Overview

In 1990 Gottfredson and Hirschi advanced a parsimonious and provocative theory of crime that was designed to explain all types of antisocial behaviors. Unlike most dominant criminological theories that focus on social/environmental factors as causes of crime, their theory focused on an individual-level factor – levels of self-control – as the key causal agent for crime, delinquency, and other forms of disrepute. More specifically they argued that persons with relatively low levels of self-control who have a criminal opportunity will, on average, commit more crime and antisocial acts in comparison with people who have relatively high levels of self-control. An impressive amount of empirical research has assessed the potential association between levels of self-control and a host of antisocial behaviors. The results of these studies have been remarkably consistent in showing that measures of self-control are among the most consistent and strongest predictors of a wide range of antisocial behaviors, including crime, delinquency, and drug use. Moreover, the link between levels of self-control and antisocial behaviors has been detected between genders, across racial/ethnic groups, and within samples collected from different countries (Pratt and Cullen 2000).

Given the robust criminogenic effects associated with levels of self-control, there has been a wave of research attempting to uncover the factors that are associated with causing variation in levels of self-control. Much of this research has been guided by Gottfredson and Hirschi's thesis that levels of self-control are largely the result of parental socialization. According to these theorists, parents who wish to raise offspring with high levels of self-control must engage in three intertwined parental management techniques. First, parents must supervise their children. Second, parents must recognize when their children are engaging in socially taxing or antisocial behavior. Third, parents must consistently correct their children's antisocial behaviors. Parents who engage in these three parenting techniques and who are attached to their children should, on average, raise offspring with relatively high levels of self-control. According to Gottfredson and Hirschi, parents do not have much time to inculcate self-control because by around the age of 10, levels of self-control are formed and remain relatively stable over the remainder of the life course.

A line of research has examined the merits of the parental management thesis and the results of these studies have provided some support in favor of Gottfredson and Hirschi's argument. For example, most studies reveal that measures of parental management techniques predict levels of self-control, with parents who supervise their children, recognize their children's transgressions, and punish their children, tending to raise offspring with relatively high levels of self-control (Gibbs et al. 1998; Hay 2001; Polakowski 1994). However, Gottfredson and Hirschi likely overstated the effects that parents have on sculpting levels of self-control. Numerous studies indicate that measures of parenting only have very small effects on levels of self-control and leave an overwhelming amount of variance unexplained. As a result, there are likely other salient factors that are causing variation in self-control that were not identified by Gottfredson and Hirschi. An emerging pool of research has pointed to the very real possibility that biological and genetic factors may be the dominant source of variation in self-control.

Genetic Influences on Levels of Self-Control

In articulating their theory, Gottfredson and Hirschi were very clear that they did not believe that genetic factors played any role in the development of self-control. However, research from multiple lines of inquiry, including developmental psychology, behavioral genetics, molecular genetics, and neurobiology, points to a very different conclusion – namely, that self-control, self-regulation, and impulse control problems are all affected in large part by genetic factors (Beaver 2009). Studies exploring the extent to which genetic variation accounts for variance in measures of self-control, and related disorders, typically employ samples that consist of twin pairs. There are two types of twins: monozygotic (MZ) twins who share 100 % of their DNA and dizygotic (DZ) twins who share, on average, 50 % of their DNA. Both types of twins, however, are assumed to share environments that are approximately comparable to each other. In other words, the environments of MZ twins are assumed to be no more similar than the environments of DZ twins. As long as this assumption is met (known as the equal environments assumption [EEA]) – and there is good evidence to indicate that it is – the only reason that MZ twins should be more similar to each other than DZ twins is because they share twice as much genetic material. So, genetic effects are detected if the similarity of MZ twins is greater than the similarity of DZ twins. And the greater the similarity of MZ twins in comparison to the similarity of DZ twins, the larger the magnitude of the genetic effect. The proportion of variance accounted for by genetic factors is known as the heritability estimate.

Although twin-based research designs provide a great deal of information regarding the genetic foundations to behaviors and traits, they also provide some of the most compelling evidence for the role of environmental factors. The reason for this is because the variance that is not explained by genetic factors is explained by environmental factors (plus error). Unlike most social science research that pools together all types of environments, twin-based research designs make the distinction between two different types of environments: shared environments and nonshared environments. Shared environments are those environments that are the same between twins and therefore make twins more similar to each other. Some of the common examples of shared environments are neighborhood conditions, family socioeconomic status, and common parental socialization factors. Nonshared environments, in contrast, consist of environments that are different between twins and that make twins dissimilar from each other. (Nonshared environments also capture the effects of measurement error.) Examples of nonshared environments include peer groups, parenting practices unique to each twin, and even different prenatal environments (especially for non-twin siblings). Together, the heritability, the shared environment, and the nonshared environment account for 100 % of the variance in any measure being studied in a twin-based research design.

Since criminological research focuses almost exclusively on the role of the environment in relation to criminal and antisocial behaviors, they have overlooked and ignored the potential role of genetic factors. As a consequence, much of the evidence that has examined the genetic basis to levels of self-control has to be culled from fields of study outside of criminology. Fortunately, an impressive number of studies have employed twin-based research designs (or variants of them) to examine the genetic origins to traits/disorders that overlap with Gottfredson and Hirschi's conceptualization of self-control. For example, studies have investigated the heritability of self-regulation, impulsivity, and attention-deficit/hyperactivity disorder (ADHD). The results of these studies have consistently revealed that genetic factors explain between 50 % and 90 % of the variance, with the remaining variance being attributable to nonshared environmental factors (Rietveld et al. 2003; Mick et al. 2002; Wright and Beaver 2005). In most studies, shared environmental factors explain none or very little of the variance. Only recently have criminologists begun to explore the genetic underpinnings to self-control and the findings have yielded results that parallel those reported by non-criminologists. Overall, genetic factors explain approximately 40–70 % of the variance, nonshared environmental factors explain between 30 % and 60 % of the variance, and shared environmental factors explain none of the variance. When taken together, the empirical research unequivocally indicates that levels of self-control are scripted, in part, by genetic factors along with nonshared environmental factors (Beaver 2009).

Although twin-based research designs represent a rich analytical tool that can be used to estimate genetic and environmental effects, they are limited in the ability to identify the specific genes and the specific environments that are involved. For instance, knowing that genetic factors account for 40–70 % of the variance in self-control is only part of the puzzle; finishing the rest of the puzzle requires searching for the particular genes which account for variation in self-control. Molecular genetic studies are useful in this regard.

Molecular genetic studies attempt to link variation in specific genetic markers to variation in certain behaviors, traits, and other characteristics (e.g., levels of self-control). To understand the underlying logic to these types of studies, it is necessary to provide some elementary background information about genes. The human genome is comprised of approximately 25,000 genes which are located on 23 pairs of chromosomes (22 pairs of autosomes and 1 pair of sex chromosomes). Because genes are located on pairs of chromosomes, all genes (except those located on the sex chromosomes for males) consist of two copies: one inherited maternally and one inherited paternally. The information encoded into genes determines virtually every physical characteristic (e.g., eye color, hair color) and influences many other unobservable traits (e.g., personality, cognitive skills). Most genes consist of only one version, meaning that all humans have the same "type" of gene. However, for a small percentage of genes, there exist at least two versions in the population. Genes that vary across people are known as genetic polymorphisms and alternative copies of the gene are known as alleles. To illustrate, suppose there was a gene for height and there were two different versions of the height gene: a short allele and a tall allele. It would be possible to inherit two short alleles (one maternally and one paternally), two tall alleles (one maternally and one paternally), or a short allele (either maternally or paternally) and a tall allele (either maternally or paternally). A person's height, therefore, would be partially a function of the alleles they inherited for this hypothetical polymorphic height gene. In reality, height is affected by hundreds of genes along with environmental factors (e.g., nutrition).

A great deal of research has examined the potential association between certain genetic polymorphisms and ADHD, impulsivity, and attention problems. The results of these studies have provided some evidence tying certain genes – especially those of the dopaminergic system – to these disorders and traits. There is some limited evidence, moreover, that genes of the serotonergic system may be involved in the development of self-control (Beaver 2009). The available evidence suggests that specific genetic polymorphisms tend to have their strongest effects on levels of self-control when they are paired to certain environments. What this necessarily means is that genetic polymorphisms are associated with levels of self-control, but the effects of these genetic polymorphisms are even more pronounced when they are coupled with adverse and criminogenic environments. These types of relationships are called gene-environment interactions, and they illustrate the incredible complexities underlying the causes of human behavior. Given that molecular genetic research involving self-control is still in its infancy, much more research needs to be undertaken to provide a more complete picture of which genetic polymorphisms may ultimately be responsible for affecting variation in levels of self-control. But, as the results of the twin-based studies reveal, genes tend to be the dominant force in structuring the development of self-control.

