement sanctions against dealers extremely direct and credible, so that dealers are in no doubt concerning the consequences of offending and have good reason to change their behavior. The strategy also brings powerful informal social control to bear on dealers from immediate family and community figures. The strategy organizes and focuses services, help, and support on dealers so that those who are willing have what they need to change their lives. Each operation also includes a maintenance strategy.

A preliminary assessment of the High Point DMI found noteworthy reductions in drug and violent crime in the city's West End neighborhood (Frabutt et al. 2004). A more rigorous evaluation of the High Point DMI is currently being conducted. Quasi-experimental evaluations of a similar DMI strategy in Rockford, Illinois (Corsaro et al. 2009), and Nashville, Tennessee (Corsaro et al. 2010), found noteworthy crime prevention gains associated with the approach. Study findings suggest that the DMI strategy generates statistically significant and substantive reductions in crime, drug, and nuisance offenses in the targeted neighborhoods.

The Links Between Third-Party Policing, Situational Crime Prevention, and Pulling Levers Focused Deterrence Strategies

Third-party policing and pulling levers focused deterrence strategies are strongly linked as both approaches seek to harness the crime control and prevention work of the police to a network of third-party partners. As suggested by Braithwaite (2000), recent transformations of governance in Western democracies have resulted in a move toward networks of power and away from state sovereignty and control. These broader societal changes have influenced crime control and policing by "changing the focus from state responsibility for preventing and correcting criminal behavior to a system where crime control and prevention networks are responsible for identifying and managing risks" (Mazerolle and Ransley 2006, p. 193). In pulling levers strategies, police work within a "network of capacity" to prevent gang and group-involved violence (Moore 2002; Braga and Winship 2006). These networks are well positioned to control risky group behavior because criminal justice agencies, community groups, and social service agencies coordinate and combine their efforts in ways that magnify their separate crime reduction effects.

When implemented properly, pulling levers focused deterrence strategies combine the "top-down" approach to crime control and prevention suggested by the third-party policing perspective with the "grassroots" approach of careful analysis and response development suggested by situational crime prevention and problem-oriented policing perspectives. As documented by Mazerolle and Ransley (2006), third-party policing initiatives often, but not exclusively, occur in the context of situational crime prevention and problem-oriented policing projects. In Boston, for instance, the Ceasefire Working Group represented a system of decentralized networks of governmental and nongovernmental agencies that mobilized to prevent and control outbreaks of serious gang violence. At the same time, the Ceasefire Working Group members carefully analyzed the nature of gang disputes and the vulnerabilities of the gangs involved to a variety of sanctions and implemented a set of violence reduction actions that were customized to the targeted gangs.

Situational crime prevention and problem-oriented policing are analytic approaches that have often, either explicitly or implicitly, taken the position that traditional law enforcement is not a desirable option in dealing with recurring crime problems (Goldstein 1990; Clarke 1997). Although situational crime prevention and pulling levers focused deterrence strategies developed separately, these approaches are complements in crime prevention and control. Focused deterrence strategies involve many elements that, at face value, appear very traditional and are thus hard to see and understand in the new light in which these strategies seek to use them. By identifying the links between the situational crime prevention and focused deterrence strategies, many of these new prevention ideas are made clearer to those seeking to these approaches to deal with crime problems. This remainder of this section builds upon prior work that locates focused deterrence approaches within a situational prevention framework (Braga and Kennedy 2012; Skubak Tillyer and Kennedy 2008).

Situational crime prevention and third-party policing strategies both seek to change criminal decision making. Third-party policing initiatives exploit the coercive nature of a range of alternative civil, criminal, and regulatory rules and laws levers to persuade (or force) the decision change. Put another way, the use of the law within third-party policing interventions is a coercive way to alter offender decisions, whereas situational crime prevention interventions seem to encourage offenders to make a more rational decision by weighing the risks and benefits of committing a crime. The common ground in influencing offender decisions shared by these two perspectives is evident in the discussion below. The core situational crime prevention areas of increasing the effort, increasing risks, reducing rewards, reducing provocations, and removing excuses provide a familiar and easy-to-understand framework to summarize the varying crime prevention mechanisms at work in pulling levers focused deterrence strategies. The discussion below is also limited to decisions to commit a criminal act, such as committing a gun homicide, rather than decisions to become involved in crime or decisions to persist or desist from criminal offending (Cornish and Clarke 2003).

Increasing Risk

Deterrence theory posits that crimes can be prevented when the costs of committing the crime are perceived by the offender to outweigh the benefits (Zimring and Hawkins 1973). Most discussions of the deterrence mechanism distinguish between "general" and "special" deterrence (Cook 1980). General deterrence is the idea that the general population is dissuaded from committing crime when it sees that punishment necessarily follows the commission of a crime. Special deterrence involves punishment administered to criminals with the intent to discourage them from committing crimes in the future. Much of the literature evaluating deterrence focuses on the effect of changing certainty, swiftness, and severity of punishment associated with certain acts on the prevalence of those crimes (see, e.g., Apel and Nagin 2011). Pulling levers focused deterrence strategies honor core deterrence ideas, such as increasing risks faced by offenders, while finding new and creative ways of deploying traditional and nontraditional law enforcement tools to do so, such as directly communicating incentives and disincentives to targeted offenders (Kennedy 1997, 2009).

Increasing the risks faced by offenders to change their decisions to commit particular crimes is a central idea in both frameworks. Pulling levers strategies aimed at "gangs," for example, are designed to alter the objective sanction environment by increasing enforcement risks faced by groups of offenders and accurately and directly communicating that change to a specific population of offenders in a manner that enhances the legitimacy of the strategy. Ongoing intelligence analysis reduces the anonymity of offending groups in the commission of their crimes. Triggering events, such as committing a homicide, result in a swift and certain enforcement response by law enforcement coupled with informal sanctions by community members intended to weaken pro-offending norms. Partnering criminal justice agencies mobilize a varied set of sanctions that are tailored to the specific crime dynamics associated with the offending group and to the varied offending behaviors of the individuals that comprise the targeted group. Beyond halting crime outbreaks by groups, the pulling levers focused deterrence strategy seeks to prevent further offending by making it risky for criminal group members to encourage pro-offending norms and narratives within their social networks.

In addition, more traditional situational crime prevention techniques are often implemented as part of the core pulling levers work in practice. Extending guardianship, assisting natural surveillance, strengthening formal surveillance, reducing the anonymity of offenders, and utilizing place managers can greatly enhance the range and the quality of the varying enforcement and regulatory levers that can be pulled on offending groups and key actors in criminal networks. In High Point, North Carolina, the interagency working group conducted call-ins with landlords of drug houses to ensure that these place managers dealt with drug problems on their properties immediately or face certain and swift law enforcement and civil code violation penalties. Similarly, the Cincinnati Initiative to Reduce Violence, a multiagency community collaborative effort to apply focused deterrence principles to reduce group-based violence, used civil forfeiture techniques to close down a highly problematic bar that generated recurring serious violence.

A particularly interesting development within focused deterrence is the realization that the "guardians" so central to traditional situational crime prevention can themselves be offenders: who nonetheless can be brought to exercise powerful influences over other offenders. For instance, in Lowell, the interagency working group recognized that they could systematically prevent street violence among Asian street gangs by targeting the gambling interests of older, influential members. When a street gang was violent, the Lowell Police targeted the gambling businesses run by the older members of the gang. The enforcement activities ranged from serving a search warrant on the business that houses the illegal enterprise and making arrests to simply placing a patrol car in front of the suspected gambling location to deter gamblers from entering. The working group coupled these tactics with the delivery of a clear message, "when the gang kids associated with you act violently, we will shut down your gambling business. When violence erupts, no one makes money" (Braga et al. 2006, p. 40). These possibilities have led to the idea of deliberately mobilizing even serious offenders as "intimate handlers" of other offenders along particular dimensions of their offending portfolio.

Reducing Rewards

In many cities facing serious gun violence problems, chronic disputes among gangs and other criminally active groups generate the bulk of homicides and nonfatal shootings (Braga et al. 2002). These disputes are often personal and vendetta-like. In these settings, violence and a willingness to be violent often confer a very desirable status on particular members within group memberships and hierarchies. The rewards of violent behavior further encourage pro-offending norms and narratives within these criminal relationships and networks. Pulling levers strategies attempt to reverse this problem by associating swift and certain negative consequences with behaviors, such as committing homicides and shootings, that once enhanced the reputation of individuals within a group and the group itself. The communication strategies explicitly make a "cause and effect" link between the actions of interagency working groups and the targeted criminal behavior by the group.

Pulling levers focused deterrence strategies have extended the concept of denying the benefits of crime beyond those accrued by individual offenders to include these powerful group processes associated with repeat violent offending (Skubak Tillyer and Kennedy 2008). Nonetheless, there is considerable overlap and cross-fertilization between focused deterrence strategies and the various intervention ideas associated with particular situational prevention actions designed to reduce the rewards associated with offending. Ideas involving concealing and removing targets can be seen in the efforts of interagency working groups to use enforcement strategies, such as enhancing and monitoring probation conditions to limit their presence in high-risk places at high-risk times, and community-based actions, such as peace walks through gang turfs, to alter the presence of gang members in public places who are often the "targets" of retaliatory violence. Disrupting illegal drug markets can also produce desirable reward-reducing effects that can counter outbreaks of violence. Limiting the ability of group members to earn money when violence erupts can certainly reduce any benefits accrued to the group by violent behavior. Ideally, the violence that once won the respect of other group members would now bring anger and disassociation by one's peers.

Reducing Provocation

In pulling levers strategies, deterrent messages are framed to address the group context from which many crime problems emerge. The groups themselves can act as another internal communication vehicle for transmitting the actual sanction risk to other offenders. As Skubak Tillyer and Kennedy (2008) describe, meaningful enforcement actions and scrutiny by law enforcement agencies can leverage the rationality of group members to no longer encourage norms that provoke the outbreaks of violence. The citywide communication of the antiviolence message, coupled with meaningful examples of the consequences that will be brought to bear on groups that break the rules, can weaken or eliminate the "kill or be killed" norm as individuals recognize that their enemies will be operating under the new rules as well.

This perspective on reducing group-based provocations to commit violence developed as the Boston Gun Project unfolded. A central hypothesis within the working group was the idea that a meaningful period of substantially reduced youth violence might serve as a "firebreak" and result in a relatively long-lasting reduction in future youth violence (Kennedy et al. 1996). The idea was that youth violence in Boston had become a self-sustaining cycle among a relatively small number of youth, with objectively high levels of risk leading to nominally self-protective behavior such as gun acquisition and use, gang formation, tough "street" behavior, and the like: behavior that then became an additional input into the cycle of violence. If this cycle could be interrupted, a new equilibrium at a lower level of risk and violence might be established, perhaps without the need for continued high levels of either deterrent or facilitative intervention. The larger hope was that a successful intervention to reduce gang violence in the short term would have a disproportionate, sustainable impact in the long term.

P

Removing Excuses

Sampson et al. (1997) emphasize the capacity of a community to realize common values and regulate behavior within it through cohesive relationships and mutual trust among residents. They argue that the key factor determining whether crime will flourish is a sense of the "collective efficacy" of a community. A community with strong collective efficacy is characterized by high capacities for collective action for the public good. Pulling levers focused deterrence strategies enhance collective efficacy in communities by emphasizing the importance of engaging and enlisting community members in the strategies developed. The High Point DMI strategy, for example, drew upon collective efficacy principles by engaging family, friends, and other "influential" community members in addressing the criminal behaviors of local drug dealers (Kennedy 2009).

Community-based action in pulling levers strategies helps to remove the excuses used by offenders to explain away their responsibility for the targeted behavior. In call-ins and on the street, community members effectively invalidate the excuses for criminal behavior by challenging the norms and narratives that point to racism, poverty, injustice, and the like. In Boston, for example, black clergy challenged gang members who attempted to use these excuses by countering that poverty, racism, and injustice were not linked to their decisions to fire shots in their neighborhoods and kill other young people who have experienced the same societal ills and life difficulties. Community members also work with law enforcement and social service agencies to set basic rules for group-involved offenders such as "don't shoot guns" and, hopefully, to alert the conscience of these offenders by appealing to moral values inherent in taking the life of another, causing harm to their neighborhood, or the pain that would be experienced by their mothers if they were killed or sent to prison for a long time in a very far away location.

The social service component of focused deterrence strategies serves as an independent good and also helps to remove excuses used by offenders to explain their offending. Social service providers present an alternative to illegal behavior by offering relevant jobs and social services. The availability of these services invalidates excuses that their criminal behavior is the result of a lack of legitimate opportunities for employment, or other problems, in their neighborhood.

A recent elaboration of these ideas has been to use persons of standing to explicitly challenge the "street code" (Anderson 1999) that in many places drives much or most "street" violence. This code has identifiable, if unwritten, elements with powerful criminogenic implications: that early death is inevitable; jail and prison nothing to fear; disrespect must be met with violence; the enemy of my friend is my enemy; the failings of mainstream others justify violent offending; and the like. A long sociology of "techniques of neutralization" (Matza 1964) puts such exculpatory norms at the center of the etiology of street violence. When, for example, "original gangsters" respected by current offenders undercut such norms, it may in turn undercut felt justification for violence and other offending.

Situational crime prevention also seeks to reduce offending by making it easier for potential offenders to comply with laws and rules. Focused deterrence strategies also do so, in some very particular ways. To the extent that street norms stand against compliance, altering them for the better facilitates compliance: the law stands against violence, but the street honor code promotes it, so vitiating the honor code makes it easier to obey the law. Many potentially violent offenders do not wish to be violent but are under very real peer pressure to be so; undercutting and even reversing group and network dynamics make it easier for them to back off. Strengthening community norms against offending makes it easier to resist both internal and external pressure to offend. The original Boston project framed this "honorable exit" from violent offending as a possible consequence of changes in objective sanction risks and group dynamics.

A recent and potentially very important strain in focused deterrence thinking has focused explicitly on the gulf, often explicitly racialized, in the "norms and narratives" of law enforcement, affected communities, and offenders. These gulfs, rooted in historical and present experiences, understandings, and misunderstandings, can have powerful impacts on the ways in which these parties understand each other and on the perceived legitimacy of law enforcement, law, and informal rules and standards. If law enforcement is seen by the community and offender groups as a deliberate racial oppressor, for example, it will be difficult for community norms to support stands against drug dealing and easier for offenders to break the drug laws. If those norms and narratives are effectively addressed – which usually includes changes in actual behavior on both sides – it becomes easier for community standards to support compliance, easier for offenders to comply, and harder for them not to (Kennedy 2009; Meares 2009; Tyler 1990).

These developments draw heavily on a rich literature addressing the "legitimacy" of law enforcement in the eyes of those subject to the law (Meares 2009; Tyler 1990). Very interestingly, one of the core findings in that literature is that even offenders obey the law most of the time. This empirical fact, of considerable theoretical and practical significance, stands in contrast to situational crime prevention's establishing assumption of the "motivated offender": the idea that we can take the presence of the impulse to offend as a given and for granted. That establishing assumption is just that – an assumption explicitly deployed as a way to break with traditional criminology's pervasive and, for applied purposes not very helpful, search for the deep causal roots of individual offending. The emerging salience of legitimacy as an idea of profound practical significance could well lead to a reexamination, and refinement, of the idea of offending in situational crime prevention.

Increasing Effort

Situational crime prevention seeks to increase the effort a criminal must expend to complete a crime through a variety of specific actions such as target hardening, controlling access to facilities, screening exits, deflecting offenders, and controlling tools and weapons (Clarke 1997; Cornish and Clarke 2003). In preventing and responding to outbreaks of serious violence by groups of offenders, many of these situational actions can be used to good effect in developing a "thicker" response to the offending groups in question. Focused deterrence responses benefit from changing the environments in which gangs and drug crews congregate, commit lesser offenses together, and launch plans for retaliation. Gang members are well known to commit a wide array of crimes (known as "cafeteria-style offending"; see Klein 1995). Making it more difficult to sell drugs at specific places, commit burglaries and car breaks, and rob passersby can be a powerful deterrent response to particular groups of offenders who rely on these illicit opportunities to generate income. Disrupting the ability of groups to associate with each other in space and time, through, for instance, controlling access to and screening exit from public housing, can slow down group processes that facilitate violence and make it more difficult for rivals to locate other group members targeted for retaliatory shootings.

Focused deterrence strategies seek to create similar dynamics. Changes in group norms and in objective risks associated with particular forms of misbehavior may, for example, make it more difficult to recruit peers for particular instances of co-offending. Ethnographic research on illicit gun markets in Chicago has shown that gangs' assessment of the law enforcement responses to gun violence leads them to withhold access to firearms for younger and more impulsive members (Cook et al. 2007). DMI's goal of fundamentally disrupting overt drug markets can greatly enhance the difficulty of drug dealing: when buyers no longer routinely "cruise" once active markets, even a motivated street dealer may find it impossible to do business.

Conclusion

The evaluation evidence briefly presented in this entry suggests that pulling levers focused deterrence strategies generate noteworthy crime reduction gains. A recently completed Campbell

Collaboration systematic review identified eleven evaluations of pulling levers strategies (Braga and Weisburd 2012). The basic findings of this review were very positive; their main effect meta-analysis reported a statistically significant, medium-sized crime reduction effect associated with the reviewed programs. Nonetheless, the authors were concerned with the lack of rigorous randomized experimental evaluations of this promising approach. Only one of the reviewed interventions was tested using a randomized experimental design.

Despite their concerns over the lack of randomized experiments, Braga and Weisburd (2012) concluded that the findings of eligible focused deterrence evaluations fit well within existing research suggesting that deterrence-based strategies, if applied correctly, can reduce crime (Apel and Nagin 2011). The pulling levers approach seems to have the desirable characteristic of altering offenders' perceptions of sanction risk. Braga and Weisburd (2012) also noted, however, that pulling levers strategies contained other complementary crime control mechanisms at work that needed to be highlighted and better understood. Applying pulling levers actions to the core set of base situational prevention ideas is very helpful in unraveling the varied pathways through which these programs produce the observed crime reduction impacts.

While originally developed from a problem-oriented project, pulling levers focused deterrence approaches share some direct links with third-party policing initiatives. The successful application of pulling levers strategies to high-risk groups, individuals, or places is heavily reliant on the coordinated actions of a network of criminal justice, social service, and community-based agencies. The police are an important, but singular, node within this network. Pulling levers strategies seek to change the behavior of targeted groups and individuals by engaging a wide range of incentives and disincentives; drawing on third-party policing activities, these "levers" can include the application of criminal and civil laws and be supported through the formation of willing (and unwilling) partnerships.

Punishment and the State

Alon Harel
Faculty of Law, The Hebrew University of Jerusalem, Jerusalem, Israel

Overview

Criminal sanctions are typically inflicted by the state and by the state alone. This entry investigates (by using tools of political philosophy) the normative rationales for the exclusive control of the state over the infliction of criminal sanctions, and further, it explores whether the state has not only an exclusive right to punish but also a duty to do so.

Criminal law sanctions require the enactment of criminal law norms, the issuing of particular judgments by courts, and, last, the physical infliction of criminal sanctions. All those functions are currently controlled by the state. Yet some legal systems were almost entirely private and contemporary theorists challenge the public control over some aspects concerning the infliction of criminal punishment. Most significantly, some recent legal reforms involve privatization of central components of the criminal law system: private prisons, private enforcement mechanisms, shame penalties, etc. This entry examines whether it is a desirable (or even a necessary) feature of criminal punishment that it be inflicted by the state and, if so, why? Could the infliction of punishment be, at least in principle, privatized and, if it could, would it be desirable?

To do so, the entry differentiates among three types of justifications for the role of the state in the infliction of punishment: *instrumentalist justifications*, *normative precondition justifications*, and *state-centered justifications*. It provides examples for each type and it shows how classical theories of punishment such as those provided by Locke, Nozick, and Rousseau fall into each one of these categories. The entry also investigates whether the state has sometimes a duty rather than merely a right to punish.

Introduction

Criminal sanctions are typically inflicted by the state. The criminal law norms that set a maximal sanction or a range of permissible sanctions are enacted by the legislature; state courts determine the sanctions within the boundaries set by the legislature; and last, the state is (typically) in charge of the physical infliction of the sanction, e.g., running the prisons (maintained by public officials). Note that while typically the legislative determination, the judicial determination, and the executive infliction of the sanction are all done by the state, it is possible to differentiate these three dimensions and privatize some of them while maintaining public control of others. The central concern of this entry is to examine whether it is a desirable (or even a necessary) feature of criminal punishment that it be inflicted by the state and, if so, why? Could the infliction of punishment be, at least in principle, privatized and, if it could, would it be desirable? The entry also investigates whether the state has sometimes a duty rather than merely a right to punish.

This entry is divided into three main parts. The first Part explains why the relations between punishment and the state raise an important question of policy. This part establishes that the intimate relations between the state and punishment are neither natural nor universal. As a matter of fact, there is currently a trend towards privatizing different dimensions of the criminal process. The second Part differentiates among three types of justifications for the role of the state in the infliction of punishment: *instrumentalist justifications*, *normative precondition justifications*, and *state-centered justifications*. Last, the third Part examines whether the state has not merely an (exclusive) right to inflict criminal punishment but also a (political and/or constitutional) duty to do so and, if so, how such a duty can be justified.

Can the Infliction of Criminal Punishment Be Privatized?

Some may find the relation between criminal punishment (and the penal process as a whole) on the one hand and the state on the other hand to be natural and self-evident. Law students learn that criminal law is a branch of public law designed to promote the public interest. Public law is contrasted with private law (e.g., contract and tort law) which is designed to promote private interests (Hall 2005, pp. 241–246). Under this view held, most famously, by Blackstone, crimes “affect the whole community, considered as a community in its social aggregate capacity” (Blackstone 1769 4th book, Chap. 1). More fundamentally, the state has, as Max Weber said, monopoly of the legitimate use of physical force (Weber 1946, p. 77). Consequently, all the dimensions of the criminal law and its execution including legislation of criminal prohibitions, the determination of guilt, the size of the sanction, the enforcement system, the prosecution, and the infliction of the criminal sanctions including the maintaining of prisons are public and are governed by public law.

Yet a historical examination reveals that the public nature of these functions is “self-evident” to lawyers only because lawyers “incline to project modern practice backwards” (Langbein 1973, p. 316). Historically, it is known that for a very long time, English law relied on private prosecution (Hay 1984; Friedman 1995, pp. 475–478). As a matter of fact, “private vengeance of the person wronged by a crime” was a primary feature of the administration of criminal justice in early English law (Stephen, 245). This system has been transformed only in the nineteenth century (Kurland and Waters 1959). While the English system was based on private prosecutors, other jurisdictions relied heavily on the private infliction of criminal sanctions. The southern states of the USA had no actual penitentiary and till the second half of the nineteenth century, prisoners were leased out by the state to private entrepreneurs (Lichtenstein 2001 p. 193). Another example of private infliction of sanctions is the rule prevailing in Roman law under which the person who committed theft and was caught in the act was given up as a slave to the person against whom the theft was committed (Jolowicz and Nicholas 1972, p. 167). While many ancient legal systems recognized the difference between offenses against the state or community and offenses against the individual, the meaning of the distinction and the scope of offenses covered by each category were very different than the ones known to us now. Offenses which are now regarded exclusively as crimes were treated as private wrongs (torts) including, for instance, theft in Roman law (Maine pp. 369–371). Last, some legal systems were almost entirely private. In recent research on medieval Icelandic institutions, it was said that Icelandic institutions “might almost have been invented by a mad economist” (Friedman 1979, p. 400). In the Icelandic system that operated successfully for hundreds of years, “Killing was a civil offence resulting in a fine paid to the survivors of the victim. Laws were made by a ‘parliament,’ in which seats were a marketable commodity. Enforcement of law was entirely a private affair” (Friedman 1979, 400). Iceland is not unique in this respect. As Friedman argues, “[T]he idea that law is primarily private, that most offenses are offenses against specific individuals or families, and that punishment of the crime is primarily the business of the injured party seems to be common to many early systems of law” (Friedman 1979, p. 400; Posner 1983, pp. 119–143).

These historical observations can be described in different ways. Some may say that the Icelandic legal system did not contain *penal* sanctions (as penal sanctions are “necessarily” or “by definition” public), while others may say that the penal sanctions were privatized in Iceland. Irrespective of how these systems are described, it is evident even to contemporary legal theorists that the division between public sanctions (criminal ones) and private sanctions (torts) is not a sharp division and that the dichotomy drawn between these two systems does not reflect the legal reality (Mann 1992). More importantly, these historical observations are not merely relics of history. Contemporary theorists, in particular economists, have also favored the “privatization” of some aspects of the penal system. It was argued that a system of private enforcement of law, in which the person who caught a criminal received the fine paid by the offender, would be more efficient than the current system in which the fine is paid to the state (Becker and Stigler 1974; Friedman 1979). Further, some “private” penal practices are being reintroduced in a new form. The victim who in the past played a major role in the criminal process both as a policeman and as a prosecutor has now become again influential figure in the criminal process (Mcdonald 1975–76; Levine 2010; Cassell and Joffee 2011). Shaming penalties used extensively in medieval times have become popular again in the USA (Kahan 1996). Although not often noticed, shaming penalties privatize the infliction of punishment as the power to determine the severity of the sanction, and more generally, the power to inflict sanctions is shifted from the state to private citizens (Whitman 1998, p. 1089). Last, the privatization of prisons has triggered a bitter debate (McDonald 1994), and in at least one country, private prisons were declared by the courts to be unconstitutional. (http://elyon1.court.gov.il/files_eng/05/050/026/n39/05026050.n39.htm; Medina 2010). These historical and contemporary findings establish that there is nothing inevitable in there being public control over the penal process. The public nature of punishment is ultimately a normative decision on the part of the polity that has been gradually eroded and its desirability ought to be subjected to normative scrutiny. The rest of this entry will be devoted to examining the justifications for the involvement of the state in the infliction of punishment.

The Justification for Public Infliction of Criminal Sanctions

This section identifies three types of justifications for the central role of the state in inflicting punishment (Harel 2008; Harel and Poart 2011). Under the first type of justification – *instrumental justifications* – the agent which inflicts the sanction must be the agent most capable of inflicting the sanction. Such an agent must make accurate judgments as to the moral gravity of the offense as well as judgments as to the appropriate sanctions, be willing and capable to invest the resources necessary to punish the offender, and have the ability to act on the basis of its judgment. Further, under an instrumental justification, the characterization of who the most capable agent is (or the most successful infliction is), is independent of the identity of the entity in charge of performing it. The state is an appropriate agent to inflict the sanction simply because (and only to the extent) that it is (likely to be) deliberative, impartial, or efficient. Under a second type of justification – *normative precondition justifications* – the infliction of criminal sanctions by the state achieves goals that could in principle be fully realized through the infliction of sanctions by non-state agents. Yet, in contrast to instrumental justifications, there are normative constraints that preclude the infliction of sanctions by agents other than the state. The agency of the state is not necessary for the success of the infliction of criminal sanctions; it is however a non-contingent normative precondition for the just infliction of criminal sanctions. Under a third type of justification – *the state-centered justification* – the infliction of criminal punishment by non-state agents is conceptually impossible, as the very infliction of criminal punishment presupposes that it is the state that inflicts it. This is not mere semantics. Under the third type of justification, punishment brings about certain goods and the goods resulting from punishment hinge on the identity of the agent inflicting it. To be considered "punishment" under this view, it is not sufficient that it hurts or causes displeasure to those who have wronged (as those can result from the actions of a private agent); it must also reflect an authoritative judgment concerning the wrongfulness of an act, and such a judgment can only be made by an authoritative entity – the state. It is false therefore to say that private individuals *ought not* to punish; they simply *cannot punish* as their acts do not constitute punishment.

Instrumental justifications consist of two major steps. First, the theorist identifies the goals of punishment: deterrence/incapacitation, retribution, etc. These goals are conceptually separable from the identity of the agent inflicting the sanction. Then the theorist establishes that the state is the most likely to successfully realize or bring about these goals. To the extent that the state is more likely/capable of realizing these goals than other agents, it ought to be in charge of inflicting criminal sanctions.

The most influential instrumental justification was made by John Locke. Although ultimately, as shown below, Locke defends a non-instrumental account, Locke developed an influential instrumentalist account. More specifically, Locke believed that the state should be empowered to inflict sanctions on those who transgress the laws of nature because the state is less partial than other agents in its treatment of offenders (Locke 1960, chap. 2). Locke believed that punishment inflicted by individuals is both possible and permissible in the state of nature (Farell 1988). But he also believed that private agents inflicting sanctions are likely to be either too lenient ("Self-Love will make Men partial to themselves and their Friends") or too harsh ("Passion and

Revenge will carry them too far in punishing others"). Law and economic theorists also defend the involvement of the state on the basis of instrumental justifications. In their view, punishment should be supplied by the state because the infliction of sanctions involves a collective action problem. An individual who inflicts a sanction has to bear the costs of inflicting the sanction himself, whereas the benefits resulting from the infliction (deterrence, incapacitation) are enjoyed by everybody. It follows that individuals will underinvest in the infliction of sanctions (Mueller 1989, pp. 9–15) Other theorists also established that private agents are less likely to be accountable than public officials and that often they may act in ways that do not promote the goals of government (Verkuil 2007, chap. 1). The lack of accountability on the part of private agents is often debated in the literature (Minow 2003; Trebilcock and Lacobucci 2003). At the same time, other economists believe that the state is not always the best agent to inflict punishment. It has been argued, for instance, that states are inclined to increase sanctions above the optimal level in order to "export" their criminals elsewhere (Harel 2012, pp. 34–35).

Note that instrumentalist justifications could be based on any theory of punishment. Instrumentalists could support retributivism and argue that the state is the agent that is most likely to inflict a sanction that is proportionate to the gravity of the wrong (and is therefore "deserved" by the criminal). Deterrence theorists could argue that the state is the most likely to inflict a sanction that deters effectively or, at least, to do it efficiently. Rehabilitation theorists would maintain that the state is more likely to succeed in integrating the criminal into society etc.

Instrumentalist arguments require establishing factual claims concerning the state. Once the goals of punishment are identified, it is necessary to show that the state makes better judgments concerning the "appropriate" sanctions, is better able to inflict the sanction, is more likely to calibrate their optimal size, etc. Further, if faced with contrary evidence, an advocate of an instrumentalist argument must be willing to concede that punishment ought to be inflicted by non-state entities. There are no principled grounds why the state ought to inflict criminal sanctions. The desirability of privatization hinges therefore on contingent factors and such factors may change from time to time and from society to society.

This observation provides a basis for criticizing the instrumentalist view. Arguably, the instrumentalist fails to capture a prevalent intuition, namely, that the involvement of the state in the infliction of punishment is not a mere contingency hinging on its (alleged) ability to "get it right." Those who challenge instrumentalist views maintain that "it is not generally accepted that I have the right simply to hurt another who has done something wrong, just because he has done it, where there is no special relation between us" (Lyons 1976, p. 210). Further, "neither one's general level of virtue nor one's particular talents in the area of punishing. . . are normally taken to establish any special claim to be the one who should punish others (Simmons 1991, p. 312) Even Locke (who developed also an instrumentalist account described above) agrees with this observation and says: To justify bringing such evil [i.e., punishment] on any man two things are requisite. First that *he who does it has commission and power to do so*. Secondly, that it be directly useful for the procuring of some other good. . .Usefulness, when present, being but one of those conditions, cannot give the other, which is a commission to punish" (Locke 1823, emphasis added).

Under this challenge, one ought to separate two questions: (a) whether an agent "deserves" to be punished or ought to be punished and (b) whether a particular agent is the "appropriate agent" to inflict the sanction (Hill 1999). To justify the infliction of punishment X by an agent Y on a wrongdoer Z, it is not sufficient to show that X should be inflicted on Z and that Y is the most likely or the most capable to inflict it. Something else needs to be shown.

This powerful intuition is evident in the context of family relationship. A child may deserve punishment, or punishment may be conducive to the child's well-being or, all things considered, it may be desirable that the punishment be inflicted. The common law has recognized the parents' privilege of moderate chastisement. But, according to the common law, the only agent for whom it is permissible to inflict the sanction on the child would be a parent or, in special cases, somebody to whom the parent delegated the power, e.g., teachers (Blackstone Book I, Chap. 16). Of course such a power granted to parents could be justified purely on instrumental grounds, e.g., that parents are more likely to inflict the "right" punishment, but it seems that beyond the purely instrumental grounds, non-instrumental concerns are also at stake (Harel 2008, p. 123).

Both normative constraints theories and state-centered theories reject the instrumental view and attempt to explain why sanctions ought to be inflicted only by "appropriate" agents and appropriateness, in their view, is not merely a contingent fact. Under the normative constraints explanations, the infliction of sanctions by "inappropriate" agents may serve the purposes of punishment (whatever these purposes are). Yet there are normative constraints on the infliction of sanctions that are not grounded in instrumental concerns. Even when the punishment inflicted by an agent X is impartial, effective, and just, it could be illegitimate and wrong simply because it is inflicted by X rather than by another agent. Under the state-centered explanations, sanctions that are imposed by the "wrong" agent do not constitute punishment at all as they fail to realize the goods that punishment is designed to realize.

Locke and Nozick defend what I labeled a normative constraints theory. Under their view, individuals in the state of nature have a right to punish (designed to prevent further wrongdoing on the part of the wrongdoer herself and on the part of others) (Locke 1960, chap. 2; Nozick 1977, pp. 3–119). Further, individuals not only have a right to punish but also a right to transfer/alienate the right to punish. Last, both Locke and Nozick believe that we can attribute to individuals a decision to transfer the right to punish to the state (based on their own concern to protect their natural rights and the greater effectiveness of the state in calibrating sanctions). The authority of the state to punish is attributable not merely to the "usefulness" of the state but also to its "commission to punish" based on the voluntary (or constructive) alienation of the right to punish. Similarly Rousseau maintains that "The punishment of death inflicted on criminals may be considered from the same point of view: it is to secure himself from being the victim of assassins that a man *consents to die if he becomes an assassin*" (Rousseau 1954, p. 31, emphasis added). Punishment inflicted by private agents is therefore impermissible not merely because it is likely to be disproportionate or unjust but also because the power to punish was transferred voluntarily (or should be regarded as if it was transferred voluntarily) by those who have a natural right to punish (i.e., individuals) to the state.

Normative constraints justifications can address the concern raised earlier against instrumentalist justifications; in particular, they can explain why the power of the state to punish does not merely hinge on contingent considerations such as the fact that the state is more likely than any other agent to make better judgments concerning the appropriate size, the type of the sanctions and/or to be better able to inflict them, etc. Under the normative constraints justifications favored by Locke or Rousseau, it is not sufficient to maintain that the state "does it better." In addition, it is necessary to establish that the individual upon whom the sanction is being inflicted agreed or consented to the infliction of the sanction by the state. The nature and the conditions required for establishing such consent on the part of individuals are different, but this condition imposes restrictions on the agents who can punish.

State-centered justifications go further and argue that the power to punish is an agent-dependent power; only the state can punish, that is, realize the goals of punishment. State-inflicted sanctions are designed to realize goals or perform tasks that cannot, in principle, be performed successfully by private institutions or individuals. To develop a state-centered justification, it is necessary to develop a theory of punishment – a theory that will explain what is particularly valuable about punishment and, then, establish that the only agent capable of realizing this value is the state.

A useful analogy is the blood feud (Harel 2008, p. 121). Anthropologists have found that blood feuds can only be performed by male relatives of the deceased (Barmash 2005, p. 24; Miller 1983, pp. 162–168). In a blood feud, it is not the mere act of killing or the death of the member of the enemy clan that counts; it is rather the performance of the killing by an "appropriate agent." The agent killing the murderer in a blood feud is not perceived as a mere means to perform the allegedly just act of killing. Instead, it is the act of killing that provides an opportunity for the appropriate agent to act in order to redress the injustice. Even closer to our concerns here is the view of Joel Feinberg who believes that "punishment expresses the *judgment* of the community that what the criminal did was wrong" (Feinberg 1994, p. 76). Although Feinberg did not envision the possibility of privatizing punishment, it seems that he could maintain that the infliction of sanctions by non-state agents may be effective in many ways; it may deter wrongdoers, incapacitate criminals, satisfy retributivist concerns, etc., but private sanctions fail to punish as they do not express the judgment *of the community* that the act is wrong.

Punishment, under such a view, is a public manifestation of condemnation and disapprobation of the criminal deed. As Nozick argues: "[r]etributive punishment is an act of communicative behaviour" and, further, Nozick believed that retribution achieves two goals. The first is "to connect the criminal to the value qua value," and the second is to connect the wrongdoer to the value in a way "that value qua value has a significant effect in the criminal's life, as significant as his own flouting of correct values" (Nozick 1981, p. 370). The view is shared also by prominent criminal law theorists who believe criminal law can only be understood as a communicative practice (Duff 2001). Unlike deterrence, and perhaps other conventional goals of punishment, public condemnation is possible in the first place only if it emanates from an appropriate agent. If a wild dog attacks me while I am stealing my neighbor's property, it does not "punish" me as the dog did not make a judgment concerning the wrongfulness of my behavior. For similar reasons, if a child or a madman hits me while I am committing a wrong, the act does not constitute punishment. Mere pain or harm resulting from committing a wrong is not sufficient to constitute punishment; the pain or harm must result from a considered judgment made by an agent capable/authorized of making such a judgment.

More generally, condemnation/judgment of a wrongful act presupposes an agent who is in a privileged status to the one subjected to the condemnation, viz., one whose judgments concerning the appropriateness of behavior are worthy of attention or respect. The wrong agent fails to punish not because it fails to inflict harm – or even inflict harm resulting from a wrongful act – but because it cannot make the appropriate judgments. In the absence of such judgments, the mere infliction of "a sanction" amounts to an act of violence (Dorfman and Harel 2013, pp. 92–96).

To complete the argument, one needs to show that the state is the only agent which can make judgments of the relevant sort. Given certain assumptions, this challenge can be met. Arguably, the state is a legitimate authority whose judgments concerning the wrongfulness of the behavior count. Further, no other entity is capable of forming judgments of the right type. The judgments of the state may count either because its judgments are more likely to be correct or true (such that conforming to these judgments is more likely to lead agents to act in accordance with reason) (Raz 1986, chap. 3) or because its decisions reflect its will and its will has normative force, or for other reasons. In any case, one may draw the conclusion that the state is an agent that can effectively condemn certain types of behavior and make judgments with respect to them while other agents cannot.

A close reading of Kant's discussion of punishment in the *Metaphysics of Morals* establishes that Kant supported a state-centered justification for criminal sanctions. In a famous passage, Kant says:

> Even if a civil society were to be dissolved by the consent of all its members…, the last murderer remaining in prison would first have to be executed, so that each has done to him what his

> deeds deserve and blood guilt does not cling to the people for not having insisted upon this punishment; for otherwise the people can be regarded as collaborators in this public violation of justice. (Kant 1996, p. 106)

Kant insists in this passage that the last murderer has to be executed *before* the dispersion of society. But why is the execution of the murderer so urgent; why could it not be postponed? Perhaps Kant believes that an attempt to remedy the injustice by executing the murderer after the dispersion of society would fail to punish for this would constitute a private act of killing rather than a public act of execution and a private killing could not be done in the name of the people as a collectivity (Harel 2008, 122).

In examining the relations between punishment and the state, we did not distinguish among the legislative act (setting the maximum sentence or the range of permissible sentences for a wrong), the adjudicative act (inflicting a punishment for a particular wrong), and the execution of the sentence, e.g., maintaining a prison. It is not surprising that privatizing the execution of the punishment, e.g., privatizing prisons, seems the least controversial. This is so because it seems that privatizing the prisons does not really count as privatizing the punishment itself, but merely the manner or the technicalities of its infliction. Under this view, there is no reason to care whether prisons are run by public officials or by private contractors (as long as legislatures and courts are the ones who dictate what the punishment is).

This claim however is not self-evident. As the petition challenging the privatization of prisons in Israel indicated (Medina 2010), private prison wardens are not mere technocrats executing state decisions. They regularly make decisions that affect the welfare of inmates such as holding a prisoner in administrative isolation, carrying out an external examination of an inmate's naked body, and using reasonable force to carry out a search. These decisions require the exercise of judgment and, arguably, they ought to be made only by agents capable of exercising such judgments in the name of the state, namely, by public officials and not by private individuals, as only the exercise of judgment on the part of the former count as the judgments made by state.

To sum up, while the instrumentalist justifications maintain that the state ought to be in charge of the infliction of sanctions to the extent that it is capable of inflicting "appropriate" sanctions in an efficient manner, both normative constraints justifications and state-centered justifications believe that the state is uniquely placed to punish. State-centered justifications also maintain that the very value of punishment hinges on the identity of the agent inflicting it. It is not that it is impermissible for non-state agents *to punish*; it is rather that no other agent *can punish* and any attempt to punish on the part of such agents is bound to fail and constitute a mere act of violence.

Does the State Have a Duty to Punish

Section "The Justification for Public Infliction of Criminal Sanctions" explored arguments concerning the right of the state to punish and, in particular, whether and, if so, why this right is exclusively that of the state. However, this leaves open an additional central question concerning the role of the state, namely, whether the state has a (political or constitutional) duty (rather than merely a right) to punish (Hill 1999).

To say that only the state has a right to punish may seem too weak without acknowledging in addition the existence of a duty to punish on the part of the state. Can the state simply fail to criminalize murder or theft (or to refuse to punish those who commit these crimes) simply if it wishes to do so? Further, even if the state has such a duty, should the duty to criminalize be constitutionally entrenched or should the decision be left to the state? Intuitively, it seems that such decisions ought not to be left to the good will of the state. To, explore these questions, let me start with a real-life case – the constitutional decision of the German Constitutional Court concerning abortion.

In 1975, the German Constitutional Court declared that the law which allowed abortion on demand during the first trimester of pregnancy was unconstitutional as it violated Article 2 section 2 of the German Basic Law protecting the right to life (39 BVerFG 1 1975; Kommers 1985, p. 371; Lange 2011, p. 2033). The Constitutional Court emphasized that abortion is an act of killing that the law is obligated to condemn through the use of criminal law. Under this view, the state had not only the right but also the (constitutional) duty to criminalize abortion (Kommers 1985, 395). As a result of reunification, the German Constitutional Court had to address the matter again, and in its later 1993 decision, the Court reiterated its commitment to the view that abortion is indeed a violation of the right to life and that the state has an obligation to protect life, including the life of the fetus (88 BVerfGE 203). Further, the Court believed that protecting life requires also criminalizing abortion. It followed that abortion ought to remain criminal although the state could substitute "normative counseling" for criminal punishment as a way of fulfilling its obligations to protect fetuses.

The German Constitutional Court adhered to the view under which the state has a (both moral and constitutional) duty to criminalize abortion. To further investigate, the soundness of this claim assume that evidence is provided to the Bundestag convincing it that decriminalizing abortion would, as a matter of fact, reduce the rate of abortions in society and, consequently, more lives would be saved if abortions were decriminalized. On the basis of this evidence, the Bundestag concludes that while fetuses have a right to life, criminalizing abortions is detrimental to the protection of the right to life and, consequently, it declares that decriminalizing abortion is constitutional.

Such a conclusion would not be absurd; yet it is not self-evident either. Arguably, even if the state could better protect life if it decriminalized murder, it ought not to do it. State punishment is not merely an instrument to protect life, freedom of expression, etc. Protecting a right, so it could be argued, involves also public condemnation of violations of the right. Punishment inflicted by the state is as much about condemning the violation of the right to life as it is about the protection of life itself. Moreover, failure to criminalize abortion implies that the life of the fetus is "at the mercy" of the mother, and this seems wrong even under the assumption that criminalization does not reduce the number or frequency of abortions. Another case which may demonstrate the scope of the duty of the state is the case of *X & Y v. the Netherlands* (8 EHRR 235 26 March, 1985) in which the European Court of Human Rights decided that the state has a positive duty to charge criminally a person who allegedly committed rape even when the victim who was mentally disabled could not bring charges against him.

Further, it could be argued that the duty to criminalize is not merely a political duty on the part of the state; arguably it ought also to be a constitutional duty. If the state has no constitutional duty to criminalize, the life of the fetus, so it could be argued, is "at the mercy" of the legislature; it hinges on the inclinations of the legislature. If the legislature decides not to criminalize abortion, the fetus' life is at the mercy of the inclinations of the mother. Even if the legislature criminalizes abortion, the life of the fetus hinges on the inclinations of the legislature, namely, on its willingness to criminalize. Arguably, it is only a constitutional duty to criminalize that can remedy these defects.

The decision of the German Constitutional Court can be rationalized precisely on the grounds that protecting the fetus' right to life is not to be left either to the mercy of the pregnant woman or to the inclinations of the legislature. The legislature must not merely criminalize abortion; it must be constitutionally obliged to do so as it is not "up to the legislature" to make decisions concerning the life of the fetus.

More generally, in the absence of entrenching a constitutional duty to criminalize violations of basic rights, the mere willingness of a legislature to criminalize can be interpreted as grounded in its good will. In contrast, the constitutional duty to criminalize does not leave the decision to criminalize to the discretion of the legislature. Consequently, upon entrenching such a duty, citizens do not live "at the mercy of" the legislature.

Conclusion

Privatization may be desirable for many reasons. It has been evident to many that the desirability of privatization is grounded in instrumental considerations. Much of the debate concerning privatization focuses on instrumental arguments.