Neurobiology and Levels of Self-Control

The findings generated from genetic research often produce a great deal of confusion concerning what they actually mean. The media, for example, frequently talks about the discovery of a gene *for* X or a gene *for* Y (e.g., the crime gene, the low self-control gene). In reality, though, genes are not "for" any particular behavior, trait, or other human characteristic; rather, they are responsible for coding for the production of proteins. So, if genetic polymorphisms continue to be discovered that explain variance in levels of self-control, then how do these genetic polymorphisms actually produce varying levels of self-control? Stated differently, if genes do not directly determine levels of self-control, then what is the mechanism that ultimately links genetic variance (i.e., different alleles for specific genetic polymorphisms) to variance in levels of self-control? While there is not a definitive answer to this question, recent research from neurobiology sheds some light on this issue.

A proliferation of neuroimaging techniques have been developed, including functional magnetic resonance imaging (fMRI), positron emission tomography (PET), and single photon emission computed tomography (SPECT), that allow neuroscientists to examine the functioning of the brain when certain tasks are being performed. If a certain region of the brain is activated during a specific task, then it is quite likely that that area of the brain is involved – to some degree – in the skills needed for the successful completion of the task. A line of neurobiological research has examined brain activity in response to tasks designed to tap self-control, impulse control, judgment, and attention. Very generally, these studies have converged to show that the area of the brain partially responsible for these tasks is the prefrontal cortex (Beaver et al. 2007).

The prefrontal cortex is situated directly behind the forehead and is often divided into three different regions to help delineate the location, direction, and function of each. The first region, the dorsolateral prefrontal cortex (DLPFC), is located in the lateral of the prefrontal cortex and has been shown to be responsible for behavioral modulation, information processing, and memory formation. The second region is referred to as the orbitofrontal cortex and is located directly above the eyes and is interconnected with the DLPFC. The orbitofrontal cortex has been shown to be involved in maintaining goal-oriented behaviors, the regulation of emotions, and to affect decision-making processes. Finally, the medial prefrontal cortex (MPFC) is housed deep within the brain and is connected with the DLPFC. The MPFC is involved in promoting tasks that necessitate a significant amount of concentration.

The coordinated functions of the DLPFC, the orbitofrontal cortex, and the MPFC are typically referred to as executive functions. Although definitions of executive functions vary, they can be generically defined as a suite of functions that are responsible for judgment, decision-making, the ability to delay gratification, the ability to anticipate the consequences of actions, and the ability to modulate behaviors and emotions. Importantly, the definition of executive functions employed by psychologists and neurobiologists overlaps considerably with the conceptualization of self-control as set forth by Gottfredson and Hirschi. In fact, there is both empirical and theoretical evidence indicating that self-control is one of the many tasks that fall within the parameters of executive functions (Ishikawa and Raine 2003).

If self-control is indeed an executive function, then what accounts for variation in executive functions and self-control? As indicated previously, brain science research has revealed that the prefrontal cortex is largely responsible for executive functions. Variation in the structure and functioning of the prefrontal cortex therefore is largely the driving force behind variation in executive functions and thus levels of self-control. For example, some people's prefrontal cortexes are highly active, and, perhaps as a result, they score very high on measures of self-control. Other people, however, have relatively underactive prefrontal cortexes, and they are, on average, more likely to score lower on measures tapping self-control. The point is that executive functions and levels of self-control appear to be tied directly to the structure and functioning of the prefrontal cortex.

Being able to identify what causes variation in the structure and functioning of the prefrontal cortex is thus the key to identifying what causes variation in executive functions and levels of self-control. Neuroimaging research has been instructive in this endeavor, wherein twin studies have been conducted to estimate genetic and environmental effects on variation in brain structure and functioning. The results of these methodologically rigorous and highly influential brain science studies have revealed that upwards of 80 % of the variance in brain structure and functioning in the brain, including the prefrontal cortex, is the result of genetic factors (Toga and Thompson 2005). Consequently, it is now possible to provide a more detailed and scientific answer to why there is variation in levels of self-control. The evidence reviewed above indicates that self-control is an executive function. Executive functions are housed in the prefrontal cortex of the brain and variation in executive functions (thereby including levels of self-control) appear to be largely affected by the structure and the functioning of the prefrontal cortex. Variation in the structure and functioning of the prefrontal cortex is the result of genetic factors and to a lesser extent nonshared environmental factors. It should also be noted that approximately 60 % of the 25,000 genes in the human genome are in some way related to coding for the brain and/or brain development. As a result, there are likely thousands of genes that affect the structure and functioning of the prefrontal cortex with each of these genes tending to have relatively small effects.

A Biosocial Critique of the Parental Management Thesis

Even though there is a vast amount of empirical research indicating that levels of self-control are under strong genetic influence, the vast majority of criminological research ignores the potential genetic influence on self-control. Furthermore, much of this research also neglects the important contributions of neurobiology. Instead, most criminological studies only examine the role that social factors – especially parenting – have on the development of self-control. Critics of genetic research frequently point out that most of the criminological research shows that social factors are critically important to all types of antisocial behaviors, including levels of self-control. These findings, in short, appear to be at odds with those garnered from genetic and neurobiological research, leading to the question of which body of research should be believed.

In order to address this issue, it is essential to explore the most common type of methodology used in criminological research: standard social science methodologies (SSSMs). With SSSMs, researchers analyze data collected about one focal child (or adolescent) per household. The child's parents and teachers may also be interviewed to collect more detailed information, but the key concern is the behavior and/or traits of the focal child. As it applies to self-control, SSSMs would collect information about the focal child's level of self-control and certain social factors, especially parental management techniques. Statistical analyses are then conducted to determine whether levels of self-control covary with the social factors. If there is a statistically significant association between levels of self-control and the variation in the social factors, then most criminologists and social scientists often interpret the results as being in line with a causal explanation (e.g., Gottfredson and Hirschi's parental management thesis).

There is a serious problem with research that is based on SSSMs – namely, that SSSMs are unable to take into account genetic factors. Recall that twin-based research designs are used to estimate the relative effects of genetic and environmental factors. In order to do so, there must be at least two siblings (e.g., twins) included in the analysis. Unfortunately, criminological research rarely includes more than one sibling in the sample and, in fact, great pains are taken to include only one child per household for statistical reasons (i.e., to preserve independence in observations). By including only one child per household, it is not possible to estimate genetic effects and thus any research that employs an SSSM is making the assumption that genes have absolutely no effect on the behavior or trait being studied (e.g., levels of self-control).

The methodological limitations of SSSMs become all the more exacerbated for studies that examine the effects of parenting on childhood and adolescent levels of self-control. Recall that according to Gottfredson and Hirschi parents must supervise their children, recognize their children's misbehaviors, and consistently punish such waywardness. These three parental management techniques require a substantial amount of time, dedication, attachment, and self-control on the part of the parents. Parents who lack these prosocial traits are unlikely to follow the parental management suggestions offered by Gottfredson and Hirschi. Indeed, there is ample evidence to suggest that parents who lack self-control, parents who have a criminal record, and parents who engage in antisocial behaviors are not the most responsible parents and thus are unlikely to engage in effective parenting tactics.

All of this is critically important because as was discussed previously, levels of self-control are highly heritable. So, if a parent has low levels of self-control they are, statistically speaking, at risk for raising offspring who also have relatively low levels of self-control purely because the parent passed on the genetic material that influences levels of self-control. Research that fails to control for genetic factors (i.e., all research using SSSMs) when examining the potential nexus between parenting techniques and their offspring's level of self-control and detects a statistically significant association between parenting and self-control may erroneously attribute that association to a parenting effect, when it is really the result of genetic transmission.

In methodological parlance, this type of an association is referred to as a spurious relationship. One common example of a spurious relationship is the well-noted association between ice cream sales and violent crime. As ice cream sales increase, so does violent crime. It would be absurd to think that the consumption of ice cream causes an increase in violence; instead, there is likely a causal factor common to both ice cream sales and violence: temperature. As the temperature increases, people are more likely to consume ice cream and they are also more likely to engage in routines that place them in contact with violent criminals. A spurious relationship therefore can be defined as an association between two variables (e.g., ice cream sales and violence) that disappears after a third variable (e.g., temperature) is taken into account. In social science research, it is nearly impossible to eliminate the possibility of spuriousness, but most research attempts to minimize spuriousness through the use of control variables (or random assignment). Importantly, the only time a control variable needs to be included in a study to prevent spuriousness is when that variable is associated with both the independent variable (e.g., parenting) and the dependent variable (e.g., levels of self-control). If it is only related to one variable or the other, then there is no need to include the control variable to prevent spuriousness.

Now it is quite easy to see how criminological research using SSSMs and examining the association between parenting and self-control is likely biased. Genetic factors are likely affecting the way a parent raises their offspring, and these genetic factors are also passed on to their children in the form of genetic material. So, a parent who is abusive and neglectful likely has low levels of self-control, and the genetic predisposition for low levels of self-control is inherited by their children. Consequently, there is no way to know for certain whether a relationship between parenting and levels of self-control is a true "parenting" effect or whether it represents a spurious relationship when an SSSM is used.

To rule out spuriousness owing to genetic factors, a twin-based research design (or variant thereof) must be employed. Only a handful of studies have used twin-based research designs to examine the link between parenting and levels of self-control. The results of these studies have revealed that once genetic factors are taken into account, there is no association between parental socialization and offspring levels of self-control (Beaver et al. 2009a; Wright and Beaver 2005). These findings have serious implications for criminological research because they indicate that research using SSSMs is likely biased in favor of finding an environmental effect when such an effect is either likely upwardly biased or completely spurious. The use of SSSMs also helps to reconcile the different findings generated by behavioral genetic studies and by criminological studies. Behavioral genetic studies use appropriate research designs that make no assumptions about the role of genetics and the environment. Criminological studies that rely on SSSMs only produce unbiased findings when the assumption of no genetic effect is met. Unfortunately, all of the available evidence strongly suggests that this assumption is violated thereby casting doubt on the accuracy of criminological studies purportedly showing a link between parenting and levels of self-control.

Policy Implications

One of the major attacks leveled against biological explanations of antisocial behaviors and traits, including levels of self-control, is that the policy implications flowing from such research will result in oppressive and inhumane practices. According to this line of reasoning, since DNA is immutable, there is no way to change levels of self-control. In other words, people are born with a fixed level of self-control.

Those who are genetically endowed with low levels of self-control are destined for a life of crime and antisocial behaviors whereas those born with high levels of self-control are likely to lead prosocial and productive lives. This logic is erroneous and is based on the confusion between the physical structure of DNA and the effects emanating from DNA.

While it is true that the physical structure of DNA is nearly impossible to change, it is not true that genetic effects are always constant. Contemporary genetic research has shown that genetic effects change over different developmental time periods, with some genes being switched on at certain periods in the life course and switched off at other times. In addition, the effects of some genes appear to be controlled, at least in part, by exposure to environmental conditions. What this necessarily means is that a gene may have a strong effect in one environment, but no effect in another environment. One gene that was found to be related to levels of self-control was shown to reduce levels of self-control when it was paired with a criminogenic environment, but it was shown to be unrelated to levels of self-control when the criminogenic environment was absent (Beaver et al. 2009a).

The finding that genes are moderated by environmental conditions holds particular promise for prevention and intervention programs designed to change antisocial traits and behaviors, such as levels of self-control. For instance, it is quite possible that intervention and prevention programs could be individually tailored to each person's unique suite of genes to create a more effective treatment program. There is some empirical evidence emerging indicating that such an approach is quite effective. A recent study, for example, revealed that a program designed to reduce externalizing behavioral problems among children was effective for children with a certain genetic variant, but ineffective for children lacking that particular genetic variant (Bakermans-Kranenburg et al. 2008). This type of research remains very new and exploratory and so the true extent of its impact remains to be determined, but it does provide some promise for increasing the effectiveness of prevention and treatment programs.

Biological and genetic research has already had a profound impact on the juvenile justice system. In a landmark Supreme Court decision, the death penalty was abolished for juveniles. The decision to abolish the death penalty was based largely on the findings generated from academic research studies. These studies, however, were not produced by criminologists showing that environmental factors contributed to violence and aggression. Rather, the studies that ultimately swayed the Court's decision were produced by neuroscientists showing that the prefrontal cortex of the brain – the area of the brain that houses the executive function – is not fully developed until the mid-20s. Because the brains of adolescents are structurally immature in relation to the brains of adults, the Court ruled that adolescents should not be held as culpable for murder. Thus, in one of the most progressive policy decisions affecting the criminal justice system, it was biological research, not criminological research, that was the driving force (Beaver 2009).

Conclusions and Future Directions

The 1990s are known as the decade of the brain largely because of the tremendous amount of research that was conducted examining how neurobiological factors are related to different types of human behaviors and traits. Thus far in the 2000s, there has been an immense amount of genetic research trying to tie specific genetic variants to human behaviors and traits. Out of these two intertwined lines of research has emerged incontrovertible evidence indicating that self-control is a largely genetic trait that is housed in the prefrontal cortex of the brain. Despite these insights into the etiology of self-control, much remains unknown about the origins of self-control. Future research, for instance, needs to explore a wider swath of genetic polymorphisms to see which ones affect variation in self-control. At the same time, it is critically important to study the environmental factors that may moderate the effects of such genes. If this endeavor is successful, then it would likely provide a rich framework from which to create programs designed to promote levels of self-control among at-risk children, youth, and adults. In order to do so, however, criminological research must go beyond the sociological factors first purported by Gottfredson and Hirschi and integrate biosocial data, methods, and findings in order to come to a greater understanding of low self-control and its influence on criminality.

Genocide

Wenona Rymond-Richmond
Department of Sociology, University of
Massachusetts Amherst, Amherst, MA, USA

Overview

Genocide, the definitive "crime of crimes," has produced hundreds of millions of victims who were murdered, raped, sexually assaulted, forcibly displaced, kidnapped, robbed, and mutilated. The most severe violations of human rights are committed during genocidal violence. The sheer number of victims and crimes should imply that genocide is central to the discipline of criminology. Yet, genocide is neglected, marginalized, and undertheorized by criminologists. For the most part, criminologists have been remarkably indifferent to the crime of genocide and failed to incorporate genocide into their research agenda. The unresponsiveness of criminologists to the crime of genocide is part of a broader pattern of collective denial.

Criminologists should have much to contribute to the study of genocide as deviant behavior and social group conflict is at the heart of the legal definition of genocide and a central focus of our discipline. Understanding how and under what conditions people commit deviant acts and why particular groups or behaviors become victimized are undeniably criminological questions. Yet, criminology has been slow moving, unresponsive, and nearly silent towards incorporating genocide within its disciplinary boundaries. This neglect is part of a larger pattern of the discipline's near failure to incorporate any form of international war crimes into their research agenda. Mainstream criminology is preoccupied with interpersonal and intranational criminal acts of violence such as homicide, rape, and robbery leaving the role of the state in acts of crimes underexplored. Far too often, criminologists consider the state as a bulwark of crime rather than the perpetrator of crime. One notable exception is critical criminologists who condemn mainstream criminology for not considering the role of the state as a criminal actor.

A sociological approach to criminology can provide crucial insights, evidence, and theories about genocidal processes by explicitly addressing the collective dynamics of state-organized criminal victimization. Yet, if the past is an indication of the future, then the lack of application and extension of traditional criminological theory to genocide either means that we cannot expect much from mainstream theories or that latent racism and collective denial have hampered attempts to make connections between intranational and interpersonal crimes with international-, group-, and state-sponsored crimes. We may well need to develop new historically grounded theories that better account for state-sponsored collective violence.

The failure of criminologists to speak about genocide is not only a missed opportunity, but it also brings the validity and ethics of the discipline into question. Using the present-day genocide in Darfur as a case study, this entry will discuss the crime of genocide, criminologists silence on the topic, the ways in which criminology can contribute to the study of genocide, current issues and controversies, and future directions and suggestions for criminologists.

Definitions

Determining whether an atrocity is labeled as genocide, crimes against humanity, or ethnic cleansing has serious legal, social, historic, and symbolic consequences. As illustrated in the ongoing debates on whether the violent conflict in Darfur is labeled genocide is contentious. On one hand is a diverse group that includes Sudanese President Omar al-Bashir and scholar Mamdani (2009) who deny genocide is occurring in Darfur. On the other hand are academics including Eric Reeves (2007) and Hagan and Rymond-Richmond (2008a, b) and the Chief Prosecutor for the International Criminal Court (ICC) who has issued warrants of arrest on the charge of genocide. Defining a conflict is more than merely semantic as each term implies different legal and symbolic consequences and can influence the international community's response to the atrocities. For example, if a violent conflict is labeled a crime against humanity rather than genocide, the evidence needed for conviction is likely reduced, and this naming of the events will lack the symbolic force and probably mean less in the collective memory than would a legal determination of genocide (Savelsberg and King 2011). In fact, all genocides by definition are crimes against humanity, but not all crimes of humanity are elevated to the symbolic significance of genocide. Similarly, the term ethnic cleaning may rightfully describe the intentions of the perpetrators, yet this does not carry the same legal meaning and recourse as a determination of genocide.

Genocide

The term genocide came into existence in 1944 in response to the Holocaust. Raphael Lemkin, a Polish-Jewish lawyer, coined the word genocide by combining the Greek word for race or tribe, geno-, with the Latin word for killing, -cide. In large part due to Lemkin's efforts, on December 9, 1948, the United Nations approved the Convention on the Prevention and Punishment of the Crime of Genocide (Genocide Convention). The Genocide Convention established genocide as an international crime. The legal definition of genocide is found in Articles II and III of the Genocide Convention. Article II defines genocide as any of the following five acts committed with intent to destroy, in whole or in part, a national, ethnic, racial, or religious group:

(a) Killing members of the group
(b) Causing serious bodily or mental harm to members of the group
(c) Deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part
(d) Imposing measures intended to prevent births within the group
(e) Forcibly transferring children of the group to another group

For a charge of genocide, only one of the five acts described in Article II Sections a, b, c, d, and e needs to be met. Article III of the Convention describes the following five acts as punishable:

(a) Genocide
(b) Conspiracy to commit genocide
(c) Direct and public incitement to commit genocide
(d) Attempt to commit genocide
(e) Complicity in genocide

Incorporating genocide into international law represents a historic and momentous advancement in recognizing the act of genocide as criminal. Yet, tragically, establishing genocide as a crime has not eliminated its occurrence. Millions of individuals have been the victim of genocide since it was legally established. Victims include but are not limited to approximately 400,000 civilians in the Vietnam War, over 1 million Bengali in Bangladesh, 100,000 Hutu in Burundi, 1.7 million Cambodians, 200,000 Bosnian Muslims and Croats in the Former Yugoslavia, over 200,000 in Ethiopia, 100,000 Mayan Indians in Guatemala, 50,000–200,000 Kurdish in Iraq, 9,000–30,000 deaths in what is referred to as the Dirty War in Argentina, 8,000 in the Bosnian genocide, and 800,000 Tutsi in Rwanda, and over 400,000 Black Africans have been murdered in Darfur.