This entry does not urge anyone to ignore or underestimate instrumental considerations, and yet it challenges the assumption that instrumental considerations are all that matter. More specifically, at least in certain contexts, and within certain domains, the instrumental concerns may be too narrow to capture the moral complexity of the considerations at stake. The relations between the state, the criminal process, and criminal sanctions are grounded in principled legitimacy-based considerations touching upon foundational questions of political morality.

These observations are important not only in theory as privatization of different dimensions of the criminal law process is not (as illustrated above) a mere fantasy. Even if a solely privately inflicted scheme of sanctions is not a realistic option, there are current reforms or reform proposals to grant private individuals the power to inflict sanctions for wrongdoing. These proposals have often been initiated and discussed by economists, sociologists, and lawyers. This entry establishes that in addition to the important insights of social science, philosophers can and should contribute to this debate.

Overview

This entry explores the relationships between rehabilitation and punishment. It begins by unpacking the different meanings of rehabilitation and some of the major criticisms that have been leveled at rehabilitation. It then goes on to examine the different meanings and purposes of punishment and where and how rehabilitation fits amongst these meanings and purposes. The entry concludes by recognizing ways in which rehabilitation can have punishing effects and by suggesting when and under what conditions punishment is rehabilitative.

Introduction

The title of this entry may seem an odd one. For many people, punishment and rehabilitation are alternatives between which we must choose, rather than potential synonyms or alternative ways of referring to similar processes. Can punishment ever *be* rehabilitation? Don't rehabilitation's supporters tend to see offending as rooted in people's experience of social exclusion and injustice, to regard the trope of individual (criminal) responsibility (on which the legitimacy of punishment ultimately depends) as misconceived, and to stress the duty of the state somehow to fix the mess that produced crime? Punishment, at least for some rehabilitationists, seems little more than a fancy cloak to drape around the otherwise nakedly vengeful instincts of those that think (absurdly, these critics would argue) that there is something sensible, appropriate, and fair about piling hurt on hurt.

And yet, many practitioners of rehabilitation – even those sympathetic to these criticisms of punishment – hold on to a belief in the capacity of people to change themselves and their situations, to make different choices, to overcome their circumstances, and to author a different and better future. Even those who are deterministic when it came to the genesis of criminal behaviors and problems somehow seem to become believers in free will or the power of human agency (even under intense social and structural pressures) when it comes to the future prospects of people undergoing rehabilitation. Moreover, many rehabilitationists also have an acute sense of justice or injustice, reflected in their demands that the state honor its obligations to those whose adverse life experiences have proved "criminogenic."

Readers will already have noted a number of paradoxes and possible contradictions in play here, in terms of how we conceive of individual and political responsibility for crime and other social harms and of how we understand and deliver fairness and justice and in our approaches to the righting of wrongs. To try to unravel some of these threads and make sense of these questions requires an examination of the contested and multiple meanings of these two terms – rehabilitation and punishment – before we can begin to understand at least some of the potential interrelationships between them.

Which Rehabilitation

Both as set of concepts and as a set of practices, rehabilitation is a "fankle." Fankle is a Scots word that translates loosely as "tangle." The unraveling – or at least the teasing apart – of the distinct threads of a fankle is a tiresome and time-consuming job, but a necessary one, if only so that we can knot them together again properly at the end.

Most textbook discussions of rehabilitation begin with dictionary definitions. Raynor and Robinson's (2009: 2) excellent book, for example, tells us that the Oxford English Dictionary defines rehabilitation as "the action of restoring something to a previous (proper) condition or status." So, rehabilitation is (1) an action that (2) restores (3) for the better. Raynor and Robinson (2009: 3) also note that the OED's supplementary definition refers to the "restoration of a disabled person, a criminal etc., to some degree of normal life by appropriate training etc." This version adds the concepts of some (4) "normal" standard, returning to which requires (5) some form of third-party intervention.

Moving on to criminological uses of the term, Raynor and Robinson (2009) argue that, despite the frequency with which (offender) rehabilitation has been discussed in the literature (and, we might add, in policy and practice), it is rarely "unpacked" and critically examined. They provide the following example of a problematic criminological description of it:

> taking away the desire to offend, is the aim of reformist or rehabilitative punishment. The objective of reform or rehabilitation is to reintegrate the offender into society after a period of punishment, and to design the content of the punishment so as to achieve this. (Hudson 2003: 26)

As Raynor and Robinson (2009) note, this statement raises a number of issues. Firstly there seem to be at least two objectives in play here: "taking away the desire to offend" (i.e., somehow changing the offender) and reintegration into society (i.e., somehow changing his or her relationship with and status in society). But how are these two objectives related? Secondly, and more directly pertinent to this entry, it suggests two different relationships between rehabilitation and punishment; in one rehabilitation comes *after* punishment, and in another rehabilitation *shapes* (the nature of) punishment. There may be a third possibility, as suggested above in the introduction, where rehabilitation is cast as an *alternative* to punishment. Finally, this description elides the distinction between rehabilitation and reform; as we will see below, for others, these two ideas are distinct but related concepts.

In an effort to clarify some of these complexities, Raynor and Robinson (2009) go on to offer their own typology of perspectives on offender rehabilitation, examining the meanings and significance of correctional rehabilitation, rehabilitation and reform, reintegration and resettlement, and rehabilitation and the law.

Correctional rehabilitation, they argue, is concerned with effecting positive change in individuals. As such it is the model most commonly associated with treatment programs or other forms of offense- or offender-focused intervention. At its heart is the notion that many offenders can change for the better, given the right support. The idea of correction implies that the offender can and should be "normalized" or "resocialized" in line with commonly accepted (though rarely explicitly articulated) standards of behavior. Raynor and Robinson make the critical but often neglected point that correctional rehabilitation is a very broad church, one that allows for almost as wide a variety of theories and methodologies about how "correction" is to be achieved as there are theories about crime causation itself. That said, correctional rehabilitation, as its name suggests, tends to be preoccupied with *changing offenders* themselves and so is closely associated with theories and methods that explain crime and target intervention at the level of the individual.

Raynor and Robinson's (2009) discussion of *rehabilitation and reform* notes that some penal theorists and historians draw a distinction between twentieth-century "rehabilitation," which was concerned with individualistic (psychological) treatment programs to correct one's personality (or attitudes and behaviors), and "reform" which refers to an earlier preoccupation with offering opportunities for education and contemplation in support of the reform of one's moral character. As a form of shorthand, we might say that religion is to reform as the "psy" disciplines (psychiatry, psychology, and social work) are to rehabilitation.

The terms *reintegration and resettlement* (or in the USA "reentry") may involve or be connected with correctional rehabilitation, but they also extend beyond it; in a sense, they imply its objective. If correctional rehabilitation is the journey, reintegration is the implied destination. Raynor and Robinson (2009) suggest that rehabilitation must lead to and involve restoring the ex-offender's status as a citizen and renegotiating his or her access to its privileges and responsibilities. Whereas correctional rehabilitation dwells on the individual and the psychological, "reintegration and resettlement" signals the sociological aspects of rehabilitation; proponents of such an approach tend to have a sharper awareness of the social rather than the individual causes of crime and of the social rather than the individual issues at stake in desistance from crime. Moreover, rather than being a mode of punishment (or a method applied during punishment), this perspective tends to stress the need for rehabilitation to act as an antidote which seeks to address, compensate for, or seek to undo the adverse, usually unintended, collateral consequences of punishment itself. Rehabilitation in this vein is sometimes conceived a duty of the state that follows from its obligation to delimit punishment and to bring it to an end.

A natural (though again often neglected) corollary of the concern with reintegration and resettlement is a concern with *rehabilitation and the law*. Though we come to it last, the earliest use of the term rehabilitation (at least in legal or criminal justice contexts), according to Raynor and Robinson (2009), was in late seventeenth-century France where it referred to the destruction or undoing of a criminal conviction and to the deletion or expunging of the criminal record. A century or so later, Cesare Beccaria (1764/1963) reflected a similar meaning of the term in arguing for the use of punishment as a way of "requalifying individuals as... juridical subjects." In this sense, punishment itself was meant to be rehabilitative in settling the putative debt that offending created. Rehabilitation was thus an end of punishment in both senses of the word; it was its proper objective *and* its final conclusion. Rehabilitation was the restoration of citizenship, not in the de facto sociological sense discussed above but in the de jure legal sense.

Raynor and Robinson's (2009) taxonomy helps us a great deal with unraveling "the rehabilitation fankle," but there are one or two further strands that we need to identify before moving on to examine which meanings and versions of punishment might be consistent with which meanings and versions of rehabilitation.

Firstly, it is worth stressing that the meanings of rehabilitation are historically, culturally, and jurisdictionally conditioned. As we have already seen, the broadly correctional form of rehabilitation has been expressed in very different ways in different times and places. Two decades ago, Edgardo Rotman (1990), in a brilliant and brief introductory chapter to his book "Beyond Punishment," summarized the history of rehabilitation as being represented in four successive models. The first two of these – the penitentiary model and the treatment model – correspond loosely to our discussion of reform and rehabilitation above. The penitentiary was seen as a place of confinement where the sinner is given the opportunity to reflect soberly on their behavior and on how to reform themselves (note "reform" rather than "rehabilitate"), perhaps with divine help. But this idea was supplanted progressively by a more scientific or medical model in which rehabilitation was understood as a form of treatment which could correct some flaw in individuals, whether physical or psychological, thus remedying the problem of their behavior.

However, in the latter half of the twentieth century, this more medical or therapeutic version of rehabilitation was, according to Rotman, itself displaced to some extent by a shift in emphasis towards a model based on social learning in which behaviors were understood as learned responses that could be unlearned. In this context, rehabilitation was recast not as a sort of quasi-medical treatment for criminality but as the reeducation of the poorly socialized. Correctional rehabilitation's interventions may have remained individualized, but they changed to reflect new theories of crime causation and thus new forms of "treatment." This distinction between these two versions of correctional rehabilitation (treatment vs. social learning) is important, partly because, as we will see in the next section, it was one that was and is often ignored by rehabilitation's critics.

Criticisms of Rehabilitation

As Bottoms (1980) notes, in a typically erudite and compelling chapter that deals with the collapse of the rehabilitative ideal, one cause of its demise was that it came to be seen as being theoretically faulty. It misconstrued the causes of crime as individual when they were coming to be understood as being principally social and structural, and it misconstrued the nature of crime, failing to recognize the ways in which crime is itself socially constructed. Moreover, rehabilitative practices had begun to be exposed as being systematically discriminatory, targeting coercive interventions on the most poor and disadvantaged people in society. Rehabilitation was also coming to be seen as being inconsistent with justice itself because judgments about liberty had come to be unduly influenced by dubious and subjective professional judgments hidden from or impenetrable to the offender. Through the development of the "psy" disciplines, experts emerged with the supposed capacity to "diagnose" what was wrong with the offender, and the offender was cast as a victim of his or her lack of insight. By implication, unless and until the offender was "corrected" by the expert, he or she could not be treated as a subject. It was argued that rehabilitation faced an associated and fundamental moral problem rooted in its attempts to (psychologically) coerce people to change. Finally, at the time when Bottoms was writing, the empirical evidence seemed to suggest that, despite its scientific pretensions, rehabilitation did not seem to work.

Powerful though it is, there are flaws in this critique. Crucially, emerging evidence about "what works?" played a vital role in challenging the last point; there is now an evidence base for rehabilitation, (McNeill, Raynor and Trotter 2010). But that evidence base, in and of itself, does not address the other four criticisms which I will label the problems of *crime theory*, of *rehabilitation and injustice*, of *dubious expertise*, and of *coerced correction*. Contemporary rehabilitation theories perhaps have more in common with a social learning or social psychological than a medicalized version of correctional rehabilitation. But, even if rehabilitation is not now based on a strictly medical model, the full force of Bottoms' (1980) criticisms is only partly deflected, and in this short entry, these criticisms can be discussed only very briefly.

While contemporary correctional rehabilitation's underlying *crime theories* avoid the pathologizing traps of individualistic positivism, they still have to engage somehow with the problem that crime is (at least in part) a social construct. We do not choose to pursue all interpersonal or social harms through criminalization; the explanandum of crime theories is itself socially conditioned. That single insight has profound consequences. It affects and infuses the normative contexts of rehabilitative work (including raising difficult questions about who and what gets selected for penal "correction" and who and what does not), and it creates a series of complex methodological quandaries about how to judge rehabilitation's effectiveness (see McNeill 2012).

The problem of *rehabilitation and injustice*, or of rehabilitation's place in or association with discriminatory justice practices, remains a challenging one, though it is hardly a criticism that applies *only* to rehabilitation and not to other criminal justice practices. That said, the problem for rehabilitation is not just systematic (if unintended) biases in terms of who gets selected for "correction" of which sorts and who gets defined as "incorrigible" but also a more technical problem of the extent to which rehabilitation's resources (principally assessment tools and interventions approaches) are sufficiently sensitive to, for example, gender differences and cultural diversity. Significant though these problems are, they are problems about the proper administration of rehabilitation rather than the concept itself.

The problem of *dubious expertise* is only partly resolved by the development of a more robust evidence base for rehabilitation. While it is true that contemporary approaches, perhaps to varying degrees, tend to formally recognize the need to treat people as active subjects in their own rehabilitation (and not simply as the passive objects of expert intervention), there remains considerable force in critiques both of the professional power of the "psy" disciplines and, more specifically, of the increasing exercise of that power not in "treatment" or "therapeutic" decisions but in influencing decisions about justice itself, specifically in relation to sentencing or release decision making. These problems will be discussed below.

Of course, the enduring problem of *coerced correction* is closely related to that of dubious expertise; coercion is a problem exacerbated in systems where increasing confidence in rehabilitation's effectiveness has coincided with the development of a "toughening up" of penal policy. One apparently minor aspect of this conjunction in England and Wales was the withdrawal of any requirement for consent to accredited program conditions within community sentences. These programs therefore involve rehabilitative treatment without consent; a development that seems to have come to pass without much critique from psychologists whose ethical standards it might seem to compromise. Though it might be said that all punishment is coercive, coercion seems to be a particular problem for correctional rehabilitation, since it seeks to change the individual rather than simply to restrain, confine, or otherwise punish him or her. That suggests a particular form of intrusion into the inner world, even the identity of the subject, in respect of which coercion raises particular moral problems.

Fortunately, Bottoms (1980) also provided some suggestions about how we might best respond to these problems. Reflecting the pessimism of the times, four of his five options imply or require a shift away from rehabilitation, at least as traditionally conceived. However, he also argued that rehabilitation could be rescued through its own correction, that is, by attending more carefully to questions of consent, by committing adequate resources to make it more likely to be effective, and by conducting our rehabilitative activities in ways which are more respectful of liberty. More specifically, the intrusions that rehabilitation imposes on the offender, he suggests, should never be greater than is merited by their offending behavior, placing rehabilitative requirements within the envelope of proportionality.

There is no space here to properly review the renaissance of rehabilitation in the 1980s and 1990s (see Raynor and Robinson 2009; Robinson 2008). However, leaving aside the better known story of the advancement of the evidence base, it is worth recalling that there was also, in the 1980s, a brief flurry of writing about new normative or philosophical approaches to rehabilitation, including Rotman's (1990) work. The "new rehabilitationists" (see Lewis 2005), much as Bottoms suggested, proposed four principles to guide rights-based rehabilitation: the assertion of the duty of the State to provide for rehabilitation, the establishment of proportional limits on the intrusions opposed, the principle of maximizing choice and voluntarism in the process, and a commitment to using prison as a measure of last resort.

However, as Robinson (2008) has cogently argued, in policy and practice (in England and Wales at least), what emerged was not a more rights-based but a more profoundly utilitarian and correctional form of rehabilitation increasingly influenced by the preoccupation with public protection and risk reduction. Under this paradigm, probation officers were required to intervene with or treat the offender to reduce re-offending and to protect the public. What is critical about this shift in focus was that the "client" or intended beneficiary of rehabilitative work is no longer the offender. Rather probation is trying to change offenders to protect the law-abiding. The offender becomes less and less an active participant and more and more an object to be assessed through technologies applied by professionals and compulsorily engaged in structured programs and offender management processes as required elements of legal orders imposed, as already noted, irrespective of consent.

These developments in the relationship between correctional rehabilitation and those "offenders" – *with whom* it engages or, worse, *on whom* it operates – are a particularly important one. The shift from *subject in* to *object of* correctional rehabilitation implies a more coercive and utilitarian conception of rehabilitation: one which leaves the individual liberties and rights of the offender much more vulnerable and one which opens up new prospects of abuses of the "power to punish," justified in the putative public interest. This form of rehabilitation may still be a process of intervention aimed at some public good, but returning to Raynor and Robinson's (2009) initial definitions, the blunting both of its restorative intent and of its commitment to the offender's interests (alongside others' interests), as well as its willingness to impose (rather than renegotiate) "norms" on objectified offenders, represents major causes for concern.

Which Punishment

Of course, it is impossible to make much sense of the relationships between rehabilitation and punishment just by analyzing rehabilitation – notions of punishment must be examined too. Conceptually and practically, punishment is arguably even more "fankled" than rehabilitation. In part, as Hudson's (2003) excellent introductory text both argues and demonstrates, this is because punishment is a quintessentially interdisciplinary subject that compels and requires criminological, legal, philosophical, and sociological scrutiny, as well as raising fundamental political and practical questions.

Tonry's (2006) commanding and authoritative overview of the purposes and functions of sentencing provides a neat framework for analyzing punishment, distinguishing between sentencing's purposes or normative functions (i.e., its justifications), its primary functions (these being the proper distribution of punishment; the prevention of crime; and the communication of threat, censure, and of social norms), its ancillary functions (in contributing to the management of an efficient and effective justice system and in securing legitimacy and public confidence), and its latent functions (the ways in which it reflects self-interest, ideology, and partisanship and how and what it communicates informally). Though he does not explain his framework in these terms, we might suggest that, with notable exceptions, philosophers and jurists tend to study and discuss the normative functions and primary purposes of sentencing, criminologists tend to examine its ancillary functions, and sociologists tend to study its latent functions. Criminological and sociological analyses will be discussed briefly in the next section. For present purposes, it is perhaps most important to clarify firstly where rehabilitation fits amongst the normative justifications of punishment.

As Tonry (2006: 16) argues:

> The overriding normative function of a sentencing system in a society committed to individual liberty, procedural fairness, and limited powers of government is to assure that individuals convicted of crimes receives the sentences that, in principle, they should

At first sight, this statement seems a little vacuous or circular – the point of doing justice is to do justice – but, at least in liberal democracies, it is vital to surface this too easily taken-for-granted assumption. If punishment involves the state in imposing harms on its citizens, then the process by which this is done must be carefully bounded and governed. But of course what is in and "out of bounds" in sentencing depends to some extent on the normative principles that govern it.

Tonry (2006) goes on to expose the enduring tensions between Kantian and utilitarian approaches to punishment. The former are essentially retrospective and concerned with the delivery of retribution or "just deserts," in proportion to the severity of the offense and the blameworthiness of the offender. The latter are essentially prospective and concerned with the delivery of preventive effects; as we noted above, these are increasingly cast as the protection of the public and the reduction of offending and re-offending. These effects can be advanced through deterrence, incapacitation, or rehabilitation. Tonry (2006: 18) notes that there "are good reasons why no relatively philosophically pure sentencing system [on either model] exists or has been seriously proposed at a policy level." He goes on to illustrate the practical problems of both Kantian and utilitarian approaches and reviews a range of attempts to construct credible hybrid theories. Whatever the conceptual merits of these theories however, there is no doubt that in practice hybrid systems abound, though this is not to say that these systems are clearly articulated, coherent, or defensible. One common feature of most hybrid systems is a commitment to some form of "limiting retributivism," in which culpability sets upper limits for the severity of any punishment to be imposed. The intrusions of punishment, in other words, must never be greater than are merited by the offender's culpability (and perhaps by the gravity of the offense).

As already noted, this limiting principle surfaced in the work of the new rehabilitationists of the 1980s and 1990s, requiring the intrusions of rehabilitation to be bounded by proportionality. Though this does represent a significant and suitable response to some of the criticisms of rehabilitation discussed above, for advocates and practitioners of rehabilitation, the direct engagement with questions of justice and deserts that it entails has often been uncomfortable. Historically, at least in some jurisdictions, probation and criminal justice social workers have often considered themselves as providers and advocates of (usually rehabilitative) *alternatives to punishment*, rather than as providers and advocates of *alternative punishments*. Somehow the notion of punishing, as opposed to supporting, supervising, treating, or helping – or even challenging and confronting – has seemed inimical to the ethos, values, and traditions of probation and social work.

More recently, a different approach to the justification of punishment has perhaps offered the prospect of resolving some of these tensions and of conceiving of punishment *as* rehabilitation (Duff 2005). The penal philosopher Antony Duff – whose theory of punishment as communication has been highly influential – has argued convincingly that we can and should distinguish between "constructive punishment" and "merely punitive punishment" (Duff 2003). Constructive punishment can and does involve the intentional infliction of pains, but only insofar as this is an inevitable (and intended) consequence of "bringing offenders to face up to the effects and implications of their crimes, to rehabilitate them and to secure... reparation and reconciliation" (Duff 2003: 181). Duff (2005) is not arguing for rehabilitation as moral education; to do so would infantilize offenders as well as calling into question their culpability for their crimes. Rather than restoring or correcting a deficit *in the offender*, moral rehabilitation aims to repair a breach *in the relationships* between the offender, the victim, and the community that the offense has created. Repairing the breach is principally the offender's responsibility; the starting point is a sincere apology which represents the recognition of the wrong done and the relational breach that it has created. But in most criminal cases an oral apology – however sincere – will not be enough:

> . . .something more is required – something that will make more forceful the apology that I owe. . .; something that will show that I am taking seriously the need to avoid such wrongs in future, and to reform myself and my conduct. Two elements of such moral rehabilitation might be, first, undertaking some burdensome task to express my apologetic repentance. . .; second, taking steps to address the causes or sources of my wrongdoing, and perhaps seeking help – whether informal or formal – in dealing with them. (Duff 2005: 19)

Duff (2005) admits that he is speaking of criminal justice as it could be, or as it should be, rather than as it is. Nonetheless, he sees in some contemporary practices at least the opportunity for this kind of penal communication and for moral rehabilitation to take place:

> The burden that the offender is required to undertake, as his punishment, can be seen as constituting a formal, and forceful, apology to his victim and to the wider community. The apology has something of the quality of a public ritual rather than of a sincere expression of personal feelings, though we may hope that it will become sincere; but it serves to make clear to the offender the wrong that he has done, and for which he owes and is required to offer this apology, and to make clear to the victim our shared recognition of that wrong. Furthermore, a probation order involves, as probation officers often put it, an attempt to. . . help the offender to confront the character and implications of his crime, and to find ways of avoiding repeating it, partly by programmes that seek to address offending behavior and its causes: by undertaking such programmes the offender is also making apologetic reparation for his crime. (Duff 2005: 19)

Duff's work also helps with a second problem, already referred to above, since he recognizes that where social injustice is implicated in the genesis of offending, the infliction of punishment (even constructive punishment) by the state is rendered morally problematic. The state itself can be seen as complicit in the offending through having failed in its prior duties to the "offender," for example, as is so often the case, where the offender was once a child in the care of the state. For this reason, Duff suggests that probation officers or social workers should play a pivotal role in mediating between the offender and the wider polity, holding each one to account on behalf of the other. Here, Raynor and Robinson's (2009) discussion of the relationships between reintegration, resettlement, and rehabilitation is relevant – the rehabilitation worker's attempt to advocate for the ex-offender and to secure access (perhaps for the first time) to the full rights of citizenship acts as the counterbalance to direct work with the offender to invite and support their moral rehabilitation. This discomfiting, mediating space is one which many probation and social workers will recognize that they occupy and through which, with or without official or public support, they seek to promote social justice within criminal justice.

There are other conceptual and empirical links that could be developed here, but to which we can only briefly refer. Duff's work also resonates with the rise of reparation or paying back as an important justification of punishment (see Robinson et al. forthcoming). Intriguingly, there is some empirical evidence that "making good" is important for many of those desisting from crime (Maruna 2001). In a sense, the relevance in this body of evidence of the concept of "generativity" – referring to the human need to make some positive contribution, often to the next generation – hints at the links between paying back and paying forward, in the sense of making something good out of a damaged and damaging past. Bazemore's (1998) work on "earned redemption" examines more directly the tensions and synergies between reform and reparation, and the broader movement around restorative justice (Johnstone and Van Ness 2007) provides possible normative frameworks within which to further debate and develop these tensions and synergies.

When Rehabilitation Is Punishment

Before trying to reach some conclusions about the relationships between rehabilitation and punishment, it is necessary to turn the entry's title around and explore "when rehabilitation is punishment" or perhaps to ask more directly "does rehabilitation hurt?"

Duff's answer to the question is a qualified "yes." There is no sincere apology and therefore no real moral rehabilitation, without at least the pain of confronting and admitting the wrong and perhaps also the incidental pains of the work required to repair the breach in relationships. But beyond this principled position, there is also a growing body of empirical scholarship which shows that rehabilitation (of the therapeutic or correctional sort) also hurts in other ways, some of which may be less productive and less defensible than the pains Duff has in mind.

There is, of course, an extensive body of scholarship, in the tradition of Gresham 1958) seminal work, on the pains of imprisonment. More recent iterations of this literature point not just to the peculiar pains of life in "supermax" conditions (King 2005) but also to the pains and harms of mass incarceration itself (Haney 2005) and to the pains and harms suffered by prisoners' partners and families through "secondary prisonization" (Comfort 2007).

Perhaps more directly pertinent here are the pains of penal rehabilitation in its current risk-focused guise. Thus, for example, there is some evidence of burgeoning resentment amongst English prisoners towards what apparently seems to them to be the capricious and illegitimate exercise of "soft power" by prison psychologists involved in key decisions about prisoner progression or release (Crewe 2009). In similar vein, Lacombe's (2008) ethnographic study of prison-based sex offender programs reveals the ways in which risk-based rehabilitation invites sex offenders to contort their perceptions and presentations of self in line with the requirements of the particular program or process to which they are subject. Cox's (2012) compelling ethnographic analysis of the pains of youth imprisonment reveals a similar picture.

These pains of risk-based rehabilitation extend beyond the prison too. The traditional absence of punitive intent in probation or criminal justice social work (noted above) does not necessarily entail an absence of "penal bite," at least if studies of those subject to community supervision are to be taken seriously. For example, researchers at the RAND Corporation in the USA found that there are intermediate sanctions which surveyed prisoners equate with prison in terms of punitiveness. For some individuals, intensive forms of probation "may actually be the more dreaded penalty" (Petersilia and Deschenes 1994: 306). More recently, Durnescu (2011) has specifically explored the "pains of probation" as experienced in Romania. Alongside deprivations of time and the other practical and financial costs of compliance, and limitations on their autonomy and privacy, probationers also reported the pain of the "forced return to the offense" and the pain of a life lived "under a constant threat." The threat in question in Durnescu's (2011) study was that of breach or revocation and with it further punishment, but the works referred to in the last paragraph also point to the threat of failing to persuade a probation officer, a psychologist, or some other professional that one's "riskiness" can be and is being properly addressed and managed.

In one sense, there is little that is truly novel in this. For a prisoner of the Eastern State Penitentiary in the nineteenth century, placed in silent and solitary confinement in the hope that he or she would repent and make his or her peace with his or her Maker, the pains of penitentiary reform were doubtless profound. His or her project of "coercive soul transformation" may have been designed and delivered somewhat differently than that directed at the late-modern risk-bearing prisoner or probationer – but both are subjected to disciplinary regimes. But what may be peculiarly demanding for the late-modern penal subject is that, rather than being left to deal, before God, with his own sinfulness and redemption, he or she is compelled to *display* the malleability of his or her riskiness and to *perform* the reduction and the manageability of his or her riskiness. At least in some risk-based systems, it is the credibility of this performance which will determine progression in and release from punishment. In those circumstances, rehabilitation is both disciplinary and punishing in a particularly potent way see (Crewe 2012).

Perhaps presaging these developments, Edgardo Rotman (1994), whose work we referred to above, draws an important distinction between anthropocentric and authoritarian rehabilitation:

> The authoritarian model of rehabilitation is really only a subtler version of the old repressive model, seeking compliance by means of intimidation and coercion. Rehabilitation in this sense is essentially a technical device to mould the offender and ensure conformity to a predesigned pattern of thought and behaviour... The anthropocentric or humanistic model of rehabilitation, on the other hand, grants primacy to the actual human being rather than metaphysical fixations or ideologies, which long served to justify the oppressive intervention of the state. Client centred and basically voluntary, such rehabilitation is conceived more as a right of the citizen than as a privilege of the state. A humanistic public policy regarding crime implies the idea of human perfectibility, which at the level of rehabilitation includes not only the offenders themselves, but also the society that bred them and the institutions and persons involved in their treatment. (Rotman 1994: 292)

This distinction, and more specifically its implication that the person engaged in rehabilitation must be treated as a moral subject and not as a material object to be manipulated or adjusted in the interests of others, seems central to many of the claims that can be made for and against rehabilitation – and to the question of its relationships with punishment.

Conclusion: When Is Punishment Rehabilitation

Returning finally to Raynor and Robinson's (2009) discussion of rehabilitation reviewed at the outset of this entry, it is now possible to discern four main forms or meanings of rehabilitation. In a recent paper, McNeill (2012) has called these psychological, judicial, social, and moral rehabilitation. These are the four strands of rehabilitation that must be "de-fankled" in order to analyze their interrelationships and mutual dependencies.

Psychological rehabilitation means essentially what Raynor and Robinson (2009) refer to as correctional rehabilitation: that which seeks to somehow change or restore the offender, to develop new skills or abilities, and to address and resolve deficits or problems. A better, less loaded term, might be "personal rehabilitation," since this need not imply that any specific disciplinary perspective or set of techniques is implied in this project of personal change.

The second form of rehabilitation concerns the practical expression of Beccaria's concern with the requalification of citizens; this is *judicial rehabilitation* – which raises questions of when, how, and to what extent a criminal record and the formal stigma that it represents can ever be set aside, sealed, or surpassed. Maruna (2011) has recently argued cogently that efforts to sponsor rehabilitation and reform must address the collateral consequences of conviction – mostly notably its stigmatizing and exclusionary effects – or be doomed to fail. No amount of correctional or psychological or personal rehabilitation and no amount of supporting offenders to change themselves can be sufficient to the tasks and challenges of reintegration, resettlement, and reentry, if legal and practical barriers are left in place.

But these barriers are not just legal – they are moral and social too. A solely correctional, psychological, or personal conception of rehabilitation is inadequate to the moral and social offense that crime represents. In simple terms, doing something for or to or (better) with the offender, even something that aims at somehow changing them so as to reduce future victimization, fails to engage with other key aspects of dispensing justice. Perhaps most importantly in moral terms, psychological rehabilitation offers no moral redress per se; it operates only on the individual "offender," not on the conflict itself and not on the victim or the community. In Duff's (2005) terms, it leaves the relational breach unrepaired. Critically, reparation – and reparative work in particular – seems capable of fulfilling this function in ways in which psychological rehabilitation in and of itself cannot, perhaps principally because reparation seems better able to convey (not least visibly) that redress is being actively provided. Though, as Duff (2005) reminds us, willingly undergoing psychological rehabilitation can convey the sincerity of the offender's apology and of his or her desire to change, it is more typically a professionalized, private, and secretive business, and not one that is explicitly bound into a process of moral rehabilitation.

Reparation perhaps speaks to the insistence that moral demands have to be satisfied, and moral communication secured, before *moral rehabilitation* can be recognized (Duff 2001; 2003, 2005). In simple terms, an offender has to "pay back" or to "make good" before he or she can "trade up" to a restored social position as a citizen of good character. As Bazemore (1998) has argued, redemption needs to be earned. This is not necessarily bad news for rehabilitation; as the Scottish Prison Commission (2008, para 33) noted, "one of the best ways for offenders to pay back is by turning their lives around." But it does mean that rehabilitation theories and practices need to engage much more explicitly than hitherto with questions of justice and reparation.

Ultimately, even where psychological or personal issues are tackled, legal requalification is confirmed, and moral debts are settled, the question of "social rehabilitation" remains. In European jurisprudence, the concept of social rehabilitation entails both the restoration of the citizen's formal social status and the availability of the personal and social means to do so (Van Zyl Smit and Snacken 2009). But social rehabilitation can also be taken to imply something that is broader, deeper, and more subjective, specifically, the informal social recognition and acceptance of the reformed ex-offender. This, rather than the advancement of the "science" of correctional rehabilitation, is perhaps the ultimate problem for rehabilitation today in practice.

Ultimately, as Fig. 1 above illustrates, this entry has tried to disentangle rehabilitation and instead to show how its four forms might, in fact, constitute not a Scots "fankle," but a kind of Celtic knot; one that weaves together these four strands and reveals their interdependencies. "Constructive punishment," to use Duff's term, can be rehabilitative; it should be rehabilitative; it must be rehabilitative. But it can only work to prevent crime if it also works to deliver justice, and that requires attention to all four strands.

Quantile Regression Models to Analyze Experimental Data

Chester L. Britt
School of Criminology and Criminal Justice,
Northeastern University, Boston, MA, USA

Distributional analysis

Overview

The typical analysis of experimental or quasi-experimental data relies on analysis of variance (ANOVA) and ordinary least squares (OLS) regression techniques to test for differences in mean levels of an outcome or dependent variable. These models assume that cases within each treatment or control group are normally distributed and that the variance of the dependent variable is constant across groups, which then allows for a straightforward comparison of means across groups to test whether there is an effect of the treatment. In the study of crime and criminal justice, there are many applications where data are not normally distributed or do not have constant variance across groups. This is not surprising, since many of the outcome measures criminologists study – number of arrests, crime rates, bail setting, and length of prison sentence – have a high degree of positive skew. It is unlikely to find that these measures are then somehow normally distributed in experimental or quasi-experimental data, even following the use of transformations, such as the natural logarithm, which are intended to reduce the skew. All these raise concerns about the use of standard ANOVA and OLS regression models.

An ample body of research has indicated that mild to moderate violations of the assumptions of ANOVA and OLS regression models will not typically alter main findings, but authors will often insert numerous caveats about the potential volatility of their statistical results, in light of these assumption violations. Quantile regression models represent an interesting contrast to the use of ANOVA and least squares regression models, since quantile regression models are not influenced by extreme values or highly skewed distributions and analyze the full distribution of the dependent variable. Where quantile regression models may be particularly useful is in picking up treatment effects in the tails of the

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,

distribution of the dependent variable. One of the frustrations commonly echoed in the conducting of experiments in criminal justice settings is the failure of treatment effects to achieve statistical significance. Quantile regression models highlight the possibility that the lack of a statistically significant effect may be limited to the mean or to a fixed range of the dependent variable. More importantly, it is possible that the treatment effect may operate differentially at the 10*th* percentile, the median (50*th* percentile), and the 90*th* percentile.

Quantile regression models represent a specific type of distributional analysis, from a much broader set of methods. In general, distributional methods offer an alternative framework for analysis that allows the researcher to assess whether the effects of independent variables on the dependent variable are constant across the distribution of the dependent variable. In roughly the last 10 to 15 years, there has been rapid growth in the availability and use of various distributional methods, particularly in research on the differential effects of background characteristics, such as education, on income and wealth (see, e.g., Buchinsky 1998; Handcock and Morris 1999). Included in the distributional methods framework are parametric quantile regression models that permit estimation of unique effects of the independent variables at any specified point in the distribution of the dependent variable. The primary purpose of this entry is to illustrate the application and interpretation of quantile regression techniques to the analysis of experimental data. As shown below, quantile regression techniques offer the potential for new findings regarding the variability of effects of treatment conditions across the distribution of the dependent variable.

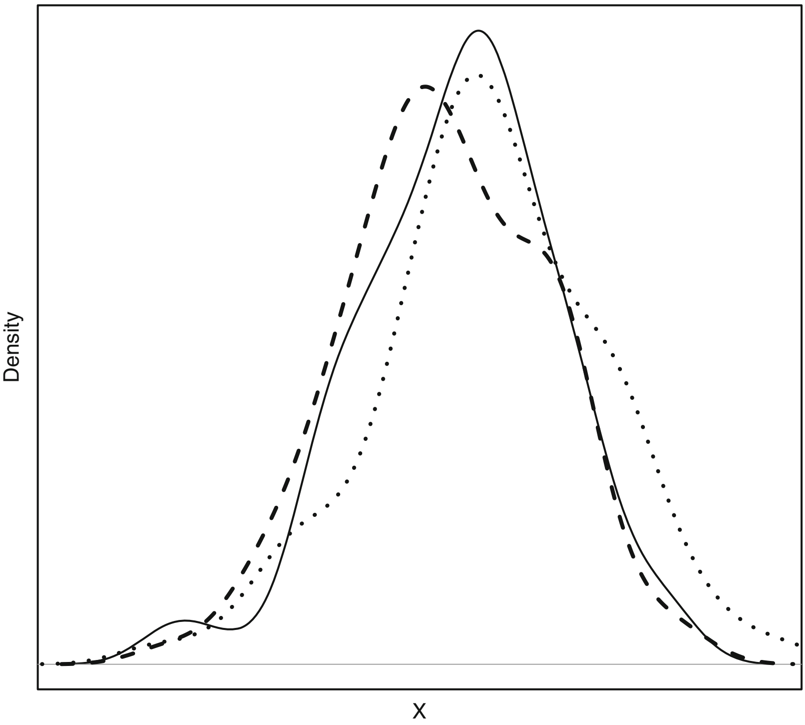
Issues with Common Approaches to Analyzing Experimental Data

Standard practice for the analysis of experimental data, where there has been random assignment of cases to a control group and one or more treatment groups, has been to test for differences in group means. In the case of one control group and one treatment group, this can be accomplished with a simple *t*-test. For situations involving random assignment of cases to three or more groups, a one-way ANOVA model will serve a similar purpose: Test for differences in group means to determine whether the treatment had an effect. For those situations where the control group may have been sampled at a different location or point in time (i.e., a quasi-experimental design) or the researcher is interested in examining the effects of other case characteristics in addition to experimental conditions, OLS regression (or ANCOVA) models may be used to examine the effect of the experimental conditions while also statistically controlling for the effects of these other case characteristics on the outcome measure. Regardless of which approach is used, however, the analyst assumes that the distribution of cases within each group is normal with constant variance.

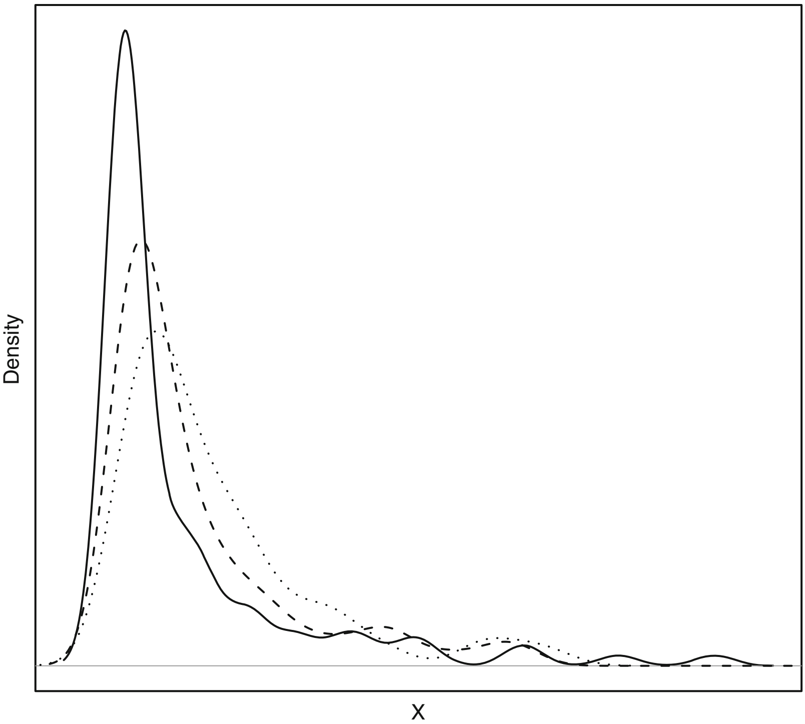
Figure 1 presents the density plots for three hypothetical groups (of 100 cases each) – one control group and two treatment groups – that meet the assumptions of an ANOVA model. Since the observations are normally distributed within each group and have approximately the same variance, the computation of mean differences using a one-way ANOVA would be straightforward.

In contrast, Fig. 2 presents the density plots for another three groups that have the same means as in Fig. 1, but the distribution of cases within each group shows a high degree of positive skew. The general shape of the plots in Fig. 2 is similar to many of the measures of interest in criminology and criminal justice, such as, self-reported delinquency and length of prison sentence. The use of ANOVA for the data as portrayed in Fig. 2 would be problematic, given the non-normal and highly skewed distribution of cases across the three groups.

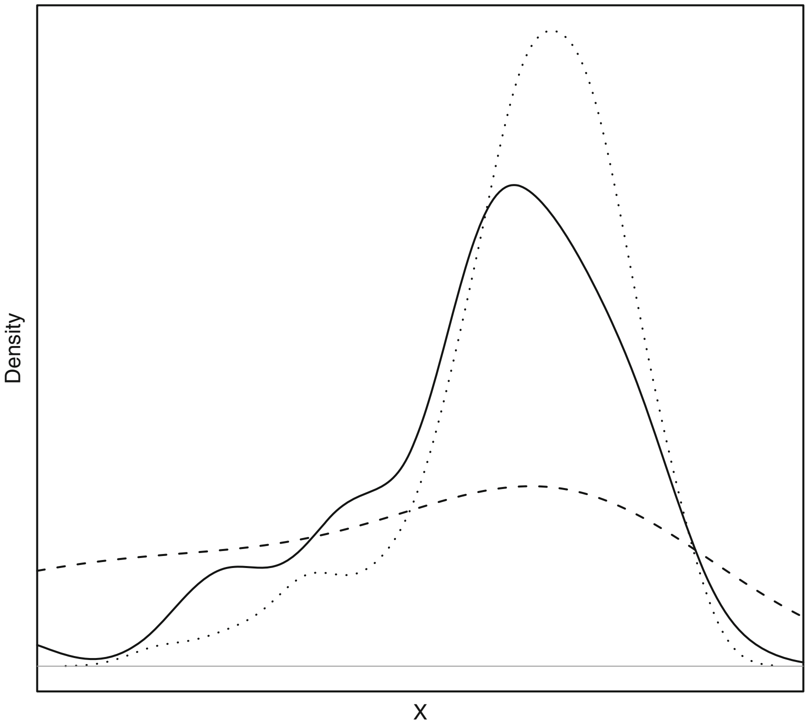
As noted above, one of the ways of attempting to address non-normal distributions like those in Fig. 2 is to transform the data, say, by taking the natural logarithm of the original value. Figure 3 presents the density plots for the three groups in Fig. 2 after taking the natural logarithm. Although the transformed distributions are less skewed, they are still non-normal and show the spread (variance) of cases to be far from similar.



Quantile Regression Models to Analyze Experimental Data, Fig. 1 Hypothetical normal curves



Quantile Regression Models to Analyze Experimental Data, Fig. 2 Hypothetical skewed distributions



Quantile Regression Models to Analyze Experimental Data, Fig. 3 Hypothetical skewed distributions: natural log

We can see from the plots in Figs. 2 and 3 that there are important differences in the outcome measure across the three groups that would not be reflected in the test for mean differences. Consequently, when looking at the full distribution of the outcome variable, we may find important differences that are obscured by looking only at the means for each group. For example, we can see that the tails of the distributions in Figs. 2 and 3 are different, but we are unable to say how different. It is this kind of question for which quantile regression models are particularly well suited: Do the groups differ at the median? at the 25*th* percentile? at the 90*th* percentile?Are these differences statistically meaningful? How do other covariates affect these apparent differences?

Fundamentals of Quantile Regression Models

Quantile regression models were initially proposed by Koenker and Bassett (1978) as a method of robust regression that would account for a non-normal distribution of error terms and as a test for heteroskedastic error terms (see also, Gilchrist 2000; Hao and Naiman 2007; Koenker and Bassett 1982; Koenker 2005). (A quantile refers to a percentile in the distribution of a variable – a quantile of 0.25, for example, would refer to the same point in a distribution as the 25*th* percentile and the median would be represented by a quantile of 0.50.) More recently, quantile regression models have been used to study income inequality (Buchinsky 1994, 1998; Handcock and Morris 1999; Mello and Perrelli 2003; Miller 2005), earnings (Eide and Showalter 1999; Eide et al. 2002; Mora and Davila 2006; Walker 2000), and wealth (Conley and Galenson 1998; Walker 2000) distributions. In criminology, Britt (2009) has shown how this model can be used to study sentence length decisions. In cases where there may be a substantial number of zeros on the dependent variable – representing censoring of the dependent variable – quantile regression models also allow for unbiased estimates of the effects of the independent variables on the dependent variable at higher quantiles, where the influence of the zeros will be minimal (Powell 1984, 1986). For example, sentencing researchers are often confronted with offenders who are not incarcerated and are effectively a "0" on the dependent variable and then excluded from further analysis. Quantile regression techniques could be used to address this concern without relying on various sample selection models that may be more or less appropriate for the analysis of sentencing decisions (Bushway et al. 2007).

The Statistical Model

Koenker and Hallock (2001) described the estimation of the coefficients of a quantile regression model by explaining how it could be reduced to an optimization problem (for detailed descriptions, see Koenker (2005) and Koenker and Bassett (1978)). At the heart of the optimization problem is the minimization of asymmetrically weighted absolute residuals. By asymmetrically weighted residuals, they mean assigning different weights to positive and negative residuals. This results in the following minimization equation for unconditional quantiles:

$$\min_{\xi \in \Re} \sum_{i=1}^{n} \varrho_\tau (y_i - \xi),$$

where $\varrho_\tau(\cdot)$ is the absolute value function that gives the τth sample quantile, y_i is the observed value of the dependent variable, and ξ is the predicted value.

To provide a point of comparison, least squares regression can be described in similar terms as minimizing the following equation:

$$\min_{\mu \in \Re} \sum_{i=1}^{n} (y_i - \mu)^2$$

to obtain an unconditional population mean, $\mu = E(Y)$. By replacing μ with a parametric function $\mu(x,\beta)$ (McCullagh and Nelder 1989), we obtain the conditional mean of Y (i.e., E(Y | x)) by minimizing

$$\min_{\mu \in \Re} \sum_{i=1}^{n} (y_i - \mu(x, \beta))^2.$$

For quantile regression, the same type of progression is used to estimate the conditional quantile by replacing ξ with a parametric function $\xi(x, \beta)$ and specifying τ (the quantile). Thus, if we wanted to estimate the conditional median function, we would set $\tau = 0.5$ (i.e., the 50*th* percentile) and minimize the function to obtain parameter estimates for the effects of x on y at the median. To obtain other conditional quantiles, we simply replace the value of τ and minimize

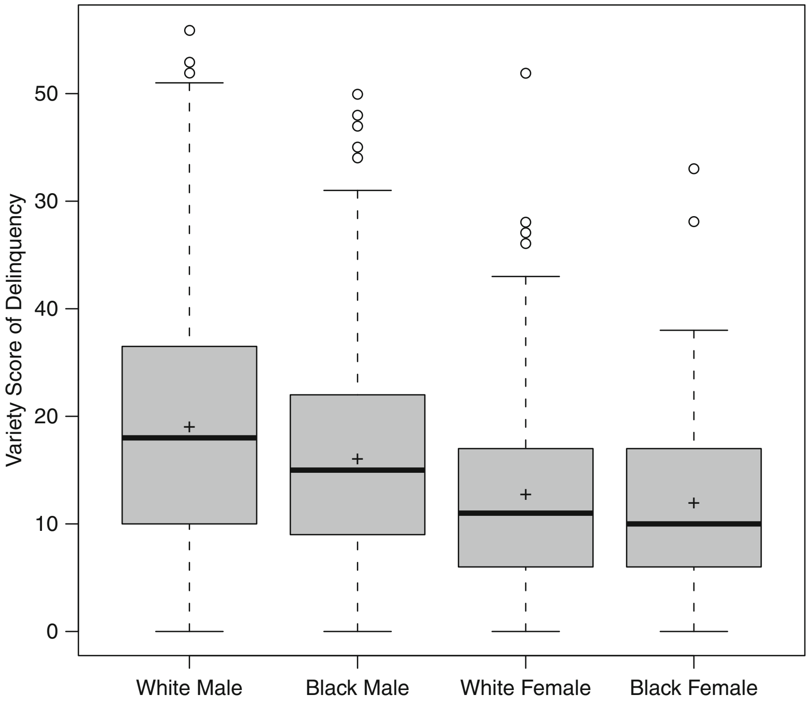
$$\min_{\xi \in \Re} \sum_{i=1}^{n} \varrho_\tau (y_i - \xi(x, \beta)).$$

Interpretation of the Coefficients

In general, the coefficients from an OLS regression model may be interpreted as the expected change in the conditional mean of the dependent variable, based on a unit change in the independent variable. The coefficients from a quantile regression model may be interpreted in a similar manner, with a key difference being the coefficients from a quantile regression model represent the effect of a unit change in the independent variable at some defined point of the conditional distribution of the dependent variable (i.e., the quantile). For example, if we had set $\tau = 0.5$ – the median of the distribution of the dependent variable – then we would interpret the coefficient as the change in the conditional median of the dependent variable based on a unit change in the independent variable. Similarly, if $\tau = 0.75$, then we would interpret the coefficient as the change in the conditional 0.75 quantile (75*th* percentile), given a unit change in the independent variable.

Quantile regression coefficients permit an examination of how or whether the effects of the independent variables change at different points of the distribution of the dependent variable. When the dependent variable has a distribution that is highly skewed, such as income, earnings, self-reported crime, and sentence lengths for convicted offenders, it is possible for the independent variables to have differential effects on the dependent variable that are conditional on a designated point of the distribution of the dependent variable.

To illustrate more directly the interpretation of quantile regression coefficients, Fig. 4 presents boxplots of a measure of self-reported delinquency



Quantile Regression Models to Analyze Experimental Data, Fig. 4 Seattle Youth Study: number of different self-reported delinquent acts by sex and race

(number of different types of delinquency) by sex and race for the sample of youth who participated in the Seattle Youth Study (Hindelang et al. 1981), which is described in more detail below. Each gray box represents the interquartile range – the range from the 25*th* percentile (lower end of the gray box) to the 75*th* percentile (upper end of the gray box). The median is represented by the horizontal line inside the gray box, while the mean for each group is represented by the + symbol. The lines extending from the gray box represent what are variably referred to as the "fence" or "whiskers" of the plot. The limits – the fence – represent 1.5 times the interquartile range. The circles appearing beyond the fence represent relatively extreme values and, in some contexts, may be treated as potential outliers. Many statistics texts contain material on the creation and interpretation of boxplots (e.g., Fox 2008). For a comprehensive treatment of boxplots, see Tukey (1977).

The interquartile range highlights some of the potential differences and similarities across the four groups, indicating a larger spread of cases for both groups of males and more compressed distributions for the two groups of females. At the 0.25 quantile (lower end of the gray box), the differences across sex start to become more apparent, where white males and black males are at 10 and 9 different delinquent acts, respectively, while both groups of females are at 6 different delinquent acts. At the median (horizontal line inside of the gray box), white males have a value of 18 different delinquent acts, while black males, white females, and black females report 15, 11, 10 different types of delinquency, respectively. The 0.75 quantile (upper end of the gray box) reveals even larger separation by sex, where the 0.75 quantile for white males is 26.5 and for black males it is 22, while the two groups of females are nearly identical (17 for white females and 16.75 for black females). The tails of the distributions are also informative. The lower end of the distribution shows virtually no difference across sex and race – the largest value at the 0.10 quantile is 5 for white males and the lowest value is 3 for white females. In contrast, at the upper end of the distribution (e.g., the 0.90 quantile), the differences are more pronounced, with values ranging from a high of 36 for white males to a low of 23.5 for black females.

The pattern of results in Fig. 4 could also be interpreted to report the relative differences at various quantiles. For example, at the 0.25 quantile, the delinquency score for white males is 1 more than for black males, and 4 more than either one of the groups of female respondents. By the median, we see that white males report 3 more acts than black males, but 7 and 8 more delinquent acts when compared to white females and black females, respectively. As we move further out on the distribution of types of delinquency, the differences become increasingly larger, where, by the 0.90 quantile, white males report 6 more acts than black males, but 9.1 more than white females and 11.5 more than black females.

Regardless of the approach used to interpret the distributional patterns in Fig. 4, the boxplots reveal interesting differences in the distribution of self-reported delinquent acts amounts by sex and race. It is also important to keep in mind that the distributions of type of delinquency by sex and race presented in Fig. 4 do not account for any other characteristics of the youths. To the extent that background characteristics (e.g., self-control, psychological stress, etc.) explain patterns of delinquency by sex and race, we would expect these differences to disappear once these characteristics had been accounted for statistically. This illustrates another way that quantile regression techniques have the potential to provide such a useful form of analysis, and allow for testing whether apparent differences in distributional patterns will disappear, once other relevant characteristics of the observations have been taken into account in a full statistical model.

Location-Shift and Location-Scale Hypotheses

The location-shift hypothesis is a test for whether a single coefficient could be used to capture the effect of an independent variable on the dependent variable across the distribution of the dependent variable. The location-shift model is equivalent to an OLS regression model where the coefficient is constant, meaning that for a fixed change in the independent variable, the conditional mean of the dependent variable is expected to change by a fixed amount. In the context of quantile regression results, if the effect of an independent variable varies around some constant value across the distribution of the dependent variable, then the effect of the variable is limited to one of shifting the location – the level – of the dependent variable.

The location-scale hypothesis is akin to testing for heteroskedasticity in the OLS model. The location-scale hypothesis reflects the possibility that as the value of the dependent variable changes in magnitude, the variance of the residuals – the spread of cases around the regression plane – will also change, sometimes increasing, sometimes decreasing. Consequently, the location-scale hypothesis tests for the possibility of a constant effect of the independent variable on the dependent variable, accounting for the increasing (decreasing) spread of cases across the distribution of the dependent variable. Koenker (2005) and Koenker and Xiao (2002a) note that the model intercept in quantile regression represents a normalized version of the residuals and to the extent the effects of the independent variable follow the same pattern as the model intercept, they represent simple shifts in location and scale of the dependent variable and residuals.

Koenker (2005) and Koenker and Xiao (2002a, b) present a test and critical values for the location-shift and the location-scale hypotheses for the full model and for the individual coefficient estimates. The critical values for the tests depend on the number of coefficients estimated, the range of quantiles, and the desired level of statistical significance; sample size has no direct bearing on the test statistic or the critical value. Practically, the calculated test statistic is compared to the critical value, and if the test statistic is greater than the critical value the null hypothesis of location shift or location scale is rejected. The rejection of the location-shift hypothesis implies that the OLS model, based on conditional means, does not provide a good representation of the effects of the independent variables on the dependent variable. Rejection of the location-scale hypothesis implies not only that the OLS model does not represent the effects of the independent variables well, but the shape of the conditional distribution of the dependent variable changes in ways not modeled by OLS, even after accounting for heteroskedasticity. In other words, there is no simple, straightforward transformation of the residuals that would result in an OLS model adequately fitting the data.

Two Applications of Quantile Regression Models

Measurement of Self-reported Delinquency

The Seattle Youth Study was an experiment conducted by Michael Hindelang, Travis Hirschi, and Joseph Weis aimed at assessing whether the method of administration of self-report delinquency items would affect the reliability and validity of the responses given by the youth who participated in the study (Hindelang et al. 1981). There were four different methods of administration of the survey that combined the form of the survey (questionnaire or interview) with conditions of administration (anonymous or non-anonymous). The 1,612 participants in the study were randomly assigned to one of the following four methods of administration: anonymous interview, anonymous questionnaire, non-anonymous interview, and non-anonymous questionnaire (for details, see Hindelang et al. 1981). Hindelang et al. (1981) performed a range of analyses to assess the reliability and validity of the self-report delinquency items and concluded that method of administration made no difference to the measurement of delinquency – each set of responses indicated a similar level of delinquency as well as common correlates of delinquency across all four methods of administration. The following discussion is intended to illustrate the application and interpretation of quantile regression techniques to experimental data and not intended to be an exhaustive reanalysis of Hindelang et al. (1981).

One of the outcome measures of delinquency created by Hindelang et al. (1981) was a variety scale that counted the number of different delinquent acts out of a maximum of 69 self-reported as having ever been committed by the youth. A boxplot of this delinquency scale by method of administration is shown in Fig. 5, revealing a high degree of positive skew in each of the four experimental conditions. A simple one-way analysis of variance shows the means across the four groups not to be significantly different ($F = 2.003$, $p > 0.10$).

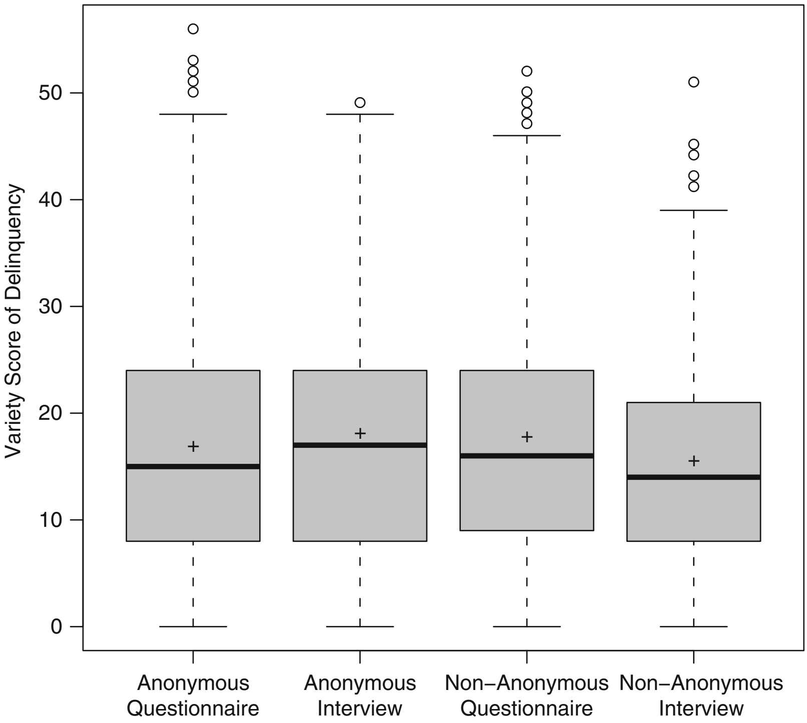
Table 1 presents the results for estimating a series of quantile regression models covering the range from quantiles of 0.10 to 0.90 for the subsample of male respondents. In order to simplify the presentation of results, female respondents were excluded, since they represented only 25 % of the sample and were not assigned to either the anonymous interview or the non-anonymous questionnaire conditions. For purposes of comparison, the OLS regression results are reported in column 2, while columns 3 through 7 indicate the results for the different quantiles. In all analyses, anonymous questionnaire is used as the reference category.

The results in Table 1 show no consistent pattern of significant effects from quantile 0.10 to 0.90 – only 1 of 15 coefficients is statistically significant at $p < 0.05$. These results imply that insofar as delinquency is measured by self-report items, the method of administration has no bearing on the variety of delinquency self-reported by the respondents. An important implication of this finding – and not one highlighted by Hindelang et al. (1981) – is that the method of administration did not affect self-reported delinquency levels among either those reporting few delinquent acts or those reporting many different delinquent acts.

Philadelphia Experiment on Bail Guidelines

In the early 1980s, John Goldkamp and Michael Gottfredson conducted an experiment in the Philadelphia courts that involved judges using a set of guidelines for making bail decisions (Goldkamp and Gottfredson 1985). Prior research had indicated tremendous variability in the bails that judges set for defendants in their courtrooms. In an attempt to test whether bail decision-making could be made more consistent and equitable, Goldkamp and Gottfredson developed a set of bail guidelines organized around (1) the severity

Quantile Regression Models to Analyze Experimental Data, Fig. 5 Seattle Youth Study: number of different self-reported delinquent acts by method of administration



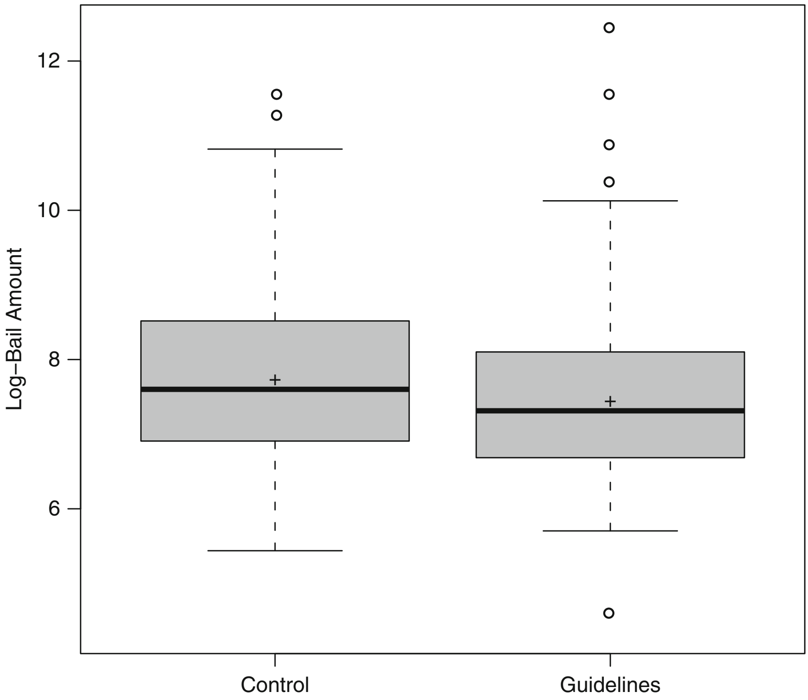
Quantile Regression Models to Analyze Experimental Data, Table 1 OLS and quantile regression results for Seattle Youth Study

		Percentile				
Variable	OLS	10th	25th	50th	75th	90th
Intercept	19.38***	5.00***	9.00***	18.00***	27.00***	36.00***
Anonymous interview	−2.11*	−1.00	−1.00	−1.00	−3.00	−4.00
Non-anonymous questionnaire	−1.62	0.00	0.00	−2.00	−3.00	−1.00
Non-anonymous interview	−1.40	1.00	1.00	−1.00	−2.00	−4.00

*p < 0.05; ***p < 0.001
N = 1,214 male respondents

of the charge offense and (2) the risk of flight or rearrest. The construction of the risk group categories and recommended bail amounts were based on an earlier pilot study in the Philadelphia courts (see Goldkamp and Gottfredson 1985 for details), so there was an empirical basis for the recommendations in the guidelines. The bail guidelines were presented in a grid format, allowing the judge to be able to cross-reference the defendant's risk group classification and current charge severity to locate a cell in the table that suggested a range of bail amounts, as well as other non-bail release options (e.g., release on recognizance (ROR)) for defendants with low risk and less severe offense charges.

Sixteen judges participated in the study: eight each were randomly assigned either to the control group (asked to make bail decisions as they had in the past) or to the experimental group (asked to follow the recommendations made in the bail guidelines grid). For all 16 judges, a quota sample of 120 total cases was selected that included an equal number of cases in each of the 6 charge severity categories (which represented a mix of felony and misdemeanor cases). The goal of the experiment was to test whether the voluntary use



Quantile Regression Models to Analyze Experimental Data, Fig. 6 Philadelphia Bail Experiment: log-bail

of bail guidelines would result in less variability and more equitable treatment of defendants across the group of judges participating in the study. Goldkamp and Gottfredson (1985) also acknowledge that some contamination is likely to have occurred. Since all 16 judges participating in the study worked in close proximity to each other, there were no doubt conversations among the judges about the guidelines. Consequently, it is possible that those judges not assigned to the experimental group could have been sensitized to their own bail decision-making practices and unintentionally altered their bail and release decisions, thereby diluting the potential effect of the treatment.

The analyses performed by Goldkamp and Gottfredson (1985) focused primarily on a distributional comparison, where they compared median bail amounts for the control and the guidelines (experimental) judges, as well as partitioning the distributions in ways that allowed for comparisons of the percentage of cases receiving bail amounts within some specified range. Their distributional comparisons highlighted differences across the two groups of judges, but there were no tests of statistical significance for differences in the medians or other quantiles. A secondary set of analyses regressed the logarithm of bail amount on the two key criteria of the guidelines grid: severity of charge offense and risk group classification. Interestingly, while they found the overall bail amounts to differ significantly across the two groups of judges, the effects of offense severity and risk group classification on bail amount requested were nearly identical for control and guidelines judges, indicating that the relative weights judges attached to these criteria were similar, regardless of whether they used the guidelines or not. They note that this finding is not that surprising, since the guidelines were empirically grounded in the prior behavior of judges in Philadelphia.

Figure 6 presents the boxplots for log-bail amount for the control and the guidelines judges – the degree of skew in bail amount (in dollars) resulted in boxplots that were so compressed that they were not useful for discerning any differences in the distributions across experimental condition. We see that the judges who were assigned to the bail guidelines condition show

Quantile Regression Models to Analyze Experimental Data, Table 2 OLS and quantile regression results

		Percentile				
Variable	OLS	10th	25th	50th	75th	90th
Intercept	5.43	4.83	5.23	5.29	6.08	6.80
Experimental group	−0.36	*0.00*	−0.31	−0.39	−0.56	−0.58
Offense severity	0.19	0.14	0.16	0.19	0.19	0.21
Risk group	*0.07*	*0.00*	*0.02*	0.08	*0.08*	*0.03*

N = 1,007 cases with Bail >0

a more compact distribution of values in the interquartile range when compared to the control group judges. The shorter fences also indicate that the distribution of log-bail amounts is more compressed among those judges using the bail guidelines compared to the group of control judges.

Table 2 presents the results from an OLS regression (Column 2) and a series of quantile regression models (Columns 3 through 7) testing for differences in the effect of guidelines participation, offense severity, and risk group classification on log-bail amount from $\tau = 0.10$ to $\tau = 0.90$. The OLS results indicate that bail amounts are about 36 % lower in those cases presented to a guidelines judge, controlling for offense severity and risk group. The quantile regression results illustrate how the use of the guidelines affects the bail amounts requested at different points of the log-bail distribution. At the $\tau = 0.10$ quantile, there is no difference in the log-bail amounts between the two groups of judges. By the $\tau = 0.25$ quantile, bail amounts are approximately 31 % lower in the guidelines group. At the median, the OLS and quantile regression results for the effect of using the guidelines are similar (showing log-bail amounts to be about 39 % lower among guidelines judges). The primary impact of the bail guidelines can be seen in those cases at the $\tau = 0.75$ and the $\tau = 0.90$ quantiles, where bail amounts are approximately 56 % and 58 % lower among those cases heard by a guidelines judge. Substantively, these results show that as we move to the upper end of the distribution of log-bail amounts, the effect of bail guidelines increases in magnitude, resulting in increasingly larger differences in cases handled by guidelines and control judges.

There are also interesting patterns to the results for offense severity and risk group. In regard to offense severity, the OLS results indicate that each unit increase in offense severity is associated with about a 19 % increase in bail amount. The quantile regression results show that at the lower end of the distribution – the 10*th* to 25*th* percentiles – the effect of offense severity falls between 14 % and 16 %. It is at the median that the quantile regression results are comparable to the OLS results, but at the 90*th* percentile, the effect of offense severity has risen to more than 21 %. The effect of risk group is more modest – the OLS results indicate that a unit increase in risk group is associated with about a 7 % increase in bail amount. Of the quantile regression results displayed in Table 2, the only coefficient to be significantly different from zero is at the median, where each increase in risk group classification is associated with a nearly 8 % increase in bail amount.

The substance of the findings in Table 2 suggest that the bail guidelines functioned in much the same way as current practice for those cases with bail amounts below the 25*th* percentile – the least serious cases and defendants. From that point on, however, the use of the bail guidelines had an increasingly greater impact of bail amounts requested, so that the further out we go in the distributions for the guidelines and control judges, the larger the differences become, even while statistically controlling for offense severity and risk group classification.

Location-Shift and Location-Scale Hypotheses

Table 3 presents the results for the test of the location-shift and location-scale hypotheses for the effects of experimental condition, offense

Quantile Regression Models to Analyze Experimental Data, Table 3 Location-shift and location-scale hypotheses test results

Variable	Location shift	Location scale
Experimental group	3.73**	3.76**
Offense severity	1.92	2.35*
Risk group	2.53*	2.42*
Full model	7.36**	6.63**

* $p < 0.05$; ** $p < 0.01$

severity, and risk group classification on log-bail. Recall that the location-shift hypothesis is fundamentally a test for whether an OLS regression model adequately represents the effects of the independent and control variables on the outcome measure. The location-scale hypothesis tests whether fixed coefficients capture the effects of the independent and control variables after taking into account the changing spread of observations across the distribution of the outcome variable.

The critical values reported in Koenker (2005) and Koenker and Xiao (2002b) for the quantile range of $\tau = 0.15$ to $\tau = 0.85$ for the full model (3 coefficients) are 4.269 ($p < 0.05$) and 5.074 ($p < 0.01$). For the individual coefficients, the critical values are 2.048 ($p \leq 0.05$) and 2.573 ($p \leq 0.01$). Note that the range of the quantile regression process was trimmed from the results presented in Table 2. The rationale for reducing the range was the volatility of the quantile regression estimates in the tails of the log-bail distribution, which can make the estimation of the test statistics problematic (Koenker 2005). The results in Table 3 show that both the location-shift and location-scale hypotheses are rejected at $p \leq 0.01$, meaning that neither an OLS nor an OLS model adjusted for heteroskedasticity adequately model the effects of experimental condition, offense severity, and risk group across the distribution of log-bail. When we focus on individual coefficients, we find that the effects of experimental condition and risk group are not at all well modeled by an OLS coefficient (with or without heteroskedasticity adjustments). Interestingly, there are somewhat contradictory results for the effect of offense severity. The location-shift hypothesis cannot be rejected ($1.918 < 2.048$), but the location-scale hypothesis is rejected ($2.350 > 2.048$), suggesting that an OLS coefficient may represent the effect of offense severity from $\tau = 0.15$ to $\tau = 0.85$.

Summary

The primary focus of this entry has been to illustrate the analysis of experimental data with quantile regression models. Typical analyses of experimental data focus on differences in the levels of the dependent variable across the control and treatment groups. Somewhat less common, but still of interest, may be a change in the scale (spread) of the dependent variable across the control and treatment groups. In either case, the analysis will often be restricted to looking at the differences in means and variances. Quantile regression models offer the opportunity to assess whether there are differences across the control and treatment groups at any specified point in the distribution of the dependent variable. Thus, with quantile regression models, we can test for effects of a treatment (or set of treatments) at each quartile (i.e., 25*th*, 50*th*, and 75*th* percentiles), the tails of the distribution (e.g., 10*th* and 90*th* percentiles), or any other point in the distribution. The substantive importance of this type of analysis is the possibility of determining whether the effects of a treatment are constant or variable across the distribution of the outcome measure. To the extent the effect of the treatment is more or less constant, a more traditional ANOVA or linear regression analysis offers a reasonable test of the impact of the treatment. To the extent the effect of the treatment is variable, quantile regression models will be useful in highlighting those points of the distribution where the treatment is more or less effective.

The results presented in this entry illustrate well the utility of quantile regression models. In the analysis of data from the Seattle Youth Study, the quantile regression results reinforced and extended earlier findings about the effect of method of administration of self-report delinquency items on the variety of delinquency reported. Consistent with results reported by

Hindelang et al. (1981), there were no effects of method of administration on variety of self-reported delinquency. The value added by the quantile regression results was the lack of difference across the full distribution of self-reported delinquency – it did not matter if the comparison involved youth who reported a small number of different acts or a relatively large number of acts (out of a possible 69).

In regard to results from the Philadelphia Bail Experiment, the OLS results suggested that bail amounts for defendants presented to guidelines judges were about 30 % lower than those for defendants whose decisions were made by the control group judges. However, the quantile regression results illustrate that the effect of participating in the guidelines only affected cases at or above the 25*th* percentile. More important, as we move to the upper end of the log-bail distribution (i.e., the cases with larger bail amounts representing more serious offenses and/or more risky defendants), the effect of participating in the guidelines increased the difference between the two groups of defendants. The effects of offense severity and risk group classification were also shown to be variable across the distribution of log-bail, although in slightly different ways. Much like the effect of participating in the guidelines, the effect of offense severity increased in magnitude as we moved from the lower to the upper end of the distribution. In contrast, the effect of risk group was limited to the middle of the distribution – the effect of risk group was not significantly different from zero in either tail of the log-bail distribution.

Why use quantile regression models for the analysis of experimental data? As noted above, one of the key benefits to using distributional analyses, such as quantile regression techniques, is they are particularly effective at testing for variations in the effects of control and independent variables across the distribution of a dependent variable. In the context of analyzing experimental data, quantile regression models would appear to offer an interesting way of teasing out the effect of a treatment at different quantiles of the distribution of the dependent variable. For example, as shown with the analysis of data from the Philadelphia Bail Experiment, we may not expect to find dramatic differences in bail amounts at the lower end of the distribution for control and guidelines judges. In part, this is due to the manner in which the guidelines were constructed – less serious offenses and defendants who pose little risk will generally be likely to be released on their own recognizance or be required to post minimal bail. At the higher levels of the distribution of bail amounts, the range of possible bail amounts is greatly expanded, which will create more opportunities for judges to exercise discretion in their bail decisions. Since the bail guidelines were intended to reduce the range of possible bail amounts by lowering the maximum amount of bail a judge should request, the finding of an increasingly greater impact of the bail guidelines at the upper end of the bail distribution is consistent with a reduction in the range of options available to the judge.

Some of the earliest work on the development of quantile regression models was focused on dealing with censored data, where there were many zero values for the dependent variable (Powell 1984, 1986). Quantile regression models represented a way of estimating unbiased effects of the independent variables on the dependent variable, where the influence of the zeros would be minimal. Practically, the addition of the zero values for the dependent variable simply shifts the nonzero values of the distribution to the right (i.e., to the higher quantiles). The ability to test for variation in the quantile regression coefficients is unaffected by the additional zero values on the dependent variable. More recently, Koenker (2005, 2008) has started to develop the statistical theory and implement a censored quantile regression procedure that will, among other options, account for zero values on the dependent variable.

There are at least two other important benefits to the quantile regression approach described in this entry. First, by making no assumptions about the distribution of the error terms in the model, quantile regression techniques effectively deal with the non-normal distribution of errors that is so common in the analysis of data on criminal behavior and the criminal justice system. Many researchers will often transform the dependent variable (e.g., by computing a logarithm) to reduce the degree of skew or recode the variable in such a way that the fundamental distribution of the variable is changed (e.g., recoding frequency of self-reported delinquent acts from a count to something that ranges from 0 to 10 or more). Second, the ability of quantile regression models to estimate variable effects of control and independent variables across the distribution of a dependent variable suggests that this technique would be particularly valuable for testing theories that either directly or indirectly imply nonconstant relationships. Beyond the issues discussed in this entry, many theories of crime and delinquency also imply that the effect of a key theoretical variable (e.g., control balance or peers) may have effects on crime and delinquency that vary by the frequency of criminal and delinquent behavior. Similarly, in the context of criminal justice decision-making, the "liberation hypothesis" suggests that judges will exercise greater discretion in particular types of cases. Standard linear regression models will not be able to detect these kinds of effects.

The primary challenge to the application of quantile regression is the need for a sufficiently large number of cases that will allow for the computation of quantiles for the numerous combinations of the values of the independent variables. There is no magic number for the size of the sample necessary – the analyses reported above relied on just over 1,000 cases, while some of the research cited above used a few hundred observations. In light of the fact that so many researchers studying crime and criminal justice issues rely on samples (and often populations) of several thousand cases, this requirement is not likely to be prohibitive in most applications.

Quantitative Methods Used by Criminologists in the Nineteenth Century

David Maimon
Department of Criminology and Criminal Justice, University of Maryland, College Park, MD, USA

Synonyms

Early quantitative methods; Historical criminology

Overview

The adoption of the "positivist approach" in the study of human behavior exposed early criminologists to a range of quantitative methods that allowed objective investigations of crime data. This entry reviews the types of data and quantitative methods used by criminologists in the nineteenth century to describe the magnitude of crime, identify offenders' unique characteristics, and search for the causes of deviance and crime. Similar to contemporary sources of "crime statistics," data on crime and criminals during this period was collected by official criminal-justice agencies and by independent scholars who observed, surveyed, and conducted scientific experiments with criminals. Due to the absence of predictive statistical tools, data analysis had mainly involved (1) classifications of crime types and construction of frequency distributions, (2) calculations of crime rates, proportions, averages, and deviations, (3) comparisons between pairs of variables, and (4) estimations of the relationships between pairs of variables using tables and graphs. The important influences of these quantitative methods on the evolution of criminological theory are discussed.

Introduction

Although the roots of criminological thinking could be traced back to the second half of the eighteenth century, it was not until the early nineteenth century, when "positivist" methods (i.e., all these methods that can predict crime and that are in harmony with the methods applied in the natural sciences (Beirne 1987)) were employed in the study of crime (Guerry 1833; Quetelet 1831) that criminology established itself as a legitimate modern social science. Drawing on the "positivist" assumption that quantitative methods should be applied in the social sciences (Quetelet 1831; Comte 1858), early criminologists adopted a range of quantitative tools (e.g., ratios and proportions, averages and deviations) in order to describe the crime problem, assess the causes of crime, and identify offenders' unique characteristics. Indeed, some scholars proposed that criminologists adopted these "positivist" methodologies in order to justify the implementation of new strategies of penalty and correction (Foucault 1979). However, most would agree that by applying quantitative methods to the study of crime, our understating of human behaviors was extended, establishing the foundation to develop crime causation theories.

This entry reviews the important quantitative methods adopted and used by criminologists during the nineteenth century. It begins with a brief overview on the emergence of the positivistic approach within the criminological discipline. It then describes the common data used by criminologists to study crime and its causes. Next, it elaborates the quantitative approaches employed by early criminologist to analyze crime and social data, using examples from early crime scholars' works. Finally, this entry concludes by discussing the unique influence of quantitative methodologies on the evolution of criminological theory. Importantly, this review encompasses articles and books that appeared between the years 1800 and 1900 and that were written in or translated into English.

Background

Positivist criminology emerged in France during the early nineteenth century as a result of the shift from an amorphous penal system (led by the ancient régime until the mid eighteenth century) to a more centralized system with a network of reform institutions (Beirne 1987). Influenced by enlightenment ideas of rationalism and humanism, and guided by the writings of prominent "classical school" philosophers (e.g., Cesare Beccaria and Jeremy Bentham), the stated objective of the new penal system was to promote moral rehabilitation among delinquent inmates (mainly alcoholics, idiots, immigrants, prostitutes, and petty and professional criminals). The penal institutions were designed to employ systematic strategies of surveillance and detention in an effort to "normalize" the conduct of the "dangerous class" (Beirne 1987). Soaring crime and increased recidivism at the beginning of the nineteenth century signaled the failure of these institutions to accomplish their task. In an effort to uncover the magnitude of crime in the country, the Ministry of Justice in France initiated in 1825 the first centralized national data collection of crime statistics. This resulted in a publication of the first annual report of national crime statistics in 1827 (Friendly 2007).

During the same time period, a positivist approach (i.e., an epistemology suggesting that natural phenomena could be empirically studied based on unbiased and objective scientific procedures) had dominated the scientific discourse within the physical sciences. Adherents of this approach suggested that unbiased scientific investigations should follow the positivist principles of observation, experiment, comparison, and historical methods (Timasheff 1967), and employ mathematical operationalization of the world. Acknowledging the unique contribution of positivist methods in the physical sciences, early social scientists (e.g., Quetelet (1831), and Comte (1858)) suggested that these methods and principles are also applicable to "social data." According to Quetelet (1831), quantitative methods could be used in the study of social data if those data are able to stand outside of the observer and are capable of being analyzed by mathematical procedures. Drawing on Quetelet's and Comte's monumental works, early social scholars developed interest in "positivist" methods and implemented them using a range of social data. This trend also influenced many crime scholars, who adopted these quantitative tools and used them to analyze crime data.

Crime Data

Similar to contemporary sources of "crime statistics" and "social data," information on crime and criminals during the early nineteenth century was collected by (1) government officials (i.e., courts and police) and by (2) individual scholars observing, surveying, and conducting experiments with criminals.

Official Crime Data. Although official efforts to collect national crime data began in 1825, the systematic collection of population-based data (i.e., social data) was initiated in the mid-fifteenth century with the London Bills of Mortality (the London Bills of Mortality were collected weekly and established the main source of mortality statistics in fifteenth-century England) (Friendly 2007). Early analyses of these mortality data demonstrated the informative value that state and public officials could gain from such "social data." As a consequence, by the mid-eighteenth century, governmental efforts to collect population-based data from its various agencies were expanding. The extensive collection of official crime statistics by the French Ministry of Justice in 1825 set the stage for the collection of data on criminal-justice agencies (e.g., police departments, courts, and prisons), as well as other population data (e.g., immigrants, prostitutes, literacy, and wealth). Beginning in the late 1830s, governmental efforts of crime data collection spread to England (Rawson 1839) and other European countries (e.g., Germany, Italy, Russia), and by the early 1850s were initiated in the USA. (Deflem 1997). While the accumulation of official crime statistics enabled early criminologists to develop an initial understanding on the distribution of crime and its magnitude, the availability of "social data" allowed these scholars to also test hypotheses regarding the social and ecological causes of crime.

Data Collected by Individual Scholars. In addition to official data collected by governmental officials, individual scholars gathered their own data on crime and delinquency directly from criminals. These scholars used a range of scientific methods – including observations, surveys, and experiments – to collect this information (Rafter 2004). Pinel, for instance, collected data on insane criminals using case studies and direct observations (Rafter 2004). Lombroso and his students collected measures of skulls, body, and morphological features of dead and alive criminals (Lombroso 1876; Lombroso and Ferrero 1893). These scholars also used experimental designs to collect data from criminals and noncriminals (Lombroso and Ferrero 1893). Finally, Mayhew (1862) and also Vidocq (Lindesmith and Levin 1937) used participant observations, testimonies by criminals, and life history documents to identify social gestures among prisoners and pickpockets. Although these methods of data collection were limited in scope, they yielded unique data sets that supported the development of biological and psychological perspectives on crime and shaped the evolution of criminological theory. The emergence of "quantitative methods" allowed early criminologists to empirically test the validity of these perspectives.

Quantitative Methods

Adolphe Quetelet was the first social scientist to apply quantitative methods in the study of crime. Drawing on his extensive background in mathematics and statistics, Quetelet believed that the same regularities and laws observed in the natural sciences could be identified in the social world. Identification of these laws, he suggested, should be based on a large amount of social data and involve the application of statistical methods and calculations (Beirne 1987; Stigler 1986). Following the publication of "*Research on the Propensity for Crime at Different Ages*" (Quetelet 1831), criminologists in France and around the globe implemented probability theory to *describe* the magnitude of crime (Guerry 1833; Rawson 1839; Levi 1880) and the work of criminal-justice agencies in their countries (Falkner 1889; Fletcher 1850; Mayhew 1862), to *identify* offenders' unique characteristics (Lombroso, 1876, 1891), and to *search* for the causes of deviance and crime (Clay 1857; Quetelet 1842). In the absence of methodologies that estimate correlations and regression coefficients (These approaches were developed around 1890 by Francis Galton and Karl Pearson (Stigler 1986)), these early crime scholars produced scientific works that: (1) classified crimes by types and presented frequency distributions; (2) calculated crime rates, proportions, averages, and deviations; (3) compared pairs of variables; (4) estimated the relationships between pairs of variables; and (5) presented quantitative graphics.

Crime Classification and Frequency Distributions. Once crime data became available to social scientists, criminologists were particularly interested in understanding the magnitude of deviance and crime. To achieve this goal, scholars like Quetelet (1831), Rawson (1839), and others (Fletcher 1841; Guerry 1833) presented annual figures on the sheer number of persons charged, convicted, and acquitted with different types of offenses. Offense type classifications were either general (i.e., distinguishing between crimes against persons and crimes against property (Quetelet 1831)) or very detailed (i.e., presenting a breakdown of all reported offenses (Rawson 1839; Fletcher 1841)). With the distinction made by official crime agencies between offenses and offenders, scholars like

Levi (1880) presented data on both the number of indictable offenses reported to the police and the number of persons apprehended for indictable offenses.

The accumulation of data on criminal-justice agencies allowed early criminologists to also describe the size, structure, and workload experienced by police stations and prisons. Levi (1880), for instance, reported the annual number of police officers in England and Wells between the years 1857 and 1878, while Fletcher (1850) provided detailed description of police wards' force size, officers' salaries, and workload in London. Prisons statistics were also popular during that time, with scholars like Mayhew (1862), Lombroso (1876), and Falkner (1889) describing the number of prisoners, their offenses, and sentence lengths in British, Irish, and American prisons, respectively.

Proportions, Rates, Averages, and Deviations. In order to allow a meaningful assessment of the magnitude of crime, early scholars adopted Laplace's method of ratio estimation (Stigler 1986) and calculated the ratios of the annual offenses to population (Guerry 1833; Levi 1880), proportions of offenders per populations (Rawson 1839), and proportions of prisoners to population (Falkner 1889). Quetelet (1831) also calculated the conviction rates of criminal offenders in France between the years 1825 and 1830, dividing the number of convicted criminals by the number of accused. Quetelet interpreted these rates as probabilities, suggesting that they indicate the chances that an average person (whom nothing more is known about) is convicted of a crime.

Next to estimating the average propensities of offenders to be convicted, Quetelet also calculated the average values of his subjects' physiques (i.e., weight, height). According to him, any aspect of a population that can be measured may produce an indicator that portrays the "average man" in that population (Quetelet 1831; Stigler 1986). This average score could then indicate either an actual physical characteristic (i.e., height, weight) or an estimated "propensity" (for instance, using crime rates to calculate the propensity to offend). Once known, this mean could be cross-tabulated with a range of demographic, social, and contextual indicators, and allow for the development of meaningful comparisons that could refine our understanding of the laws of the social world.

Comparison between Pairs of Variables. Drawing on Quetelet's (1831, 1842) influential works, numerous early crime scholars compared the distribution of crime measures across a range of social groups, time periods, and geographical regions. These comparisons included calculations of social groups' share in producing crime, and the overall proportions of offenders in the group. Results were mainly reported using tables. Levi (1880), for instance, reported that only 20 % of those committed to trial between the years 1857 and 1878 in England and Wales were women. Focusing on the differential involvement of different age groups in crime, Rawson (1839) Fletcher (1841) and Levi (1880) ordered several age categories (e.g., under 17 years, between 17 and 21 years) and compared the proportion of offenders in each category. These scholars also reported the proportion of male and female offenders across the different age categories. Finally, Fletcher (1841) calculated the "proportion of offenders" across level of instruction in the United Kingdom between the years 1836 and 1842, finding that less than 10 % of offenders were able to read and write well.

Numerous early studies also compared crime statistics across countries and various geographical regions (Levi 1880; Lombroso 1911; Rawson 1839; Fletcher 1850). Rawson (1839), for instance, compared the proportion of offenders within different age groups in England and France and found that in both countries, more than 30 % of male and female offenders were between 21 and 30 years of age. Analyzing data from England and Wales, Levi (1880) compared the average number of persons committed for trial across 51 counties and found substantial variation across counties. Finally, Falkner (1889) compared the proportion of female convicts in 27 states, finding high proportion of female convicts in North Carolina and Maryland, yet low proportions in Texas and Colorado. It should be noted that in the absence of appropriate methodologies allowing examination of significant differences (for instance, t-tests and/or one way ANOVA), early criminologists were limited in the informative value of their comparisons.

While comparisons of crime proportions and averages were common among early scholars that used official crime data, such comparisons were rare among scholars like Lombroso and his students that collected data directly from criminals (using observations and experiments). Thanks to the relatively low number of observations, these scholars used the actual values of the measures to generate comparisons between individuals. In the "Criminal Man," for instance, Lombroso (1876) compared the circumference of 66 criminals' skulls, and reported that these skulls were "abnormally small." In the third edition of this book, Lombroso also presented comparisons between the anomalies in the brains of 28 criminals as well as comparison between the anomalous physical characteristics of 219 male criminals. Indeed, Lombroso's comparisons were accepted with suspicion in the criminological field. Nevertheless, along with comparisons of crime proportions and averages, these comparisons set the stage for the emergence of the first attempts to assess relationships between pairs of variables, and provided fertile ground for the development of sociological, psychological, and biological explanations of crime.

Estimations of the Relations between Pairs of Variables. In further efforts to identify the causes of deviance and crime, several criminologists investigated the joint variation between crime indicators and social, psychological, and biological measures. In the absence of methodological tools allowing statistical estimation of the relationships between measures, these scholars used tables to organize the values of their measures and then looked for consistent variation between these measures. Rev. John Clay (1857), for instance, was interested in the relationship between the number of criminals, beer houses, and schools attendants in geographic areas. To test these relationships, he composed a table listing 40 counties in England and presented the number of criminals (per 100,000 of the population), beer houses (per 100,000 people), and attendants at school (per 10,000) in each county. Observing the joint variation of these measures, Clay determined that beer houses are associated with high levels of crime, while attendance in school is associated with low levels.

This approach allowed early scholars who represented different criminological perspectives to empirically assess the validity of their theoretical arguments. Lombroso and Ferrero (1893), for instance, compared the variation of cranial capacities across groups of normal and criminal females. In line with Lombroso's theory of the criminal man (Lombroso 1876), these authors found that the cranial capacity of female criminals and prostitutes was lower than the cranial capacities of normal females. Focusing on the social causes of deviance and crime, Durkheim (1897) compared the variation of suicide rates with the percentage of married couples across 16 Italian provinces. Consistent with the assumption that low integration increases the probability of suicide, Durkheim found that provinces with a low percentage of marriages experienced high suicide rates, while provinces with a high percentage of marriages experienced low rates. The availability of quantitative graphics further supported these early comparisons, allowing visualization of the relationship between measures.