While the Genocide Convention provides a legal definition of genocide, legal and social scientific definition may differ. Many scholars have critiqued the legal definition for being too narrow and thereby omitting political groups and social classes from legal protection. Some have extended the meaning of genocide beyond the legal definition to embrace atrocities left outside the meaning of genocide. Examples of altering the definition include nonlethal acts that threaten the security of members of a group (Lemkin 1946), emphasizing the role of the state (Horowitz 1980), highlighting the one-sided mass killing by the state or other authority (Chalk and Jonassohn 1990), and specifying genocide as "politically motivated mass murder" (Chirot and Edwards 2003: 15).

Crimes Against Humanity

Crimes against humanity are defined differently in the Rome Statute and the statutes of the International Tribunals for the Former Yugoslavia (ICTY) and Rwanda (ICTR). The International Criminal Court (ICC) defines crimes against humanity as acts such as murder, enslavement, torture, rape, enforced prostitution, sexual violence, enforced disappearance, crime of apartheid, and "other inhumane acts of a similar character intentionally causing great suffering, or serious injury to body or to mental or physical health" when they are "committed as part of a widespread or systematic attack directed against any civilian population, with knowledge of the attack."

Collective Denial

Why do so few criminologists study genocide? And why has the work of the few that studied genocide, such as Ralph Lemkin and Sheldon and Eleanor Glueck, been largely forgotten? What can account for a discipline that specializes in crime, virtually ignoring the crime of genocide? Violence, murder, rape, property destruction, and victimization provide the foundation for the vast amount of research conducted by criminologists, yet when these crimes are perpetrated in their most extreme form, as is the case in genocides, criminologists fain interest.

A review of presentations at criminology annual conferences and journal publications exposes the failure of criminologists to speak about genocide. An examination of presentations at two annual crime-centered conferences and articles published between 1990 and 1998 in 13 top criminology journals reveals that out of 19,304 presentations, only 18, or .001 %, addressed genocide and out of 3,138 published article, only 1 was devoted to the crime of genocide (Yacoubian 2000: 12–13). Considering the fact that approximately one million people were murdered in the genocide in Rwanda and the genocide in Former Yugoslavia and two international tribunals were established during this time frame, the silence of criminologists is even more shocking and shameful.

Hagan and Rymond-Richmond (2008a) argue that sociologists and criminologists should incorporate genocide in their research agenda and end their silence on the "crime of crimes." The failure of criminology to engage in the study of genocide is a critique also applicable to its parent discipline, sociology. For example, Fein (1979) reviewed introductory sociology texts from 1947 to 1977 and found that few acknowledged genocide. A survey of texts in anthropology produced a similar pattern of neglect on the topic of genocide (Shiloh 1975).

Methodological Challenges

There are methodological challenges associated with studying genocide; however, they are not insurmountable and should not be used as an excuse for the discipline's lack of research on the crime of crimes. In addition to several methodological challenges, reasons for the limited research on genocide by criminologists include a lack of empathy for the crime because genocide and its victims appear distant since the crime was not likely experienced firsthand, an unwillingness to examine the United State's genocidal origins, perceived low-status topic, and latent racism.

Initial methodological difficulties include the catastrophic and heartbreaking possibility that entire groups and places may be eradicated because of massive killings. Documenting this bloodshed is imperative, but difficult without survivors. Additionally, entering into conflict areas might not be possible. The states' participation in genocide, as perpetrator, silent bystander, or ineffective intervener, as well as their role in covering up the atrocities can make data collection arduous. As is the situation in the genocide in Darfur, states have denied entry to outsiders, which may include researchers, humanitarian workers, journalists, and even security monitors. In addition to the difficulties of entering into a conflict zone for research purposes is the reality of potential physical and mental harm occurring while conducting research during or in the aftermath of genocide. Further methodological challenges include insufficient education on the topic of genocide in criminology. In fact, Yacoubian (2000: 8) found that only 3 out of 21 criminal justice, criminology, or justice studies programs that offered doctoral degrees provided a course on international crime. Finally, potential genocide researchers may be deterred by the claim that each genocide is so unique and particular that it is impossible to make comparisons or general claims.

Methodological challenges makes studying genocides difficult, yet one solution includes "extending time demands beyond neat packaged and predictable schedules based on survey-research or other easily amenable source of data" (Fein 1990: 6). Research methods available to criminologists and social scientists more broadly have inherent limitations and/or difficulties. Yet, these limitations can potentially be overcome and may lead to methodological advancements. Furthermore, "imperfect" data should not be used as an excuse for not researching genocide or a tactic use to shame scholars into participating in and thereby perpetuating the silence on genocide. "Perfect" data is hard to obtain and potentially impossible as each method suffers from some bias or limitations. Rather than dismiss "imperfect" data, the more challenging and intellectually engaged activity is to make an assessment on the quality of the data and, if appropriate, analyze the data and be transparent about the limitations in publications. Good scholarly work addresses these issues anyway.

Latent Racism

Hagan and Rymond-Richmond (2008a) speculate that genocide has been a marginalized topic of research for criminologists because of latent racism and a belief that the study of genocide is overly emotional and not worthy of academic research. Three individuals devoted a part of their career to writing books and articles about genocide and war crimes, yet few criminologists today acknowledge their efforts. Sheldon Glueck and his wife Eleanor are best known for their contributions to developmental criminology and their research on genocide is nearly forgotten, and Lemkin is barely known to criminologists at all. Laub and Sampson (1991: 1408) speculate that the Glueck's may have suffered from institutionalized anti-Semitism and sexism in American academia. This may account for why they and their research on genocide were marginalized. Horowitz (1980: 3) shares the speculation that research on genocide is limited due to its perceived low academic status and states that sociologists feel "a studied embarrassment about these issues, a feeling that intellectual issues posed in such a manner are melodramatic and unfit for scientific discourse."

Criminological Approach to Genocide

Historically orientated scholars have dominated the study of genocide. While their contributions have been indispensable, theory testing and development has been underdeveloped (Hagan and Rymond-Richmond 2009). Public health researchers have also made important contributions and the benefits their research has provided to genocide victims is commendable and life saving. Yet, they have a distinct approach, which typically only examines deaths in the refugee camps or IDP camps and does not specifically examine the issue of violence death. Nor is there typically an attempt by public health researchers to understand the causes of genocide and to asses blame. In addition, race scholars and political sociologists typically advance the literature and theories of ethnic and national violence. Yet criminologists may have as much to contribute on ethnic violence as sociologists who specialize in race and political issues.

Criminologists should have much to contribute to the study of genocide as deviant behavior, and social group conflict is at the heart of the legal definition of genocide and a central focus of our discipline. Criminologists are fundamentally concerned with understanding the relationship between victim and the perpetrator; characteristics of perpetrators; social, economic, and communal costs of victimization; effects of sanctions on deterring criminal behavior; and the context in which criminal actions are facilitated. Criminologists should explore if current theories such as strain, social-psychological, control, social learning, social disorganization, collective efficacy, conflict, techniques of neutralization, and feminist theories that are commonly used to explain intranational crimes can also account for the criminal behavior of genocide perpetrators. Alternatively, is there a need to develop entirely new theories? For example, techniques of neutralization may be a crucial process individuals experience as a way to rationale not only interpersonal crimes but also genocidal crimes (Sykes and Matza 1957 and Alvarez 1997). Social-psychological theories of obedience to authority and group conformity, developed from well-known studies such as the Stanford prison experiment, may be essential to understanding collective violence.

Additional questions tailored to the crime of genocide, yet firmly rooted in mainstream criminological concerns, include: Can rehabilitation, reintegration, and or restorative justice reduce violence as it has been shown to do for crimes that are more "traditional?" What effect does being a victim of genocide have on one's likelihood of becoming a perpetrator? What are the financial, emotional, communal, and household effects of being a genocide survivor? Can "bystander effects" be extended to include not only individuals but also states and the international community at large? If there were desistors to the crime, what where their characteristics and the context in which the desistance occurred? What are the physical, biological, economic, social, economic, and regional characteristics of perpetrators? Is there an unequal distribution of genocidal violence in particular locations, and if so why? What role, if any, does concentrated disadvantage and social disorganization have in genocide? Do genocide victims and perpetrators know each other, as is typically the pattern when there is a single perpetrator? Does formal and informal social control deter criminals and reduce future criminal opportunities? Can collective efficacy in the form of mutual trust and cohesion, traditionally theorized to reduce neighborhood crimes, be extended to account for the crime of genocide? Do parallels exist between hate crimes and genocide with the underlying connection being racism and dehumanization?