Quantitative Graphics. By the end of the first half of the nineteenth century, all the major modern forms of data visualization (including bar-charts, histograms, time-series charts, and thematic maps) had already been invented (Beniger and Robyn 1978; Friendly 2009) and their advantage in presenting patterns, distributions, anomalies, and variations of measures was highly acknowledged. Guerry (1833) and Quetelet (1831) took active part in developing these statistical graphics. Guerry (1833), for instance, was first to produce histograms (Karl Pearson coined the term "histogram" in 1895 to describe this form of statistical graphical presentation (Stigler 1986)) by arranging ordered categories for continuous measures (i.e., age, months) and using columns of equal width to represent the frequency of each category of the data (Beniger and Robyn 1978; Friendly 2007). Generating a histogram to compare the distribution of different types of crimes over age categories, Guerry observed that indecent assault is more common during childhood and less frequent during adulthood. In his late editions of *L'uomo delinquente*, Lombroso (1889, 1896) also employed bar-graphs and histograms to compare the distributions of criminals' and noncriminals' cranial capacities, height and arm span, and parents' age. Finally, Dexter (1899) composed a histogram to compare the frequency of murder and suicide incidents over conditions of temperature. Interestingly, although utilizing bar-graphs for comparison purposes, there is no indication that early criminologists were aware of the scatterplot (first scatterplot was published in 1833 in an astronomy journal (Friendly 2007)).

In addition to bar-charts and histograms, time-series charts were commonly used by early scholars (Guerry 1833; Lombroso 1876; Du Bois 1899; Dexter 1899; Mayhew 1862). Taking advantage of increasingly accumulating annual crime data, scholars produced time-series plots to describe the fluctuation of crime over time. Guerry, for instance, presented a time-series line graph of death sentences and executions in France between the years 1825 and 1855 (Friendly 2007). Employing the unique visualization allowed by time-series diagrams, Mayhew (1862) produced a time-series chart describing the fluctuation of corn price and the ratio of criminals to population between the years 1834 and 1849 in London. Finally, Lombroso (1896) produced a graphical analysis of periodic variation of alcohol consumption in ten countries (including the USA) between the years 1870 and 1895.

The invention of the statistical shaded map by Dupin in 1826 (Friendly 2007) initiated a series of publications featuring shaded maps and describing the distribution of crime rates across geographical regions. Balbi and Guerry were first to use shaded maps for portraying crime rates across the departments of France (Friendly 2007). In their innovative work, these scholars also compared the spatial distribution of crime against persons and crime against property and education level using a set of shaded maps of France (Friendly 2007). In 1833, Guerry refined these maps (using more complete data) and added three additional shaded maps displaying the distribution of illegitimate births, donations to the poor, and suicide in France. Guerry's unique approach that compared the spatial distribution of crime data over a range of social measures had been accepted with enthusiasm in the criminological field, and was adopted by many prominent scholars (Quetelet 1842; Levi 1880; Mayhew 1862; Durkheim 1897; Lombroso 1876). Drawing on Enrico Ferri's analysis of homicide in Italy, Lombroso (1876), for instance, compared the spatial distribution of murder, parricide, and poisoning in Italy. Levi (1880) presented the spatial distribution of indictable offenses and offenses subject to summary jurisdiction between the years 1857 and 1876 across counties in England and Wells and compared it with the spatial distribution of ignorance, amount of savings, and poverty. Finally, Durkheim (1897) presented shaded maps displaying the spatial distribution of suicide rates across counties in France and compared it with the spatial distribution of wealth, family size, and alcoholism.

Summary and Conclusions

In sum, the accumulation of crime data and the adoption of quantitative methods to study crime supported early criminologists' efforts to describe the magnitude of crime, identify offenders' unique characteristics, and search for the causes of deviant behaviors. These data and methods paved the way for the development of "positivist criminology." Indeed, the common quantitative tools available during the nineteenth century were relatively limited in their ability to generate statistical inferences from a sample. Nevertheless, these initial methodologies permitted the construction of frequency distributions, calculations of crime rates, proportions, averages and deviations, and comparisons between pairs of variables. These methods were employed in a considerable amount of early criminological studies and extended our understanding of crime and delinquency.

Next to their value in describing criminals and crime, these early quantitative methods also influenced the evolution of criminological theories. Specifically, the shift from a traditional medieval view of the universe to a philosophy favoring physical facts required empirical validation of scientific explanations of the world. According to this new philosophy, the world could be characterized by mathematical and statistical principles that a rational mind could grasp. The major advantage of these early quantitative tools was their ability to operationalize the world (e.g., producing crime rates) and investigate the relationships between different constructs through scientific research. This allowed early crime scholars to offer theoretical explanation for the causes of crime, draw research hypotheses from these theories, test these hypotheses empirically, and then refine their explanations. Lombroso's (1867) consistent modification of his original thesis of the criminal man is only one example of this process. Thus, the application of quantitative methods in the study of crime shifted the focus of criminological research from narrow discrete observations to broader discussions portraying general principles on the causes of crime.

Overview

This entry provides an evaluation of quantitative news media studies of crime. The entry includes a summary of how scholars have approached the study of news media using quantitative content analysis over the last 20 years by identifying what type of news media have been studied, how they have been studied, sampling designs, types of analysis conducted, and how reliability issues have been addressed. In addition, gaps in the approach and specific suggestions for moving forward in this important research area are discussed.

Studying the presentation of crime and criminal justice in the news media is important for several reasons. First, most of the public has infrequent direct experiences with the criminal justice system. It is because of this limited direct experience with crime that the media have great potential to influence how the public thinks about it.

Second, the news media are critical to public debates about policy issues. The public is overwhelmed with the amount of information available on various issues and is ill-equipped to do the types of analysis that might lead to a critical understanding of these issues. What the media provide is a brief, limited discussion of the factors related to policy decisions. Policymakers recognize the significance of the media, providing reporters access to information, hearings, and individuals that can provide the context that guides these debates.

Third, although scholars have historically been interested in understanding the images of crime and criminal justice, this interest appears to have grown dramatically in the past 20 years. For example, research indicates that only 36 crime and media studies were published between 1975 and 1995 (Chermak 1998). In contrast, research conducted for this entry identified nearly 100 studies published between 1990 and 2010 to examine. There are multiple factors that have probably contributed to the increases in research in this area, including the general awareness of the important role that media play in society, the increase in number of news outlets, and changes in how the public engages the mass media. Scholars appear to have taken note of these factors, and the end result has been a significant increase in research examining media, crime, and society.

In the sections that follow, quantitative media content studies are examined. In the next section, what has been uncovered in past research is highlighted. The methodology used to evaluate the quantitative media research is then discussed. The findings are then discussed and followed by a conclusion.

Prior Research Examining Crime News

This section reviews studies that have used quantitative content analysis to examine news media portrayals of crime. First, a brief overview of common theoretical approaches used by scholars to explain apparent discrepancies between the actuality of crime and news media representations of crime is discussed. Second, a selection of key findings from relevant studies are highlighted. Third, how past research findings vary across types of media and research designs is addressed.

In the past, scholars have relied primarily on two general theoretical frameworks to account for discrepancies between news media representations of crime and the actuality of crime captured in crime statistics. The first explanation suggests that crime news content is shaped largely by the structure of the dynamic newsmaking process and the need to efficiently package and sell news to audiences (Fishman 1980). Scholars have used this structural perspective to explain why extraordinary, and especially serious, crimes are overemphasized in the news. The second explanatory model maintains that cultural typifications, often based on shared expectations of "normal crime" participants and situations, influence crime story coverage decisions. This perspective explains why racial and ethnic minorities are often portrayed differently than whites as crime participants.

Crime is an everyday occurrence, and crime stories are a consistent feature of the daily news cycle (Chermak 1994; Graber 1980; Surrette 1998). The constant stream of potential crime stories requires reporters to make daily news selection decisions. Newsmakers select which crimes fill available news space and which crimes are ignored. To work most efficiently, "crime beat" reporters develop relationships with sources that provide reliable information about local crime (Chermak 1994; Ericson et al. 1989). Reporters' close working relationships with police are especially useful because they permit access to official information about crimes from trustworthy sources. As police largely control the information released to reporters, official police sources maintain substantial influence on crime news coverage (Ericson et al. 1989).

Crime reporters also take cues from fellow newsmakers regarding which crimes stories are of most interest to audiences (Ericson et al. 1987, 1989). Understanding audience preferences is important to selling news (Chermak 1994; Sheley and Ashkins 1981). For instance, research has shown that media consumers are often most interested in "human interest stories" or stories with which audiences can sympathize. Such stories tend to simultaneously evoke sympathy for victims of crime and disdain for those that commit them. Newsmakers also consider crimes involving extraordinary or novel circumstances newsworthy and likely to catch consumers' attention. Serious crimes, usually involving acts of street violence, are also considered particularly newsworthy and lead newsmakers to adopt the mantra of "if it bleeds, it leads."

The first explanatory model suggests that organizational practices of news agencies and shared understandings of newsworthiness structure the newsmaking process and result in discrepancies between news media representations of crime and crime statistics. Moreover, it has been suggested that overemphasis on novel and serious forms of violence may lead to increased public fear of crime and perceived risk of victimization (Liska and Baccaglini 1990). Disproportionate amounts of coverage devoted to crimes against females or vulnerable groups, such as children and the elderly, create the false impression that these groups are the most likely to be targeted. This is especially true when crime stories fail to provide adequate context.

The second explanatory model suggests that news media rely on cultural understandings of "normal" crime elements and expectations of typical victims and offenders (Pritchard and Hughes 1997; Sudnow 1965). This perspective maintains that traditional indicators of newsworthiness, such as novelty and crime seriousness, may be less important for explaining why some crime participants receive disproportionate amounts of news attention. This perspective maintains that newsmakers rely on cultural scripts that outline typical victims and offender types and typical criminal situations in which they are most likely to be involved (Gilliam and Iyengar 2000). Crime scripts are rooted in gendered and racialized stereotypes of crime participants and the criminal behavior most associated with them. Negative portrayals of racial minorities as threatening predators may be linked to the dominant ideologies and worldviews of news agency personnel (Bjornstrom et al. 2010; Blalock 1967). Scholars have relied on this perspective, for instance, to explain why relatively rare forms of violence, such as female-on-male crime or white-on-black crime, receive disproportionately less news attention despite representing uncommon crime characteristics (e.g., Lundman 2003). In sum, the cultural typification perspective remains useful for explaining discrepancies between actual criminal participation of racial and ethnic minorities and news media portrayals of minorities as crime victims and offenders.

Key Findings of Past Research

Drawing from these theoretical perspectives, prior content analyses of crime news have revealed that news media representations are often misaligned with established crime patterns. Most studies have focused on print news, though others have also examined television news (Entman 1992; Entman and Rojecki 2000; Graber 1980; Sheley and Ashkins 1981). While similar newsmaking processes dictate selection decision-making for print and television news media formats, representations of crime vary across formats (Ericson et al. 1991; Sheley and Ashkins 1981). Television news content, for instance, is focused more on capturing stories visually through dramatic imagery. Therefore, stories that can be told through brief video footage are often preferred. Selling television crime news is also much more competitive than selling newspapers due to the presence of rival news organizations contending for ratings, thus making marketability more important than newsworthiness (Sheley and Ashkins 1981). While newspaper editors have more flexibility in filling news space (Chermak 1995:122), telling crime stories in video segments that may last just minutes or less can be challenging.

One of the most consistent findings has been that violent crimes are overrepresented in news media (Chermak 1994; Ericson et al. 1991; Graber 1980; Surrette 1998). In one notable study, Graber (1980:39) found that murders made up only 2 % of Chicago crime and over 26 % of all crime mentions, while the more common and less serious crimes received substantially less coverage. The few studies that have compared news media coverage across multiple research sites have found that this finding holds across cities (e.g., Graber 1980). Furthermore, it tends to be the most heinous of violent street crimes that are likely to be covered and sensationalized. Relatively rare forms of serious violence, such as murders involving multiple victims or random victims, are considered particularly newsworthy (Hall et al. 1978). On the other hand, nonviolent forms of crimes (e.g., white-collar crime) receive less attention from the news media (Chermak 1995; Graber 1980).

As for portrayals of crime participants, females generally receive more news attention as crime victims compared to males. Other victims that can be portrayed as vulnerable, such as especially young and elderly victims, are also considered “worthy victims” and receive disproportionate news attention (Chermak 1994; Graber 1980). The opposite is generally true of offenders, as male offending tends to be overrepresented by news media. Victims involved in deviant lifestyles (e.g., gangs, drugs) may also be considered less worthy victims and receive substantially less news media attention (Chermak 1994; Pritchard and Hughes 1997; Gruenewald et al. 2011). Research has found that the race of crime participants also remains important. Past studies, for instance, suggest that whites are more likely to be portrayed favorably as victims, while victims of color are more likely to be portrayed less favorably and are generally overrepresented as offenders (Bjornstrom et al. 2010; Chiricos and Escholz 2002; Dixon et al. 2003; Entman 1992; Entman and Rojecki 1994, 2000).

Different research approaches have been used by scholars to analyze crime news content. These approaches can be distinguished by if, and how, they rely on outside sources of crime data. One approach, for instance, has been to study news media crime content for a particular period of time without comparing crime representations to actual crime statistics. This type of study is concerned with content-analyzing characteristics of crimes that are covered, thus ignoring crimes not covered by news media. Studies have compared characteristics and roles of crime participants across race and gender categories (e.g., Dixon et al. 2003). This research has found that racial-ethnic minorities are more likely to appear as dangerous offenders linked to street violence than as victims (Chiricos and Escholz 2002; Dixon et al. 2003; Entman 1992; Entman and

Rojecki 1994, 2000). On the other hand, other racial minorities, such as Latinos and Asians, are often underrepresented as crime participants.

A second approach has been to compare news media coverage of crime to aggregate crime statistics in order to gauge the extent that news reflects the actuality of crime. Past research on news media coverage of crime has suggested that "...media crime reporting apparently bears little resemblance to the 'reality' of police statistics" (Sheley and Ashkins 1981:503). Official crime data sources aid in capturing general patterns of known crimes. Some scholars have relied on aggregate crime statistics, such as those from the FBI's Uniform Crime Report, and local news media coverage in a particular city to study news portrayals of crime. Others have used police statistics from a single city. Graber's (1980) seminal study comparatively examined Chicago police department crime statistics and local newspaper coverage (*Chicago Tribune*). In another important study, Chermak (1995) examined representations of crime victims in the news media for multiple cities and found that news media representations of crime are distorted in a number of ways. In particular, his research demonstrated how serious crimes and crimes against victims belonging to vulnerable groups received disproportionate news attention. Content-analyzing crime stories from multiple print and electronic news sources, Chermak (1995) compared incident, suspect, and victim crime characteristics presented in Uniform Crime Report statistics. Overall, Chermak's (1995) work revealed how these characteristics interacted to affect the newsworthiness of criminal events.

A third avenue of research has been to comparatively examine local news coverage of actual crimes. Though there have been exceptions (e.g., Sheley and Ashkins 1981), nearly all of these studies have focused on newspaper coverage of homicides. There are a number of benefits to conducting his type of content analysis (Pritchard 1985). One benefit is that it is possible to ensure that crimes are occurring within geographic locales that news organizations actually cover. Linking local coverage to local crimes guarantees apples are not being compared to oranges (Pritchard 1985:501). Another benefit to comparing local news coverage to actual crimes also helps to ensure that crimes actually occurred during the time period under consideration by content analysts. Most importantly, however, is that linking actual crime data with local news coverage allows content analysts to comparatively examine the similarities and differences between crimes that are covered with those crimes that are ignored (Pritchard 1985).

The vast majority of these "distortion analyses" have studied homicide (Gruenewald et al. 2011; Johnstone et al. 1994; Lundman 2003; Peelo et al. 2004; Pritchard 1985; Pritchard and Hughes 1997; Sorenson et al. 1998). In addition to being the most serious form of violent crime, studying homicide in this way has strategic advantages. In particular, police homicide data are likely to be reported and fully investigated. This process often creates lengthy, in-depth detectives' records that identify characteristics of offenders, victims, and situations. These characteristics then become both "search words" when seeking news media coverage of each homicide and potential indicators of newsworthiness for newsmakers to use in their news decision-making.

Findings have emerged from this growing body of research that supports both the structural and cultural explanations of crime news media distortion. Similar to findings on crime news in general, past studies have found that homicides viewed as more serious or extraordinary, such as those involving multiple victims, tend to receive more newspaper coverage (Johnstone et al. 1994). In addition, victims perceived as "vulnerable," such as young or elderly victims, are generally overrepresented (Sorenson et al. 1998). As for race, white victims are more likely to be covered than racial and ethnic minority victims (Johnstone et al. 1994; Peelo et al. 2004; Sorenson et al 1998). When black and Hispanic homicide victims receive news print coverage, then it tends to be less extensive coverage (Lundman 2003; Pritchard and Hughes 1997). Cultural typification explanations have also been utilized to explain discrepancies in news media coverage across race. While female homicide victims are also considered more vulnerable and newsworthy than male victims, recent studies have found that the victim and offender race may, in some instances, make female victim homicides less newsworthy (Lundman 2003). Other similar studies have found support for the claim that newsmakers rely on cultural scripts based on racialized and gendered stereotypes to evaluate crime story newsworthiness (Pritchard and Hughes 1997; Gruenewald et al. 2011; Lundman 2003).

Research Findings

This section discusses the basic characteristics of the sample of articles, presenting information about the frequency and types of journals that published media and crime-related content analyses, the types of media sources used in each study, the research methodologies employed, the level of statistical analyses, and finally reliability issues. Between 1990 and 2010, 95 articles were published that used content analysis of one or more media sources to study crime or the criminal justice system. Of those articles, only 25 % were published prior to 2000, while the remaining 75 % of the sample was published between 2000 and 2010. The identified articles were in 54 different journals, with *Criminal Justice & Popular Culture* publishing the most ($n = 7$), followed by *Justice Quarterly* ($n = 5$), *Deviant Behavior* ($n = 4$), and *Journalism Quarterly* ($n = 4$). The remaining 50 journals published less than four articles each over that 20 year period, 31 of which only published one article.

The topics explored in the 95 articles varied widely. Some types of crimes researched included homicide, terrorism, illicit drug use, domestic violence, identity theft, white-collar crime, carjackings, and school shootings. Other factors studied in relation to media coverage of crime included characteristics of victims and offenders such as their race/ethnicity, gender, age, and where they lived. Although the crimes and themes studied were not consistent, all used some type of media and content analysis to answer their basic research questions.

In order to identify the media and samples used in the studies, each article was coded for the media type, number of sources, sample dates, keywords used to identify appropriate content, and the subsequent sample size. These studies used a range of media types to answer their research questions. Data from newspapers were used in 77 % of studies, 28 % of studies used television news, and 7 % use magazines such as *Time* or *Newsweek*. In addition to media sources, 41 % of the articles supplemented their content analysis with non-news sources, such as police and court data, census data, survey data, and even medical records and coroner reports. Of all the articles reviewed, 85 % listed the number of sources they used for the content analysis. In 22 % of that subsample, only one media source was used, while almost a third of the articles used two or less sources. The vast majority of articles (78 %) used ten sources or less. When considering the full range of sources used, one article used 771 sources, skewing the average numbers of sources used to 21, even though the median number of sources used was 4, and the mode was 1.

Ninety-five percent of the articles specified the date range used to collect their sample. The earliest start date for materials used in the content analysis was 1892, while one study each collected data beginning in the 1940s, 1950s, and 1960s. Three studies began collecting data in the 1970s, 15 in the 1980s, 52 in the 1990s, and 16 after 2000. A little less than a third of the studies had a date range that was a year or less (31.1 %), 46.7 % took their sample from 2 years or less, and 81.1 % of the articles took their sample from a time period that was 10 years or less. The average time period from which a sample was drawn was 2,303 days (63 years) and the median was 1,096 (3 years). The minimum number of days was 3, while the maximum was 14,608 days or 40 years.

Within the identified sources, 59 % of all articles in the sample reported using some form of keywords or phrases to search for materials. Of that 59 %, 36 % did not list the keywords or phrases used. Of the remaining 64 %, the average number of keywords or phrases used was 47, with a median of 2 and a mode 1. In addition, only

28 % of all studies also used some type of random sampling to select media content, while the rest collected data on a universe of coverage. Sampling techniques used included simple random samples, stratified sampling, and constructed weeks. The units of analysis varied across study, some of which included newspaper articles, television news stories, quotes, and crime events. Almost all articles (97 %) reported their sample size. The smallest sample size was 23 and the largest was 55,000. The mean sample size was 1,771 and the median was 474. Thirty-seven percent of the studies had a sample size of 200 or less, and three quarters had a sample size of 1,000 or less. Within each sample, the number of variables used in each study ranged from 1 to 51, with an average of 11 and a median of 9. A little more than 40 % of the articles collected data on more than 10 variables. Some of the variables of interest included source type, crime type, location in paper, number of stories per crime, article or report length, and victim, offender, and incident characteristics.

Specific to the types of analyses presented in each article, the highest level of analysis for 26 % of the articles was multivariate, while 28 % analyzed data at the bivariate level, and 45 % presented information using only univariate analysis. Types of multivariate analysis included binary and multinomial logistic regression, OLS regression, path analysis, Poisson regression, negative binomial regression, and time series analysis. In addition, 19 % of the studies supplemented the empirical component of the research with a qualitative component. Importantly, only 41 % ($n = 39$) of the studies reported measuring reliability. Of that 41 %, all but one of the authors provided the actual reliability statistic. The lowest reliability score reported was 0.10, while the highest was 1.00. The average reliability score reported was 0.88 with a media score of 0.89. The types of reliability scores reported included Cohen's Kappa, Scott's Pi, intercoder reliability, coefficient of reliability, and Cronbach's alpha.

This descriptive information produces an idea of the type and frequency of articles being published that use a content analysis of media to look at one or more aspects of crime and the criminal justice system. In the next section, the implications of this data on the current and future field of crime and media research are discussed.

Discussion

After reviewing previous research that has studied media coverage of crime and criminal justice, this entry discussed preliminary findings from a study of all peer-reviewed articles published on these topics between 1990 and 2010. This study focused only on articles published about media organizations in the United States. It is important to note that books, edited volumes, and book chapters were excluded from the analysis. There were several critical findings that were discovered. First, the use of quantitative content analysis has grown dramatically. There are several explanations for this growth, including that several disciplines, including criminal justice and criminology, have increasingly relied on quantitative methodologies and access to media content is virtually uninhibited because of open source databases and newspaper retrieval services. Second, most of the studies have been published in the past 10 years. This provides evidence that the field has embraced these technologies and there are much higher expectations regarding the level of sophistication with media analysis. Third, it is interesting that most of the studies focus on a single type of medium (either newspaper or television) and articles are selected from a narrow range of sources. This is somewhat surprising because access to a broad range of sources is relatively easy because of the existence of multiple media databases. Fourth, it is also important to note that almost 75 % of the articles relied on simple statistics rather than multivariate analysis. Although quantitative content analysis has grown dramatically, there still appears to be a lack of sophistication and rigor regarding statistical analysis. Finally, less than half of the articles reported basic reliability statistics.

This is an important study that should open up dialogue about the use of different statistical techniques to study crime and justice in the news.

Future research should look more closely at the variations in coverage by discipline, topic, and media source. The vast majority of articles using multivariate statistics use what has been referred to as "media distortion analysis" – where the researcher compares an "objective reality" to a "media reality." Other studies of basic content issues, however, continue to rely on simple univariate statistics. Although these studies provide some general understanding of the coverage of key issues in the media, future research will have to consider how such statistical techniques might be more broadly used.

Media studies are critically important and engage various issues and different disciplines in interesting ways. This study provided evidence of this impact and revealed a wide variety of disciplines that have examined how news media cover crime-related issues. The good news is that scholars are looking to various types of methodologies and techniques to study these issues more closely. The downside is that there remains much room for improvement. It seems vital that future research continues to consider how different methodologies (both quantitative and qualitative) and statistical techniques can be used to further the understandings regarding images of crime and criminal justice in the news.

Race and Ethnicity in Social Disorganization Theory

April Fernandes[1], Suzanna Ramirez[2] and
Robert D. Crutchfield[1]
[1]University of Washington, Seattle, WA, USA
[2]The University of Queensland, St. Lucia,
Australia

Overview

Race and ethnicity were central to the early formulations of Social Disorganization Theory, and consideration of these social categories remains significant in contemporary criminological research. In what came to be known as the Chicago School, scholars took Durkheimian conceptions of social solidarity and social disruption and created what today is known as Disorganization Theory to explain changes that were happening in the city around them. Many transitions were occurring in Chicago, as well as other Midwestern and Northeastern cities, but one of the most important of those was dramatic demographic shifts in the population as a result of migration. While earlier streams of immigrants to the United States came predominantly from Western and Northern Europe with physical features, cultural practices, and patterns of behavior that were not too dissimilar from the native population, the latter part of the nineteenth and the early twentieth centuries saw an increasing number of migrants coming from Eastern and Southern Europe. Large groups of immigrants began to populate Chicago and other American cities from countries like Italy, Greece, Poland, and Czechoslovakia. They were predominately Catholic, with languages and cultural traditions that differed dramatically from the previous immigrant waves from England, Scotland, Wales, Ireland, France, and Scandinavian countries.

During this same period, as a result of what has come to be known as the Great Migration, African-Americans moved out of the rural South to escape the oppression of Jim Crow laws and to find a better economic future into the cities of the North and West. Cities like Chicago, which needed industrial workers, were prime places for these movers to settle. Similarly, rural whites, also seeking a better economic future, moved into these cities looking for jobs.

For those early American sociologists, the changing city became their urban laboratory. They wanted to know how the changes they observed impacted social life, and a central concern was how these social forces affected crime and delinquency. Social Disorganization Theory became a critical tool for exploring and explaining the patterns that they observed. Because racial and ethnic differences were

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,

central to the dynamics of this shifting urban landscape, early scholars used the important concepts of ethnic heterogeneity and ethnic succession to develop the theory used today. Both concepts will be described below, but essentially those scholars believed that when too many different groups lived in close proximity, resulting in racial and ethnic heterogeneity, the social solidarity required for an organized society could not be developed and maintained. Also, they came to believe that crime, delinquency, and other social problems were not properties of the ethnic groups that inhabited these disorganized neighborhoods, but were instead characteristics of the place. As different groups moved into that space, they would take on the levels of problems that went with the space. As the ethnic composition of neighborhoods changed, the crime rates would remain roughly the same, and there would be ethnic succession in the neighborhoods and in criminal activity.

Historical Context

Race and Ethnicity in Early Chicago School Human Ecology

Chicago School sociologists Park and Burgess ([1925]1967) provided the concentric zone hypothesis as a model of how American cities grow and adapt to change. Borrowing from the literature on plant and animal ecology, Park and Burgess's work in urban ecology was aimed at understanding both spatial relationships of social and psychological experiences and how the spatial structure of relationships within the city shaped behavior among city inhabitants. As such, this model was one of an ideal process of change rather than a static state of what cities look like (Stengel 1964).

The concentric zone hypothesis of urban growth suggested that American urban cities grew due to ecological factors, radially by concentric zones. Zone one comprises the central business district, where land is the most expensive and the most desirable particularly for commercial real estate. Zone two is the zone of transition, housing both older factories as well as cheap housing. This zone, the most undesirable area of the city, is the first point of entry for the city's newest immigrants and typically has the highest crime and poverty rates. Recent immigrants typically moved first into these areas of the city due to the availability inexpensive housing and proximity to co-ethnics and industrial employment. However, once they improved their social and economic status, immigrants, oftentimes in subsequent generations, were able to move out of this zone into more desirable areas of the city. Zones three, four, and five contained homes of blue-collar workers, middle-class residences, and upper middle-class single-family homes, respectively.

Park and Burgess ([1925]1967) argue that cities are constantly changing, growing in concentric patterns due to a process of invasion, where one population seeks to take over from another, and succession, where one population finally takes the place of another. The most striking example of this process of change is the invasion and succession of different ethnic groups into and out of city neighborhoods. Critical to the Park and Burgess model of invasion and succession of the population in urban areas was the idea that competition between inhabitants acted as the mechanism for neighborhoods to achieve equilibrium after social change, particularly the invasion of a new group into the community. Park argued that similar to the process that leads to biotic changes, cultural changes within a community occur by the same mechanism of competition. In the natural communal order of an urban area, competition for land use and economic resources determines the location of residential areas as well as the distribution of the population throughout the city. Less successful population groups will naturally inhabit the least desirable areas of the city. As new groups move in, such as new immigrant populations, competition for resources allows older immigrant groups who have become more economically stable over time to move out to more desirable areas allowing newer inhabitants to take their place.

In their classic study, The Polish Peasant in Europe and America, sociologists Thomas and Znaniecki document the transition of Polish peasants into American life, noting the struggles immigrants have in assimilating into American culture and the resulting social disorganization of the immigrant group ([1918]1996). Polish immigrants, newly arriving in American cities, brought with them the norms and morals of the old country and immersed themselves in smaller Polish communities that were unable to provide cultural and normative structures that would offer support in the face of marital conflict, disagreements between neighbors, mental health issues, and unemployment in their new country. The disorganization of the Polish peasant immigrant community is highlighted in the transition to the American way of life. New Polish immigrants struggled with economic dependency and conflict resolution with neighbors and strangers. The American economic system does not offer jobs like those the peasants were accustomed to in their home country, and therefore, immigrants found it easy to move from one job to another, unafraid of job loss, because they had developed little attachment to the positions they were able to obtain. Though the Polish community may still be intact in numbers, it now exists within the wider American community that does not recognize the function or influence of the familial or community group. Kin and kith bonds becomes broken as the church and community lose significance and power within American society, and therefore, are unable to provide support or social control when needed.

The incidence and nature of homicide illustrates the distinct nature of the social relations of Polish immigrants and the community in the American city. In the home country, stranger murders were rare since peasants had few social ties to those outside their economic and familial group, thus motives for violence rarely existed. Where social ties in American life have loosened for the Polish immigrants, contact with those outside the community is more frequent, defensive and hostile at times, and full of mistrust. The potential for a violent interaction with others can no longer be effectively subdued by kin who are now scattered, nor does the Polish community have the normative authority to intervene in the struggles of individuals.

African-Americans and Social Disorganization Theory

The African American experience in the American city, and with the process of invasion and succession, is distinct from those of other migrant groups such as the Poles discussed previously. African American migrants from Southern states inherited the most undesirable residential areas of the city. Unlike European immigrant groups, the African American experience is marked by formalized discrimination, which forced segregation of the group into the most undesirable areas of the city and restricted access to employment and education. Segregation policies and practices inhibited such essential transitions, limiting the ability of African Americans to amass savings, acquire stable jobs with good pay, and move into more desirable areas. As the “black belt” of Chicago expanded, the area became overcrowded due to the extreme density of housing from within, causing white residents and immigrants to flee to other parts of the city.

Sociologists documenting neighborhood conditions in Chicago show that African American residential areas suffered from a high rate of death and disease such as tuberculosis, mental health issues, and infant deaths (Drake and Clayton 1945). In addition, these areas were also highest in poverty and juvenile delinquency, indicative of social disorganization. Unlike African American residents, other immigrant groups who initially moved into distressed, disorganized inner-city areas were not constrained to the black belt of Chicago or other similarly disadvantaged sections of other cities.

However, these undesirable or “blighted” residential areas were invaded by warehouses and industry. The land was seen by city planners and real estate investors as more valuable for industrial establishment rather than residential areas due to its close proximity to the central business district. Therefore, investment in housing decreased because the land is more valuable for industrial establishment, while at the same time, the cost of rent was pushed up in areas already concentrated with disadvantage. Where housing investments were being made, gentrification of these areas pushes African American residents into suburban neighborhoods shared by industrial sites such as steel mills (Drake and Clayton 1945).

Ethnic Succession in Neighborhoods and Crime

Shaw and McKay's (1942) seminal work documenting the spatial patterns of male juvenile delinquency across the city of Chicago is the hallmark of Social Disorganization Theory. Shaw and McKay found that Chicago neighborhoods where male juvenile delinquency was highest were characteristically higher in poverty, residential instability, and ethnic heterogeneity. They argued that these characteristics were indicative of social disorganization which leads to some neighborhoods having higher crime rates than others. Though their work did not test this, Shaw and McKay speculated that weak social ties were the mechanism that inhibited those living in disorganized neighborhoods from combatting neighborhoods problems such as crime and delinquency.

The neighborhoods in Chicago characterized by high rates of foreign-born residents, recent immigrants, and migrants from the rural South were those with high levels of ethnic heterogeneity. Language barriers, differences in cultural and social norms, and residential instability of immigrants moving away from neighborhoods of first residence are thought to inhibit the formation of close social ties to other residents, thus decreasing the capacity for neighborhood informal social control and increasing the potential for crime.

Where Park and Burgess ([1925]1967) noted the patterns of invasion and succession for land use and industry, Shaw and McKay (1942) highlighted the patterns of ethnic and racial invasion and succession in Chicago neighborhoods and the relationship to patterns of male juvenile delinquency. Though the zone of transition experienced invasion of new immigrants and succession of older more established immigrants to more desirable areas of the city, levels of crime and delinquency remained stable over time in the same neighborhoods. This finding suggested that delinquency was tied to place rather than people or groups. Shaw and McKay argue that neighborhood crime and delinquency rates remain stable over time due to a process of cultural transmission, whereby the patterns, norms, and values that support delinquency are transmitted down through successive generations.

Shaw and McKay point towards the conflicting presence of norms and values within communities that are characterized by ethnic heterogeneity as a partial explanation for high rates of juvenile delinquency in some Chicago neighborhoods. Diversity in the cultural background of residents in the zone of transition did not foster cooperation or agreement on how to solve community problems. In addition, the constant movement of Chicago residents out from the center to more desirable neighborhoods led newer immigrants to identify with areas of residence where they planned to move rather than where they were first living. Thus, the problems that plagued their neighborhood of first residence were unlikely to be troubling to those who planned to move elsewhere.

Shaw and McKay also documented that in the African American neighborhoods of Chicago, the characteristics of social disorganization were particularly exaggerated. Like Drake and Clayton, they compared the experience of white immigrants who were able to achieve more satisfactory conditions of living and working with African Americans unable to make similar achievements due to legal restrictions on procuring residence (enforced segregation), education, and employment. As a result, African American residents of Chicago were unable to move outwardly to more desirable areas of the city, and thus, conditions of living remained in a state of concentrated disadvantage, social disorganization, and increasing crime and delinquency.

Race and Ethnicity in Contemporary Social Disorganization Theory

A central feature of Social Disorganization Theory is the argument that there is stability of crime within geographical areas. In the tradition of social disorganization, race and ethnicity are not significant as markers of cultural or behavioral proclivities for criminal offending but rather serve as indicators of pervasive social disadvantages that are affiliated with racial status. The inequality that is endemic in the educational, occupational, residential, and criminal justice contexts for people of color erects structural barriers that prevent effective social organization. European immigrants to the United States in the nineteenth and twentieth centuries faced similar restrictions, with continuing parallels to the contemporary experience of Latinos, African-Americans, and some Asian communities.

Contemporary versions of Social Disorganization Theory continue to emphasize basic principles of the theory, including informal social control and neighborhood solidarity, but scholars have added emphasis on economic disadvantage and social and cultural isolation. As was the case with their predecessors, racial and ethnic residential patterns are central to the discussion. Increased immigration and shifts in the economic and occupational market suggests that the mechanisms once understood to drive the social disorganization of neighborhoods need to consider economic and political changes and the influence on the urban environment and, consequently, the nature of neighborhood crime.

While consistent with Shaw and McKay's original formulation, Sampson and Wilson (1995) offer unique theoretical mechanisms that explore modern determinants of geographically concentrated criminal activity, emphasizing the role of neighborhood disadvantage. This work builds on Wilson's earlier research (1987) that recognizes the vital role of deindustrialization as a cause of economic disadvantage as well as pervasive residential segregation and social isolation, all causes of crime and delinquency. The decline of the urban manufacturing cities that characterized the industrial era resulted in a decline in the number of jobs available to workers with limited skills levels and low educational attainment, which disproportionately affected African-American men. The flight of middle-class whites and African-Americans from the urban core resulted in residential areas that were bereft of institutional and organizational markers of stability. Wilson suggests that these macro labor market changes contributed to the social isolation of many African-Americans who continued to live in poor urban neighborhoods, resulting in higher social disorganization and an increase in rates of violent and property crimes. Sampson and Wilson (1995) suggest that the breakdown of residential organization can be attributed to the concentrated level of economic disadvantage and the inability of residents left in the urban center to form protective relationships with neighbors. The social isolation fostered by limited residential mobility, family disruption, and high rates of poverty weakens the informal social control mechanisms that guard against the rising tide of violent and property crime.

Bursik (2000) highlights the transition from Shaw and McKay's ecological model of social disorganization to the contributions of the systemic model, which underscores the role of interactional networks that regulate behavior within neighborhoods. These networks provide the foundation for informal social control measures to control criminal behavior in the community. The breakdown of social organization is indicative of the dissolution of institutional and organizational ties to the broader community. The loss of middle-class residents, businesses, and community organizations from the urban center left the central neighborhoods with limited opportunities for public engagement and financial mobility. The exodus of residents signaled the loss of viable community structures that would aid in sustaining neighborhood cohesion. Bursik (2006) emphasizes the role of political, economic, and social network links external to the neighborhood environment in the pursuit of regulating disorderly or unacceptable behavior. The activation of these ties and their accompanying resources is predicated on the social organization of a given neighborhood. In truly disadvantaged environments, the access to these external resources is hindered by the societally disadvantaged position of its residents (Wilson 1987). Therefore, the ability to organize collectively for broader control mechanisms to combat criminal activity is limited. Predominately African-American, inner-city neighborhoods are especially affected by this process because they are more frequently characterized by hyper-disadvantage (Wilson 1987), residential segregation (Massey and Denton 1993), and as a consequence, they experience high rates of both property and violent crime (Peterson and Krivo 2010). In socially disorganized communities, social capital formation is hindered, and in communities with increased proportions of immigrant populations, the ability to effectively build and sustain these network ties is constrained by language and cultural barriers (Peterson and Krivo 2010). But recent research indicates that, contrary to the logic of early Chicago School theorists, this is not the case for all immigrant groups. Such exceptions will be discussed below. Essentially, it can be said that the social isolation experienced by many communities of color and especially some inner-city African-American neighborhoods, in tandem with increased levels of economic disadvantage, weakens the connection between neighbors, which in turn inhibits social control, allowing more crime to occur.

Sampson and Wilson (1995) highlight the substantial differences between the economic deprivations experienced by African-Americans compared to their white counterparts. They contend that an accurate comparison is not feasible given that poor whites nearly always reside in areas with less concentrated disadvantage than African-Americans, a consequence of racial residential segregation. As a result, the conditions that tear at the fabric of social organization – poverty, residential instability, and family disruption – are more pervasive and concentrated in African-American communities, making studying and replicating such circumstances in white neighborhoods an impossibility. The extent to which racism and de jure and de facto discrimination have altered the trajectories of African-Americans in the urban centers creates levels of economic, educational, occupational, and political inequity that cannot be matched in even the poorest white neighborhoods. Economically disadvantaged whites are not as isolated from nonpoor people as are their African-American counterparts. Poor whites tend to live in closer spatial proximity to socially organized middle-class communities. Therefore, disadvantaged white residents are able to benefit from the social and community resources that are most often lacking in low-income neighborhoods. The access to grocery stores, schools, community centers, and other fixtures of vibrant neighborhoods is a stark departure from the conditions in low-income African-American neighborhoods. Furthermore, these conditions, and the subsequent high crime rates that follow, remain constant over time. The toxic mixture of isolation and disadvantage ensures that the social control mechanisms will be further weakened, inhibiting the ability of African-American communities to organize effectively against crime. Consistent with Shaw and McKay's original conception, the crime conditions that exist are not racially or ethnically dependent but are rather a reflection of the structural conditions endemic to the geographical place.

New Directions

Spatial Proximity and Concentration

This social isolation is further compounded by the geographical and spatial divide between low-income communities. A major development of contemporary Social Disorganization Theory addresses the geographical concentration of disadvantage and isolation, with African-Americans often segregated in veritable islands of similarly disadvantaged others (Peterson and Krivo 2010; Sampson and Bean 2006; Sampson and Morenoff 2006). Peterson and Krivo (2010) analyze the spatial distribution of these neighborhoods, finding that low-income African-American communities are more likely to be located in a dense geographical network, bordering areas situated in similar economic straits. The spatial concentration of disadvantage heightens the levels of social isolation that residents experience, further segregating these populations from more prosocial and economically mobile segments of the population. Sampson and Morenoff (2006) suggest that this may represent a type of spatial vulnerability, where neighborhoods with low social control and collective efficacy detrimentally affect the conditions present in adjoining communities. In their analysis of Chicago neighborhoods, Sampson and Morenoff's (2006) results indicate that there was a diffusion process that spread the concentrations of high poverty rates across a densely clustered region as the national occupational landscape evolved in the late 1970s and 1980s. This geographic isolation compounds the social segregation that pervades low-income African-American communities, inhibiting the creation of social capital and the ability to establish effective informal social control. The spatial proximity of a given community in a city-wide context is affected by the influence of surrounding communities, allowing neighborhoods with strong shared value sets and personal ties to be undermined by those who do not similarly value social control but nevertheless live in close geographic proximity. These residents may be able to form strong bonds with specific fellow neighbors; however, their ability to organize effectively against crime when surrounded by socially disorganized, high-crime communities is severely limited. The permeability of adjacent geographical boundaries facilitates the spread of the detrimental effects of poverty, heightening the levels of social disorganization. Sampson and Morenoff (2006) assert that the social isolation coupled with the concentration of disadvantage promotes a vicious cycle in low-income African-American communities due to the weakness of collective efficacy. While the research focus has traditionally centered on intra-neighborhood dynamics, the inter-neighborhood research suggests that cultural and economic disadvantages are not spatially contained (Peterson and Krivo 2010; Sampson and Morenoff 2006; Morenoff 2005). Because of this diffusion, the isolation of poor African-Americans is compounded by the structural and informal barriers of the broader society. While other racial and ethnic groups face similar disadvantages, their outcomes differ from the traditional dire predictions of Social Disorganization Theory.

Contemporary Immigration and Social Disorganization Theory

Sampson and Bean (2006) reconsider Social Disorganization Theory in light of changes in immigration and mobility patterns in recent decades. Despite the original focus of the theory on ethnic heterogeneity, recent empirical work has been dominated by analyses of African-American and white neighborhoods, eschewing discussion of other racial and ethnic groups. Continuing Latino immigration has fostered a renewed interest in the dynamics that underlie ethnically heterogeneous communities and the impact on the organizational structure of neighborhoods. Extending his earlier work with Wilson (Sampson and Wilson 1995), Sampson and Bean consider the paradox that has emerged in the literature, which finds that Mexican immigrants, living in extreme economic disadvantage, experience fewer incidents of violent crime than second- and third-generation Latinos (Martinez et al. 2006; Morenoff 2005). While impoverished and historically disadvantaged African-American communities share some similar conditions with the newly immigrated Latino population, crime outcomes diverge. A number of explanations for these differences have been hypothesized, ranging from the extent of residential segregation and isolation from middle-class white communities and divergent cultural values to the severity of systemic discrimination and differential employment patterns. While African-American and Latino communities are matched on conventional predictors of violent crime, economic disadvantage, and relative social isolation, their differences on key deprivation indicators suggest immigrant status can be a protective factor. Martinez and his colleagues (2006) find that concentrated immigrant populations are not predictors of homicide at the aggregate level, which is inconsistent with the traditional pattern for African-Americans. Sampson et al. (2005) suggest that the formation of densely populated immigrant communities and the lower incidents of family disruption in Latino immigrant communities account for their lower levels of violent crime rates. While Latino immigrants face constraints on employment, residential mobility, and educational attainment, their rate of offending does not subsequently increase. Instead, researchers posit that the protective influence of their strong family and kinship ties and integration into ethnic enclaves help to ameliorate the negative effects associated with these social limitations (Peterson and Krivo 2010). The formation of ethnically homogeneous immigrant communities could similarly foster social capital among residents, producing higher levels of collective efficacy and resulting in strengthened controls against criminal activity. The formation of collective efficacy in these communities may be predicated on the shared culture, values, and language among Latino immigrants and the ability of residents to interact in spite of economic and geographic deprivation. While the original conception of Social Disorganization Theory suggested that ethnic heterogeneity constructed barriers to the formation of social capital, the evolving empirical work points to a set of unique mechanisms and processes that explain the formation of capital and collective efficacy. While African-American communities remain largely homogenous due to residential segregation, Latinos have not experienced the same levels of isolation and, therefore, often reside in more integrated neighborhoods. The research on this particular topic within the Social Disorganization Theory tradition is at a nascent stage; the continued consideration of contemporary immigrant populations holds the promise of a more nuanced understanding of the complex dynamics that underlie neighborhood crime and safety.

Conclusion

Racial and ethnic divisions have been central to the development of Social Disorganization Theory, and they remain so today. The concepts of racial and ethnic heterogeneity and ethnic succession have retained their continued empirical significance for criminologists as contributing forces to the process of social disorganization. Focusing on the process of ethnic succession diverts the onus of social disorganization from specific racial and ethnic groups to the social and structural conditions of these communities. Heterogeneity though may be more complex than the early Chicago School theorists expected. This is not to suggest that they were wrong when they hypothesized that mixing different languages, cultures, traditions, and religions together within a residential setting would inhibit the formation of social organization, but recent research suggests that a more nuanced understanding is needed. African-American communities are racially homogenous, but those marked by considerable social and economic disadvantage are more disorganized. In contrast, neighborhoods with more recent Mexican immigrants exhibit similar levels of homogeneity and disadvantage, yet local crime rates are comparatively lower. As contemporary versions of Social Disorganization Theory move forward, one of the challenges for scholars will be to evaluate and develop critical analyses of these patterns.