Competing Understandings of Genocide

Among the established explanations of genocidal victimization are the following six. First is a state insecurity approach that focuses on justifiable reactions to insurgent threats (e.g., Posen 1993). Second is a primordial explanation that emphasizes hatreds so long standing that they are considered exogenous (e.g., Kaplan 1993). Third is the population-resource perspective where competition for life-sustaining resources is considered (Diamond 2005). According to this perspective, opportunities and incentives are greatest, and resources most strained, in densely settled areas. Fourth is the instrumental perspective that emphasizes state-based ethnopolitical entrepreneurs who advance their interests by cultivating public fear and disrespect of subordinate groups (see Hardin 1995; Valentino 2004). Fifth is the constructionist approach that emphasizes racial symbols and identity manipulation by elites (e.g., Kaufman 2001). Finally, the sixth approach is a cognitive framing approach that identifies the shifts that appear during emerging conflicts as ranging from "normal" to "crisis" scripts or frames (Oberschall 2000).

Hagan and Rymond-Richmond (2008a, b) synthesize these six approaches into what they call a critical collective framing approach to explain the atrocities in Darfur. In addition, the theory builds on Coleman's (1986) social action theory and draws on criminological theories including Sampson's (2006) and Matsueda's (2007) concepts of collective and social efficacy and Sutherland's (1947) differential social organization theory. The theory helps to explain the link between microlevel social actions transforming into macro-level systems leading to organized genocidal victimization.

Rape and Genocide

Most people associate genocide as massive killing for the purpose of wiping out an ethnic group in whole or in part. Rape and sexual violence is not as frequently associated with genocide, despite its similar ability to be used as a tool of ethnic cleansing and genocide. As recognized in the groundbreaking *Akayesu* judgment by the International Criminal Tribunal for Rwanda, rape may "constitute genocide in the same way as any other act as long as they were committed with the specific intent."

Horrifically, rape and sexual violence are widespread in genocidal conflicts around the world. Rape is intended to terrorize women, dehumanize victims, destroy families and communities, and or to control the biological and cultural reproduction of women through impregnating victims. The genocide in Darfur exemplifies rape committed as a means to control the biological and cultural reproduction of women. Due to the patriarchal structure of Darfurian society, lineage is determined by patrilineal descent, thereby determining children of Black-African rape victims as Arabic. Intergroup rape is a means of controlling biological and cultural reproduction through "changing the race" and is a powerful weapon of destruction. In the Darfur genocide, there are numerous reports of perpetrators using racial epithets during the rapes and stating their intentions of impregnate female victims. For example, a Black-African genocide survivor reported that her Arabic attacker raped her and said, "You will have Arab babies" (Hagan and Rymond-Richmond 2008a). Another survivor reported that her Arabic attacker screamed, "We will kill all men and rape the women. We want to change the color. Every woman will deliver red. Arabs are the husbands of those women" (Hagan and Rymond-Richmond 2008a).

Estimating the number of rape victims during genocide is exceptionally challenging due to stigma, deaths resulting from health injuries suffered by rape victims, and because their assailants kill some victims after the rape. In the Rwandan genocide, estimated rapes total 500,000. Many of the rape victims were killed shortly after being raped. In Congo, rape estimates vary from 15,000 to 40,000. A study of Darfurian survivors residing in refugee camps in Chad analyzed by sociologists and criminologists Hagan et al. (2009) found that 4 % reported personal sexual victimization. Examining sexual victimization by gender demonstrates that women were sexually victimized at a greater rate than men were. Seven percent of the women in the full sample reported personal sexual victimization.

The stigma and legal ramifications Darfurian rape victims suffer is severe. Raped women are frequently disowned by their family and ostracized by their community. Adding to raped women's pain is a commonly held belief by the Sudanese that unwanted sex cannot make a woman pregnant. Therefore, if a woman becomes pregnant, it is believed that she was not raped. Making matters worse, under Public Order 1991/Criminal Order 1991, sex outside of marriage, premarital sex, and prostitution are prohibited. Rape in Sudan is considered sex outside of marriage or premarital sex done without the consent of the victim. Therefore, survivors of rape can be convicted for sex outside of marriage (called zina) unless they can prove that they did not consent to intercourse. Unmarried women convicted of zina can receive 100 lashes and married women can be stoned to death.

As a result of detrimental social and legal consequences, reports of personal sexual victimization are drastically underreported and women are more likely to report sexual victimization of others than they are to report sexual victimization of self. For example, when Darfurian genocide survivors were asked in the same survey discussed above to report on sexual victimization of other villagers rather than personal sexual victimization, the percent increased dramatically from 4 % to nearly 30 % (Hagan et al. 2009).

Racism and Genocide

Racially specific intent is central to the legal definition of genocide. However, the Genocide Convention has been criticized for being vague on how to prove intent. The ICTY and the ICTR have provided some clarity for determining perpetrator's intent. The use of racial epithets during an attack has been established in international law as an indicator of motivation and intent. The *Akayesu* decision in Rwanda (UN 1998), the *Jelisi* decision in Bosnia (UN 1999), and the Trial Chamber in *Kayishema* and *Ruzindana* emphasize the importance of spoken language as evidence of genocide.

To understand the motivations and intention of the perpetrators in the genocidal violence in Darfur, Hagan and Rymond-Richmond (2008a, b) relied on the testimony of the surviving victims and witness. The data reveals that the predominately Arabic attackers were yelling racial epithets as they killed, raped, abducted, and destroyed the homes of Black-African villagers. As exemplified below, these epithets involved tropes of slavery and dehumanization:

> "You donkey, you slave; we must get rid of you."
>
> "You blacks are not human. We can do anything we want to you. You cannot live here."
>
> "You blacks are like monkeys. You are not human."
>
> "Black prostitute, whore; you are dirty—black."

The documentation of racial epithets used during the attacks provides evidence that the violence was racially motivated and the intent was racially specific. Hagan et al. (2005) further demonstrate that perpetrators use of racial epithets significantly affected the degree of total victimization during the attack.

Current Issues, Controversies, and Debates

Defining Genocide

As discussed above, defining genocide is a controversial topic. Criticisms include the assertion that the legal definition of genocide is too narrow, thereby excluding groups from protection. Steps forward may include altering the definition of genocide by revisiting sections of the Convention that are frequently critiqued for being ambiguous, namely the issue of intent and what qualifies as "partial" group destruction. Criminologists should seriously consider expanding upon the legal definition of genocide by utilizing insights from their discipline to develop a criminological definition of genocide.

Genocide in Darfur

Among the global atrocities occurring at the time of this writing is a genocide occurring in the Darfur region of Sudan. The genocidal conflict began in February 2003 and is still disastrously ongoing. More than 400,000 Black-African Darfurians have been killed, and 2–3 million have been forcibly displaced (Hagan and Rymond-Richmond 2005). The perpetrators are the Sudanese government and the Janjaweed, who are almost exclusively Arab. The victims are Black Africans. Unlike Southern Sudan, where religious differences are frequently attributed as the cause of conflict, in Darfur, the Arabs and Black Africans practice the Muslim religion. The root cause of the genocidal conflict in Darfur is racial and ethnic hatred (Hagan and Rymond-Richmond 2005, 2008a, b).

A number of significant changes have occurred since the genocide began in 2003. First, the violence that started in Darfur has spread to South Kordofan region. Second, the county of Sudan split into two separate nations. In July 2011, South Sudan officially declared its independence from Sudan. Third, the International Criminal Court (ICC), which became operational on July 1, 2002, has issued warrants of arrest for President Omar al-Bashir, Hussein, Harun, Kushayb, Garda, Nourain, and Jamus for their participation in the genocide in Darfur. The establishment of ad hoc and permanent international criminal tribunals makes it possible to resolve international crimes such as genocide. The International Criminal Tribunals for the Former Yugoslavia (ICTY), the International Criminal Tribunal for Rwanda (ICTR), and the International Criminal Court (ICC) have jurisdiction for the crimes of genocide, crimes against humanity, and war crimes. The most historically significant warrant of arrest by the ICC is for Sudanese President Omar al-Bashir. This is the first time a sitting head of a state was issued a warrant by the court. Charges filed by Chief Prosecutor Luis Moreno-Ocampo against President Bashir include war crimes, crimes against humanity, genocide, rape, and mass murder as genocide. Of these charges, rape as genocide is the most groundbreaking. Prosecuting the crime of rape as genocide is unprecedented for the ICC and relies on two lesser-known ways of destroying a people: "causing serious bodily or mental harm to members of the group" or "deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part." Prosecuting President Bashir with genocide including using rape as a form of genocide will provide a legal precedence for the International Criminal Court to pursue rape as a form of genocide in the future.

Additional legal means to reduce crime and inequality include enforcing Sudanese laws against rape and eliminating Public Order 1991/Criminal Order 1991. Flogging, amputating, and formalizing the death penalty for a wide range of offenses including adultery, embezzlement, and "corruption" were restored under this order. The order includes numerous criminal acts, which are vaguely defined permitting those in power to select who is criminal and what to call a crime. Women in particular have been targeted, victimized, and controlled under Public Order 1991.

Conclusion and Future Research

The boundaries of criminology must expand beyond focusing on individual criminal actions to include crimes committed by the state. Within the discipline, we can look at the subdiscipline of critical criminology for guidance. The inclusion of genocide into criminological research should be accompanied by revisiting the pioneering work of Glueck, Lemkin, and criminologists who worked on this marginalized topic as well as interdisciplinary appreciation for research on mass atrocities and war crimes conducted by anthropologists, historians, political scientists, social theorist, psychologists, and philosophers.

A second recommendation for future research is to theorize about the ways in which perpetrators of genocide and war crimes more broadly resemble and depart from "ordinary" delinquents more commonly studied by criminologists. Are they a vastly different type of criminal? Can their behaviors be explained through mainstream criminological theories or is there a need to develop new theories to account for war criminals? To what extent can mainstream criminology theories that frequently view criminals as engaging in delinquent behavior account for genocidal violence in which the perpetrator is potentially committing a crime of obedience? In what ways can we account for the role of the state in genocidal violence?

Third, criminologists can make value contributions to understanding the consequences of genocidal victimization. Indeed, one of the most resilient findings in victimology is that victimization does not end after an attack. Crime victims typically continue to suffer socially, economically, and psychologically after an attack. Similarly, victimization does not end after a genocidal attack (Rymond-Richmond and Hagan 2012). Fourth, researchers must study the behaviors, motivations, and emotions of perpetrators. Most of what we know about the motivations of perpetrators comes from the perspective of the victim. While telling and important, augmenting this data with the perspective of the perpetrator could provide vital insights into the causes, process, and preconditions and quite possibly illuminate potential solutions to eliminating genocide.

Fifth, while the Genocide Convention contains two provisions that obligate signatories to the Convention to intervene to halt genocidal violence, it has invoked fairly weak international efforts to intervene. The concept of laws on the books and laws in action has been studied by criminologists and other social scientists to illuminate and theorize about this disjuncture. Criminologists may be able to contribute to our understanding of why this disjuncture exists between states obligation to intervene in the genocide and their minimal efforts to do so. Moreover, and potentially more importantly, criminologists may be able to identify mechanisms that move from recognizing genocidal occurrences to international intervention.

In addition, the importance of genocide research, the unique contributions criminologists can make, and the increased financial necessity when conducting research abroad should be recognized by funding agencies such as the National Institute of Justice (NIJ). A review of NIJ-funded research projects during the years 1995, 1996, and 1997 demonstrates that $140 million dollars was awarded to 529 different research projects and only one, or .002 %, was tenuously associated with international crime (Yacoubian 2000: 14). Since this review does not address how many of the proposed research projects focused on genocide, it is difficult to know whether the virtual nonexistent NIJ funding is due to a lack of proposals on the topic or whether NIJ also engages in silencing genocide.

The terms "activists" and "scholar" have often been pitted against each other as if one cannot be both. Hagan and Rymond-Richmond (2009) insist that criminologists can conduct methodologically strong, peer-reviewed research that embraces activisms. Outside of criminology, there is a little more acceptance of merging the two together. In sociology, this is referred to as public sociology, and in anthropology, it is called action anthropology. In criminology, the term used to describe Hagan and Rymond-Richmond's research is activists' criminology. As good, reflexive researchers acknowledge, each researcher has their own bias, experience, race, class, gender, and even theoretical inclinations that affect the topics we choose and the lens in which we view our data. Acknowledging positionality does not negate responsible, good research.

Criminologists have a scholarly and moral obligation to build a "new criminology of genocide" (Matsueda 2009). Understanding the context of genocide, the motivations of the criminals, and the cumulative effects of victimization are important steps criminologists can make towards preventing their future occurrence. Furthermore, through the collection and analysis of data, criminologists can play a role in criminal prosecution of the perpetrators by providing information on the participation of the state, the degree of the destruction, and the racial nature of the genocide.

The building of a new criminology of genocide may well require criminologists to move beyond the familiar and comfortable mainstream. This is not completely uncharted. Feminist, Marxism, peacemaking, and postmodernism theory have modeled how this may be accomplished. Sutherland's work nearly 50 years ago on white-collar crime is another example of expanding the boundaries of criminology. It is time Raphael Lemkin's concept of genocide is incorporated into the research agenda of criminologists. If for no other reason, neglecting to study the crime of genocide is to miss an opportunity to make significant contributions to the discipline.

Geo-forensic Analysis

▶ Applied Geographical Profiling

Geographic Profiling

D. Kim Rossmo
School of Criminal Justice, Texas State
University-San Marcos, San Marcos, TX, USA

Overview

Geographic profiling is a criminal investigative methodology for analyzing the locations of a connected series of crime to determine the most probable area of offender residence. Its major function is suspect prioritization in investigations of serial crime. The technique is based on the theories, concepts, and principles of environmental criminology. Crime pattern, routine activity, and rational choice theories provide the foundation for understanding the target patterns and hunting behavior of criminal predators.

These theories suggest a method for describing the mathematical relationship between offender travel and likelihood of offending. This relationship can be described by a buffered distance-decay function that looks in cross-section rather like a volcano with a caldera. The function is encoded in a computer algorithm. Geographic profiling uses specialized crime-mapping software based on this algorithm to determine the most probable area of offender residence from the spatial pattern of the crimes.

Geographic profiling has turned out to be a robust and versatile methodology. Originally developed for analyzing serial murder cases, it was subsequently applied to rape, arson, robbery, bombing, kidnapping, burglary, auto theft, credit card fraud, and graffiti investigations. A number of innovative applications outside law enforcement also exist, with geographic profiling being used in military operations, intelligence analysis, biology, zoology, epidemiology, and archaeology.

Introduction

Geographic profiling is a criminal investigative methodology for analyzing the locations of a connected series of crime to determine the most probable area of offender residence (Rossmo 2000). Its major function is suspect prioritization in investigations of serial crime. A criminal investigation involves two tasks – finding the offender and proving guilt. Guilt can only be established by a confession, a witness, or through physical evidence. The task of finding an offender, a particular challenge in a "whodunit" investigation of a stranger crime, involves collecting, prioritizing, and evaluating suspects. High profile cases often have thousands of suspects and consequent problems of information overload. In such situations, geographic profiling can assist in case information management.

Geographic Profiling

History

Geographic profiling is typically employed in cases of serial violent or property crime, though it can be used in investigations of single crimes involving multiple locations or significant aspects of geography (Davies and Dale 1995; Knabe-Nicol and Alison 2011). Police have long used ad hoc mapping efforts to support certain criminal investigations. The first recorded use of investigative spatial analysis was during the Hillside Stranglers investigation in 1977. The Los Angeles Police Department analyzed the sites where the murder victims were abducted, their bodies dumped, and the distances between these locations, enabling them to identify the area where the killers were based. A similar analysis, using spatial means and distance-time factors, was conducted in 1980 during the Yorkshire Ripper inquiry in England (Kind 1987). More sophisticated models emerged from research conducted at Simon Fraser University's School of Criminology in Canada (Rossmo 1995). The technique was first implemented operationally in the Vancouver (British Columbia) Police Department's Geographic Profiling Section in 1995.

Theory

Geographic profiling is based on the theories, concepts, and principles of environmental

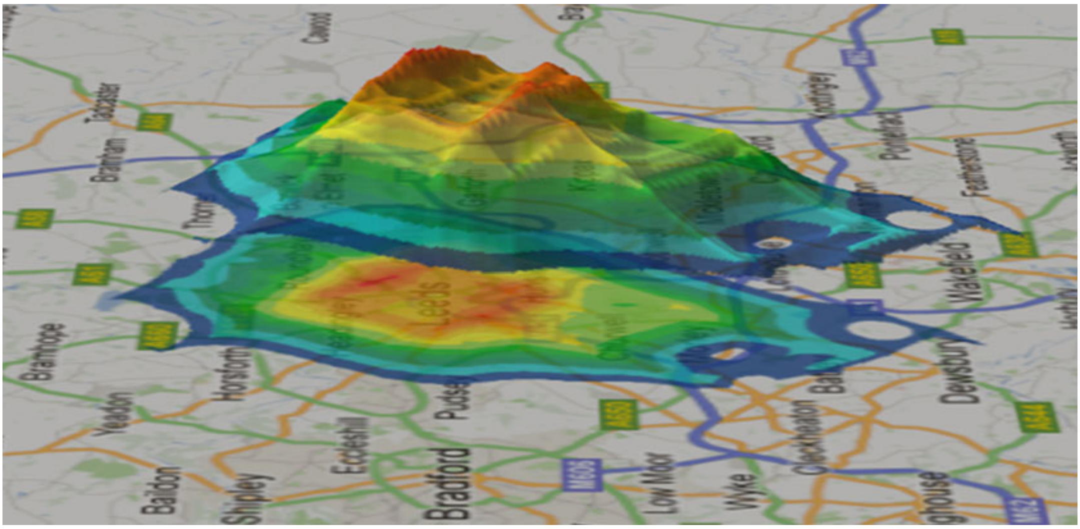
criminology. Crime locations are not distributed randomly in space but rather are influenced by the road networks and features of the physical environment. This focus on the crime setting – the "where and when" of the criminal act – offers a conceptual framework for determining the most probable area of offender residence. Environmental criminology is interested in the interactions between people and their surroundings and views crime as the product of offenders, victims, and their setting (Brantingham and Brantingham 1981, 1984). The three theories underlying geographic profiling – crime pattern (Brantingham and Brantingham 1981, 1993), routine activity, and rational choice (Clarke and Felson 1993) – provide the foundation for understanding the target patterns and hunting behavior of criminal predators.