As is obvious, much of the literature has focused on American cities, but not all of it. For example, Sampson and Wikström (2008) used data from Stockholm to study the comparative dynamics of collective efficacy in Sweden. Other countries, for example, Australia, Canada, or South Africa, have very different racial and ethnic dynamics than the United States. That said, it is very likely that in these countries and elsewhere, if the population is marked by racial and ethnic divisions or changing immigration patterns, the influences of social organization and disorganization will have accompanying consequences for crime and criminality in these communities.

Overview

Opinion surveys in the United States often report that citizens believe that race influences how police officers treat the public. This entry summarizes a recent meta-analysis by Kochel et al. (2011) that examined the existing empirical evidence on the relationship between race and a police officer's decision to make an arrest. The findings support the conclusion that black suspects are more likely to be arrested than white suspects when encountering a police officer. This effect does not appear to be the result of various alternative hypotheses, such as the demeanor of the suspect or other observable legal and extralegal factors. Although the research consistently supported a racial bias hypothesis, the strength of the effect across studies did vary. Additional research is needed to better understand the factors that influence this relationship.

Background

Harvard University Professor Henry Louis Gates, Jr., was arrested for disorderly conduct in July of 2009 (Cambridge Review Committee 2010). Police arrived at his home in response to a call from a neighbor reporting a possible break-in. In fact, Professor Gates and a friend had forcibly opened a stuck door. When the police arrived, Professor Gates was already in his home. The police report indicated that in the course of questioning professor Gates, he acted inappropriately toward an officer who had requested identification from the professor and had asked him to step outside. The professor claimed that he was treated inappropriately and that it was due to his race. The officer claimed otherwise.

Professor Gates' perception that he was treated unfairly by the police is a common perception among blacks in the United States. Perceptions of racial bias on the part of the police are strongly related to race and ethnicity. A 2002 survey of the general public by Weitzer and Tuch (2005) showed that 75 % of blacks and 54 % of Hispanics believe that local police treat minorities worse than whites. This is in stark contrast to the roughly 76 % of whites who think that the police treat whites and minorities equally. Personal experiences with the police also differ substantially between racial and ethnic groups. Based on this survey, 37 % of blacks, 23 % of Hispanics, and 1 % of whites reported that they believe they were treated unfairly by the police because of their race or ethnicity. Professor Gates' perception that he was treated unfairly by the police is a common perception among blacks in the United States.

A fundamental question raised by the Gates case and the public opinion surveys is whether this perception of racially biased treatment by the police accurately reflects police behavior. Police agencies and the general public should be concerned that a high percentage of minorities believe that they are being treated unfairly by the police. This undermines police legitimacy (see [encyclopedia entry on this topic]) and reinforces racial tensions. However, an important issue is whether this perception of racially biased treatment by the police accurately reflects police behavior.

The research challenge is that in the absence of overt racist behavior, such as a racial epithet, it is difficult to know whether race played a role in an individual case, such as that of Professor Gates. To address this problem, social scientists have compared the arrest rates for white and black suspects under similar circumstances from a large number of police–citizen encounters (Although the treatment of other racial and ethnic minority groups is matter of concern, most studies focus on the comparison of whites and blacks). The credibility of such results rests on how well the research established the "under similar circumstances" comparison. The goal is to ensure that an observed difference in arrest rates between a white and black citizen is not the result of different levels of evidence, criminal behavior, or other issues that might be confounded with race. Numerous studies of this type have been conducted over the past several decades. Prior reviews of these studies, including a blue-ribbon academic panel, judged the findings to be so mixed that they have been unable to draw a definitive conclusion. The National Research Council's Committee to Review Research on Police Policy and Practices concluded that "the evidence is mixed, ranging from findings that indicate bias against racial minorities, findings of bias in favor of racial minorities, and findings of no race effect" (Skogan and Frydl 2004, pp. 122–123). Similarly, a working group of 45 social scientists formed by the American Sociological Association also was unable to draw a firm conclusion on this issue (Rosich 2007). Both of these groups relied on traditional narrative review methods and both called for additional research to better understand whether and under what circumstances police behave in a racially biased manner.

More recently, Kochel et al. (2011) published a meta-analysis of these studies. Meta-analysis is a useful tool for assessing the strength and consistency of evidence regarding a hypothesis, such as the effect of race on arrest, across multiple studies. It has also proven to be useful in areas where narrative reviews arrive at equivocal conclusions. Kochel and colleagues' meta-analysis concluded that the evidence does support the contention that the police are more likely to arrest a minority than a white suspect under similar circumstances. The methods and findings of this meta-analysis are summarized below, followed by a discussion of key issues and controversies related to this issue.

Meta-analysis of Race and Arrest

Summary of Methodology

The sample of studies included in the Kochel and colleagues' (2011) meta-analysis was comprised of observational studies of police–citizen encounters that examined the relationship between a citizen's race/ethnicity and arrest. To be included, these studies must have collected data at the level of individual suspects/encounters and measured arrest (versus a less severe alternative) and the suspect's race/ethnicity. There were several research designs that met these criteria. The two most common were field studies where researchers observed and recorded extensive data on police–citizen interactions and existing records generated by police officers, the majority of which were data routinely collected as part of police incident reports or vehicle and pedestrian stops. Also included were a survey of crime victims and a study based on data extracted from juvenile referral records.

Kochel and colleagues developed and implemented a systematic search strategy designed to identify all available studies that met the inclusion criteria for the review. This review was restricted to studies conducted within the United States, so the results cannot be generalized to other countries. To minimize publication-selection bias, both published and unpublished studies were sought and included. This process identified 40 documents that reported the results of 23 distinct research projects and 27 independent data-sets. Information was coded from these studies that reflected each study's method of data collection, sampling strategy, sample size, geographic location and years of data collection, crime type, age and sex of the samples, the data source, document type, type of statistical analyses applied, independent variables included in statistical models, and finally the statistical effect size(s) for the relationship of race on arrest.

The effect size for this meta-analysis was the odds ratio. The odds ratio is an index that compares the odds of an arrest for one group (blacks or minorities) with the odds of an arrest for another group (whites). As such, an odds ratio of 1 indicates no difference between the two groups. These odds ratios were coded so that values greater than 1 indicated bias against minorities and values less than 1 indicated bias against whites.

All of these odds ratios were based on statistical models that included additional variables that might influence police arrest discretion, such as the severity of the crime or the demeanor of the offender. As such, these odds ratios were all adjusted for observed features of the encounter, most commonly using logistic regression. A few studies relied on probit regression models or ordinary least squares models. Findings from these models were converted into odds ratios that were directly comparable to those being calculated from the logistic regression models.

Summary of Results

Kochel and colleagues coded 120 odds ratios across the 27 independent data-sets that reflected a contrast between white and black or minority suspects. When the contrast was between white and minority suspects, the minority sample was predominantly black. Thus, these results focus on the white versus black difference in likelihood of an arrest.

The multiple odds ratios from a single data-set reflected variations in the statistical models estimated on the data. This occurred both within a single publication and across publications based on a common data-set. These different models typically varied the set of independent variables included. These multiple odds ratios from a single data-set do not provide statistically independent information on the direction and magnitude of any race–arrest relationship. To address this, Kochel and colleagues restricted any given analysis to a single odds ratio per independent data-set. Thus, no analysis could include more than 27 odds ratios.

To ensure that results were not overly influenced by the specific odds ratio selected from a given data-set, Kochel and colleagues performed several analyses with different selection rules. These included calculating the average odds ratio for each data-set, selecting the smallest odds ratio for each, selecting the largest odds ratio for each, and selecting the odds ratio that met explicit criteria that they believed represent the best (most accurate) effect size for each. The selection criteria for the best effect size within a data-set gave preference to odds ratios that: (1) were based on a logistic regression model rather than an OLS or probit regression model; (2) had a standard error that was reported directly and not imputed from other information, such as sample size; (3) were based on the full sample, rather than a subset; (4) were from models where the operationalization of the dependent variable was clearly arrests versus no arrest, rather than some other less severe alternative sanction; (5) had a race variable that represented black versus white, rather than minority versus nonminority or white versus nonwhite; (6) were based on a statistical model that included demeanor as an independent variable, (7) were based on a statistical model that included officer characteristics, and (8) were based on a model with the largest number of independent (control) variables.

Table 1 presents the meta-analytic mean for these four sets of odds ratios. The meta-analytic method used was the random-effects inverse-variance weight approach. This is a conservative approach to meta-analysis and explicitly assumes meaningful variation across studies in the estimate of the race–arrest relationship.

Each of the four methods of selecting one odds ratio per data-set produced an overall mean effect size that was statistically significant. The range in the mean odds ratio across these four sets was 1.32 for the smallest odds ratio per data-set and 1.52 for the largest odds ratio per data-set. Using the average and best odds ratio within each data-set produced very similar results (1.45 and 1.38, respectively). These results suggest that minorities have a higher odds of arrest than nonminorities in a police–citizen encounter. The different selection models showed that the results were robust to which effect size is selected from each data-set.

Race and the Likelihood of Arrest, Table 1 Meta-analysis results of odds ratios for the effects of race on arrest (27 odds ratios per mean)

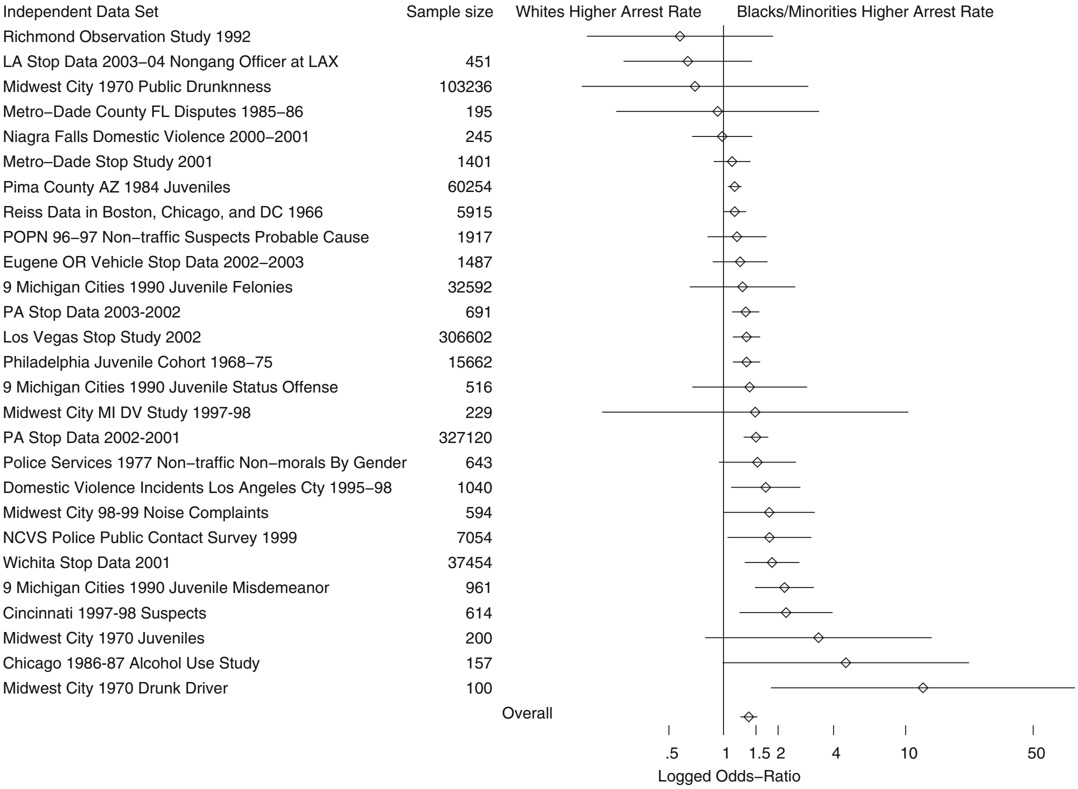
		95 % C.I.	
Analysis	Mean odds ratio	Lower	Upper
Average	1.45	1.28	1.64
Smallest	1.32	1.16	1.50
Largest	1.52	1.32	1.74
Best	1.38	1.24	1.53

Data from Kochel and colleagues (2011). Mean odds ratios based on a random-effects inverse-variance model estimated via method-of-moments

Figure 1 presents a forest-plot for the distribution of odds ratios for the set of effect sizes designated as the best from each data-set. Figure 1 shows that only 4 of the 27 odds ratios were in the negative direction with blacks or minorities having a lower odds of arrest. This would be expected by chance. What is of greater interest is the pattern of results across studies and this pattern supports the hypotheses that race affects the likelihood of arrest.

By conventional standards, these effects are small. To interpret the magnitude of the effect in meaningful terms, Kochel and colleagues converted the overall mean odds ratio of 1.38 (model based on the best effect size within each data-set) into the probability of arrest for minorities and blacks relative to whites. This conversion is based on an assumed arrest rate of 20 % for whites, roughly the average across all samples. Using this value as the benchmark, an odds ratio of 1.38 is equivalent to an arrest probability of 0.26 for minorities and blacks and 0.20 for whites. This is a difference that is large enough to be of practical concern.

Focusing solely on the mean ignores the variability in results across studies. This variability exceeded what would be expected from sampling error alone. Thus, there are true differences in the effect of race on the likelihood of arrest across these studies. Some studies show a stronger race effect than others. Kochel and colleagues performed a series of moderator analyses to explore this variability. These analyses examined both methodological and theoretical explanations for differences across studies.



Race and the Likelihood of Arrest, Fig. 1 Forest-plot of the best effect size within each data-set (From Kochel and colleagues 2011; Reproduced with Permission from Criminology)

An important methodological consideration is how the data were collected. Three basic approaches were used across the studies reviewed. The method least susceptible to bias is the use of trained field researchers accompanying police out in the community and coding extensive information about each police–citizen encounter. However, an officer may be affected by the observer's presence, altering what they do. There is some evidence to suggest that officers are less passive and more legalistic in the presence of an observer (Mastrofski and Parks 1990; Mastrofski et al. 2010; Spano 2007). This may reduce the likelihood of finding a race–arrest relationship. This was the method used for 10 of the 27 data-set. Police officer's documentation of encounters with citizens was the data source for another 16 data-sets. This method is arguably likely to underestimate any racial bias, as officers would want to present their behavior in a positive light, given strong disincentives in most police agencies toward overt racially biased behavior. A single data-set was based on surveys of victims. As reported by Kochel and colleagues, although the victim survey produced a larger odds ratio (1.79), the officer reported and field researcher data produced highly similar means (1.39 and 1.36, respectively). The differences across these means were not statistically significant and the overall finding of a positive race–arrest relationship is clearly not being driven by a single method.

These studies also differed on the statistical methods used. Once again focusing on the best estimate per data-set, most models were estimated using logistic regression methods (23 of 27), two used probit methods, and two used ordinary least squares methods. The mean for the probit models was highest and the mean for the OLS models was lowest, although not by enough to account for a significant amount of variability in the odds ratios.

Theoretically, several variables may moderate the race–arrest relationship. In considering these variables, scholars have distinguished between disparity and discrimination. The logic is that disparate experiences by race when explained away by legal factors present during the encounter are not discriminatory (Skogan and Frydl 2004, p. 124). Therefore, differential rates of arrest for minorities and whites that dissipate when accounting for legally relevant factors indicate a disparity but not discrimination. Legally relevant factors would include the seriousness of the offense, amount of evidence against the suspect, the presence of a victim supportive of arrest, the presence of a witness on the scene, the suspect being under the influence of drugs or alcohol, or the discovery of additional criminal acts during the course of the officer–citizen interaction.

Kochel and colleagues examined the disparity versus discrimination issue by comparing odds ratios based on statistical models that either did or did not include each of the above legally relevant factors. The differences were trivial, statistically nonsignificant, and failed to explain the positive race–arrest relationship. That is, adjusting for legally relevant disparity did not attenuate the overall finding of discrimination against blacks.

It is possible that individually, these legal factors contribute little to explaining the race–arrest relationship but collectively they might. Kochel and colleagues examined this by assessing the relationship between the number of these factors included in a model and the size of the race–arrest effect using a meta-analytic regression model. The analysis showed that as more legally relevant factors were controlled, the odds ratio became smaller. However, this effect was very small and statistically nonsignificant. The race–arrest relationship remained even for those models with the highest level of statistical control for legally relevant factors.

The suspect's demeanor was an important extralegal factor that has been examined by roughly half of the studies included in the Kochel and colleagues review. Research supports the idea that a suspect's demeanor affects the arrest decision. It is important to note that some disrespectful behavior is illegal, such as physical resistance, and as such is legally relevant to an arrest decision. Other disrespectful behavior is generally not, such as using disrespectful language, and should not be considered by an officer in the arrest decision. What may appear as racial discrimination may be more appropriately attributed to suspect demeanor if demeanor and race are confounded. That is, an officer making a decision to arrest may not be reacting to a suspect's race but rather to his or her disrespectful behavior. This hypothesis is not supported by the existing data. Statistical models that adjusted for demeanor produced effect sizes roughly comparable to models that did not. Thus, controlling for the demeanor of the suspect did not attenuate the race–arrest relationship.

Key Issues and Controversies

It remains possible that unaccounted for legal and extralegal aspects of the police–citizen encounter could explain the race–arrest relationship, reducing the odds ratio to zero. This is a challenge with all observational research. It is impossible to know if all possible confounds have been accounted for. However, the most likely culprits have been addressed in the literature on this topic, thus increasing the confidence that can be placed in the conclusion that race plays a role, possibly unintentionally, in the arrest decision.

An important hypothesis in this literature has been that the observed race effect is a function of differential demeanor between white and black suspects when encountering a police officer. Research does indicate that police are affected by the demeanor of a suspect in their arrest decision. If on average, the demeanor of black suspects is more hostile than white suspects, then this would produce a differential arrest rate between the two groups. As discussed above, the evidence reviewed by Kochel and colleagues does not support this hypothesis. Other plausible confounds, such of severity of the offense, also failed to explain away the race–arrest relationship.

The robustness of the finding of racial bias to plausible alternative explanations should not obscure the variability in findings across the studies included in the Kochel and colleagues' meta-analysis. Clearly this effect varies.

The meta-analysis did not identify any explanations for this variability but the authors did theorize about possible ecological factors that might be explored in future studies (Klinger 2004). Four possibilities were discussed. The first has to do with the character of the organization, such as how actively the organization attended to unequal treatment of citizens according to their race or the degree of professionalism and bureaucracy of the police agency. Second is the context of who benefits or is served by an arrest. A police officer's decision to make an arrest may be affected as much by who benefits (e.g., the race or other characteristics of a victim) as who suffers. Third, the neighborhood context may affect an officer's discretionary judgment regarding an arrest. Police may exert their authority in more racially differentiated ways in some neighborhoods than others. And finally, differences in the race–arrest relationship may reflect the level of political power of a given minority group within a police jurisdiction. Little is known about the role of these ecological factors on police decision making.

Conclusion

In summary, the existing evidence supports the conclusion that blacks have a higher likelihood of arrest than do whites. The research does not demonstrate the causes of this racial disparity, nor does it point to a clear policy response for dealing with it. What it does establish is that where there is smoke there is indeed fire regarding racial disparity in the arrest practices of American police. This certainly shows that further efforts to delineate the legal and ethical implications of racially differentiated policing are based on a solid empirical foundation. Future empirical research should move beyond just testing for a race effect and examine what accounts for variation in this relationship and the effect of any policies designed to reduce it.

Race Issues in Probation and Parole

Kathryn D. Morgan
Department of Justice Sciences, The University of Alabama at Birmingham, Birmingham, AL, USA

Overview

This entry examines the relationship between race and probation and parole decisions and the issue of racial disparity in granting probation and parole. Previous research suggests that race is an important variable at every level of processing where criminal justice authorities have the power to make discretionary decisions. This entry focuses on two levels of discretionary decision-making in the criminal justice process and how race affects decisions made at those levels. Probation is an alternative to incarceration that allows the individual to remain in the community maintaining family and community ties, and employment while avoiding the stigma of prison. Parole is granted to an individual who has served a portion of the sentence and is released back into the community to serve the remainder of the sentence under supervision. Statistics consistently show that African-American and Hispanic defendants are less likely to be granted probation and parole and more likely to be sent to prison and stay longer than Whites. While discussing the statistics, this entry covers possible reasons for this sentencing disparity. Is the disparity based on race or legal variables such as seriousness of the offense and criminal history? Finally, the entry will conclude with suggestions for future research.

Probation and Parole as Corrections Programs

Fundamentals of Probation

There has been a proliferation of programs designed to be correctional rehabilitation programs. Despite the attacks on rehabilitation and the shift away from the rehabilitative ideal in the 1970s, community-based corrections have continued to proliferate in the United States correctional system. Probation and parole are two of those programs. Many of those in correctional programs in the community are on probation and parole, causing probation and parole populations continue to increase annually. In 2008, approximately 5.1 million offenders were supervised in community corrections programs. Of that number, probationers accounted for 84 % or 4.2 million and parolees accounted for over 800,000 or 16 %. By the end of 2009, the numbers of adults supervised under probation and parole continued to increase, making it clear that probation and parole are important programs in the criminal justice system (Glaze and Bonczar 2010). Statistics for adjudicated juveniles reveal a similar pattern. Probation remains the most common disposition for juveniles who have been adjudicated as delinquent as indicated by 2007 data, showing that 56 % of these delinquent juveniles received probation.

Although probation and parole are used synonymously and viewed as the same, they are very different programs. Probation is an alternative to incarceration where the sentencing judge decides to suspend the imposition of the sentence and place the defendant on probation. The judge and the probationer sign a probation order which constitutes a contractual agreement between the court and the probationer. The probationer must obey all probation conditions to remain in the community under conditional release. The probationer is supervised under the jurisdiction of the court; therefore, all requests for amending the probation order must be approved by the court from which the case originated. If violations occur, the case may be referred back to this same court for revocation proceedings.

While parole also represents conditional release, it is only granted after an offender has served at least one-third of the sentence in prison. After serving the required period of time, the Parole Board may consider the inmate for parole release. If the Parole Board believes that the inmate is ready to return to society, he or she is released to parole supervision with rules and regulations known as conditions of parole. Unlike probation, parole is an administrative matter where the Board of Pardons and Parole has jurisdiction over the inmate. Changes to parole conditions and violations of those conditions are handled by the Parole Board.

Probation is granted by the presiding judge after a review of the presentence investigation report and a consideration of other factors including the severity of the offense; the seriousness of the prior criminal history, sentencing guidelines, the defendant's age, rehabilitation potential and attitude, and the relationship with his or her family. There has also been controversy regarding the impact of race/ethnicity, gender, and social class on the judge's sentencing decision. Research findings have been inconclusive about the extent to which these variables influence judges' decision to grant probation or incarcerate. Some studies have concluded that the strongest predictors of sentencing are severity of the offense and criminal history (Kleck 1981; Spohn and Welch 1987). Other sentencing experts have argued that these variables do affect judges' decisions in deciding to grant probation or incarcerate. Petersilia and Turner (1998) state that with the exception of drug cases, the type of attorney influences probation granting decisions. Those with a private versus public attorney are more likely to get probation instead of prison. Spohn and Welch (1987) found that in borderline cases where defendants may be sentenced to probation or incarcerated, White defendants will usually be granted probation and Black defendants will be incarcerated.

Fundamentals of Parole

Approximately 15 % of those going to prison serve their entire sentence. Over 75 % of all inmates are released through either *discretionary or mandatory release*. *Mandatory Release* which grew out of the determinate sentencing approach, occurs when the inmate has served the entire sentence minus the good time. When the inmate is sentenced to prison, a "mandatory release date" which includes good time and other credits is calculated during the classification period. When the mandatory release date arrives, the inmate must be released and cannot be held longer than the actual sentence. Mandatory release is presently used by the federal government and those states operating under a determinate sentencing structure. Recent statistics indicate that mandatory releases have surpassed discretionary release by a parole board. In early 2000, forty-one percent (41 %) of the inmates released were granted a mandatory release. *Discretionary Release* occurs when an inmate is released as a result of decisions made by parole boards or commissions. Until the mid-1970s, all states and the federal government had systems of discretionary release where the parole board determined how much the time the person spent in prison and the time of return to the community. Discretionary release is associated with the indeterminate sentencing structure where the judge sets a minimum and maximum term of incarceration and the parole board determines the release time within these limits. Discretionary parole grew out of the rehabilitation model, releasing a person at a time when he or she would benefit most from being released. Determinate sentencing abolished parole in about 20 states and the federal government.

Race Issues in Probation and Parole

One of the most important controversies in criminal justice and criminology today focuses on whether or not there is disparate treatment of racial and ethnic minorities in the criminal justice system. Blacks and Hispanics are disproportionally represented at every phase of the Criminal Justice System. One area where the disproportionality has been most acute has been in incarceration rates. According to 2009 incarceration data, over 1.6 million prisoners were incarcerated in state and federal prisons, and Black and Hispanic males had highest incarceration rates. Blacks represented almost one million of that total prison population. Black males, who comprised over 40 % of the prison population, were incarcerated at a rate of 4,749 per 100,000, six times the incarceration rate for White males. Hispanic males were incarcerated at a rate of 1,822 per 100,000 Hispanic men. White males were incarcerated at a rate of 708 per 100,000 White men. Do these numbers reflect the existence of racial bias by criminal justice authorities charged with making discretionary decisions? Several criminologists have suggested that there is racial disparity at every level of processing where criminal justice authorities have the power to make discretionary decisions. Police are more likely to arrest, verbally and physically abuse, harass, and profile racial and ethnic minorities. Criminal courts have been accused of promoting not only a racial bias but an economic bias that results in racial and ethnic minorities being denied or unable to afford bail, using court-appointed attorneys, and ultimately receiving more severe sentences. Some criminologists conclude that racial bias by decision-makers does not result in more severe sentencing outcomes for racial and ethnic minorities. Black and Hispanic defendants commit more serious offenses and have more severe criminal histories. Others suggest that even when racial disparities exist, they are not the result of systematic racial bias but the unintended consequences of well-intended crime control policies designed to reduce crime and protect society such as the War on crime and drugs. These "get tough" policies resulted in the unintended consequences of higher arrests, prosecutions, and incarcerations of Blacks who were disproportionately affected (Kleck 1981; Wilbanks 1987; Tonry 1994).

Race and Probation

At the end of 2009, there were over four million adults under probation supervision in the United States. Whites comprised 55 % of the probation population while 30 % of the population was Black defendants and 13 % were Hispanic. In some states such as Texas and Oklahoma, the percentage of Whites on probation increases to as high as 69 % and the percentage of Blacks on probation falls to 20 %. It is commonly believed that probation and presentence reports may favor White over minority defendants, causing judges to award probation to Whites more than minorities. Additionally, Whites are more likely to receive probation in jurisdictions where Blacks and Whites receive prison sentences of similar duration. Petersilia (1985) found that in California, 71 % of the Whites convicted of a felony are placed on probation compared to 67 % of Blacks and 65 % of the Hispanics convicted of a felony. In their study of sentencing in Michigan Courts, Spohn and Welch (1987) found that in "borderline" cases, in which judges could impose long probation sentences or short prison terms, Whites were more likely to get probation and African-Americans were more likely to get prison.

Drug policies associated with the "War on Drugs" dramatically increased the number of incarcerated Blacks and Hispanics. Longer sentences for drug users, mandatory sentences for possession of crack cocaine, and reclassifying misdemeanor drug possession of crack cocaine to felony possession resulted in more Blacks being arrested, prosecuted, convicted, and incarcerated for drug offenses. Approximately two-thirds of the drug users are Whites, but Blacks comprise 62 % of those incarcerated for drug offenses. Whites make up only 36 % of those in prison for drug charges (Walker et al. 2004). Blacks are often sent to prison for drug offense and serve as much time in prison for a drug offense as Whites serve for a violent offense. Clear and Dammer (2000) suggest that there is a bias that operates in the selection process for discretionary community programs such as probation that results in Blacks excluded. Black offenders are likely to be young, poor, uneducated, unskilled, and have a more serious criminal history than their White counterparts. Therefore, they are viewed as less suitable for these programs.

Wilbanks (1987) suggests that offense severity and severe criminal histories cause Black defendants to have higher high incarceration rates and lower probation sentencing rates. Black defendants, according to Wilbanks, commit more severe crimes and have more severe criminal histories.

The pattern persists with juvenile defendants; White juveniles may be granted probation while Black juveniles are sentenced more severely. A study of juvenile probation presentence reports reveals that the delinquency of Black juveniles is viewed as the result of negative attitudes and personality disorders, and the behavior of White juveniles is explained as the product of the school and family problems. As a result, White delinquents are sentenced to probation because their behavior problems can be addressed through community treatment and intervention programs. Since personality disorders are less responsive to such interventions, Black juveniles are incarcerated in order to protect the community (Mauer 2006).

The fact that fewer Blacks and Hispanics are sentenced to probation is not only a race issue, but a class issue. More Blacks and Hispanics remain in jail pending trial because they cannot afford monetary bail. Many of these same defendants use court-appointed attorneys and are tried by juries of Whites because Blacks from lower class neighborhoods are less likely to report for jury duty.

Race and Parole

At the end of 2009, there were 800,000 adults under parole supervision in the United States. Forty-one percent of the parole population was White. Blacks comprised 39 % of the parole population, and 18 % of those on parole were Hispanics. Although Black inmates make up approximately 62 % of the prison population, only 39 % of those released on parole are Black.

Findings of previous research reveal that race has an impact on parole release decisions. In a study of racial discrimination in three states, Petersilia (1985) found that Black and Hispanic defendants not only received more severe sentences than White defendants who had similar criminal records and were convicted of similar crimes but consistently served longer sentences than Whites sentenced to prison. Black inmates serve longer sentences, are less likely to receive parole, and often have additional criteria to satisfy. Carroll and Mondrick (1976) discovered racial inequities in parole decisions by comparing those decisions for Black and White inmates. They found that Black inmates not only served longer sentences before being paroled but had to show proof of participation in and completion of some institutional treatment program. This criterion was not required for White inmates being considered for parole. Results of another study found that when first time offenders are being considered for discretionary release, Black first time inmates usually serve 4 months longer than Whites (62 months vs. 58 months) (Hughes et al. 2001).

Some studies suggest that race does not significantly impact parole release decisions. Instead, legal, social, and institutional variables are the most significant predictors of parole release decisions. In a study of 958 youthful offenders, Elion and Megargee (1978) found no differences in the actual amount of time served, but a significantly higher percentage of Whites than Blacks were granted parole. Blacks who were granted parole served a smaller portion of their sentences than did Whites who were granted parole. Blacks who were denied parole served a greater portion of their sentences that Whites who were denied parole. They suggest that these differences are attributed to social, legal, and institutional variables and not race. Scott (1974) initially concluded that Black inmates serve more time and are less likely to be paroled than White inmates. However, when he controlled for the seriousness of the offense, his findings showed that Whites were less likely to be paroled than Blacks, causing him to ultimately infer that parole boards make no distinction between races when considering criteria for parole. Black and White inmates are paroled at about the same rate. In a study of the parole release process in Alabama, Morgan and Smith (2008) found that while race was not a significant predictor of parole release decisions, Black inmates served more time before being considered for parole release. While there were twice as many Black inmates as White inmates eligible for parole release and selected for a parole release hearing, fewer Black inmates were actually chosen for parole release by the parole board.

Conclusions and Future Research

Probation is a correctional alternative that allows convicted defendants to remain in the community under supervision; it is a privilege granted to defendants. Parole is granted to convicted defendants who have been sentenced to prison and served at least one-third of the original sentence. Both practices are designed to promote rehabilitation. When looking at the racial compositions for offenders supervised in these two programs, there is some concern for racial bias by judges and parole board members who are responsible for decision-making at these two levels. While Blacks make up only 13 % of the US population, Black inmates accounted for almost one million of inmates incarcerated in the nation's prisons. At the same time, they make up 30 % and 39 % of the probation and parole populations. While the question of racial bias is real, other explanations have been offered to explain this racial disparity. Some have argued that incarceration numbers are high because Blacks commit more crimes than Whites. The trend is that the Black arrest rate is disproportionate to the 13 % that they represent in the population. Recent review of arrest rates for index crime reveals that Blacks constituted 40 % of all arrests for violent crime and 30 % of the arrests for property crimes. With the exception of murder and robbery, the actual percentages of crimes committed are higher for Whites. It is also possible that police who use discretion in decisions about arrests could also exercise a racial bias. Other arguments focus on crime severity. According to these arguments, Black offenders commit more violent crimes that usually granted probation. Proponents of this argument point to the fact that UCR data indicate that Blacks comprise 40 % of all of the arrest for violent crimes and make up 50 % and 57 % of the arrest for murder and robbery. It has also been stated that Blacks have more severe criminal histories that make them poor risks for probation and more disciplinary infractions in prison that reduce the likelihood of being selected for probation and parole supervision The War on Drugs disproportionately affected Blacks by increasing incarceration rates for Blacks. In an effort to reduce drug supply, tougher sentencing policies were implemented. One such policy was a mandatory prison sentence for possession of crack cocaine, found most often in the Black community. Even though the numbers of Blacks using drugs fall far below that of Whites, Blacks are most often arrested, prosecuted, convicted, and incarcerated for nonviolent drug offenses.

The fact that Blacks and Hispanics are less likely to be granted probation and parole has implications for individuals, families, and communities. When defendants are granted probation, they remain in the community and are able to keep the jobs that they have or with the assistance of the supervising probation officer, they are able to secure employment to comply with probation conditions. When individuals are incarcerated, it takes them out of the labor force. Once released, they are viewed in a negative manner by employers; most employers are unwilling to hire ex-offenders. Failure to get and maintain suitable employment often results in individuals committing more crimes and being returned to prison. The economic impact affects not only the offender but also dependents. Incarceration affects family stability, the socialization of the children, and the psychological well-being of children. Children feel humiliation, guilt, and shame when a parent is incarcerated, often believing that they contributed to the parent's incarceration. Children may be labeled and stigmatized. Some recommendations to address this disparity include reserving prison for serious or violent offenders, expanding the use of intermediate sanctions especially for nonviolent minority offenders. There should also be a racial impact statement of every change in justice policy. These statements would prospectively assess the implications the policy shift would have on minority involvement in the justice system so that the policy can be evaluated on the basis of its consequences. Finally, it is evident that more empirical investigation needs to focus on decisions made at crucial decision points in the criminal justice system.

Race, Ethnicity, and Youth Gangs

Adrienne Freng
Department of Criminal Justice, University of Wyoming, Laramie, WY, USA

Overview

It is difficult to talk about gang membership without including a discussion of race/ethnicity. The two seem invariably linked in our society, both in terms of research and our common perceptions of gang members (Esbensen and Tusinski 2007). Early gang research focused on White ethnic groups, whereas more recently, racial/ethnic minorities such as African Americans, Hispanics, and increasingly Asians and American Indians represent the groups of interest (e.g., Chin 1996; Hagedorn 1988; Major et al. 2004; Moore 1991; Vigil 2002). While the connection between race/ethnicity and gang membership remains in the spotlight in our society, the fact remains that a paucity of information regarding differences between racial/ethnic groups exists, making policy recommendations somewhat complicated.

This entry will explore the similarities and differences in gang membership between various racial/ethnic groups. As we come to understand the race/ethnicity/gang membership relationship more clearly, the intent is to develop ideas on how to become more effective at preventing gang membership among the various racial/ethnic groups. The entry begins by presenting descriptive information concerning race/ethnicity and gangs. Next, the evidence regarding shared factors for gang formation and membership between and within racial/ethnic groups is examined. Third, it explores the evidence supportive of risk factors that are "race/ethnicity specific" or unique to one or a few groups. Fourth, recommendations to inform programming regarding the connections between race/ethnicity and gang membership are provided.

Race/Ethnicity and Gangs

In our society, gang membership is often portrayed, especially by the media, as a minority issue affecting the barrios and inner cities of the United States (Esbensen and Tusinski 2007). Minority youth do, in fact, represent the majority of gang members. The National Gang Center (2010) reports that law enforcement indicates that 84 % of gang members are racial/ethnic minorities, with 49 % being Hispanic and 35 % being African American. However, increasing numbers of Whites are reporting gang membership as well (Esbensen et al. 2010; Freng and Winfree 2004; National Gang Center 2010). For example, self-report studies indicate more extensive involvement of Whites, as much as 24 % of gang members, as compared to 9 % reported by law enforcement (Esbensen et al. 2010; National Gang Center 2010).

Another recent development includes gangs becoming more multiracial (Starbuck et al. 2001). In a survey of law enforcement, agencies reported that one-third of gangs were ethnically/racially mixed (Starbuck et al. 2001). This percentage was higher in those jurisdictions that also reported a later onset of gangs. So, for example, agencies that reported gang onset as 1991–1992 as compared to 1981–1985 indicated that 55 % of gangs consisted of racial-/ethnic-mixed membership (Howell et al. 2002). As gang membership becomes more diverse in terms of race/ethnicity, it begins to call into question some of our basic assumptions regarding race/ethnicity and gang membership. So, no longer can we exclusively talk about African American, Hispanic, or Asian gangs, as more and more gangs consist of individuals from a number of racial/ethnic groups.

Sources of Information on Gang Membership

Our information on the race/ethnicity/gang membership relationship has traditionally come from three primary sources: official (law enforcement) data, self-report data, and ethnographies. Each of these data sources provides valuable information regarding gang membership but also offers different pictures concerning the involvement of racial/ethnic minorities in gangs. For example, both official and self-report data indicate that gangs are comprised primarily of racial and ethnic minorities. However, discrepancies between these data sources regarding the extent of involvement of racial/ethnic minorities arise (National Gang Center 2010). Some of this disparity could be due to the fact that the racial/ethnic makeup of a gang tends to reflect the racial/ethnic composition of the community. For example, while the National Gang Center reports that overall 9 % of gang members are White, this percentage increases to 17 % in rural counties and 14 % in smaller cities where populations as a whole tend to consist of larger percentages of Whites (National Gang Center 2010). Likewise, African American and Hispanic gang members are the most prevalent in larger urban areas (National Gang Center 2010). Thus, since the majority of data on gangs is generated from large cities, these populations are often the ones represented, giving the impression that gang membership is solely a minority issue.

The disparities in the estimates between law enforcement data and self-reports are also often tied back to the nature of each of these data sources and the various ways to define gang membership. Although defining a gang may seem straightforward, many definitions abound resulting in significant consequences in terms of informing policy and decisions about resource allocation as well as impacting a community's level of fear of crime, especially as it relates to race/ethnicity (Ball and Curry 1995; Decker and Kempf-Leonard 1991; Huff 1998; Klein 1969; Miller 1975). Many estimates and policies are based on data from law enforcement agencies; however, some gang experts believe these estimates are "probably conservative because many jurisdictions deny, often for political and image reasons, that there is a problem, especially in the early stages of youth gang development in a community" (Huff 1998, p. 1). Others, however, suggest that policies and practices of law enforcement such as conducting intelligence programs that result in lists of known gang members based on overt characteristics such as tattoos, wearing of colors, and clothing can significantly overestimate the problem. These practices can be problematic and impact data if they are not consistently purged as, contrary to popular belief, most gang members are only in the gang for about 1 year (Thornberry et al. 2003). On the other hand, although research has supported the validity and reliability of self-reports, many argue that they represent an under- or overestimation of the problem as well (Loeber et al. 1998). In other words, individuals may claim gang membership when they really might be considered peripheral to the gang, while others might not claim gang membership in an effort to keep that information from law enforcement and researchers.

Adding to the confusion are results collected by ethnographic studies (Fleisher 1998; Hagedorn 1988; Moore 1991; Vigil 2002). These typically concentrate on one particular gang comprised of a certain racial/ethnic group in a specific site. Most of these studies have been completed in large urban areas and with minority gangs, further contributing to the perception that gangs consist exclusively of racial/ethnic minorities and resulting in a tendency to separate gangs into groups such as African American gangs, Hispanic gangs, Asian gangs, and American Indian gangs. By doing this, the intricacies within groups, such as the differences between Chinese and Vietnamese gangs, as well as the multiracial nature of emerging gangs are ignored (Starbuck et al. 2001). Additionally, although ethnographies have contributed significantly to our understanding of the race/ethnicity/gang connection, they restrict the ability to generalize the findings to other groups such as Whites or to other locations such as rural and suburban areas, thus limiting our overall knowledge of how race/ethnicity impacts gang membership.

Reasons for Joining Gangs

The delinquency and gang literature is replete with various explanations as to why individuals from various racial/ethnic groups join gangs. Within this literature, the reasons for joining gangs tend to fall within two main frameworks. The first framework proposes that different etiologies or distinctive causal processes are responsible for racial/ethnic disparities in gang joining. In other words, differences in the types of factors that result in gang membership vary by group. On the other hand, the second framework suggests that the reason for more gang involvement among racial/ethnic minorities relates instead to the differential exposure of minority individuals to risk factors associated with gang membership. While there have been few efforts to empirically assess these specific orientations, the perspectives utilized to explain gang membership allude to both of these types of processes.

Early explanations outlining reasons for why individuals join gangs did not directly address the connection to race/ethnicity. Instead, they outlined conditions related to gang membership to which individuals from various minority groups were exposed, emphasizing the connection to poverty, discrimination, immigration, and urbanization and the resulting social isolation, which are still key concepts today. Theories, such as the social disorganization perspective, propose that community or environmental factors ultimately impact crime (Shaw and McKay 1942). As such, crime and gang membership is not actually related to a group of people (i.e., racial/ethnic minorities), but instead is a result of environments to which minorities are often relegated, characterized by high unemployment, elevated high school dropout rates, deteriorated housing, poverty, a significant number of single parent households, and high mobility rates, as well as industrialization, urbanization, and immigration (Klein 1995; Short and Strodtbeck 1973; Spergel 1964).

Strain and opportunity theory also points to various conditions that are experienced by racial/ethnic minorities that might result in gang membership. These theories indicate that crime is a result of lower-class frustration or strain that develops due to the inability to achieve social and financial success (Cloward and Ohlin 1960; Merton 1968). They suggest that the ability to achieve wealth and power is stratified by socioeconomic class; thus, strain occurs in those areas like disorganized slums where minorities are concentrated and conventional avenues to success are blocked. To relieve strain, people may be forced to use deviant methods to achieve their goals, such as theft, selling drugs, or joining gangs. This is mainly because while legitimate opportunities are blocked for individuals in these areas, illegitimate opportunities are plentiful. Additionally, since the availability of both legitimate and illegitimate opportunities varies across social groups, these theories also suggest that gangs emerge based on the characteristics of the community, not the individuals.

Recent work by Decker and Van Winkle (1996) suggests that threat is a key to gang development. In socially disorganized communities, where social control is at a minimum and where minority populations often live, threat rules the daily existence of individuals in the community. This threat can manifest itself in a variety of ways. One way is to perpetuate the cycle of violence. So, for example, as individuals become isolated from their communities, they become involved in violence, which further isolates them, resulting in more violence (Decker and Van Winkle 1996).

The social learning perspective proposes that individuals learn the norms, values, and behaviors associated with criminal activity from close intimate relationships with criminal peers, including other gang members (Akers 1973; Sutherland 1939). In communities, such as those with concentrated populations of racial/ethnic minorities, norms, values, and behaviors that are conducive to gang membership are prevalent and in fact have in many instances become entrenched into the community. The youth begin to learn from older individuals, thus perpetuating the attitudes and behaviors, resulting in gang behavior among multiple generations.

Other research examines the effects that concentrated disadvantage, including the changing economic structure and poverty, has had on gang development, specifically among African American groups (Hagedorn 1988; Moore 1991; Wilson 1987). During the 1980s and 1990s, jobs became scarce, and the conditions leading to the urban underclass started to breed gangs that have now become a permanent part of many urban communities. As jobs decreased and became more skilled, minority individuals had a harder time getting productive employment, thus affecting the aging out process. Minority youth no longer were able to achieve success through work because of the deindustrialization of urban areas, and thus they continued in the gang longer, making it more institutionalized within the community. Gangs then became their own social institution and a mechanism by which to "make it" in urban inner city environments (Moore 1991; Hagedorn 1988; Wilson 1987). However, while the gang fulfills the needs and provides resources for individuals in these communities in the short term, long term this involvement alienates youth from society and decreases their economic and social capital (Fleisher 1998). As a result, gang members are not socialized to enter mainstream society and pass this on to their children, thus creating an intergenerational transmission of these issues (Fleisher 1998).

More recently, Anderson (1999) considered these elements in the development of a subculture among African Americans in Philadelphia. While Anderson did not specifically address gangs in his work, his general ideas seem applicable. As with strain and opportunity theory, while not specifically addressing racial/ethnic issues, this view represents conditions that are over-representative of racial/ethnic minority populations and ties violence to structural characteristics such as poverty, unemployment, a perceived lack of quality in basic services, and discrimination. This subcultural perspective deals explicitly with gangs as a group that includes its own norms and values that are contrary to the main culture. Individuals adopt these values and create groups, such as gangs, to deal with the isolation and alienation that they experience. Anderson (1999) suggests that in disorganized minority communities, a code develops among all individuals related to toughness and respect that assists in navigating the streets. The expectation of toughness is entrenched in the behaviors of the "street" kids, while the "decent" kids utilize it to make their way in an environment characterized by constant threats (Anderson 1999). In other words, whether an individual is involved in a gang or not, they participate in and perpetuate the norms and values that are conducive to gang membership.

Explanations focusing on gang membership among African American groups tend to emphasize factors such as economics and poverty, while those examining Hispanic groups often include elements of immigration and discrimination (Vigil 2002). The multiple marginality framework (Vigil 2002) proposes that the historical background of the specific racial/ethnic groups is important in understanding how gangs develop in various communities. For example, African American and Hispanic gangs developed largely due to poverty, while Salvadoran and Vietnamese gangs arose based on migration due to civil war. These individual reasons for gang development result in exposure to various ecological, economic, social-cultural, and psychological stresses creating what Vigil (2002) refers to as multiple marginality. The more of these risks and stresses an individual experiences, the more cumulative disadvantage they face, resulting in marginalization from society. This marginalization process is set in motion by macro-historical and macrostructural factors such as immigration and discrimination, which ultimately negatively affects ecological/economic factors. As families and individuals experience these various stresses, their ability to exert social control is minimized. Gangs develop in response to this lack of social control and step into this void to provide socialization in the context of the streets. They then become a way of adapting to marginalization and provide a way to cope with the stresses of urban street life (Vigil 2002).

Risk Factors for Joining

Criminological theory and research point to a number of elements that contribute to gang membership among racial/ethnic minorities. However, much of this information still does not answer an important question: Do individuals from diverse racial and ethnic groups join for different reasons? This concern is tied intricately to programming issues as these results have led to different opinions about whether we require race/ethnic specific programming or not. Some evidence that there are different reasons does exist. Freng and Winfree (2004) examined racial/ethnic differences in reasons given for joining the gang. They found that Whites reported joining for reasons such as protection and friends in the gang, while African Americans and Hispanics tended to join more for protection and money and because peers or family were involved in the gang. Interestingly, contrary to popular belief, no group reported that they joined the gang due to force (Freng and Winfree 2004).

Recently, the risk factor approach has moved gang research in a promising direction. This perspective, developed out of the public health model, examines those factors that put an individual more at risk for gang membership or conversely protects against gang membership. The research based on this perspective does indicate some similarities between groups but also points to some differences. However, while the literature on risk factors for gang membership has become more extensive over the last decade, it still remains underdeveloped in terms of the extent to which risk factors remain constant across racial/ethnic groups (e.g., Curry and Spergel 1992; Freng and Esbensen 2007; Freng and Winfree 2004; Hill et al. 1999; Thornberry 1998; Thornberry et al. 2003).

Some researchers (Curry and Spergel 1992) propose that different factors explain gang membership among African American and Hispanic gang members, while others (Freng and Esbensen 2007) have found few differences between African American, Hispanic, and White gang members. African American gang members tend to be more influenced by social or interpersonal variables such as having family members in gangs, gang members in their classes, and friends who used drugs (Curry and Spergel 1992). Hispanic gang members, on the other hand, seem to have more intrapersonal risk factors such as educational frustration and peer and school self-esteem (Curry and Spergel 1992). For current gang members, differences have also been found (Freng and Esbensen 2007). For Whites, ecological and economic factors, such as parents with lower educational levels and increased levels of social isolation, are more important. On the other hand, for African American and Hispanic gang members, social control and street socialization elements, such as low school commitment, poor opinions or interactions with the police, and being socialized on the street, symbolize the significant risk factors. These differences do not appear for those that report ever being a gang member, however (Freng and Esbensen 2007).

Key Issues

Several weaknesses characterize the current gang research, limiting our knowledge regarding race/ethnicity and its tie to gang membership. The primary problem with most of the literature currently available is that it largely ignores race/ethnicity as an explanatory factor. In other words, cross group comparisons examining actual differences between groups remain relatively rare (Curry and Spergel 1992; Freng and

Esbensen 2007; Freng and Winfree 2004). Instead, race/ethnicity is largely used as a control factor, resulting in little information regarding actual differences or similarities. Additionally, what little research is available indicates some conflicting results on whether the same risk factors impact the various groups (Curry and Spergel 1992; Freng and Esbensen 2007; Freng and Winfree 2004). Organizations or individuals hoping to address the gang problem are thus at somewhat of a disadvantage in knowing what factors should be focused on for which groups.

Additionally, much of the gang research concentrates on specific gangs in particular urban areas that represent racially/ethnically homogenous groups (e.g., Chin 1996; Hagedorn 1988; Moore 1991; Vigil 1988). While this can present detailed information about African American gangs in Chicago or Hispanic gangs in Los Angeles, for example, it does not provide beneficial information about whether these groups are similar or different in their characteristics, attitudes, or behaviors. Furthermore, the research over the past 20 years has largely concentrated on African American and Hispanic groups, ignoring the increasing problems of gangs among Asians, American Indians, and Whites (e.g., Chin 1996; Hagedorn 1988; Moore 1991; Vigil 1988).

Finally, while the research is limited on racial/ethnic differences in joining the gang, an even greater paucity of information exists regarding racial/ethnic disparities in leaving the gang. As we begin to understand that individuals often spend a short amount of time in the gang, with the average being less than 1 year, this topic becomes even more relevant (Thornberry et al. 2003). While research points to a number of reasons and processes for why and how individuals exit the gang, examinations as to whether these reasons or processes remain consistent across racial/ethnic groups remain rare, if not nonexistent (Decker and Lauritsen 2006). Understanding the intricacies of this relationship and whether it varies for the different groups is imperative in terms of focusing our intervention strategies toward removing individuals from gangs.

Policy Issues and Recommendations

Without fully understanding the nature and extent of the problem, we are unable to thoroughly address it. The only sure way to know how best to address the issue of gang membership is to initiate more research that considers these ongoing issues, expanding beyond focusing on specific racial/ethnic gangs in specific locations, ignoring race/ethnicity as a explanatory variable, and the concentration of certain racial/ethnic gangs to the exclusion of others. This additional research will help to more completely understand the nature of gangs and assist in developing prevention efforts. While the reasons for joining should guide us in developing programming principles, surprising little information regarding differences between racial/ethnic groups actually exists, thus making developing recommendations for strong policy practices difficult. While research and theoretical explanations have focused on the importance of larger, social-structural factors (e.g., poverty, immigration, discrimination, and social isolation) which differentially impact the lives of individuals from different races/ethnicities, programs focusing on these elements would of course be much more costly and complex and thus often do not present realistic solutions. Thus, policies tend to concentrate more on individual factors, which have been assumed to be more manageable and malleable.

When considering preventing gang membership, the defining question is the following: Is race/ethnic specific programming needed? The question asks whether the general prevention programming currently utilized that targets individuals regardless of their racial/ethnic group status is sufficient or if we need more targeted programs that focus on specific factors related to gang membership for the various groups. Some evidence exists that perhaps racial/ethnic specific programming is not necessary, but that general prevention programming with some racial/ethnic group sensitive elements may provide some promising practices in effectively addressing a problem that still largely impacts minority populations (Esbensen et al. 2010). In other words, general prevention programming should be effective, in theory, if individuals from different racial/ethnic groups share similar risk factors. For example, targeting factors such as having family members in the gang, a factor tied to gang membership for African Americans, should also have an impact on gang membership for individuals regardless of their racial/ethnic background.

On the other hand, differences in both the reasons that gang members give for joining gangs and the risk factors associated with gang membership for the various groups are apparent (Curry and Spergel 1992; Freng and Esbensen 2007; Freng and Winfree 2004). This perhaps points to the need for some race-/ethnicity-specific or race-/ethnicity-sensitive programming targeting more specifically those factors tied to gang membership for each group (Esbensen et al. 2010). However, our lack of knowledge of racial/ethnic differences hinders our ability to evaluate the need for these types of programming. Unfortunately, no evidence-based programs directly aimed at addressing racial/ethnic differences in risk factors for gang membership exist. Additionally, without more extensive evaluation of programs that are currently in place, knowing the impact on gang membership among various racial/ethnic groups is difficult. Currently, little evidence of the effectiveness of general prevention programs for individuals from various racial/ethnic groups exists (Wilson et al. 2003), resulting in a lack of knowledge of whether the current programs in existence actually work to decrease gang membership among the various racial/ethnic groups. Thus, until more is known about the differences in reasons for joining the gang and risk factors for the various racial/ethnic groups, perhaps it would be sufficient to consider general prevention programming or expand upon existing promising programs to ensure that they are culturally appropriate and relevant.

Overview

The term "racketeering" is often used as a synonym of organized crime, although it cannot be limited to it. Indeed, it is a broader concept, encompassing a wide range of criminal activities. Such activities have to be committed on a continuative basis and as part of an ongoing criminal group which presents a certain degree of organization.

Section "Defining Racketeering: Origins and Core Elements" provides an overview of the main features of the phenomenon since its first appearance and of its development across different contexts. The various criminal activities that can be committed as part of a racketeering pattern are also examined. Section "Examples of Racketeering: The Case of the Italian Mafias" further develops the issue by providing actual examples of racketeering. The case of the Italian Mafias is analyzed, being extortion racketeering their core business.

Although extortion racketeering is commonly associated with organized crime, it can be performed in a casual or a systemic way. This depends on the market opportunities and characteristics of organized criminal groups. The prevalence of causal or systemic patterns across the European continent is examined in section "Extortion Racketeering in Europe."

Defining Racketeering: Origins and Core Elements

The term "racketeering" was originally coined by the Employers' Association of Chicago in 1927 (Witwer 2004, p. 200). It was intended to describe an emerging pattern of criminal conspiracies, aimed at extorting money from legitimate businesses and exerting a monopolistic control over certain (legal or illegal) markets. Collusive arrangements and extortion practices were not a novelty within businesses and labor unions. What the Employers' Association was more concerned about was the increasing involvement of organized crime syndicates in such practices (Witwer 2004).

The power of organized crime groups in the Unites States, in particular of the Italian Mafia, significantly increased between the end of the 1920s and the beginning of the 1930s. In that period, criminal opportunities were created by prohibition which mainly affected the vice industry (Witwer 2004; Scotti 2002). Bootlegging, as well as illegal gambling and prostitution, became profitable – and at the same time risky – activities. Criminal organizations were able to expand their influence over the illegal (and legal) sphere, for example, by extorting money from vice entrepreneurs in exchange of protection from potential assaults or external competition. The infiltration of the labor unions further increased organized crime control over legitimate businesses and its capacity of penetrating the institutional and political system (Scotti 2002). Infiltration in the legal economy may occur by using legitimate businesses as a front cover for criminal activities or by depriving them of their profits through loansharking and extortion (Kelly 1999). When extortion racketeering is established, the relationship between perpetrators (organized crime groups) and victims (businesses) can be of a predatory, parasitic, or symbiotic nature, according to the durability of the relation (short- or long term) and the degree of "complicity" between criminals and their victims. The different types of relationship will be analyzed more in detail in section "Extortion Racketeering in Europe," which specifically addresses the issue of extortion racketeering and, therefore, of the relationship between extorters and victimized businesses.

It was with the aim of curbing the infiltration of legitimate businesses by organized crime that the US Congress, in 1970, enacted the Racketeer Influenced and Corrupt Organizations Act, better known as RICO or RICO Act (Blakey 1990; Blakey and Blakey 1997; Black 1986).

RICO made it unlawful to receive and acquire income from an enterprise, as well as to conduct or participate in the conduction of the enterprise affairs, through a pattern of *racketeering activity*. "Racketeering activity" identifies "*specified felonies* committed as part of a *criminal enterprise* and as part of a *pattern*" [emphasis added] (Albanese 2011, p. 99):

- *Specified felonies*. Specified crimes which may result in a "racketeering activity" can be grouped – for merely operational purposes – into four main categories, not to be considered however as mutually exclusive: (1) violence (i.e., murder, kidnapping, arson, extortion), (2) provision of illegal goods and services (i.e., gambling, prostitution, counterfeiting, drugs), (3) corruption (i.e., bribery, extortion, embezzlement), and (4) commercial or other types of frauds (Blakey 2005). For a detailed description of the specified felonies, see the United States Code 18 U.S.C. § 1961-1.
- *Criminal enterprise*. The term enterprise is intended to include broadly "any individual,

partnership, corporation, association, or other legal entity, and any union or group of individuals associated in fact although not a legal entity" (United States Code 18 U.S.C. § 1961-4). In other words, a criminal enterprise refers to any group – or even an individual associated to it – whether legal or illegal, officially formalized or just existing, that is used as a base for committing criminal activities (Albanese 2011).

- *Pattern*. The pattern indicates two or more of the specified felonies committed within a period of 10 years (excluding any period of imprisonment of the offender) (United States Code 18 U.S.C. § 1961-5).

In order to be considered as a punishable offense according to RICO legislation, racketeering should provide that (a) two or more specified offenses are committed, (b) within a 10-year period, (c) by a person who is involved (e.g., employed, associated, related) in the activities of an *ongoing criminal enterprise*.

The innovative feature of RICO legislation was that, rather than focusing on specific offenses, it was instead centered on the ongoing criminal enterprise. What is illegal, and therefore punished, is the participation in a group that commits certain types of offenses (Albanese 2011, pp. 100–101). As such, an individual who belongs or is in a way associated with the ongoing criminal enterprise can be charged with racketeering even if the criminal offenses have been physically committed by other members (Schneider 2005; Abadinsky 2009). This provided prosecutors with an effective tool to charge, prosecute, and convict mobsters, gangsters, and other organization leaders. Before the introduction of RICO, such a result would have represented a challenging task, in that traditional criminal laws were directed at prosecuting single and specific offenses. By doing so, the heads of a criminal enterprise (i.e., an organized crime family) were hardly sentenced, since usually they were only indirectly involved in the commission of crimes (Blakey 1990).

In addition to criminalizing racketeering, the Congress also provided extended penalties and unique criminal and civil instruments to combat such an offense (Blakey 1990). The maximum criminal penalties originally established under RICO consist of a $25,000 fine and 20 years imprisonment. The civil RICO provisions also allow to seize and confiscate property and other goods assumed to be the proceeds of a racketeering activity. The purpose is to attack criminal assets and deprive criminal enterprises of their economic resources. Inclusion of the forfeiture provisions under the civil law represents one of the most significant and, at the same time, most controversial aspects of RICO (Schneider 2005). The burden of proof requested by the civil laws is lower compared to the criminal ones, so that the government may seize and confiscate assets from a criminal enterprise involved in racketeering activities without notice and "ex parte" (Schneider 2005; Albanese 2011).

Although it was originally elaborated to counter directly traditional organized crime groups – in the sense of the mafia-type organizations – and their (il) legal activities, RICO legislation cannot be considered as merely limited to organized crime. RICO provisions have demonstrated to be broader in their scope, being successfully applied even in the fight against political corruption, white-collar crime, and violent groups (Blakey 1990). Legitimate business enterprises have been charged as well (see, e.g., the court case *Sedima, S.P.R.L. v. Imrex CO.*) (Schneider 2005). RICO is intended to reach any sort of enterprise, whether legal or illegal, provided it has been involved in a pattern of racketeering activity.

The following cases provide an account of the variety of situations in which RICO has been used. In 2000, the decision of a federal judge in Los Angeles ruled that the local Police Department could be sued as a racketeering enterprise, in that some corrupt police officers had allegedly robbed, beaten, framed, and shot suspects (Albanese 2011; ABCNews 2000). In a similar way, in 2002, the governor of Louisiana was convicted under RICO, due to his involvement in various corrupt criminal schemes related to the riverboat gambling license process (Albanese 2011; United States Court of Appeals 2002). In 2008, the leader of a Colombian Drug Cartel was convicted under RICO with the charge of being at the head of a racketeering enterprise that engaged in murder, narcotics trafficking, money laundering, and bribery (Albanese 2011; Department of Justice 2008).

RICO has not been immune from criticism. An improper and overused resorting to the civil provisions of RICO has been noticed, for example, in the civil suits among legitimate commercial enterprises (see Schneider 2005, pp. 662–663).

In contexts other than the USA, as, for example, in the Eastern and some Southern European countries (especially Italy and Spain), the term racketeering could keep a more specific focus. It often refers to typical organized crime activities, such as illicit gambling and prostitution, transportation of stolen goods, loan-sharking, and, above all, extortion.

Examples of Racketeering: The Case of the Italian Mafias

As the history of Italian organized crime shows, extortion and protection represent the core businesses of the Italian Mafias (Savona 2012). For the purpose of this essay, the term "Italian Mafias" refers to the Sicilian Cosa Nostra, the Calabrian 'Ndrangheta, and the Campanian Camorra.

Gambetta (1993), in his book *The Sicilian Mafia*: *The Business of Private Protection*, defines the mafia as an "industry which produces, promotes and sells private protection." Protection is provided not only to legitimate businesses but also to criminal actors operating in the underworld.

In the upperworld, the mafia exerts a "para-state" function by taking advantage of the state's inefficiency in properly preserving legal transactions and free competition from potential abuses. In the underworld, protection is needed because criminal activities are usually carried out in a context free from any formal rule and where no sort of protection by the state is envisaged (Arlacchi 1988). In such a setting, illegal actors resort to the services offered by those agencies – namely, mafia-type organizations – which are able to regulate potential conflicts and provide protection against other cheating and competing criminals (Varese 2001; Transcrime 2009).

Protection becomes extortion when the mafia benefits from a service that it does not actually provide (Gambetta 1993). More precisely, extortion is "the obtaining of property from another, with his consent, induced by wrongful use of actual or threatened force, violence, or fear, or under color of official right" (The United States Code 18 U.S.C. § 1951(b)(2)).

When extortion is committed on a regular basis, it turns into racketeering. Extortion racketeering has been defined as "an institutionalized practice whereby tribute is collected on behalf of a criminal group that, in exchange, claims to offer (. . .) protection" (Volkov 2002, p. 1). Italian Mafias resort to it as a means of territorial sovereignty and a financial resource.

Through extortion racketeering, organized crime can first of all control the territory and the economic and political activities being implemented in it. In doing so, the mafia also consolidates its presence as part of the local culture, thus favoring the establishment of a "cultura mafiosa" (mafia culture) (Savona 2012). This means that people gradually become used to the mafia presence and therefore accept it, or even cooperate with it, in order to achieve some sort of benefits in terms of protection and advantages against competitors. In a similar way, through extortion, organized crime groups can infiltrate legitimate businesses and get hold of them when extorted entrepreneurs are no longer able to pay.

At the same time, extortion represents a source of income used by criminal organizations to finance their illegal activities and sustain the maintaining costs of the organization (e.g., payment of the affiliates, maintenance of the families of incarcerated members, military expenses) (Paoli 2003, p. 165).

As pointed out by Paoli (2003), the spread of extortion racketeering on a large scale has been driven by the fact that it is an easy crime to carry out and represents a rapid way to make money: "it does not requires a high initial investment, it carries low managing costs and, in areas where the state's protection in not regarded as adequate or reliable, it is also a low-risk operation" (Paoli 2003, p. 165). As such, extortion racketeering became one of the main resources by which the Italian Mafias achieved territorial sovereignty in Sicily, Calabria, and Campania. These are the Southern Italian regions in which the Italian Mafias have traditionally established themselves.

In its more "typical" form, extortion racketeering consists of a periodical money payment (the so-called pizzo) required by criminal organizations from legitimate businesses under the threat of violence and intimidation. In some other cases, it can take the form of either extortion in goods and services (such as the imposed removal of merchandise from a company) or extortion of the workforce (through the violent control of the local labor market) (Paoli 2003; Daniele 2009). In this regard, Monzini (1993, pp. 22 et seq.) distinguishes among different types of extortion: (See also Transcrime 2009, pp. 22-23)

1. *Extortion protection* consists in a criminal system, similar to taxation, by which regular payments are imposed using violent means. A long-lasting relationship usually develops between the extortionist and the extorted, so that a sort of legitimization of the mafia's presence and its control over the production gradually arises (Daniele 2009).
2. *Labor racketeering* is a means of violent negotiation established within single production units. The mafia extorts the workforce by controlling access to the labor market and employment.
3. *Monopolistic racketeering* is a specific market strategy enforced by the use of violence and aimed at physically eliminating competitors and creating monopolistic coalitions. Such a result is achieved by establishing a monopolistic control on the access to those resources which are crucial for a given sector.

It is interesting to note that, when extortion racketeering is carried out in mafia contexts, organized crime uses a certain degree of "professionalism" (Savona 2012). First of all, as suggested by Grasso and Varano (2002, p. 80), the mafia does not select the territory on which to establish the extortion racket. It rather prepares it. This means that in many cases the extortionists are the actors creating the conditions for the demand of protection to arise: that is, some minor crimes are committed by the same criminal organizations in order to generate a common sense of insecurity (Transcrime 2009, 22).

Furthermore, the mafia does not target its victims randomly. On the contrary, it selects them according to their vulnerabilities (Grasso and Varano 2002, p. 78; Savona 2012). First of all, the economic activity performed by the victim has to be located within the zone of influence of the mafia (Grasso and Varano 2002, p. 78). This enables Mafiosi to exert successfully their intimidating power. Secondly, the business carried out by the targeted company has to be attractive for the organized crime group (Savona 2012, p. 8), which means offering high profits at low risks. Finally, instruments and infrastructures needed for the production (e.g., warehouses, restaurants, shops, excavators, vehicles, and other machinery) must be exposed and well visible, so that they can be easily identified and targeted by the extortionists. At the same time, the entrepreneur is aware that the company's business will be closed down should those facilities be destroyed (Grasso and Varano 2002, p. 78; Savona 2012, p. 8). Once a racketeering relationship has been established, defining the type (money, goods, services, etc.) and the amount of the payment represents the next step. When imposing a protection racket, mafia groups often evaluate the economic resources of the victims and calculate the amount of money they are willing to pay (Savona 2012). Even when threatening or frightening the entrepreneur, the mafia decides the extent to which violent actions should be performed, in order to avoid that the victim reports to the police.

Extortion practices carried out by the Italian Mafias are directed not only to legitimate businesses but also to other criminals. The Neapolitan Camorra, for example, has imposed its control over the urban underworld, by establishing a comprehensive system of taxation of all the illegal traffics taking place in its territory.

Payments are required to criminals in the form of shares of the revenues arising from theft, prostitution, smuggling, gambling, and other criminal markets (Monzini 1993).

As such, extortion racketeering can be regarded, rather than as a single activity, as a hub where different spheres (legal and illegal) intersect (Savona 2012). Scientific literature has widely recognized that organized crime activities are placed along a continuum, so that it is difficult – and probably improper – to separate strictly criminal activities from non-criminal ones. The selection of the area, in which it is better to operate, depends on the risks and opportunities related to it. The Italian Mafias have engaged in both criminal and non-criminal activities since high opportunities and low risks were available in illegal businesses as well as in legal ones.

Some differences among the three mafias, especially as regards "what" is concretely done and "how," can be noted. Such a choice is in fact influenced by many factors: know-how, culture of the organization, and social and economic factors. So, for example, the Campanian Camorra is heavily involved in illegal trafficking of waste and counterfeited goods, while this is not the case for the Sicilian Mafia. In a similar way, drug dealing has been one of the main activities of the mafia in Sicily during the 1970s and the 1980s, whereas now it is one of the core businesses of the Calabrian 'Ndrangheta. Despite these differences, some similarities can be outlined. Among them, extortion and infiltration in the legitimate sphere represent features that are common to, and characteristics of, all three Italian Mafias (Savona 2012).

Extortion Racketeering in Europe

This part draws mainly on a precedent analysis (Savona and Zanella 2011, pp. 261–267).

Moving to a broader level of analysis (Europe), market opportunities and variations in the characteristics of organized criminal groups can give rise to different types of extortion racketeering: *systemic* and *casual* racketeering. Extortion racketeering is *systemic* when it is deeply rooted and extended across a territory, being a core part of the activities of organized crime groups. Extortion racketeering is *casual* when it is not extended across a territory since criminal organizations do not routinely engage in such a criminal activity.

These different types of extortion racketeering are shaped by four interrelated variables: (a) market opportunities, (b) the organizational structure of criminal groups, (c) their presence at local level, and (d) the victim/offender relationship.

In other words, on the one hand, the more organized criminal groups focus their activity on the local territory because of market opportunities, the more they develop a monopolistic position and a consequential hierarchical structure, and the more they establish parasitical and symbiotic relationships with their extortion victims, the more extortion racketeering becomes *systemic* (i.e., widespread and continuous). On the other hand, the more criminal market opportunities are open to transnational activities, the more criminal groups are organized in networks, and the more they establish predatory relationships with their extortion victims, the more extortion racketeering becomes *casual*.

The four variables and their interrelations are better described below:

(a) *Market opportunities*

Extortion is an old and simple crime committed by organized crime when the risks are low and the benefits are high. It occurs in contexts where (1) the victims do not report the crime and (2) are willing to pay the protection tax. These two conditions often arise within close-knit ethnic communities (e.g., among Italians at the beginning of the nineteenth century in New York City or among Chinese communities in the USA or in Europe). The low risks connected to this ethnic homogeneity and the consequent control of the territory are balanced by high benefits related to possible criminal market opportunities only. Extortion is systemic when other criminal alternatives are not available or cannot be adopted because of the low expertise of the group and its organization.

(b) *Organizational structure of criminal groups*

Although there is not a direct relationship between the organizational structure of criminal groups and extortion, the literature and the data show that where extortion is practiced on a large scale, and is systemic, the groups that engage in it are organized hierarchically. Where extortion is more casual, their structure is more flexible (taking the form of a network).

Due to their structure, which enables a lasting presence in a given territory, hierarchical criminal groups gain in reputation and may exercise effective threats of contingent violence against their victims. Moreover, these threats are reinforced by the fact that those threatened believe that these criminal groups "can corrupt legitimate authority or in some other way ensure that they avoid apprehension" (Reuter 1994, p. 95) and can act as an industry which produces and sells private protection (Gambetta 1993).

These elements of reputation – that is, the ability to neutralize law enforcement by means of corruption and the production and sale of protection – are closely related to the type of organized criminal group. Criminal groups with network structures "are not interested in, or capable of, exercising such a quasi-political power" (Paoli and Fijnaut 2004, p. 608). They are too small and ephemeral to be able to carry out systemic extortion racketeering. Only in a few cases they are involved in casual extortion racketeering practices. Networks may openly use violence to heighten their capacity to commit extortion, but they tend to be short lived because they lack the necessary structure and expertise.

In sum, although it is not automatic, the relationship between hierarchical structure and systemic extortion, on the one hand, and flexible structure and casual extortion, on the other, can be explained by means of the other variables shaping extortion: the local dimension of the organized crime action, its control over the territory, and the victim/offender relationship.

(c) *The presence at local level*

Why does extortion proliferate when organized crime operates at local level? And why is control of the territory so important? The explanation resides in the relationships between organized crime groups and local politicians, administrators, and businesses. The local level is the dimension where collusion with organized crime is easier and reciprocal exchange more profitable. Extortion racketeering is used to finance the criminal organization and its criminal activities and to consolidate its capacity to control local resources such as property, markets, services, and votes.

Criminal groups which exercise intense control over the local territory tend to commit systemic extortion racketeering within legal markets and in the underworld. As far as the legal markets are concerned, extortion racketeering is often viewed as the key "to infiltration and baronial domination of sections of the legitimate economy" (Bell 2000, p. 183). In regard to the underworld, it has been noted (Landesco 1968) that extortion racketeering is often used to "protect" criminal markets. By collecting extortion money from criminals, organized criminal groups establish a form of tax levying system which facilitates the establishment of monopolistic areas and creates barriers to entry that make criminal offenses less attractive.

(d) *The victim/offender relationship*

When analyzing the victim/offender relationship in extortion racketeering cases, it should be considered that "the boundaries between victim and accomplice are often (...) blurred" (Blok 2008, p. 8). These boundaries create the difference between systemic and casual extortion racketeering.

When networks are involved in extortion racketeering, they establish predatory relationships with their victims. Being unable to establish lasting relationships with them, criminal networks consequently act with the "aim or effect to destroy or bleed to death" (Passas 2002, p. 21) the victims, exacting considerable extortive payments in a short period. This is typical of casual extortion racketeering.

By contrast, hierarchical criminal groups, benefiting from their reputation and durability, may establish parasitical or symbiotic relationships with their victims. This contributes to making extortion racketeering systemic.

The relationship is "parasitical when the aim is to preserve the viability of the target, such that illegal benefits can be extorted on a more or less regular basis" (Passas 2002, p. 21). By establishing a lasting relationship with the victim, the offender "harms the host a little at a time, without killing it, or only kills it in slow motion" (Felson 2006, p. 196). In other cases, the relationship may be symbiotic in nature, so that the victim becomes a "friend" of the extorter. The victim thus gains an advantage that is not "simply that of avoiding the likely damages that would otherwise ensue, but can extend to assistance in disposing of competitors, or protection against the threat of isolated bandits, and against the risk of being cheated in the course of business transactions" (Gambetta 2000, p. 166).

Systemic and Casual Extortion Racketeering: The European Case

The link between the presence of casual or systemic extortion racketeering and the variables indicated above has been recently investigated in a study on extortion and organized crime in the 27 European Union Member States (Transcrime 2009). This study analyzed the complex variety of criminal organizations present in the 27 EU Member States, the criminal market opportunities they exploit, the differences in their organizational structures (some are hierarchical, some take the form of a network, some are permanent, some are more ephemeral) together with their differing criminal activities and control over the territory, and the various relationships they establish with their victims.

The study explained that extortion racketeering is casual in most of the European Union Member States (EU MS). The only exceptions are the Eastern EU MS (Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia, Slovenia) and some EU MS in the South of Europe, namely, Spain and Italy.

When the geographical locations of the 27 EU MS are divided into four clusters, the following patterns emerge (see Caneppele et al. 2009, pp. 253–254):

1. *Northern Europe* (Denmark, Estonia, Finland, Latvia, Lithuania, Sweden). Owing to the prevalence of smuggling activities in this region, extortion racketeering is casual in Denmark, Finland, and Sweden. In fact, these countries are distinguished by the presence of criminal organizations that do not exercise control over the territory because they are transnational in their smuggling activities. Proximity to Russia and the Caucasian countries and the presence of hierarchical criminal groups have generated systemic extortion racketeering in Estonia, Latvia, and Lithuania.
2. *Western Europe* (Austria, Belgium, France, Germany, Ireland, Luxembourg, the Netherlands, United Kingdom). Owing to the structure of the organized criminal groups operating in this area and to their transnational activities, extortion racketeering is casual. Most of the countries in this area suffer from extortions carried out within close-knit ethnic communities. This is the case, for example, of Austria, Belgium, France, Germany, Luxembourg, and the United Kingdom.
3. *Central/Eastern Europe* (Bulgaria, Czech Republic, Hungary, Poland, Slovakia, Slovenia, Romania). Because of its proximity to the Balkans, this region is an important transit area for criminal goods and services and in particular for smuggling and trafficking activities. However, the likely hierarchical structure of the criminal organizations operating in this area, together with their strong presence at local level, makes extortion racketeering systemic in countries such as Bulgaria, Czech Republic, Hungary, Poland, Romania, Slovenia, and Slovakia.

4. *Southern Europe* (Cyprus, Greece, Italy, Malta, Portugal, Spain). The region is highly heterogeneous. Differences outweigh similarities in the structure of organized crime groups operating in these countries, and this is also reflected in the different ways in which extortion racketeering is conducted. Extortion racketeering is casual in most of the countries belonging to this cluster.

In two countries – Italy and Spain – extortion racketeering is systemic. In Spain, it is systematic because it is carried out by terrorist groups belonging to ETA which are well structured and rooted in the territory (see Transcrime 2009, Spain country profile). As seen above, in Italy, the phenomenon is mainly linked to mafia-like organized crime, for which extortion racketeering plays a fundamental role in terms of both exercising control over the territory and financing criminal activities.

Overview

Experimental criminologists pay close attention to baseline equality between the treatment and control groups. When the study groups are not similar to one another, this introduces biases and confusion in the interpretation of the treatment effect. Often simple random assignment procedures are used to create similar groups, where the entire sample is divided in half into treatment and control conditions. However, research shows that this simple process does not always work. By chance alone, one group can be larger and have more of a particular type of participants or type of traits. Such instances make it difficult to compare "like with like," which is one of the cornerstones of randomized controlled trials. Instead, experimentalists and statisticians advise using randomized block designs, in which cases are randomly assigned within homogeneous blocks of participants, rather than from the overall sample. The variance within the blocks is minimized, which decreases the experimental "noise" and increases the statistical power of the test. Randomized block designs can also be used to "force" size equality in order to create exactly the same group sizes, something which cannot be done with simple random assignment. Below, instances in which it is optimal to use randomized block experiments are discussed, as well as how to design them, and the obstacles to avoid when using these designs. The general type of randomized block designs is introduced, along with two special cases: permuted randomized block designs and matched pairs, which are useful in small-scale studies where group-size equality is particularly important and when unmasking of the random allocation sequence does not create a source of concern.

Introduction

In randomized controlled trials, the experimental and control groups should be as similar to one another as possible. Without this equality prior to the administration of the treatment to the experimental group and not to the control group, the advantages of the experimental approach are dramatically diminished. Therefore, researchers conducting randomized controlled trials pay particularly close attention to the way cases are assigned to the treatment conditions of the study and work hard to preserve the integrity of this process, in both the design and implementation of the study.

Such balance – or group comparability – is achieved using a process of random allocation of cases into treatment and control groups. Probability theory predicts that the equal chance of each case to be assigned to either treatment or control conditions (e.g., a 50-50 chance) creates two groups that are likely to be similar to one another – except for the intervention that "experimental participants" are exposed to but "control participants" are not. Because participants are assigned to groups by chance, the likelihood that the experimental group will turn out to be different from the control group is significantly minimized when compared with a nonrandom assignment procedure. Therefore, any baseline traits that could explain the relationship between the treatment and outcome are equally divided between the two study groups, and the potential effect of these traits is believed to be controlled for by this design. Thus, the only explanation for any difference in outcomes between the experimental and control groups ought to be attributable to the treatment effect, and nothing else.

In practice, researchers use various techniques to produce a random assignment sequence. The most popular of these techniques is simple random assignment, in which the researcher divides the entire sample into two (or more) groups, using a basic algorithm. For example, if there are 200 cases in a particular study, 100 would receive the treatment, and 100 would serve as the control participants – and that assignment to the two groups is completely random. All statistical software packages, including various online calculators, can easily produce a random assignment sequence that would enable the researcher to allocate his or her cases in such a way.

However, while this simple random assignment procedure is likely to provide an overall balance, equality is not guaranteed. The risk of creating unequal groups still exists, despite the random assignment, when the allocation is not restricted. Unbalance can become a problem in the form of unequal group sizes (e.g., 90 compared to 110 participants) or one group "holding" more participants with a particular trait (e.g., more females than males or more motivated participants in one study group than the other). These problems can be quite concerning, and a large body of literature has tried to deal with these issues over the years (see Ariel and Farrington 2010; Weisburd and Taxman 2000). For example, unbalance is usually associated with a lower statistical power of the research design (see Lipsey 1990; Weisburd and Taxman 2000), particularly in small samples. This means that the ability of the test to show there are indeed differences between the study groups *because* of the intervention is greatly diminished. It has also been shown that interpreting the results from an unbalanced trial may lead to reaching biased conclusions about the true outcome effect of the tested intervention (Torgerson and Torgerson 2003).

The Randomized Block Design

Understanding that simple random assignment cannot guarantee the necessary balance between the groups has led researchers to try and anticipate and overcome the problem, and certain measures can now be taken to address it. Some are more successful than others. For example, it was (and perhaps still is) commonly assumed that increasing the size of the sample is associated with more balance and, in turn, with greater statistical power. But, as Weisburd et al. (1993) have shown, there are instances in which there can be an inverse relationship between sample size and statistical power. Especially in heterogeneous samples, larger samples are likely to include a wider diversity of participants than smaller investigations. Because it is necessary to establish very broad eligibility requirements in order to gain a larger number of cases, large trials tend to attract a more diverse pool of participants. This increases the variability in the data as there is more "noise," which makes it difficult to detect the effect of the treatment. Therefore, the design benefits of larger trials may be offset by the implementation and management difficulties they present.

Given Weisburd et al.'s (1993) and similar research findings, along with a broader understanding of the shortcomings of simple random assignment, clinicians and statisticians have developed other research designs to more adequately handle unbalanced groups or high variability. One type which is slowly gaining recognition and is being applied more and more in experimental criminology is called the randomized block design. The concept behind randomized block designs is generally straightforward: if the researcher knows before he or she administers the treatment that certain participants may vary in significant ways, this information can be utilized to his or her advantage. The researcher can use a statistical design in which all participants are not simply randomly allocated directly into experimental and control groups. Instead, they are randomly allocated into groups *within* blocks.

The randomized block design is used in order to decrease the variance in the data (Lachin 1988). Unlike simple random assignments, where units are unrestrictedly distributed at random to either treatment or control groups (or more than two groups, as the case may be), units in a randomized block design are allocated randomly to either treatment or control *within* pre-identified blocks. The blocking process is established based on a certain criterion, which is intended to divide the sample, prior to assignment, into subgroups that are more homogeneous (Hallstrom and Davis 1988). Then, within these blocks, units are randomly assigned to either treatment or control conditions.

Variations of this design were implemented in some of the most influential studies in criminal justice research, particularly in place-based criminology, such as the Jersey City Problem-Oriented Policing Experiment at violent places (Braga et al. 1999). Recently, Weisburd et al. (2008) have used this design in an experiment on the effects of the risk-focused policing at places (RFPP) approach to preventing and reducing juvenile delinquency. Before administering the treatment, they found considerable variability in the characteristics of violent places selected for the study, which jeopardized the statistical power of the evaluation. In this case, the impact of the treatment will be more difficult to detect when there is a large variability in the assessment of study outcomes. The data were thus more adequately managed under a randomized block design. As in other hot-spot experiments (e.g., Ariel and Sherman forthcoming), the randomized block design is advantageous because it decreases the variations that characterize places, such as the drug activity, and structural and cultural characteristics. In several hotspots experiments, it was found that an examination of the distribution of arrest and call activity in the hot spots before the experiment revealed that the places fell into distinct groups – for example, high, medium, and low criminal activity blocks. Therefore, hot spots randomly allocated to experimental and control conditions *within* each of these conditions created more homogeneous groups of hot spots.

Randomized block designs can be used in person-based experiments as well. Similar issues arise in analyses of individuals in schools, prisons, and other environments, and so blocks can be created in these studies as well (see, e.g., Ttofi and Farrington 2012). For example, a large randomized controlled trial was conducted to test the hypothesis that differences in wording of letters sent to taxpayers in Israel would affect various aspects of their taxpaying behavior, such as the amount of money they were willing to report and pay to the tax authority (Ariel 2012). Nearly 17,000 taxpayers were randomly assigned to different groups, each receiving a different type of letter. However, a large sample of taxpayers introduced high variability. For example, the sample included very poor taxpayers as well as very rich taxpayers. The size of the sample also increased the likelihood that, in one of the study groups, there would be a disproportionally larger number of extremely rich taxpayers, so their effect on the results could skew the conclusion. Therefore, the sample was divided, before random assignment, into blocks of income levels. Within each of these income-level blocks, the participants were then randomly allocated into the different letter groups. Therefore, this procedure allows for measurement of not only the overall effect of letters but also of specific effects within the blocks (i.e., effect of letters on participants with different income levels).

Designing a Randomized Block Experiment

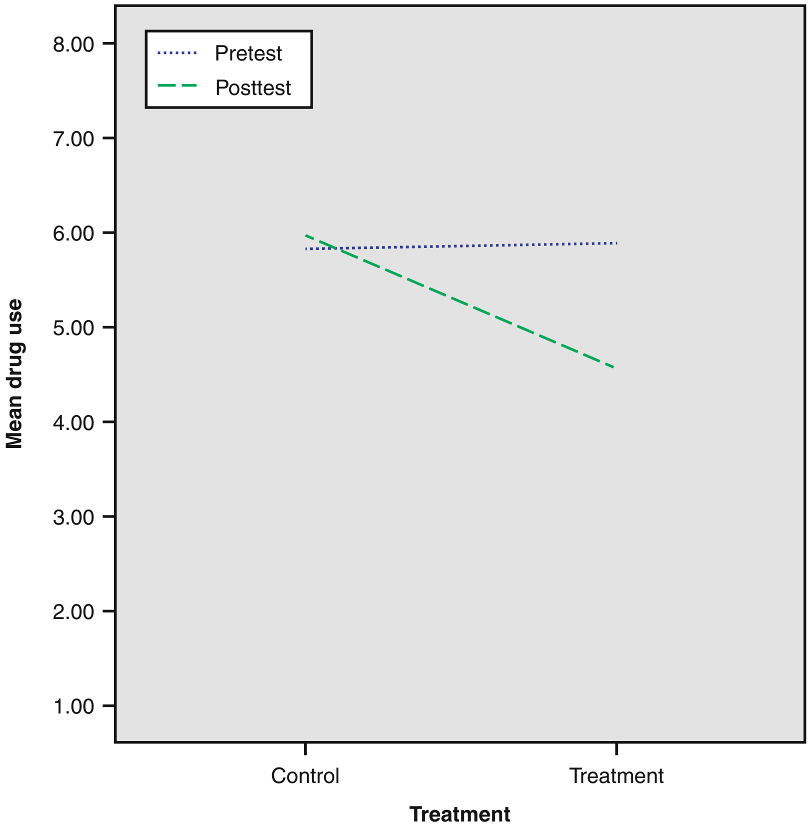
Consider the following hypothetical trial as a way to show the benefits of blocking and when this design should be considered. Imagine a trial with one experimental group consisting of 52 drug-addicted offenders, treated in an antidrug program. Another group of 48 drug-addicted offenders serve as the control group, receiving no drug treatment. The allocation to treatment and control is done randomly. The experiment is conducted in order to evaluate the merits of the program, where success is nominally defined by a decrease in drug use (on a scale of 1–8, 8 being the highest and 1 being the lowest). However, unlike other drug treatment programs, this particular treatment is very costly. Therefore, unless very high success rates are registered, the facilitators will be unlikely to recommend its implementation in the future. All eligible participants selected for this trial are known to be drug abusers before entering the program. Prior to the treatment, the drug use level was not statistically different between the two groups (both averaging about 5.85 on the said scale).

At the 6-month follow-up period, drug use was measured again for both groups. Results show that the program was successful: there was an overall 15 % reduction in the treated experimental group, when compared with the untreated control group. A visual depiction is presented in Fig. 1. At the same time, considering the costs of the program and that there was “only” a 15 % reduction, the policy implication is to not recommend further implementation of the program.

However, a closer look at the distribution of the pretest scores indicates that the sample is comprised of drug abusers of four different types of drugs (with no crossovers): marijuana, MDMA, alcohol, and heroin. Generally speaking, it could be hypothesized that drug abusers of these different drugs are not addicted in the same way (based on both pharmacological and psychobiological qualities of these substances). Therefore, the prospective success rate of the drug intervention program is also hypothesized to be different for each subgroup; it is likely that getting clean from a heroin addiction or alcohol addiction is more difficult than from marijuana or MDMA. Thus, dividing the overall sample based on the type of drug should produce more homogeneous subgroups, whose chance to get clean is different.

One primary advantage of looking at the study this “blocked” way is that even if the strength of the treatment effect within each block is similar, more precise estimates of the magnitude of

Randomized Block Designs,
Fig. 1 Hypothetical drug treatment trial: simple random assignment



the treatment effect can be discovered because the intra-block variance is reduced. Because the "treatment estimate" is comprised of both the drug program and the variability, the treatment effect is likely to be larger within each block when the "noise" is reduced. It therefore becomes "easier" to see the effect, because the variance is reduced by the creation of homogeneous subgroups.

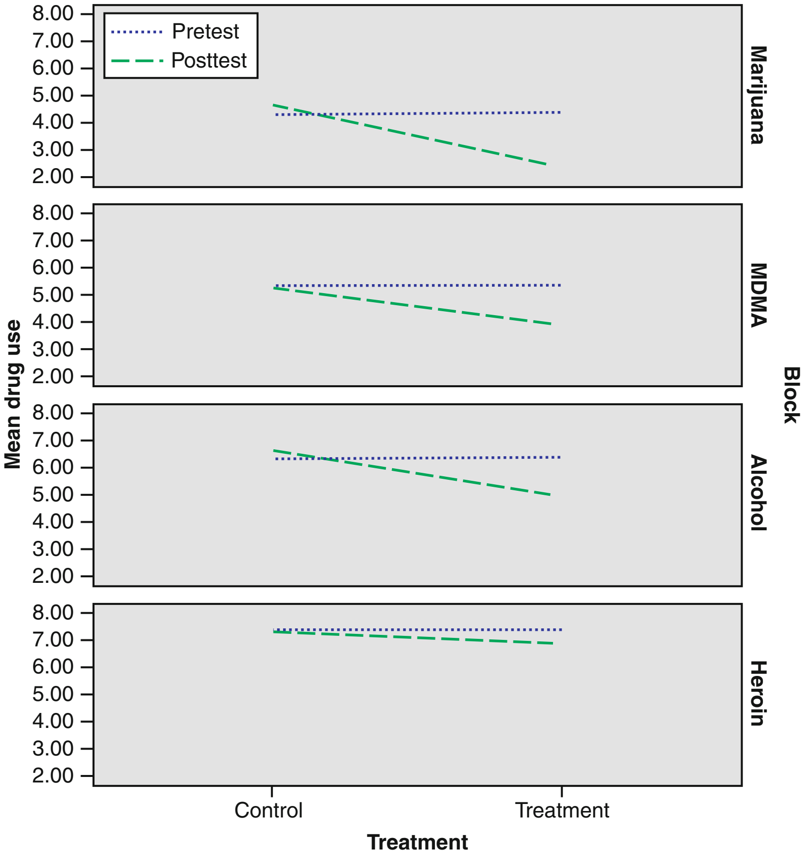
With this in mind, imagine another experiment, which is substantially similar to the one above: the treatment is delivered in the very same intensity and method as in simple random assignment, to a similar group of participants. However, the participants are grouped within "blocks of drug type," which creates blocks of participants who are likely to be more similar to one another, at least in terms of the type of drug to which they are addicted.