Computer Systems

Geographic profiling uses specialized crime-mapping software to determine where an offender most likely lives. The mathematical relationship between offender travel and probability of offending can be described by a buffered distance-decay function that looks, in cross-section, rather like a volcano with a caldera. The function is encoded in a computer algorithm. Working from the point pattern of the crime locations, the computer software produces a jeopardy surface – a three-dimensional probability surface – outlining the most probable area of offender residence (see Figs. 1 and 2 below). Those positions higher on the jeopardy surface (colored red) are more likely to contain the offender's residence, those lower, less likely. A police investigator can then prioritize suspect addresses or other locations by their position on this probability surface.

A geographic profiling program includes an analytic engine, geographic information system (GIS) capability, database management, and powerful visualization tools. *Rigel*, based on the Criminal Geographic Targeting (CGT) algorithm developed in 1991 at Simon Fraser University, was the first commercial geographic profiling system. Two similar geographic profiling programs, *CrimeStat* and *Dragnet*, primarily used for research rather than police operations, were later released in 1999.



Geographic Profiling, Fig. 2 Geoprofile for Operation Lynx

Law enforcement agencies can use geographic profiling software to optimize their limited resources. The performance of a geoprofile is determined by a measure called the hit score percentage (HS%), defined as the ratio of the size of area that has to be searched, following the geoprofile prioritization, before the offender's base is found, to the total hunting area. For example, if the crimes in the series covered 10 square miles, and the geoprofile located the offender in 1.5 square miles, then the HS% would be 15 %. The smaller the HS%, the more precise the geoprofile's focus and the better its performance. An evaluation of geographic profiles prepared for operational cases that were eventually solved showed that the mean HS% was 5 % and the median 3 % (Rossmo 2011).

Process

The process of generating a geographic profile involves a number of steps, beginning with determining which crimes are connected in a series, evaluating the case information, creating the geoprofile, and finally recommending investigative strategies. This process is described in more detail below.

Linkage Analysis

The investigation of a crime series starts with determining which specific offenses are connected together. This procedure is known as linkage analysis or comparative case analysis. Every crime in the pattern can be considered a piece in a jigsaw puzzle; the more pieces, the more information; the more information, the more detailed the overall investigative picture. Linkage analysis identifies case similarities and common suspects, leading to information sharing between detectives and different police jurisdictions. When a case is solved, more crimes may be cleared and the courts can sentence convicted offenders more appropriately.

A linkage analysis requires the comparison of similarities versus differences for both connected and unconnected crimes; connected crimes should show more similarities than differences and unconnected crimes, more differences than similarities. There are three main methods used to link crimes: (1) physical evidence; (2) offender description; and (3) crime scene behavior (Rossmo 2000). If present, physical evidence such as DNA or fingerprints can establish crime linkage with certainty. In contrast, the other two methods are probabilistic in nature; witness descriptions vary in their accuracy, and offenders do not always exhibit the same modus operandi.

Signature – unique behaviors not required for the commission of the crime, such as certain fantasy-based sexual routines in a rape series or the inscription of “FP” (for “fair play”) by the New York Mad Bomber – provides a solid link if present; unfortunately, signature is rare. Proximity in time and place between crimes significantly increases their likelihood of being connected.

After a linkage analysis has been completed, the connected crime locations, distinguished by site type, are entered into the system by street address, latitude and longitude, or digitization. These optional entry methods reflect the reality that crime can happen anywhere – houses, parking lots, back alleys, highways, parks, rivers, and even mountain ravines.

Considerations

An exploratory analysis of the data is next conducted. Several different crime factors and environmental elements need to be considered in the construction and interpretation of a geographic profile:

1. Crime sites – While the locations of the crimes are essential to a geographic profile, the types of crime sites are also important. A homicide, for example, can involve separate or combined encounter, attack, murder, and body disposal sites; each site type has a separate analytic meaning.
2. Temporal factors – When the crimes occurred (date, day of week, and time of day) and their chronological order provide valuable context for understanding the crime sites. Temporal information may also provide insight into the offender’s routine activities.
3. Hunting style – A criminal’s hunting method (defined as the search for, and attack on, a victim or target) influences his or her crime site pattern (Beauregard et al. 2011). Hunting style is therefore an important consideration in geographic profiling.
4. Target backcloth – The target backcloth is an opportunity surface representing the availability of potential targets or victims in a given area. An offender’s choice options may be limited if the target backcloth is constrained or patchy (e.g., a criminal preying on street sex workers in a red light district). This may reduce the importance of certain types of crime sites (victim encounters) in the preparation of a geographic profile.
5. Arterial roads and highways – People, including criminals, do not travel as the crow flies. They follow street layouts and are more likely to travel along major arterial routes, freeways, or highways. Crimes often cluster around freeway exits.
6. Bus stops and rapid transit stations – Offenders without vehicles may use public transit or travel along bicycle or jogging paths. The locations of these routes and their access points may be an important consideration for understanding the crime patterns of such offenders.
7. Physical and psychological boundaries – Movement is constrained by physical boundaries such as rivers, lakes, ravines, and highways. Psychological boundaries, resulting from socioeconomic, ethnic, or race differences, also influence movement.
8. Zoning and land use – Zoning (e.g., residential, commercial, industrial) and land use (e.g., stores, bars, businesses, transportation centers, major facilities, government buildings, military institutions) provide important keys as to why an offender may have been in a particular area.
9. Neighborhood demographics – Some sex offenders prefer victims of a certain racial or ethnic group. These groups may be more common in certain neighborhoods than in others, affecting spatial crime patterns.
10. Displacement – Media coverage or police patrol presence can cause spatial displacement, affecting the locations of subsequent crime sites. Any displacement issues have to be compensated for in a geographic profile.

Creating the Geoprofile

Once all these various factors are considered, a scenario, involving a subset of crime locations most relevant for determining the offender's residence, is created (e.g., non-independent crime sites will be excluded). The next stage is the actual generation of the geographic profile. Conducting hundreds of thousands of iterations of its criminal hunting algorithm, the software assigns probability values (depicted with a color spectrum) to each pixel in what is typically a 40,000-pixel grid overlaid on a map of the crime sites. The final output is a color two-or three-dimensional map that shows the most likely area of offender residence (see Figs. 1 and 2 below). The geoprofile can then be used as the basis for a number of police investigative strategies.

Investigative Strategies

The function of a geographic profile is to focus a criminal investigation. Police agencies have employed a number of strategies over the past 20 years that take advantage of this spatial prioritization. The development of these approaches has been an ongoing interactive process involving investigator input and operational experience (Daniell 2008). Geographic profiling investigative strategies can be broadly divided into suspect-based and area-based approaches, depending on whether individuals or locations are being prioritized. It should be emphasized that a geographic profile is only one of many techniques in the detective's repertoire. However, it can increase effectiveness and efficiency and, in some situations, make possible an investigative approach that would otherwise not be feasible.

Suspect-Based Strategies

Suspect prioritization involves the assessment of individuals, including suspects, persons of interest, and known criminals. One of the benefits of geographic profiling is the ubiquity of address-based record information (estimated to be as high as 85 %). Potential suspects and investigative leads can be found in a variety of databases: police dispatch, record management, and jail booking systems, sex offender registries, and parolee and predatory violent criminal lists.

Data banks are often geographically based, and parole and probation offices, mental health clinics, social services offices, schools, and other agencies located in prioritized areas may provide information of value. Several commercial companies offer law enforcement agencies the ability to search multiple personal information databases. Their systems (e.g., Accurint and AutoTrack) use proprietary data-mining algorithms to sample and select large quantities of data electronically and assign them to individual profiles.

A department of motor vehicles (DMV) record search for a suspect vehicle can be focused by cross matching an offender's description from driver's licenses files and prioritizing the results using geographic profiling. The combined search parameters act as a linear program to produce a manageable list of records.

Area-Based Strategies

Area prioritization involves the allocation of police resources for such activities as surveillance, canvassing, and directed patrolling (for an interesting case example involving a serial burglar, see Rossmo and Velarde 2008). It has also been used to focus intelligence-led DNA screens ("bloodings") in which individuals are prioritized based on geography, criminal record, age, and other relevant criteria. In certain missing person cases that are suspected homicides, geographic profiling can help determine probable body disposal sites or burial areas if a suspect has been identified.

Operation Lynx

Operation Lynx was the name of a major police operation that investigated a series of five brutal rapes in central England from 1982 to 1995. The first victim was attacked in December 1982 in a parking lot in Bradford by a man with a Scottish accent. The offender forced his way into her car and then drove to a deserted airport where he raped her. A month later, the second victim was abducted in a similar manner from the parking lot of a Leeds hospital. Afterward, the offender abandoned her in an industrial area in the central part of the city. He continued this pattern, raping a woman in Leicester in May 1984 and another in Nottingham in May 1993. The last victim, a student, was attacked in a multistory parking garage in Leeds in July 1995. The offender put crazy glue over her eyes so she could not see him.