Notice that the *overall* 15 % reduction compared to the control group is still expected to be registered. This is depicted in Fig. 2. As can be seen, the overall treatment-to-control magnitude of difference is the same across blocks. However, the *intra*-block reduction is different, because there is less variance in the data. The blocking procedure shows that the Heroin Block is less receptive to the treatment (6 % decrease in drug use), as arguably expected from this subgroup, compared, for example, to the Marijuana Block or the MDMA Block (51 % and 34 % decrease, respectively). Given such findings, the policy implication could then be to continue using the program for certain types of addictions in light of the high success rate, but not for others with a lower success rate.

Planning Randomized Block Designs

When designing randomized block experiments, particular attention is drawn to three elements:

Randomized Block Designs, Fig. 2 Hypothetical drug treatment trial: randomized block design



the treatment effect (and the variance associated with it), the blocking criterion (i.e., the variable which divides the sample prior to random assignment), and the interaction between the treatment factor and the blocking factor – though the latter is generally ignored in criminal justice research and therefore omitted from the discussion. There are different ways to "block" the study participants, depending on the type of study. The blocking criterion is usually based on the natural cutoff points of the outcome variable of interest, at its baseline level – for example, the number of police calls for service in hot-spot experiments (e.g., Ariel and Sherman forthcoming). The blocking criterion can be nominal or categorical as well, such as gender, ethnicity, or crime type.

The model can be extended to account for several treatments and several blocks. However, there are a limited number of interventions that one research project can study. It seems that using only one treatment and one control condition in each block is more effective, because the test statistic becomes more "stable" than with multiple conditions and blocking criteria. At the same time, it is not clear how many blocking factors should be allowed before the design becomes too "messy" – though Friedman et al. (1985, p. 69) understandingly claimed that, for studies of 100 participants, blocking using up to 3 factors is still considered manageable.

It is most important that each block should contain all treatments and that each treatment should occur an equal number of times in each block (Chow and Liu 2004, pp. 136–140). Many of the experiments on policing crime in places are constructed in this way, such as the ones reviewed in the introduction.

As in all experiments, it is desirable that the administration of the treatment in terms of potency, consistency, and procedures is identical in each block. This means that the overall experimental design is replicated as many times as there are blocks, and each block can be viewed as a disparate yet identical trial within the overall study (Rosenberger and Lachin 2002). If the administration of the treatment was different in each block, it would be rather difficult to analyze the treatment effect. Therefore, maintaining the same treatment across the study blocks is advised.

Lastly, randomized block designs were found to be particularly advantageous when there are "several hundred participants" (Friedman et al. 1985, p. 75), but recent studies suggest that randomized block designs can also be useful in much smaller studies, especially in place-based experiments, in which the unit of analysis is geographical areas rather than human participants (see review in Gill and Weisburd 2013).

Permuted Randomized Block Design

The design presented earlier reduces the variance in the data caused by certain prognostic or other general variables. However, these models are less useful to address time-related biases created by sequential assignment of units. There are times when the researcher needs to achieve near-equality in the number of units assigned in each block to different treatments, at any stage of the recruitment process, not only at the end of the study. A special type of block randomized design is required to achieve this.

First introduced by Hill (1951; see Armitage 2003), the "permuted randomized block design" (PRBD) was developed in order to deal with these conditions. The PRBD is most appropriate when there is a strong need for both periodic and end-of-the-experiment balance in the number of participants assigned to each study group in each block. This is the case, for example, in small studies, or studies with many small subgroups (Rosenberger and Lachin 2002, pp. 41–45).

Suppose that a care provider cannot wait for more victims of a similar type to surface, in order to provide them with much-needed services at the same time (for instance, group counseling). This is a small study, with only 40 participants, so it is important to have an equal assignment of cases to treatment and control conditions. Furthermore, the treatment must be delivered as soon as possible. However, the simple random assignment procedure is not optimal, because of the increased threats such as selection bias and chronological bias (Kao et al. 2007, p. 364). A PRBD model can be used instead. With 40 participants, the researcher can break the sample up into 10 blocks, with 4 participants in each block, and one treatment group (T) and one control group (C). In each block, there are exactly six possible arrangements of the treatment and control: CCTT, TTCC, CTTC, TCCT, TCTC, and CTCT. Each block is randomly allocated to one of the six arrangements. This process is then repeated 10 times (as the number of blocks), until all 40 participants are assigned to all conditions.

This procedure is relatively straightforward and provides several advantages. It "forces" group size equality by guaranteeing that there is exactly 50–50 % assignment of treatment and control participants. Furthermore, the procedure controls for time-related biases as well: using six combinations masks the next assignment sequence and therefore avoiding, at least somewhat, the risk of selection bias (but not without reservations as soon discuss). Many find it quite elegant as well, and over the years, the PRBD has become very popular in clinical trials (Abou-El-Fotouh 1976; Cochran and Cox 1957; Rosenberger and Lachin 2002, p. 154). However, in criminology, this approach is quite rare (Ariel 2009).

Matched Pairs Design

A different yet related random allocation procedure is the pairwise matching assignment (see Rossi et al. 2006). Matched pairs, in which each member of the pair is assigned to either treatment or control conditions, can also be used to achieve maximum equivalence. The researcher is able to gain more statistical power from reduced variance rather than increased sample size. In this procedure, participants are often rank-ordered based on a particular variable (e.g., the number of previous arrests), and then every pair is randomly assigned to treatment or control conditions. Thus, the top two offenders would be assigned at random, one to the control group and the other to the experimental group, and then the third and fourth participants would be assigned in a similar way, then the fifth and the sixth, and so on until the last two cases. Each pair can be viewed as a "block"; in the example above, there are 20 blocks.

Matched pairs assignments are appealing, as they produce exactly the same group sizes. However, they do pose some threats. First, any interference with the "natural" randomization of case allocation can potentially introduce bias. Particularly in sequential assignments (i.e., a trickle flow process), knowing the allocation of the first case ("treatment") immediately unmasks the assignment of the second case ("control"), and this can lead to selection bias. Second, by matching in pairs of ranked cases, one assumes that the "pairing criterion" (e.g., number of previous arrests) does not introduce a systematic bias to the procedure. Great caution should therefore be used when randomly assigning in pairs. Nevertheless, there can certainly be instances in which this design is a good fit. Hot-spot experiments can potentially benefit from this type of random allocation (e.g., Braga and Bond 2008).

A matched pairs design may also help to solve the problem of differential attrition. If one member of a matched pair drops out, the other member of the pair can be deleted as well, thus retaining the randomized design within matched pairs. For instance, in hot-spot experiments, it is conceivable that some "treatment hot spots" will have to be excluded *after* random assignment, if they are too far away from all other hot spots and difficult for the police to reach within reasonable time. In this case, the experimenter can drop the problematic "treatment hot spot," along with the paired "control hot spot," without jeopardizing the equivalence between the experimental and control groups. Nowadays, members of a pair can be matched on numerous variables by using propensity score matching (see, e.g., Apel and Sweeten 2010).

A Closer Look at the Blocking Criterion

Blocking on key variables is expected to create blocks of participants which are more similar to one another than in the generally heterogeneous random sample. In certain cases, it is immediately obvious that blocking should be utilized for the purposes of reducing experimental error resulting from variance. The advantage of blocking the data according to type of drug use, as in the hypothetical drug treatment trial presented above, is very clear. But there are other instances when the advantages of blocking are not as apparent.

Because the decision to block the data is usually based on qualitative grounds, there is always the risk that the researcher has made a poor decision. In an ordinal-level variable, for example, this means that the natural cutting points of the data might be misplaced, therefore implementing a grouping criterion that creates blocks in which the units within each block do not share common characteristics. In a study of tax evasion, for example, blocking the data according to income levels in a way that is intended to divide the sample into disparate socioeconomic backgrounds could go wrong if the researcher mistakenly categorized participants, so the blocks do not contain taxpayers with similar socioeconomic attributes. Thus, if the blocking is wrong, the block design will be disadvantageous compared with using an ordinary complete randomization design; such a procedure could actually be counterproductive and increase the error rate, because it increases the intra-block heterogeneity.

A practical approach to deal with this situation would be to ignore the blocking factor in analyses (Friedman et al. 1985). Disregarding the blocking effect is acceptable, because ignoring this factor should result in a more conservative statistical test. Analyzing the data this way will mean that the researcher sacrifices both power and precision, but not the overall integrity of the study, as long as the researcher implicitly reports this procedure.

Subgrouping Using Blocking or Subgroup Analyses

The last issue to consider in regard to these designs is whether pre-random blocking is at all necessary. Randomized block designs decrease the variance of the data and increase the precision and statistical power of the test. This is achieved by the pre-randomization blocking procedure. However, ordinary post hoc subgroup analyses, which are generally used in analysis of variance procedures (such as Tukey's HSD, Scheffe, Bonferroni, and the like), are used for exactly the same reason. These analyses allow the researcher to evaluate the treatment effect on particular groups or subgroups of participants. But in this context, they can also be used to theoretically homogenize the data according to certain key variables, much like a blocking procedure. Therefore, should data homogenization be dealt with before or after random assignment?

Subgroup analyses are customarily viewed as a natural step that comes after testing for main effects. These analyses can provide valuable information about both planned and unanticipated benefits and hazards of the intervention. At the very least, researchers use them to establish treatment benefits in subsets of participants. It makes sense to first assess the treatment by comparing all experimental units with all control units (or before–after, depending on the design) and then to account statistically for any covariates or other baseline variables. It seems that most clinicians agree with this rationale as 70 % of clinical trial reports include treatment outcome comparisons for participants subdivided by baseline characteristics at the post-randomization stage (Adams 1998; Assmann et al. 2000).

At the same time, however, as logical as subgroup analyses may be in theory, it is well established that they are often misleading. In fact, the medical community often rejects such findings (Moye and Deswal 2001), as the methods and procedures implemented are commonly misused (Assmann et al. 2000). Among some of the concerns raised against subgroup analyses, Moye and Deswal (2001) emphasize that "lack of prospective specification, inadequate sample size, inability to maintain power, and the cumulative effect of sampling error" complicate their interpretation. Some researchers go as far as saying that the most reliable estimate of the treatment effect for a particular subgroup is the overall effect rather than the observed effect in that particular group (Schulz and Grimes 2005). Therefore, using subgroup analysis instead of blocking the data before random assignment may actually be ill-advised.

Moreover, because virtually any covariate can be used to cluster units into subgroups, it allows, at least from a technical standpoint, the ability to generate multiple comparisons. This subgroup analysis is a source of concern, because it increases the probability of detecting differences simply by chance alone (type I error). It is not uncommon for researchers to be tempted to look for statistically significant, often publishable, differences between subgroups. It is therefore recommended that, without proper planning and sound rationale for conducting the analysis, subgroup analyses should not be considered as a replacement for pre-randomization blocking. Subgroup analyses should be justified on theoretical grounds a priori, in order to avoid the appearance of improper data mining. As described by Weisburd and Britt (2007, p. 320), "this is a bit like going fishing for a statistically significant result. However, sometimes one or another of the pairwise comparisons is of particular interest. Such an interest should be determined before you develop your analysis... if you do start off with a strong hypothesis for a pairwise comparison, it is acceptable to examine it, irrespective of the outcomes of the larger test. In such circumstances, it is also acceptable to use a simple two-sample t-test to examine group differences." Schulz and Grimes (2005, p. 1658) further developed this argument, by emphasizing that "seeking positive subgroup effects (data-dredging), in the absence of overall effects, could fuel much of this activity. If enough subgroups are tested, false-positive results will arise by chance alone.... Similarly, in a trial with a clear overall effect, subgroup testing can produce false-negative results due to chance and lack of power."

Thus, subgroup analyses can be misleading. The interpretation of their results should be seen as exploratory because they can suggest but not confirm a relationship in the population at large. Despite this recognition in other disciplines, most criminal justice experiments do not take multiple tests into account. It leads one to wonder how many of the findings from criminal justice experiments, in which hundreds of outcomes are reported, are really "true effects."

Notwithstanding reservations just reviewed, subgroup analyses should not be completely neglected. There are times when they can replace pre-randomization blocking designs. This, however, should be done with caution. When the researcher specifies at the beginning of the trial (i.e., in the experimental protocol before "going live" with experiment) that the efficacy of the treatment for a particular subgroup or a particular block is of particular interest and part of the research goals, then subgroup analyses can be considered. When this is the case, there are good strategies that can be used to estimate the effect size in subgroups created after random assignment (see Moye and Deswal 2001). Practically, reporting the proposed analyzes in the experimental protocol can substantially reduce the "going fishing" bias described earlier.

Conclusions

Under certain conditions, randomized block designs are more useful than simple random allocation procedures. They allow the researcher flexibility and control over the number of conditions assigned to the participants, as well as the number of blocks that are used to homogenize the data. By reducing the intra-block variance, the treatment estimates are more accurate because of the increased statistical power and precision of the test statistics.

The various statistical models designed to accommodate the different types of blocking techniques provide the researcher with accuracy that is generally superior to that which can be obtained using simple random allocation. This is particularly the case when the trial is small – several hundred or less – or when the blocking criterion is "good." These blocking procedures can deal with certain shortcomings that cannot be eliminated by randomization: increased data variance, outliers, time effects due to sequential assignment, missing data, and covariance imbalance. Blocking procedures can also create a more accurate estimate of the treatment effect – not by altering the effect of the treatment or the sample size, which are held constant, but by decreasing the variance. Therefore, given their clear advantages, these designs are gaining popularity in criminal justice research, and one should expect that they will be used more often in the future.

Overview

Randomized experiments are a type of experimental design that uses random assignment to gain equivalence between groups in a study. They are used most often to evaluate the impact of interventions on outcomes. This entry summarizes the rationale for a randomized experiment, provides the essential components of the design and an example from the policing literature, and briskly highlights its history and status as the “gold standard” for evaluation research. The entry concludes with a description of barriers to experiments and some of the problems in the field that threaten the design.

Background

Experimental research attempts to show a causal relationship of an independent variable (e.g., higher levels of patrol) on a dependent variable (e.g., arrest rates). In experimental research, the researcher uses various methodological approaches to control for the observed and unobserved factors that may influence the dependent variable. The major goal of experimental research is to strengthen internal validity, that is, ensuring that the observed impact is explicitly related to the changes in the independent variable (i.e., treatment condition). There are a wide variety of competing methods in experimental research used to strengthen internal validity, but randomized experiments are considered by many researchers to be the “gold standard.”

A randomized experiment is a type of design that uses random allocation of participants or other units of analysis in order to gain equivalence between subjects or units studied. Although randomized experiments may be used to test theoretical questions, they are most often used in criminal justice to evaluate the impact of interventions, programs, or policies. Randomized experiments that take place in the field, as is often the case in criminal justice, are also referred to as randomized field trials. They are also referred to as randomized control trials (RCT), true experiments, or randomized field experiments.

Although several quasi-experimental approaches are gaining popularity in the social sciences, including criminology (e.g., propensity score matching, regression discontinuity), there is consensus that randomized experiments are optimal for drawing causal inferences between independent and dependent variables. Randomized experiments, when implemented with good fidelity, permit researchers to explain observed findings as a result of the treatment or intervention, ruling out confounding factors that may explain findings.

Internal Validity

To better understand the strength of randomized experiments, a discussion of internal validity is warranted. A research design in which the impact of the intervention can be clearly distinguished from other observed factors is known as having high internal validity. If there are confounding factors involved in the impact of the intervention, then the experiment is considered as having low internal validity. Shadish et al. (2002), among others, have identified the most common threats to internal validity:

1. *Selection*: the preexisting differences between treatment and control subject or units.
2. *History*: an external event occurring at the same time of the study that may influence impact.
3. *Maturation*: changes in subjects or units between measurements of the dependent variable. These changes may be of natural evolution (e.g., aging) or due to time-specific incidences (e.g., fatigue, illness).
4. *Testing*: measurement at pretest impacts measurement at posttest.
5. *Instrumentation*: changes to the instrument or method of measurement in posttest measures.
6. *Regression to the mean*: Natural trends may cause extreme subjects or units who score extremely high or low during the pretest to score closer to the mean at posttest.
7. *Differential attrition*: the differential loss of subjects or units from the treatment group compared to the control group.
8. *Causal order*: the certainty that the intervention did in fact precede the outcome of interest (Farrington and Welsh 2005).

To further illustrate the importance of internal validity, let us suppose a researcher is interested in evaluating the impact of a youth court on a juvenile recidivism. The internal validity is considered high, if at the end of the evaluation, the researcher can show that the change in juvenile recidivism among the intervention groups is due only to the intervention (i.e., youth court) and no other confounding factors were at play. The researcher must show through either research design or analytical procedures that all confounding factors are accounted for in the measurement of outcomes. If the researcher is unable to account for other factors such as seriousness of first offense or the maturation of the study population, he or she must note that the observed effects may be due to other factors. If few threats to validity (or potential confounding factors) are not accounted for, the internal validity of the study would be considered low.

Generally speaking, a randomized experiment has the highest possible internal validity, because this approach allows the researcher to assume that other confounding causes of the outcome of interest, known and unknown, are not systematically influencing the study results. High internal validity in randomized experiments is gained through the process of randomly allocating the treatment or intervention to the experimental and control or comparison groups. Through random assignment, the researcher is not just randomizing the treatment. He or she is randomizing all other factors that may influence the outcome of the treatment. Thus, there is no systematic bias that increases the odds of one unit's assignment to the treatment group and another unit's assignment to the control or comparison group. This is not to imply that the groups are the same on every characteristic – it is very possible that differences may occur; however, these differences can be assumed to be randomly distributed and are accounted for in the probability distributions that underlie statistical tests of significance. Regardless, neither the treatment group nor the control group should have an advantage over the other on the basis of known or unknown variables. Thus, randomized experiments are the only design that allows the researcher to assume statistically unbiased effects (e.g., Boruch 1997).

The goal of most randomized experiments in criminology and criminal justice, as in other social science fields, is to disentangle the impact of the treatment or intervention from the impact of other factors on the outcomes that are to be tested. A randomized experiment allows the researcher to attribute differences between the groups from pretest to posttest as a result of the treatments or interventions that are applied. At the conclusion of the study, the researcher is able to assert, with confidence, that the difference is likely a result of the treatment and not due to other confounding factors. It is more difficult for nonrandomized studies, even a high-quality quasi-experimental design, to make this assertion. This advantage is underscored by Farrington (1983):

> The unique advantage of randomized experiments over other methods is high internal validity. There are many threats to internal validity that are eliminated in randomized experiments but are serious in non-experimental research. In particular, selection effects, owing to differences between the kinds of persons in one condition and those in another, are eliminated. (1983, p. 260)

Other Experimental Designs

Randomized experiments are distinguished from quasi-experiments and natural experiments by the random assignment of subjects or units. Indeed, these other methods have been developed as a way to approximate "true" experiments when random assignment is not possible. For example, researchers use matching, statistical methods, a comparison group, time series analyses, and other methods to create a quasi-experimental design (QED).

Researchers also take advantage of naturally occurring events to conduct natural experiments. Natural experiments often occur due to an unplanned event, which can allow for an evaluation of a particular factor or intervention. For example, when overcrowding forces the early release of certain prisoners, researchers can use this unplanned event to evaluate the impact of early release on recidivism. Although this example may show a direct short-term impact of early release on recidivism, it still suffers from potential for selection bias, as those selected for early release may be very different than prisoners remaining incarcerated.

Although QEDs and natural experiments are often necessary and can have high interval validity compared to other designs, they are generally considered less rigorous than a well-implemented randomized experiment, because they cannot control for unknown factors.

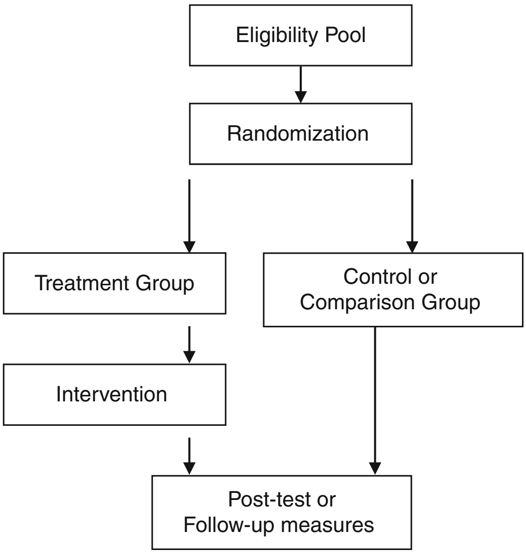
There is some debate among criminologists and across other fields in social and physical sciences, as to the type of bias that results from utilizing nonrandomized rather than randomized studies when examining program or intervention effects. Some may argue that the differences between well-designed nonrandomized studies and randomized experiments are negligible if not slightly skewed towards randomized experiments (Lipsey and Wilson 1993); however, it has been shown that in criminal justice nonrandomized experiments routinely overestimate program success when compared to randomized experiments (Weisburd et al. 2001).

Example of a Criminological Experiment

The general structure of experiments in criminology is usually similar in design regardless of the area or question of interest. Generally, experiments in criminology start with an eligibility pool, randomization, group allocation, and post-test measures relevant to the dependent variable of interest (Fig. 1).

The eligibility pool is made up of those participants or units that are eligible for the experiment. Units of analysis can be individuals or aggregated groups or other entities that are often found in clusters. For example, in an experiment that evaluates the impact of increased foot patrol on crime rates, the eligibility pool may be individual officers who "walk the beat," in a specific area, and who have a specific number of years of experience. Or the unit of analysis could be the geographic area or "beat" that will be assigned to different conditions. The eligibility pool is thus comprised of those patrol officers (or patrol "beats") that meet criteria for inclusion in the study.

Next, researchers randomly assign members from this pool of eligible participants or units to the study conditions – often a treatment group and a control or comparison group. Historically, randomization was carried out through a simple coin flip. There are now many ways to randomize subjects, but most often researchers rely on computerized statistical software to carry out randomization. Some researchers may simply use the rule of odds and evens – that is, assigning every other case to one particular group. This is often referred to as alternation and is considered quasi-random assignment as the assignment of the numbers used is not actually random. The most critical factor in randomization, however, is that each case has the same probability or likelihood of being selected for the control group as the experimental group and that the assignment is based purely on chance. Garner (1977) argued that "equal probability assignment" should replace "random assignment" when discussing such studies with practitioners as it sounds orderly and fair rather than chaotic and unfair.



Randomized Experiments in Criminology and Criminal Justice, Fig. 1 Basic Experimental Design

In the usual criminological experiment, eligible cases are randomly assigned to one of two groups – treatment or control. Experiments in criminology may have more than two groups. But typically, an experiment is comprised of a group that receives the treatment or intervention and a control or comparison group that does not.

It is also quite common in a criminological experiment for the control group to actually receive something rather than nothing. For example, in the foot patrol example, the control group may receive treatment as usual, or the same number of foot patrol officers as typically employed.

Experimental designs can include any number of outcomes, from one to scores. If the randomization was implemented with fidelity, it should produce two equivalent groups on the pretest or baseline measures related to the outcome of interest. The researcher then conducts analyses to determine if the intervention had any impact on the posttest or follow-up measures of the outcomes of interest.

An Illustrative Example of a Place-Based Randomized Field Study: The Minneapolis Hot Spots Patrol Experiment

Randomized experiments in criminal justice, as with most fields, involve the random assignment of individuals. However, as shown in the design example above, it is possible to randomized larger units such as schools, police beats, transportation stops, or city blocks. When these larger entities are randomized, it is often referred to as cluster, block, or place-based randomized trials. The Minneapolis Hot Spots Patrol Experiment (Sherman and Weisburd 1995) provides an example of a place-based experimental design. In that study, the investigators wanted to determine in the least equivocal manner whether intensive police patrol in clusters of addresses that produced significant numbers of calls for service to police, also known as "hot spots," would reduce the levels of crime calls or observed disorder at those places.

To conduct the experiment, the investigators established a pool of 110 hot spots that were eligible for random assignment. This pool of eligible hot spots was then randomly assigned to the innovation group receiving intensive police patrol and a control group that received normal police services. In the Minneapolis study the investigators randomly assigned the hot spots within statistical blocks, or groups of cases that are alike one to another on characteristics measured before the experiment. Such block randomization is not required in randomized experiments, but as noted above is a method for further ensuring the equivalence of treatment and comparison or control groups.

The strength of the randomized experiment, if it is implemented with full integrity, is that it now permits the investigators to make a direct causal claim that the innovation was responsible for the observed results. If the researchers had simply looked at changes over time at the treated hot spots, it would have been difficult to claim that the observed changes were due to treatment rather than a natural change in levels of crime or disorder over time. Similarly, if the researchers had tried to statistically control for other potential causes in order to isolate out the effect of treatment, it could be argued that some unknown or unmeasured factor was not taken into account. In the Minneapolis study the researchers found a statistically significant difference between the treatment and control hot spots. Random allocation of subjects to treatment and control conditions allowed the authors to assume that other factors had not systematically confounded their results.

History of Randomized Experiments in Criminology and Criminal Justice

While there is evidence that randomization in experiments was used as early as 1885 (Hall 2007), most scholars credit Sir Ronald Fisher and his publication on *The Design of Experiments* (1935) as the first discussion that argues for randomization as a necessity to establish group equivalence. The medical world was the first field that used randomized experiments extensively in the field. The first randomized experiment is credited to Austin B. Hill and associates in a 1948 paper on streptomycin treatment of pulmonary tuberculosis. The work done by Hill during this time is still highly celebrated in the medical field as it paved the way for the first half century of randomized control trials (Weisburd and Petrosino 2004).

Randomized trials in criminology may have started as early as 1937 with the Cambridge-Somerville Youth Study, but the publication was not issued until 1951 (Powers and Witmer 1951) – this is likely the first criminological trial in modern times. Researchers created a youth eligibility pool from youth who were considered as "troubled kids" by their teachers and police, and matched the youth on basic characteristics. Next in the experiment, researchers randomly assigned the youth to a treatment counseling group or a no-treatment control group. The findings consistently stated no positive gains and even negative gains for the treatment group (Weisburd and Petrosino 2005).

Although Fisher and Hill generated much excitement around randomized trials in their respective fields, criminological trials were sparse in the first decade since its debut in the field. Experiments in criminology only found momentum after Campbell and Stanley (1963) published their comprehensive guide to *Experimental and Quasi-Experimental Designs for Research*. The publication provided researchers with a design template to carry out high-quality criminological research. Even then the randomized trial was touted as champion in the hierarchy of experimental design for its high degree of internal validity (Weisburd and Petrosino 2004). Randomized trials during President Lyndon Johnson's campaign – perhaps spurred on by the credibility seen throughout the medical world – were used frequently to evaluate the social endeavors designed in the "Great Society" campaign. Soon after this federal adoption, randomized trials fell out of favor with the administration as researchers would consistently report that government programs show no impact or even negative outcomes. Despite Campbell's (1969) decree that

> The United States and other modern nations should be ready for an experimental approach to social reform, an approach in which we try out new programs designed to cure specific social problems, in which we learn whether or not these programs are effective, and in which we retain, imitate, modify, or discard them on the basis of apparent effectiveness on the multiple imperfect criteria available (Campbell 1969, p. 409)

randomized experiments in criminology faded from center stage for more than a decade (Weisburd and Petrosino 2004). David Farrington's (1983) review of high-quality randomized experiments in criminal justice showed that between 1957 and 1981 there were only 41 eligible studies, of which only 35 included offending outcomes. Probably more important than the fact that only 30 % of the studies found a significant effect is the relative dearth of experiments in criminology compared to other social and physical sciences (Farrington 1983).

However, experimentation in criminology received a boost during the 1980s. First, the Minneapolis Domestic Violence Experiment (Sherman and Berk 1984), in which 330 male domestic violence suspects were assigned to the treatment (arrest on the spot) group or one of two comparison groups – mediation or separation for 8 h – was conducted. A 6-month follow-up found that arrests significantly reduced subsequent domestic violence, and the study received wide media attention and led to police departments across the USA to adopt mandatory arrest policy for misdemeanor domestic violence incidents. These results also led the US Department of Justice, under James Stewart, to support randomized experiments (Farrington and Welsh 2005; Weisburd and Petrosino 2004). Although replications in other cities were conducted with mixed results, this study is still considered a monumental factor in the promotion of randomized experiments in criminology and criminal justice (Farrington and Welsh 2005). In fact, the exposure from the Minnesota study and subsequent works led to NIJ funding more than two dozen experiments over the next several years (Weisburd and Petrosino 2004).

It was just 2 years later that Farrington et al. (1986) released their acclaimed work *Understanding and Controlling Crime*, which emphasized the unequivocal need to use randomized experiments whenever possible in criminological evaluations. The investment in experimental criminology continued in waves through the 1990's and has increased considerably into the twenty-first century.

Experiments as the Gold Standard in Criminology and Criminal Justice

There is a strong consensus that experiments are the gold standard for evaluation research in criminology and criminal justice. This is reinforced by seminal reviews that appraise the methodological quality of evaluation evidence. For example, Sherman et al. (1997) conducted a comprehensive review of evaluations across many criminal justice sectors to produce their report to congress on crime prevention entitled, "What Works, What Doesn't, What's Promising." As part of the review, Sherman and colleagues developed the Maryland Scientific Methods Scale (SMS), a set of criteria for scoring – evaluations, largely based on internal validity. The highest rating, "5," is reserved for evaluations that utilize "random assignment of program and control conditions to units" (Farrington 2003).

Another example of the rising status of experiments is the creation of organizations to promote such studies. For example, the Academy of Experimental Criminology was founded in 1998 to recognize researchers who successfully led randomized field experiments (Weisburd et al. 2007). The American Society of Criminology created a Division on Experimental Criminology (DEC).

It is also the case that the use of experiments in justice field settings is increasing. As a follow-up to earlier work, Farrington and Welsh's (2005) review showed that randomized experiments with offending outcomes that fit their review criteria grew from 35 between 1957 and 1981 to 1983 between 1982 and 2004 – an increase of over 200 %.

Barriers to Randomized Experimentation

Although randomized experiments have been widely recognized for their internal validity rigor for over 50 years, they comprise a comparatively small portion of the evaluation portfolio in criminology. For example, Petrosino (2003) examined abstracts of impact studies relevant to childhood intervention in the leading bibliographic databases for each field. The proportion of abstracts to RCTs or possible RCTs ranged from 17 % to 18 % for juvenile justice and K-12 education to 68 % in health care. And despite the increase, Farrington and Welsh (2005) were still discouraged to find as few RCTs as they did in their survey of the literature.

Why do randomized experiments encompass a small percentage in the overall catalog of research when they are widely regarded as the gold standard in research? Farrington and Welsh (2005) note that although randomized experiments are advantageous, there are "many ethical, legal, and practical difficulties that face researchers who wish to mount a randomized experiment." For one, some argue that it is legally irresponsible to provide treatment or judicial sanctions at random or to withhold necessary treatment from individuals. Boruch (1997) and others have countered this argument by noting that it is unethical to provide untested treatments and that programs are sometimes provided to persons haphazardly without evidence of their effectiveness.

Another barrier to RCTs is that randomized trials are considered too expensive. The feature of the RCT that generates the highest costs is actually not specific to randomized experiments: it is the longitudinal nature of the data collection (i.e., following treatment and control units and collecting data on various outcome measures). The Coalition for Evidence-Based Policy (2012) has argued for using large-scale administrative data for outcomes (as opposed to field data collection from surveys or interviews) to decrease costs in data collection.

Another common criticism of randomized experiments is that it emphasizes internal validity, but at the expense of external validity. External validity is the ability to generalize findings from a study to other settings. Some researchers argue that experiments set up an artificial setting with treatment and control conditions that do not approximate real world conditions.

Problems in the Field

The three major issues that threaten experimental findings of randomized experiments are as follows:

1. If the random assignment protocol was violated in substantive ways
2. If there was substantial attrition or differential loss of subjects from the study
3. If there was no clear contrast between the treatment program and control condition

Randomization integrity. Randomization is the cornerstone of true experiments. There are a number of missteps that may adversely affect the integrity of random assignments. For example, program staff may have a vested interest in manipulating the randomization assuring certain participants are funneled into certain groups. It has been shown that this type of violation occurs more frequently with practitioners than with researchers; thus, whenever possible, researchers should control the randomization and practitioners should remain blind to the group allocation. Furthermore, researchers should determine the eligibility pool with practitioners before randomization occurs, monitor assignment throughout the study, and train practitioners and data collection staff in the importance of research integrity (Petrosino 2005).

Attrition. Attrition is the loss of cases from study groups after randomization. Researchers must also be proactive in retention efforts to ensure minimal attrition throughout the study. It is very difficult, especially in the criminal justice field, to track participants for long periods of time, which is required to assess intermediate and long-term treatment impact. When participants attrite for one study group more so than another, it is called differential attrition. Differential attrition is particularly hazardous when determining confidence in the treatment impact, because often this causes a change in the composition of the groups. This is a threat to the experiment's internal validity when the treatment group differs in some important way from those who leave the study (Petrosino 2005).

Treatment-control group contrast. The intent when conducting an experiment is to test a specific treatment's impact on a given outcome variable relative to the comparison condition. To test the impact, the treatment and comparison must indeed be distinguishable from one another. On occasion, when the treatment is only a slight alteration from the comparison condition, it may only take a small change in intensity of treatment or comparison condition to create indistinguishable groups. This difference in conditions must be maintained; otherwise, the comparison and any results would be meaningless (Weisburd and Petrosino 2004).

Conclusion

Despite barriers to experiments and the hurdles researchers must jump to conduct a well-implemented RCT, experimental criminology has grown exponentially over the past several decades. There are signs that this trend will continue in criminology. First, the publicity from successful medical field trials has led to greater acceptance of this research in other fields. Second, tighter governmental accountability has created a surge in evidence-based research. The public expects the programs funded by tax dollars to be rigorously tested (Weisburd and Petrosino 2005).

Sensitive questions

Overview

In survey research it is often problematic to ask people sensitive questions because they may refuse to answer or they may provide a socially desirable answer that does not reveal their true status on the sensitive question. To solve this problem Warner (1965) proposed randomized response (RR). Here a chance mechanism hides why respondents say "yes" or "no" to the question being asked.

Thus far RR has been mainly used in research to estimate the prevalence of sensitive characteristics. RR can be used in, for example, self-report studies on criminal behavior (compare, e.g., the two meta-analyses in Lensvelt-Mulders et al.2005). In the Netherlands, much research has been funded by the Expert Centre for Law Enforcement of the Ministry of Justice in the area of regulatory noncompliance in areas as the taxi-driving law, under regulations for food retailers, the law of individual rent subsidy, and the law on agricultural chemicals. Elffers et al. (2003) give an overview of early research in this area. This line of research has been fine-tuned in research funded by the Dutch Ministry of Social Affairs and Employment on regulatory noncompliance among receivers of benefits (compare Lensvelt-Mulders et al. 2006, for a "best practice"). Typically, in this line of research the survey consists of RR questions on sensitive behavior and questions that may explain the psychological and background characteristics of respondents who are more likely to indulge in this behavior. Elffers et al. provide a theoretical background for the development of the psychological characteristics that they coin the table of eleven, as there are 11 explanatory areas.

It is not uncommon that researchers wrongly believe that the RR procedure has the drawback that it is not possible to relate the sensitive characteristics to explanatory variables. However, statistical tools have been developed to relate the sensitive variables to explanatory variables. Univariate RR data can be analyzed with a version of logistic regression that is adapted so that it can handle data collected by RR. Multivariate dichotomous RR data can be handled using a model from item response theory that assumes a latent variable that explains the answers on the RR variables. This entry ends with a discussion of a recent development in the analysis of multivariate RR data, namely, models that take into account that there may be respondents that do not follow the instructions of the RR design by answering no whatever the sensitive question asked.

Introduction

Is it possible to measure sensitive behavior such as noncompliance with rules and regulations that govern public life using surveys? Because it is well known that questions about compliance behavior with rules and regulations may not yield truthful responses, the randomized response (RR) method has been proposed as a survey tool to obtain more honest answers to sensitive questions (Warner 1965). In the original RR approach, respondents were provided with two statements, A and B, with statement A being the complement of statement B. For example, statement A is "I used hard drugs last year" and statement B is "I did not use hard drugs last year." A randomizing device, for instance, in the form of a pair of dice determines whether statement A or B is to be answered. The interviewer records the answer "yes" or "no" without knowing the outcome of the randomizing response device. Thus, the interviewee's privacy is protected but it is still possible to calculate the probability that the sensitive question (A and not B) is answered positively.

Meta-analyses have shown that RR methods can outperform more direct ways of asking sensitive questions (Lensvelt-Mulders et al. 2005). Importantly, the relative improvements in validity increased with the sensitivity of the topic under investigation. This entry of the encyclopedia will show recent developments of in the analysis of RR data, focusing on regression models relating the sensitive question(s) measured with RR to explanatory variables, and models that take into account that there may be respondents that do not follow the instructions of the RR design by answering no whatever the sensitive question asked.

In this manuscript the examples stem from surveys conducted for the Dutch government on noncompliance in social welfare (Lensvelt-Mulders et al. 2006). In the Netherlands Dutch employees must be insured under the Sickness Benefit Act, the Unemployment Insurance Act, the Health Insurance Act, and the Invalidity Insurance Act. Under each of these acts, an (previously) employed person is eligible for financial benefits provided certain conditions are met.

Most of the examples focus on six RR questions, four of which are health-related and the remaining two are work-related. The health questions are:

1. Have you been told by your physician about a reduction in your disability symptoms without reporting this improvement to your social welfare agency?
2. On your last spot-check by the social welfare agency, did you pretend to be in poorer health than you actually were?
3. Have you noticed personally any recovery from your disability complaints without reporting it to the social welfare agency?
4. Have you felt for some time now to be substantially stronger and healthier and able to work more hours, without reporting any improvement to the social welfare agency?

The work-related questions are:

1. In the last 12 months have you moonlighted while receiving your IIA benefits?
2. In the last 12 months have you taken on a small job alone or together with your friends that you got paid for without informing the social welfare agency?

The remainder of the entry is structured as follows. First the analysis of RR data without explanatory variables is discussed. Next, logistic regression adjusted for univariate RR data is described. After this the analysis of multivariate RR data is discussed. This section discusses how regression approaches are to be adjusted in the light of new models that take into account the fact that part of the sample may not be following the RR instructions laid out by the researcher.

Models for Randomized Response Data

Univariate RR Data, No Explanatory Variables

This section discusses the analysis of univariate RR data, where no explanatory variables are involved. The forced response design (Boruch 1971) is used as an example of an RR design.

Assume that the sensitive question asks for a "yes" or "no" answer. The forced response design is as follows. After the sensitive question is asked, the respondent throws two dice and keeps the outcome hidden from the interviewer. If the outcome is 2, 3, or 4, the respondent answers yes. If the outcome is 5, 6, 7, 8, 9, or 10, the respondent answers according to the truth. If the outcome is 11 or 12, the respondent answers no. Let Y be the latent binary RR variable that denotes the true status on the sensitive item, and let Y^* be the observed RR variable that denotes the observed answer on the randomized sensitive question, with "yes" = 1 and "no" = 2. Then

$$\begin{aligned} P(Y^* = 1) &= P(Y^* = 1|Y = 2)P(Y = 2) \\ &\quad + P(Y^* = 1|Y = 1)P(Y = 1) \\ &= 1/6 + 3/4P(Y = 1) \end{aligned} \tag{1}$$

By writing $P(Y^* = j) = c + dP(Y = 1)$, other designs can be described in the same way (compare Böckenholt and van der Heijden 2007). As a first example, in the original Warner design an individual is allocated to either statement A, with probability p, or to statement B, with probability $1 - p$, with $p \neq .5$. The sensitive question in group A is "do you belong to the sensitive population?" and in group B "do you not belong to the sensitive population?" Now $c = (1 - p)$ and $d = (2p - 1)$. A second example is the Kuk (1990) design (see van der Heijden et al. 2000, for an application). Here a (indirect) "yes" or "no" question is asked using two decks of cards with red and black cards. In the right deck the proportion of red cards is 8/10, while in the left deck it is 2/10. The respondent is asked to draw one card from each deck and keep the color of the cards hidden from the interviewer. Next, the question is asked. Instead of answering the question directly, the respondent names the color of the card he took from the related deck, that is, when the answer is "yes," the respondent names the color of the card he took from the right stack (thus, red is associated with "yes"), and when the answer is "no," he names the color of the card from the left stack (thus, black is associated with "no"). In this case we have $c = 1/5$ and $d = 3/5$.

The estimation of $P(Y = 1)$ in Eq. 1 is straightforward when the parameters are in the interior of the parameter space. If the estimate of $P(Y = 1)$ is between 0 and 1, then solving Eq. 1 provides so-called unbiased moment estimates. These moment estimates are equal to the maximum likelihood estimates (MLEs). It is however possible that the moment estimates are outside the unit interval, for example, when the observed proportion in the data is lower than 1/6 (chance level). In that case the MLEs are set to 0. See van der Hout and van der Heijden, 2002, for a detailed discussion.

Extended introductions can be found in Fox and Tracy (1986), Chaudhuri and Mukerjee (1988), and Chaudhuri (2011).

Example

In the 2002 survey 1,760 recipients of disability benefits were asked the six RR questions as presented above using the Kuk method. The respective point estimates with 95 % bootstrap confidence intervals for the four health items are .03 (.004–.052), .04 (.012–.061), .07 (.046–.098), and .13 (.102–.156). For the two work items the respective estimates are .16 (.128–.184) and .08 (.050–.103).

Univariate RR Data and Explanatory Variables

In logistic regression the dependent variable is predicted from one or more covariates. The logistic regression model for RR data is given by

$$\pi_{1i}* = c + d\frac{1}{1 + \exp(-\boldsymbol{x}_i^t \beta)} \qquad (2)$$

$\pi_{1i}*$ is the probability that individual i has score $Y = 1$, $\boldsymbol{x}_i$ the vector with the covariate scores of individual i, and $\boldsymbol{\beta}$ the corresponding vector with regression parameters.

The outcome of the RR logistic regression procedure can be interpreted in the usual way (see, e.g., Agresti 2002). The β-parameters reveal the relation between the covariates and the probability of a sensitive true status, and the significance of each parameter can be assessed using Wald tests. Chi-square tests can be used to assess the fit of the model if the observed RR data are counts that allow comparison with fitted values under the RR logistic regression model, and differences between models can be tested using likelihood ratio chi-square tests.

An early reference to logistic regression for RR data is Maddala (1983, pp. 54–56), and an elaborate discussion can be found in Scheers and Dayton (1988). Lensvelt-Mulders et al. (2006) extend the logistic regression procedure so that it can incorporate person weights that make it possible to weight a sample toward population characteristics, if known.

Example

As an illustration an example taken from Lensvelt-Mulders et al. (2006) is reported. The dependent variable is the work item “In the last 12 months have you taken on a small job alone or together with your friends that you got paid for without informing the social welfare agency?” The explanatory variable is “I think it is more beneficial for me not to follow the rules connected to my disability insurance benefit,” abbreviated as “benefit,” that is measured on a five-point scale and has a mean of 3.67 and a standard deviation of.777. Many more explanatory variables have been measured in this survey, motivated from a rational choice framework; see Lensvelt-Mulders et al. (2006) and Elffers et al. (2003) for details.

The logistic regression model logit (noncompliance) = constant + b * benefit has estimates.765 for the constant and.751 for b. In order to study the impact of these estimates, the estimated probability of noncompliance for the mean value of benefit (i.e., 3.67) and the mean plus or minus one standard deviation (i.e., 3.67 +.78 = 4.45 and 3.67 −.78 = 2.89) are compared. For the mean value of benefit, the estimated probability of noncompliance is 12 %, for 4.45 the estimated probability is 20 %, and for 2.89 the estimated probability is 7 %. This shows that benefit has a strong relation with the decision not to comply with the above disability insurance benefit regulation: the more profitable people perceive that noncompliance is, the more often they do not comply with this work regulation.

Multivariate RR Data

The data from multiple RR items can also be modeled with item response models. The simplest version of this class of models is the

Rasch model (Rasch 1980). For RR data, this model is given by

$$\pi_{1i}* = c + d\frac{1}{1+\exp(-\theta_i - \gamma_j)}, \qquad (3)$$

(see Böckenholt and van der Heijden 2004, 2007; Fox 2005). In this model, the parameter γ_j captures the sensitivity of item j, and the parameter θ_i captures the propensity of the individual i to comply with social security regulations. Since the precision in estimating individual differences in rule compliance is a function of the number of RR items per respondent, more precise measures of compliance can be obtained in multiple- than in single-item studies for equal sample sizes.

Second, mixture versions of the IRR models are developed to allow for respondents who do not follow the RR instructions. Thus, one mixture component consists of respondents who answer RR items by following the RR design and the other component consists of respondents who do not follow the RR design by saying "no" to each RR item, irrespective of the outcome of the randomizing device. These are called "self-protective" (SP) responses. By allowing for the possibility that not all respondents may follow the RR instructions, substantially higher estimates of noncompliance are found than the estimates obtained with current RR methods.

Example

Table 1 reports the goodness-of-fit statistics obtained from fitting the IRR models to the work and health items for the 2002 and 2004 surveys. Fit statistics obtained when considering the health items only are also included. Because a minimum of three items is needed to identify an IRR model without covariates, IRR models are not estimated separately for two work items. The first set of fitted models is based on the baseline RR assumptions represented by Eq. 1 and serves as a benchmark for the (mixture-) IRR models. The second part of Table 1 is obtained by fitting a Rasch version of Eq. 3 to the health item set and by fitting a multidimensional Rasch version of Eq. 3 to both item sets simultaneously.

Randomized Response Methods, Table 1 Fit statistics of RR models for work and health items

Survey year	Health items G2 (*df*)	Health and work items G2 (*df*)
1. Homogeneous compliance		
2002	124.0 (11)	282.4 (57)
2004	56.2 (11)	184.4 (57)
2. Heterogeneous compliance		
2002	39.0 (10)	100.6 (54)
2004	23.8 (10)	95.6 (54)
3. Heterogeneous compliance and SP "no" sayers		
2002	14.9 (9)	54.2 (53)
2004	10.8 (9)	63.5 (53)

The homogeneous-compliance models require the estimation of two- and six-item location parameters when applied to the four health items and the four health and two work items, respectively. None of the reported fits are satisfactory, indicating that the assumption of no individual differences does not agree with the data. This result is supported by the fit improvement obtained from the IRR models that allow for heterogenous compliance behavior without requiring item-specific discrimination parameters. With one additional parameter for the health items and three additional parameters for the bivariate covariance matrix of the health and work items, these IRR models imply major fit improvements. However, despite the better fit, these models still do not describe the data satisfactorily.

As shown by a residual analysis of the data, the main reason for the misfit is that the outcome of self-protective responses (i.e., consistent "no" responses to the items) is greatly underestimated by these models. Thus, more respondents than expected under the IRR models give exclusively "no" responses when asked questions about their compliance with the health and work regulations. A mixture component can address the problem of extra "no" responses. The models' parsimonious representation appears to be in good agreement with the 2002 and 2004 survey data as indicated by the fit statistics in Table 1.

Most importantly, the mixture-IRR models provide more accurate estimates of the noncompliance rate in the population of interest

Randomized Response Methods, Table 2 Noncompliance estimates and 95 % bootstrap confidence intervals

Domain	Item	No SP correction	SP correction
Health	1	.002 (.000, .015)	.033 (.010, .050)
	2	.014 (.000, .034)	.053 (.033, .075)
	3	.048 (.027, .070)	.083 (.055, .112)
	4	.085 (.063, .107)	.130 (.087, .159)
Work	1	.030 (.009, .052)	.074 (.050, .096)
	2	.110 (.086, .133)	.159 (.104, .190)

than RR methods that do not allow for response biases. Table 2 contains the noncompliance estimates and their 95 % bootstrap confidence intervals obtained under both the homogeneous-compliance model without a response bias correction and under a mixture model for the response bias correction. For example, for the health domain, the bias-uncorrected noncompliance percentages for the four items are estimated as 0.2 %, 1.4 %, 4.8 %, and 8.5 %, respectively. In contrast, in the model with the mixture component, the corresponding estimates are 3.3 %, 5.3 %, 8.3 %, and 13.0 %. These differences are substantial and demonstrate the value of the proposed approach for the analysis of RR data. By not taking into account possible response biases, the incidence of noncompliance is severely underestimated. It should be noted that these estimates do not include the mixture component consisting of the SP respondents. Thus, it is possible that even the response bias-corrected estimates are too low if some or all of the SP respondents are noncompliant as well.

Future Directions

Despite the fact that the respondents' privacy is protected by the RR design, it is not always perceived as such by the respondents. Because RR forces respondents to give a potentially self-incriminating answer for something they did not do, it is susceptible to self-protective responses (SP), that is, respondents answer "no" although they should have responded "yes" according to the randomizing device (see, e.g., Edgell et al. 1982). The online questionnaires used were designed in such a way that the outcome of the dice is not recorded and this was mentioned in the instructions given to the respondents. As a result, the respondents were free to give a different answer than the forced "yes" or "no" induced by the dice. Although RR performs relatively well, by eliciting more admittances of fraud than direct-questioning or computer-assisted self-interviews (Lensvelt-Mulders et al. 2005), noncompliance probabilities might still be underestimated if SP is not taken into account.

Recently, several studies have focused on the detection or estimation of SP when RR methods are used. Clark and Desharnais (1998) showed that by splitting the sample into two groups and assigning each group a different randomization probability, it is possible to detect the presence of SP responses and to measure its extent. Böckenholt and van der Heijden (2007) use a multivariate approach to estimate SP by proposing item randomized response model (Eq. 3), where a common latent sensitivity scale is assumed for a set of RR variables, and the response behavior that does not follow the RR design is approached by introducing mixture components in the IRR models with a first component consisting of respondents who answer truthfully and follow an item response model, and a second component consisting of respondents who systematically say "no" to every item in a subset of items. A similar approach is adopted by Cruyff et al. (2007) who worked out the same idea in the context of log-linear models.

The paper of Böckenholt and van der Heijden (2007) also provides insight into characteristics of respondents who have higher probabilities to use SP. Two important variables are the perceived clarity of the instructions (respondents who found the instructions to be clear are more likely to state the truth) and education (respondents with a higher education are also more likely to state the truth). It is important to try out the instruction in a pilot study, possibly using a cognitive survey lab, to see how the RR questions are perceived (see Lensvelt-Mulders and Boeije 2007). Lensvelt et al. (2006) present a best practice that may be used as a starting point.

Rational Choice and Prospect Theory

Kyle J. Thomas and Thomas A. Loughran

Overview

Scholars interested in decision making under risk have traditionally relied on the standard economic assumptions of expected utility (EU) theory (von Neuman and Morgenstern 1947) to specify the process by which individual actors make decisions. Under the EU framework – which serves as the foundation for deterrence and rational choice theories of crime going back to seminal work by Becker (1968) – an individual actor faced with a risky outcome is expected to select the specific behavioral action that yields the maximized anticipated payoffs. Importantly, the utility of behaviors are weighted by their probabilities of occurrence. The domain of the utility function in this model is absolute benefits and costs, whereby individual decisions of a course of action are dependent solely on the mathematical outcome of the difference between the probability of experiencing the utility of a behavior and the probability of experiencing disutility. Over time, however, researchers in behavioral economics and psychology have become increasingly aware that expected utility theory is not an adequate descriptive model of preferences under risk. For instance, consider the famous example posed by Tversky and Kahneman (1987) of an outbreak of avian flu that is expected to result in the death of 6,000 individuals. A national government has two plans to combat the pandemic: Plan A has a 100 % chance of saving 2,000 people, while plan B has a 1/3 chance of saving 6,000 people and a 2/3 chance of saving no one. Note that the expected utility in plan A (2,000 × 1 = 2,000) and plan B (6,000 × 1/3 = 2,000) is the same, but research indicates that individuals overwhelmingly select plan A, the more certain option (Tversky and Kahneman 1987). In other words, individuals do not make decisions based exclusively on the expected outcomes, but have a tendency to overweight more certain behavioral choices. Interestingly, Tversky and Kahneman (1987) demonstrate that this preference for certainty only holds when the risky outcomes are framed as losses, but does not hold when framed as gains. In other words, if the same hypothetical pandemic is framed as a 100 % chance of saving 4,000 lives (plan A; 4,000 × 1 = 4,000) and a 2/3 chance of saving 6,000 lives (plan B; 6,000 × 2/3 = 4,000), individuals overwhelmingly select plan B – the more risky option. This suggests that preferences for risk can be situational depending on whether the individual is faced with the risk of gaining value or losing value.

The above examples are just two instances of violations of assumptions of standard expected utility theory, but many others exist. In response, several alternative models have been put forth that seek to address the shortcomings of expected utility theory. The most prominent model is *prospect theory*, developed by the cognitive psychologists Daniel Kahneman and Amos Tversky (1979). Prospect theory provides several alternative predictions that explain observed exceptions to the standard economic assumptions of expected utility theory. First, rather than choices being a function of absolute benefits and costs, value is determined by the *gains* and *losses* of an action relative to a reference point. Second, probabilities in the expected utility model are replaced by decision weights in prospect theory, which allows individuals to be more sensitive to expected losses than they are to expected gains (i.e., loss averse) and for marginal changes to be less impactful as they move away from the reference point (i.e., diminishing returns). Moreover, prospect theory posits that individuals have a tendency to underweight outcomes that are merely probable in comparison to outcomes that can be obtained with certainty. All of these predictions have received considerable empirical support, and prospect theory remains a prominent descriptive framework for the way people make decisions in the face of risk and uncertainty (Starmer 2003).

Despite its utility in understanding decision making under risk, few studies to date have applied prospect theory to the study of crime (see Loughran et al. 2011). This entry outlines the value of incorporating prospect theory to the study of crime and deviance and to rational choice and deterrence theories more specifically. The entry begins by briefly specifying the standard economic assumptions prevalent in expected utility theory. Next, it provides a brief overview of violations to these standard economic assumptions, findings that were pivotal in Kahneman and Tversky's development of prospect theory. Finally, the entry then describes the core tenets of prospect theory, and its descriptive advantages for understanding choices when faced with risky and uncertain situations, and concludes by highlighting some important questions that prospect theory raises about criminal decision making.

Fundamentals of Expected Utility Theory

Expected utility theory is a model of decision making under risk, where each behavioral action leads to a set of outcomes that can be either beneficial or costly to the actor. Importantly, the probability of each outcome is known, which enables individuals to make informed decisions when faced with risk. The core principle of expected utility theory is based on the standard economic assumption that individuals select the behavioral option that has the maximum expected utility. More specifically, the utility of each outcome is weighted by their associated known probabilities, and individuals choose the behavioral action that has the highest weighted final sum (Luce and Raiffa 1957).

They key components of expected utility theory have been incorporated into prominent criminological perspectives such as rational choice and deterrence theories (see Becker 1968; Cornish and Clarke 1986). From these theoretical perspectives, an individual is expected to offend if $p * U(\text{Benefits}) - p * U(\text{Costs}) > 0$, where $U(*)$ is a utility function that standardizes various costs and benefits from offending into comparable units, and p is that perceived probability (between 0 and 1) of experiencing an outcome. This model suggests that an individual will decide to commit a crime if the benefits from offending outweigh the potential costs. The known probabilities p are important in this model: For instance, as p increases with regard to the costs of crime, the net benefits of offending necessarily decrease. In other words, the deterrent effect of certainty on offending increases monotonically with increments of risk. What constitutes a "benefit" and "cost" of crime varies considerably across perspectives. For instance, early work in deterrence and rational choice focused almost exclusively on monetary gains and costs deriving from formal sanctions (Becker 1968), while more recent works have broadened these choice perspectives to allow benefits to include things such as prestige and social status, and costs to include things such as disappointing loved ones, moral regard, and shame (Cornish and Clarke 1986; Grasmick and Bursik 1990; Paternoster 1989). In general, the calculus of rational choice is generally not well understood, but there is strong evidence that the risk of detection, or the ostensible weight in this rational choice calculus, is associated with offender decisions (Nagin 1998).

Regardless of the outcomes that constitute benefits and costs, the process outlined in expected utility theory is thought to be a descriptive model of how individuals actually behave in risky situations. Importantly, the expected utility model makes several important implications with regard to the decision-making process. For instance, expected utility theory does not specify the functional form of the decision-making process. In this way, it is at least implied that utilities and their associated probabilities affect choices in a linear fashion, where a 10 % increase in the probability of an outcome has the same marginal effect at all points on the probability continuum (an increase in the certainty of arrest from 10 % to 20 % has the same marginal effect as an increase from 60 % to 70 %). Further, the expected utility model assumes that individuals treat benefits (gains) and costs (losses) in a similarly weighted manner. In monetary terms, a $100 gain that may be accrued by engaging in a behavior is treated the same in an individual's calculus as a $100 loss.

The core tenets of expected utility theory are prevalent throughout the field of criminology. However, research in behavioral economics has identified several situations where the predictions of expected utility theory are violated.

Violations of Expected Utility Theory and the Foundations of Prospect Theory

Kahneman and Tversky (1979) begin their seminal paper on prospect theory by presenting the results of several laboratory experiments that involve hypothetical choices. Many of their findings explicitly contradict the assumptions of expected utility theory, suggesting that individuals appear to make irrational decisions under some circumstances of risk. However, Kahneman and Tversky (1979) were able to demonstrate that the apparent irrationality has considerable consistency. Accordingly, they attempted to develop a description of decision making under risk that can explain the following observations:

1. People do not tend to make choices in terms of their net utility as predicted by expected utility theory, but instead code the outcomes of behavioral choices as *gains* or *losses* relative to a reference point. The reference point usually corresponds to one's current assets or the status quo but can also include one's expectations, and represents the zero point on one's value scale. Accordingly, the expected utility of a choice is thus evaluated as deviations from this subjective zero scale, such that "the same level of wealth... may imply abject poverty for one person and great riches for another – depending on their current assets" (Kahneman and Tversky 1979, p. 277). Put simply, objective benefits and costs of behavioral choices can have considerably varied effects across individuals, depending on one's initial asset position.
2. Because individuals encode outcomes in terms of gains and losses relative to reference points, the framing of choice options can be critical in an individual's decision. Take, for instance, the avian bird flu example presented in the introduction, where individuals are asked to select one of two programs seeking to prevent spread of the disease. We noted that when the outcomes are framed as lives saved, respondents overwhelmingly select the sure gain of 2,000 lives rather than the 1/3 chance at saving 6,000 lives. When framed as lives lost, however, individuals tend to reject the sure loss of 4,000 deaths and prefer to take the risk. This relationship can be interpreted as support for the idea that individuals are risk-averse with regard to gains and risk-seeking with regard to losses, but Starmer (2003) argues that it is just as important to understand how the consequences are interpreted. In other words, though the 4,000 lives lost is objectively the same in both situations, the framing of the scenario influences whether they are interpreted as gains or losses. Accordingly, Kahneman and Tversky go to some length to explain this in their discussion of editing and heuristics.

As will be detailed more below, prospect theory suggests that individuals edit choice prospects using a variety of heuristics, prior to evaluating their utility. One of the most important editing processes, discussed above, is the coding of outcomes as gains or losses relative to a reference point. Kahneman and Tversky go on to note that, though the reference point is typically one's current assets, "the location of the reference point, and the consequent coding of outcomes as gains and losses, can be affected by the *formulation of the offered prospects...*" (Kahneman and Tversky 1979, p. 274, emphasis added). Thus, the framing of behavioral choices can determine an individual's reference point and, in turn, whether prospects are interpreted as gains or losses. This framing effect has been demonstrated across numerous experimental studies (McNeil et al. 1982; Tversky and Karhneman 1986).

Situational characteristics can play a major factor framing the way that individuals code and evaluate prospects when making decisions. Importantly, as Levy (1992) notes, such framing effects can often be subjective, particularly when there is ambiguity with regard to the status quo. In any sense, the framing of behavioral choices can play a major role in offender decision making. For instance, framing and the use of availability heuristics may explain why individuals systematically overpredict the certainty of arrest in self-report studies of offending. Much of individuals' knowledge about the crime comes from media accounts, which can cause individuals to perceive the status quo on the certainty of arrest to be high. When faced with situations where offending is possible, however, individuals may develop a new status quo from which to analyze behavioral choices. Similarly, an individual who is socializing in a group where the perceived status quo is conformity, he/she is likely to hold conforming values as well. If that same individual is present in a group that espouses pro-delinquent values, then that individual is likely to develop a new status quo and make behavioral choices that are relative to this new reference point (Warr 2002). The point is that many of the field's most dominant explanations of crime emphasize the importance of subjective beliefs – such as perceived certainty of arrest or social reinforcement – but often treat such beliefs as static across different situations. A more nuanced understanding of the roles of subjective beliefs may be garnered by understanding how situations frame prospects and influence the decision-making processes of individuals (see Manski 2004).

3. Though Kahneman and Tversky (1979) note that individuals make behavioral choices based on changes from a reference point, they also find evidence that individuals treat gains differently from losses in two ways. First, individuals tend to be risk-averse when it comes to gains and risk-seeking when it comes to losses. A person is risk-averse if he/she prefers a certain prospect (x) to any risky prospect with expected value x. A person is risk-seeking if he/she prefers to accept risk to secure benefits or avoid losses. For instance, a person is considered risk-averse if they prefer $50 guaranteed to a 50 % chance of winning $100, while a person is risk-seeking if they prefer a 50 % chance of winning $100 to $50 guaranteed. The results of Kahneman and Tversky's experiments explicitly contradicted the descriptive model of expected utility theory with regard to the differential treatment of gains and losses. When faced with the hypothetical prospect of *gaining* money, Kahneman and Tversky (1979) found that 82 % of participants preferred the certain outcome of gaining $3,000 to an 80 % chance of gaining $4,000 and a 20 % chance of gaining nothing. Note that the expected utility is actually higher in the latter option ($3,200 vs. $3,000), but respondents are overwhelmingly risk-averse and prefer the more certain, although smaller, payoff. Conversely, when faced with the hypothetical prospect of *losing* money, individuals are substantially more risk-seeking. Kahneman and Tversky show that 92 % of participants preferred to gamble on an 80 % chance of losing $4,000 and a 20 % chance of losing nothing over a certain loss of $3,000. Again, in this scenario, individuals chose the option with the lower expected utility, which directly contradicts the assumptions of expected utility theory. This pattern has been demonstrated across a wide range of behaviors (see Edwards 1996).

4. Kahneman and Tversky (1979) also find that individuals treat losses different than gains in that (i) the utility functions of gains and losses differ such that the shape of the utility function is concave for gains but convex for losses and (ii) that the utility function is steeper in the domain of losses. Tversky and Kahneman (1992) interpret these as two general properties of decision making under risk: *diminishing sensitivity* and *loss aversion*. "Diminishing sensitivity holds that the psychological impact of a marginal change will decrease as we move further away from a reference point" (Starmer 2003, p. 128). Thus, with a reference point of zero, the difference between a gain of $10 and $20 will seem larger than the difference between a gain of $110 and $120. This trend is known in the economic literature as *diminished marginal utility*. For losses, the same principle is known as *diminished marginal disutility* and also has implications for offender decision making – i.e., the marginal change in increasing the severity of sanctions from 1 year to 2 years would have a larger impact on offending than the increase from 11 years to 12 years.

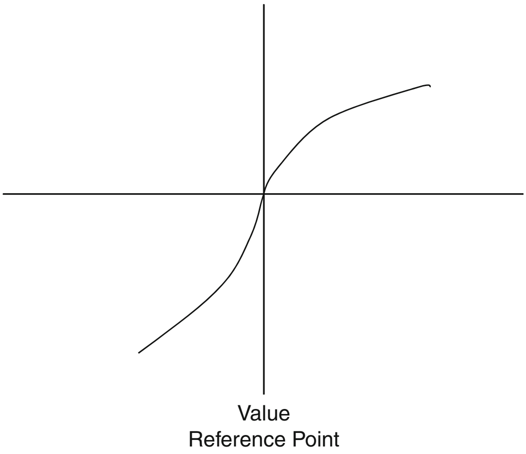
   The second property (ii) discussed with regard to the utility function of gains and losses, loss aversion, is the idea that "losses loom larger than corresponding gains" (Tversky and Kahneman 1992). This is to say that individuals place a higher value on a good that they already possess than to one that they do not. Thus, when presented with a scenario where there is a 50 % chance of winning $50 and/or a 50 % chance of losing $50, Tversky and Kahneman have demonstrated that individuals find the latter option distinctly unattractive.
5. As noted in the introduction, one finding of Kahneman and Tversky (1979) that contradicts expected utility theory is that individuals have a tendency to overweight outcomes that are certain and underweight outcomes that are merely probable, what Kahneman and Tversky label *the certainty effect*. For example, consider choosing between an 80 % chance of receiving $4,000 and a 20 % chance of gaining nothing versus a certain gain of $3,000. Notice that the expected payoff is higher in the former option (EU = $3,200), but research indicates that individuals are more prone to select the second option. Moreover, research also indicates that individuals have a tendency to treat extremely likely, but uncertain, outcomes as if they are certain, which is known as the *pseudocertainty effect* (Tversky and Kahneman 1986). The point is that individuals have a tendency to weight probabilities near 0 and 1 greater than would be anticipated in expected utility theory. Consequently, studies have also contradicted the assumptions of expected utility theory that utilities of risky outcomes are weighted linearly by their probabilities. For instance, a change in the probability of experiencing a loss from .10 to 0 is weighted more heavily than a change from .70 to .60.

Fundamentals of Prospect Theory: An Alternative Model for Choice Under Risk

It is apparent that several of the central predictions of expected utility theory are regularly violated in instances where decisions are made under risk. Prospect theory attempts to incorporate these observed violations in order to provide a more descriptively valid theory of risky decision making. In prospect theory, choice is modeled as a two-phase process: the editing phase and the evaluation phase. In the first phase, prospects are "edited" using a variety of decision heuristics. The purpose of the editing phase is to conduct a preliminary and simple analysis of the offered prospects. By using various heuristics, individuals conduct several operations that transform outcomes and their associated probabilities to allow for a simple evaluation of the prospects. Kahneman and Tversky (1979) note that there are several mental operations that occur in the editing phase for each individual prospect: *coding* which defines each prospect as either a gain or loss relative to a neutral reference point, *combination* which combines the probabilities of identical outcomes, and *segregation* which segregates the riskless components of prospects from the risky components. Moreover, Kahneman and Tversky (1979) also note that individuals compare two or more outcomes in the editing phase using the following: *cancellation* which discards the common components of different prospects, *simplification* which is rounding probabilities, and *detection of dominance* which discards outcomes that are easily dominated by other outcomes.

The editing phase is critical in the decision-making process and is one of the most distinguishing features of prospect theory. It allows individuals to prepare outcomes and their associated certainties of occurrence prior to evaluation. Note that the editing phase in prospect theory incorporates many of the observed anomalies to the standard expected utility theory. For instance, reference points become the relative point at which individuals evaluate gains and losses rather than simply assessing the absolute cost and benefits of behavior. Moreover, prospect theory allows for reference points to be determined not solely by one's current assets but also by one's expectations and by the way in which the prospects are framed. Further still, and contrary to expected utility model, the preference ordering of outcomes "need not be invariant across contexts, because the same offered prospects can be edited in different ways depending on the context in which it appears" (Kahneman and Tversky 1979, p. 275). These features of prospect theory can make complex choice situations difficult to predict, as the editing process is influenced by the norms and expectations of the individual actor (Tversky and Karhneman 1986). Because of this, Kahneman and Tversky (1979) largely focus on the second phase of decision making, but it remains noteworthy that certain individual and contextual factors can reasonably be used to predict that editing process and the determination of status quo reference points.

Once the editing phase is complete, choices among edited prospects are determined in the evaluation phase. In this phase, individuals select the maximized edited prospect as determined by a simple decision-weighted utility function that transforms probabilities into weights that impact the overall value of the prospect and evaluates the subjective value of each outcome relative to a reference point that serves as a zero point on a value scale (see Kahneman and Tversky 1979, p. 275). Hence, value is determined by the deviation of each outcome from the reference point.



Rational Choice and Prospect Theory, Fig. 1 Value Function According to Prospect Theory (Kahneman and Tversky, 1979)

In prospect theory, outcomes are evaluated using a utility function shaped like that presented in Fig. 1. Notice that this function has several important qualities. First, the function is slightly kinked at the reference points (Starmer 2003), where $x_i = 0$. Another quality of this function is that it is concave for gains and convex for losses. These properties are important as they indicate diminishing sensitivity as described above – i.e., the psychological impact of a marginal change decreases the further one gets from the reference point. A third quality of this value function is that it is steeper in the domain of losses, which implies that individuals tend to be more loss averse. Thus, many of the properties of prospect theory's value function have been observed in experimental assessments of decision making under risk.

The decision-weighting function specified in prospect theory also possesses some important qualities. It should be noted that decisions weights are inferred from choices in a manner that is similar to probabilities in expected utility theory, but these decision weights are not probabilities and should not be interpreted as such. Instead, the "decision weights measure the impact of events on the desirability of prospects, and not merely the perceived likelihood of the events" (Kahneman and Tversky 1979, p. 280). This distinction is important because it allows the decision weight to be influenced by factors other than the probability of an outcome. For instance, ambiguity, or the uncertainty about the level of certainty one has with regard to the outcome, can also impact the decision weight. As will be noted below, this feature of the decision weight is an important quality of prospect theory and has important implications for understanding the decision to offend (Loughran et al. 2011).

The decision-weighting function has several other important features. For instance, Kahneman and Tversky (1979) propose a weighting function where "large" probabilities are underweighted and "small" probabilities are overweighted. In fact, the function is not defined for probabilities at or near 0 or 1, because "people are limited in their ability to comprehend and evaluate extreme probabilities" (Kahneman and Tversky 1979, p. 282). In particular, individuals are likely to completely ignore unusually small probabilities and exaggerate extremely high probabilities. Kahneman and Tversky (1979) note that this has another important implication: It suggests that the decision weight function is relatively shallow in the midpoints, but changes abruptly near the endpoints, which is consistent with the certainty effect described above.

In summary, prospect theory is an important alternative description of decision making under risk, because it is well suited to account for many of the observed violations of expected utility theory. The certainty effect, framing effects, loss aversion, ambiguity in uncertainty, and the finding that utility is evaluated as deviations from a reference point can all be explained by prospect theory, and this theoretical perspective is highly influential in understanding social behavior (Levy 1992).

Future Directions

The Role of Prospect Theory in Criminology

Research in behavioral economics and psychology has consistently found support for the general tenets of prospect theory. Nevertheless, the importance of prospect theory, with few exceptions (see Loughran et al. 2011), has not been integrated into criminology. Indeed, models testing offender decision making have relied almost exclusively on the descriptive model of rational choice theory, a model of decision making under risk that we know is violated in many circumstances. Given the shortcomings of expected utility theory in predicting decisions under risk, prospect theory has the potential to be highly influential in understanding offending behavior.

Loughran and his colleagues (2011, 2012b) have begun to integrate prospect theory into deterrence theory, and the results of their studies have suggested that the predictions of prospect theory fit offending data better than those derived from expected utility theory. To be sure, most studies assessing the relationship between perceived certainty of arrest and probability of offending have, at least implicitly, assumed that the relationship is linear. However, as noted above, prospect theory predicts that the relationship between certainty of risk and behavior is nonlinear, and laboratory studies have indicated that individuals only begin to weight potential losses when the certainty of experiencing an outcome is around 30 %. This was described as a "tipping effect" whereby probabilities below this were essentially underweighted or disregarded all together. This, of course, has significant implications for deterrence theory, as it challenges the functional form of the certainty-offending relationship that marginal changes in certainty affect probability of offending in a linear fashion. In support of prospect theory, Loughran and Colleagues (2012b) showed that individuals tend to weight perceived probabilities of risk non-linearly. Specifically, perceived risk only had a deterrent effect when the probability of arrest exceeded a threshold of .3 to .4, and there was a substantial increase in the marginal effect after that. Thus, Loughran et al.'s findings provided empirical support for the nonlinear probability weighting proffered by prospect theory.

In another study, Loughran et al. (2011) extended prospect theory to assess if ambiguity, or uncertainty about the true probability of detection (Camerer and Weber 1992), in the certainty of arrest was important in understanding criminal decision making. Though not a formal test of prospect theory per se, the results were consistent with framing effects. Using two different data sources, they found that ambiguity in the perceived risk of detection was a deterrent when the perceived risk was low, yet actually encouraged offending when the risk was higher.

These are the only two studies to date that have incorporated prospect theory into the study of crime. Though underdeveloped given the empirical support for prospect theory and the important role of choice in criminological theories (Akers 1990; Cornish and Clarke 1986; Paternoster 1989), this gap in the literature does provide avenues of future research that can shed considerable light on our understanding of offending behavior.

For instance, the idea that individuals make decisions based on gains and losses from a reference point raises some interesting questions regarding the decision to engage in crime and has considerable implications for criminological theory, beyond the commission of economic crimes. For example, the cost of experiencing an arrest and the gains in social status incurred when engaging in crime are typically measured as objective and absolute benefits/ costs, and researchers rarely model these costs and benefits as losses and gains relative to a reference point (i.e., one's current social status among friends). Moreover, the predictions of prospect theory also raise important questions regarding the measurement of crime and delinquency in self-report questionnaires, suggesting that the framing of questions may influence responses and that individuals may have a tendency to utilize response strategies that are highly contingent on the status quo rather than their own subjective beliefs (see Loughran et al. 2012a, forthcoming).

It may also be useful to understand how diminishing sensitivity and loss aversion affect individual decisions to offend. Many criminological theories highlight the importance of rewards to crime (Akers 1998; Cornish and Clarke 1986), but prospect theory would make distinct predictions regarding the functional form on the relationship between rewards and offending. Does the proportion of one's deviant peers affect delinquency in a linear fashion? Or would the data suggest that delinquent peers have a diminishing marginal utility when it comes to promoting deviance? Loss aversion suggests that individuals may be more influenced by the threat of losing social status and material assets than they are by the potential or gaining such things. Further, loss aversion predicts that individuals are more risk-seeking after experiencing losses in their assets. How does this affect decisions to participate in illegal markets? Are individuals more likely to initiate into or increase their involvement in markets after experiencing losses to income (both legal and illegal)? These are just two examples, but diminishing sensitivity and loss aversion have implications for a wide range of criminogenic influences.

Another avenue for future research in the role of prospect theory and crime concerns certainty in decision weighting. Research in deterrence theory has found only a weak relationship between perceived likelihood of arrest and offending (Pratt et al. 2006), leading some scholars to question whether individuals consider the threat of sanctions before deciding to offend and the rationality of offenders. But criminogenic situations are often such that individuals have almost certain gains (stealing money) but relatively less certain losses (being arrest). In this way, it may not be that individuals are irrational in their decision making or fail to consider potential costs, but rather are attracted to the more certain gains that are involved in the risk. In other words, though individuals have perceived that the cost of an arrest is relatively high, this disutility maybe underweighted because of the lack of certainty in experiencing the loss, relative to the gains.

Conclusion

Deterrence and rational choice theories continue to be two of the most prominent perspectives in criminology. Though our understanding of offender decision making has unquestionably advanced in recent years, most research assessing criminal choice is based off of the standard economic assumptions of expected utility theory that have repeatedly been shown to be violated in situations involving choice under risk. Prospect theory is an alternative model to decision making under risk that can explain many of these shortcomings (Tversky and Kahneman 1992). To date, prospect theory has not yet been widely integrated to the study of crime and delinquency. While this is unfortunate, it does provide a plethora of opportunities for scholars interested in offender decision making to apply the predictions of prospect theory – which oftentimes differ greatly from predictions derived from traditional expected utility theory – to the decision to engage in criminal and deviant behaviors and in turn further advance the field's understanding of criminal choice.

Rational Choice Theory

Bill McCarthy and Ali Chaudhary
Department of Sociology, University of
California Davis, Davis, CA, USA

Overview

Rational choice theory refers to a set of ideas about the relationship between people's preferences and the choices they make. There are several variants of rational choice theory and this essay refers to these collectively as the rational choice approach (RCA). The conceptual foundations of the RCA originate in Cesare Beccaria's1764 essay *On Crimes and Punishments* and Jeremy Bentham's 1789 work, *An Introduction to the Principles of Morals and Legislation*. One school of thought, the deterrence approach, builds on Beccaria's insights that effective punishments need to be swift and certain (Paternoster 2010). Alternative uses of the RCA focus on Bentham's formalization of the idea that the motivations for actions, criminal or otherwise, are universally grounded in individual self-interest and the desire to maximize pleasure and minimize pain. As a result, punishments require a level of rationality if they are to influence people's perceptions of the pleasures and pains associated with particular choices.

Beccaria's and Bentham's approach to crime and punishment initially had some influence on punishment and social control practices but the ideas associated with the "classical school" were superseded by two centuries of biological, psychological, and sociological explanations. Their disciplinary differences notwithstanding, these explanations of crime emphasize the uniqueness and pathological nature of criminal behavior. They argue that crime occurs because biological, psychological or social conditions motivate people to break the law. Ideas from the classical school began to remerge in a revival associated with the economist Gary Becker's (1968) *expected-utility* model of criminal decision-making, the work on "reasoning criminals" by criminologists Derek Cornish and Ronald Clarke (1986), and sociologist Jack Gibbs' writings on social control (citations for works cited but not included in the references can be found in McCarthy (2002) and Paternoster (2010)). The RCA approach to crime builds on Beccaria's and Bentham's founding principles and the centrality of self-interest for understanding behavior. The RCA uses terms such as rational or preferences that have different popular and disciplinary meanings. The following outlines the key assumptions behind the approach and explains the meaning of key terms.

The Rational Choice Approach (RCA)

According to the RCA approach:

1. People have preferences for outcomes (goods, services, states of being, etc.); preferences do not typically refer to actions or behaviors.
2. People's preferences are influenced by the expected benefits of an outcome, relative to its costs. There are several types of potential benefits (e.g., monetary, emotional, and social) and costs (e.g., opportunity, external, sunk as well as monetary, emotional, and social). The anticipated cost-benefit ratio associated with an action is an indicator of its expected utility.
3. People can order their preferences for outcomes from most to least valued. Preferences are relatively stable: they do not change during a decision, but can be modified as a result of new information.
4. People's assessments of the benefits and costs of outcomes are influenced by the information they collect. Gathering information is however, itself a cost. Thus, although people prefer to have all available information when making decisions, choices are made frequently with incomplete information. People may believe they have adequate information when they do not, they have imperfect memories, and they often miscalculate. In other words, people have *subjective expectations* about the utility they will receive from their choices.

5. Preferences are also influenced by people's orientation to time. Individuals with a positive time preference will need greater future compensation in order to forgo a present benefit, whereas those willing to forgo a current benefit for a lower level return in the future have a negative time preference. Time preferences are not fixed across all decisions but are influenced by several factors, including a person's current level of a valued outcome.
6. Preferences are further affected by attitudes toward risk and uncertainty. People do not have a preference for risk taking in itself (i.e., risk taking is not an outcome); rather, people's attitudes toward risk taking influence the utility they associated with an outcome. A risk-averse person generally refuses to accept what is calculated to be a fair gamble; those who generally have a preference for taking fair gambles, rather than a sure thing are risk-seekers; and between these extremes are people who are risk-neutral: those who are generally indifferent to accepting or refusing a fair gamble. Some rational choice theorists assume that risk disposition if relatively fixed, whereas others assume it will vary across types of decisions and situations.
7. Rational actions are those that are consistent with the above assumptions. Common shorthand is to describe such actions as being consistent with the maximization of utility. Determining a behavior's "rationality" depends on knowing, or making assumptions about a person's information, preference ordering, and approach to risk-taking, and time discounting. People's rational choices may, therefore, result in different behaviors, even when they are faced with the same situation.
8. The RCA does not preclude people from acting irrationally and people may pursue a course of action inconsistent with their preferences for a variety of reasons. Their decisions may be negatively influenced by an intense emotion or a sudden change in context. They may have limited cognitive skills that reduce their ability to use effectively the information they gather or to reflect upon previous choices, or they may be unaware of the interests that motivate them (these may be equally obscure to observers). Explanations of behavior that emphasize false consciousness, habitus, national culture, inertia, determinism (biological, psychological, or social) or similar forces suggest that these may also prompt people to make choices that are inconsistent with their preferences.
9. The RCA does not argue that people always think in ways typically associated with rationality as used in common discourse (e.g., reasoned, thoughtful, reflective), nor does it assume people undertake literal calculations. In its simplest form, the RCA refers to the consistency between people's preferences and choices. It is also a probabilistic, rather than a deterministic approach: it explains how most people make many of their decisions, without assuming that *all choices* can be explained. It does not assume that people are always conscious of their attempts to maximize their interests but simply argues that many of their actions can be understood as rational. As is the case with other accounts, the RCA simplifies the complex causal origins of behavior; however, its value lies in its parsimonious, elegant explanation that has considerable predictive power.

The RCA and Crime

In contrast to biological, psychological and sociological explanations of crime, the RCA approach assumes that crime can be understood "as if" people choose to offend by using the same principles of cost-benefit analysis they use when selecting legal behaviors. Thus, the decision to offend is influenced by people's preferences, their attitudes toward risk and time discounting, and their estimates of an illegal opportunity's availability, costs and benefits, versus a legitimate opportunity's availability, costs and potential for realizing the same or comparable returns. Or, as more commonly expressed by economists, people offend when the subjectively expected return to crime (i.e., the benefits-costs ratio) exceeds what they believe they will obtain by spending the same time and other resources to pursue legal activities (Mehlkop and Graeff 2010).

The RCA differs from many theories of crime in that it provides an account of how people's preferences affect their choices, rather than explaining the source of their preferences. Thus, it is a sharp contrast to theories that argue that crime is a result of low self-control, differential association, weak social bonds, strain, labeling, disadvantaged neighborhoods, or other social experiences or forces. Indeed, many of these explanations assume that offending is irrational and suboptimal.

Theoretically, the RCA approach shares some, but not all of the features of other explanations of criminal decision-making, such as routine activity theory, the reasoned-offender approach, and the criminal-event perspective. Although the RCA contrasts with theories that explain the origins of choice, there is a considerable conceptual overlap between the RCA and more sociological theories of offending and suggestions for theoretical integration are common. However, it is incompatible with explanations that argue that structural conditions or socialization produce character defects that make an offender's decision-making distinct from that of non-offenders. In sum, the RCA provides a fruitful approach to understanding criminal decision-making, and can be combined with explanations of the origins of preferences, and the availability of the mechanisms, or instruments, by which preferences are realized (see Dahlbäck 2003 for a more detailed explication of the RCA to crime).

Incentives and Crime

Punishment Costs

Most of the early RCA research investigates the hypothesis that all else equal, increases in punishment should decrease offending. A large number of studies have explored the deterrent effect of capital punishment (most of the research discussed here uses US data). The general finding is that executions have little deterrent effect (Levitt and Miles 2006). There is however, evidence that the costs associated with incarceration act to deter offending. Early studies have a number of shortcomings, but recent research has used more sophisticated methods and higher quality data to investigate this relationship. In their review, Levitt and Miles (2006) note that a number of recent studies find that increases in incarceration rates are associated with subsequent declines in arrest rates; however, the size of the effect is modest (i.e., a 1–10 % reduction in arrest rates for a comparable increase in prison populations), and the escalation of the cost of imprisoning people may make incarceration a less prudent deterrent.

Recent investigations that use individual-level data also document a deterrent effect for several, but not all types of offending. Research on inmates finds large deterrent effects emanating from the certainty of punishment, and smaller, generally insignificant effects from the severity of sanctions (Grogger 1991). However, punishment effects are conditional. The certainty effect is greatest for serious felony crimes and for whites, and declines in strength for non-serious offenses, blacks and Hispanics. In contrast, the severity effect is positive for whites and negative for blacks. Related research reports that inmates who successfully offended – that is who were not arrested for their crimes – are more likely to think that they could avoid being arrested in the future if they re-offended (Horney and Marshall 1992).

A number of earlier studies reported little effect of policing on crime, whereas more contemporary research that uses sophisticated methods and richer data finds that increases in the number of police have nontrivial but modest negative effects on crime (e.g., a 3–5 % reduction for a 1 % increase in the number of police; see Levitt and Miles 2006). There may however, be a ceiling effect: at some point police may have arrested most of the offenders involved in serious violent or property crimes, they may then turn to arresting offenders who commit more trivial or victim-less crimes (e.g., drug use) in part because police use crime and arrest rates to justify their employment and the need to hire more officers.

Similar to imprisonment, increases in policing may not be the most efficient way to deter crime.

Related studies focus on individual differences in perceptions about the likelihood of punishment and the consequence of this variation for crime. Many of these investigations use vignettes or hypothetical situations to measure people's willingness or intention to offend in the future. For example, a recent study of adults finds that individuals who believe that the probability of detection is low are significantly more willing to commit a tax fraud in the future (Mehlkop and Graeff 2010). Research on adolescents also finds that youth who believe that arrest is both likely and costly are less likely to have committed a theft or violent crime (Matsueda et al. 2006).

Economic Costs

The RCA approach suggests that economic costs, such as a loss of legitimate income, also influence offending. Consistent with this hypothesis, research on inmates reports a strong, negative effect of legal income on crime and a positive relationship between crime and the length of a current jobless spell (Grogger 1991; also see Uggen and Thompson 2003). As well, relatively minor criminal activity complements employment, whereas employment and serious crime are substitute activities. Thus, research that pools data on minor and more serious crime may erroneously conclude that employment does not affect criminal activity.

Other investigations also demonstrate a connection between a decrease in wages and offending. For example, research suggests that that declining wages in the USA in the 1970–1980s may have contributed considerably to youth crime increases in these years, with a 20 % fall in wages leading to a comparable increase in offending (Grogger 1991). Moreover, rising wages explain a considerable amount of the decline in offending that occurs with age.

Comparable analyses find that economic incentives and opportunity costs exert a powerful influence on offending. For example, the odds that an offender will stop offending increase with legal earnings and they decrease with illegal ones (Pezzin 1995). Furthermore, although the number of past convictions encourages desistance, the magnitude of this effect is considerably smaller than that of legal wages.

Other Costs

Sociologists have contributed further to the economic approach to crime's costs by proposing a more inclusive approach to crime's liabilities. These costs include the stigma and rejection by significant others that can accompany state sanctions; commitment to normative values; beliefs that the legal system is just and moral; and the guilt and shame that sanctions and norm violations may induce. Research that uses vignettes finds that many of these factors are better predictors of a willingness to offend in the future than is the possibility of arrest (see Nagin 1998). Moreover, studies that allow individuals to list the potential costs of crime find an even broader array of concerns. For example, when asked about the potential costs of shoplifting a sizable proportion of subjects reported including "bad karma," being banished from a store and the potential that it would be a gateway act that would lead to more serious crime (Bouffard et al. 2010).

Perceptions about social and state sanctions probably have the greatest influence on particular people: individuals who have a considerable stake in society, have internalized norms that prohibit offenses, are embedded in networks of people who appear to follow the law most of the time and whose criminal experiences are limited to a small number of common petty offenses. In other words, these perceptions may have their greatest effects on those who have few of the motivations or opportunities that encourage crime. Consistent with this claim, research finds that strong connections to normative society discourage crime. For example, in the study of tax fraud cited earlier, general support for the legal code is negatively associated with a willingness to offend (Mehlkop and Graeff 2010).

Research on homeless youth explores the deterrent effect of a different type of criminal cost: physical harm (McCarthy and Hagan 2005). Many people use violence in responding to illegal activities (e.g., victims, bystanders, police, and other offenders) and perceptions about the dangerousness of crime are negatively related to theft, drug selling and prostitution, independent of other costs, benefits and background variables. Research that asks people to describe the potential costs of crime also finds that danger is an important concern for many individuals (Bouffard et al. 2010).

The Benefits of Crime

Crime may provide a number of benefits that range from monetary returns, the excitement or thrill of the crime, to respect or status. However, critics of the RCA approach to crime typically argue that the returns to crime are so meager that they cannot be realistically viewed as incentives. Although many offenders do not profit much from their crimes, the illegal incomes of others exceed those provided by legal employment. For example, research on Washington DC drug-sellers finds that they earned monthly incomes that were more than double the median amount earned in legal jobs (Reuter et al. 1990). Other studies find Chicago crack dealers earned an average wage of $11 an hour, a substantially higher wage than the available unskilled labor jobs; moreover, although low end “foot soldiers” often made below minimum wage, several gang leaders earned between four and eleven thousand dollars a month (Levitt and Venkatesh 2000). A related study on homeless youth reports that, on average, youth who sold drugs earned three times the average legal daily wage earned from legitimate employment (McCarthy and Hagan 2001). This investigation also documents that many offenders have reasonable expectations about crime’s financial returns: offending is positively associated with the anticipation that crime will bring greater returns than legitimate employment, but is unrelated to the belief that crime will provide “lots of money.” As well, the belief that crime will provide a financial return is related to a willingness to offend in the future (Mehlkop and Graeff 2010).

Both human and social capital contribute to success in normative activities such as employment, and criminal parallels to conventional capital may influence illegal success. For example, McCarthy and Hagan (2001) find that previous experiences contribute to illegal earnings, as does specialization, a willingness to work cooperatively with others, and the number of connections with other offenders and the support these associations provide.

Other research finds that the belief that crime will provide a psychic thrill or excitement, coolness or respect, or simply good feelings are related to offending or the willingness to offend in the future. For example, Matsueda et al. (2006) find that youth who reported that offending was exciting, would enhance their “coolness,” and that both of these were likely to happen to them, reported greater involvement in theft. McCarthy and Hagan (2005) also report a positive association between offending and the perception that crime is exciting in their research on theft and drug selling among homeless youth. They also find however, that the perception does not contribute to all types of crime: the view that prostitution is exciting is unrelated to selling sex. Nonetheless, a recent meta-analysis of the results from 13 investigations that examine the returns to crime finds that the majority of studies report positive significant associations between offending and offenders’ perceptions that crime will provide valued returns (Baker and Piquero 2010).