These crimes spanned multiple police jurisdictions, resulting in significant investigative problems. Finally, in 1996, the crimes were officially linked. The various police agencies formed Operation Lynx, which eventually became, with over 180 police officers from five different police forces, the largest manhunt in England since the Yorkshire Ripper inquiry. Investigators recovered DNA from semen and blood found at two of the crime scenes, but unfortunately, the offender was not on the UK National DNA Database. They also had a partial fingerprint from one of the victim's vehicles, though it lacked a sufficient number of points for an automated fingerprint identification system (AFIS) comparison. Investigators then decided to try a manual search of the fingerprint files of West Yorkshire Police – a jurisdiction of two million people. A prioritization scheme, one element of which was geography, was developed to focus the search.

In 1997, the Vancouver Police Department was asked to prepare a geographic profile for the case (Rossmo 2000). Unfortunately, even though each rape involved multiple locations, the crime series was spread over 13 years and several areas, suggesting the offender had operated from different bases. Generating separate geoprofiles for each city would have resulted in the critical loss of information. Investigators, however, had linked a stolen Ford Cortina to the second attack. The owner's credit card had been left inside the vehicle, and someone had used it to make numerous purchases throughout Greater Leeds. If this person was the rapist, then the geographic profile could also include these locations.

Proceeding on this basis, a geographic profile was prepared from the 20 locations of the Leeds crimes and credit card purchases. The result focused on two neighborhoods in central Leeds – Millgarth and Killingbeck. Consequently, the manual fingerprint search was narrowed by age (35–52 years), criminal record (minor offenses), residence area (Millgarth or Killingbeck), and Scottish origin, among other parameters. In March 1998, after 940 h of examining more than 7,000 prints, a match was made to a man named Clive Barwell. DNA subsequently confirmed he was the rapist. Barwell resided in Killingbeck, and his address was in the top 3.0 % of the geoprofile; his mother, who used to beat him when he was a child, lived in Millgarth. In October 1999, after Barwell pled guilty in court, he was sentenced to eight life terms in prison. He is still a suspect in the murder of a young woman.

Barwell may have been found sooner, but it turned out he was not Scottish. He had faked an accent in order to mislead police. He was also listed as being in prison during the Nottingham attack; an undocumented release gave him the opportunity to rape again.

In the hunt for Barwell, detectives engaged in 24,324 actions, knocked on over 14,000 doors, tested the DNA of 2,177 men, and reviewed an additional 9,945 suspects. A total of 33,628 names were entered in the inquiry's computer system, more than in any other case in British policing history. Operation Lynx is a dramatic example of the importance of suspect prioritization. Given the multijurisdictional nature and time span of the crimes, the manual fingerprint review would never have been successful without narrowed search criteria and a geographic focus.

Figure 1 shows the top 10 % of the three-dimensional jeopardy surface created with *Rigel* for Operation Lynx in 1997. Figure 2 shows the full two-dimensional geoprofile; the blue square in the southwest of central Leeds marks Barwell's address, and the one in the northeast, his mother's address.

Training

The Vancouver Police Department (VPD) implemented the first geographic profiling training program in 1997. The Royal Canadian Mounted Police (RCMP), Ontario Provincial

Police, British National Crime Faculty (now part of the Serious Organised Crime Agency or SOCA), and the Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF), among other agencies, have all had personnel trained in the methodology. The National Law Enforcement and Corrections Technology Center-Southeast Region (NLECTC-SE), working with the VPD, expanded geographic profiling training to property crime investigations in 2001 (Rossmo and Velarde 2008). Training is now available for police investigators and crime analysts internationally through various universities and police agencies. Over 600 people, representing 264 law enforcement, intelligence, and military agencies from 14 countries, including Australia, Canada, England, Wales, Korea, The Netherlands, South Africa, Sweden, Switzerland, Thailand, Turkey, and the United States, have now been trained in geographic profiling.

Future Directions

New Applications

Geographic profiling has turned out to be a robust and versatile methodology. Originally developed for analyzing serial murder cases, it was subsequently applied to rape, arson, robbery, bombing, kidnapping, burglary, auto theft, credit card fraud, and graffiti investigations. It has also been used to refine probability calculations in familial searches of DNA databanks (Gregory and Rainbow 2011). Some of the more interesting applications have included the geoprofiling of payphone locations in a murder case, cellular telephone switch tower sites in kidnapping cases, stores where bomb components were bought, locations of credit card purchases and bank ATM withdrawals in a rape case, and, in a historical analysis, the locations of anti-Nazi postcards left on the streets of Berlin, Germany, during the early 1940s. Geographic profiling has also found a number of innovative applications outside law enforcement, including uses in military operations, intelligence analysis, biology, zoology, epidemiology, and archaeology (Rossmo 2012).

Counterinsurgency and Counterterrorism

Traditional military responses to insurgency attacks in Iraq and Afghanistan, often quasi-criminal in nature, are usually not possible because of the civilian nature of the surrounding population. Counterinsurgency operations therefore require intelligence analysis and some form of investigative response. These attacks have underlying spatial and temporal patterns, enabling the use of geographic profiling by military analysts to determine the most probable locations of enemy bases (Brown et al. 2005; Kucera 2005). For example, urban and countryside insurgency problems have included attacks from improvised explosive devices (IEDs), vehicle bombs, land mines, rocket-propelled grenades (RPGs), mortars, and snipers. Insurgents typically obtain their heavier armaments and munitions from supply centers – homes, mosques, warehouses, and various other buildings. For geographic profiling purposes, the insurgent attack locations are equivalent to crime sites, while their supply centers are equivalent to offender bases.

Terrorism is a covert threat, and important patterns can be lost in the large volume of data collected by counterterrorism and intelligence agencies. Geographic profiling models can be used to prioritize suspects, tips, and leads. While it has seemed to some that terrorists, with transnational structures and decentralized networks, lack a geographic structure, it turns out that they do. Many minor terrorist actions are ordinary crimes, such as robbery, theft, and credit card fraud. Even major terrorist attacks of targets specifically selected for their symbolism require the establishment of terrorist cells in the areas of operation. In both situations, a geographic relationship exists, whether it is the target determining the locations of the terrorist cell sites or the terrorist cell sites determining the location of the target. Bennell and Corey (2007) retrospectively applied geographic profiling to terrorist bombings in France and Greece. They concluded that when appropriate assumptions are met (an area requiring further research), geoprofiles of terrorism can be accurate. Rossmo and Harries (2011) analyzed the site patterns of

Marxist and Jihadist terrorist cells in Turkey and Spain and found they possessed internal geospatial structures that could be quantified.

Biology and Epidemiology

Biologists have adopted geographic profiling models to the study of animal predation. The technique has been used to describe foraging patterns of different colonies of bats in Scotland (Le Comber et al. 2006), discriminate spatial search processes and predict nest locations of bumblebees (Raine et al. 2009; Suzuki-Ohno et al. 2010), and investigate the nonrandom nature of white shark attacks in South Africa (Martin et al. 2009).

Geographic profiling has also been used in epidemiology research to locate the origins of infectious diseases, including contaminated water sources for cholera and mosquitogenic breeding pools for malaria (Le Comber et al. 2011). Source populations of invasive species have been identified from geographic profiles of their current locations (Stevenson et al. 2012). The expansion of geographic profiling to these other domains demonstrates the reach and power of the environmental criminology approach.

Future Improvements

Future improvements in geographic profiling require an integration of both scholarly research and operational experience. One area that requires more study is the journey to crime. While many studies have measured the distance between offenders' homes and their crime sites, only a few have examined the exact nature of their crime journeys. Rossmo et al. (2011) mapped and analyzed the spatial-temporal patterns of a group of reoffending parolees on an electronic monitoring program with a global positioning system (GPS). Their research revealed the characteristics of actual crime trips and provided a more nuanced understanding of offenders' spatial patterns. Bernasco (2010) studied the spatial influence of offenders' residential history on their crime locations. He found past residences still influenced where a criminal offended provided he or she had recently moved and had lived in the prior residence for a period of time. Summers et al. (2010) used maps in interviews of convicted property offenders, gaining insights into how they view space and search for criminal targets.

Combining geo-demographics and other area-based information with the point pattern analysis of geographic profiling is another approach with potential (Rossmo et al. 2004). Levine and Block (2011) developed a Bayesian approach to geographic profiling that integrates historic offender residence data with journey-to-crime estimations. However, while Bayesian models may be useful for prioritizing geographic areas, they cannot be used for suspect prioritization as their calibration is based on known offender residences.

Conclusion

The stranger nature of serial crime creates challenges for police investigations. Geographic profiling can help detectives prioritize suspects and manage information in such cases. It is only one of several available tools and is best employed in conjunction with other police methods. As addresses are a common database element, geographic profiling can be used as a decision support tool in a variety of contexts. The overall geographic pattern of a crime series is just as much a clue as any of those found at an individual crime scene.

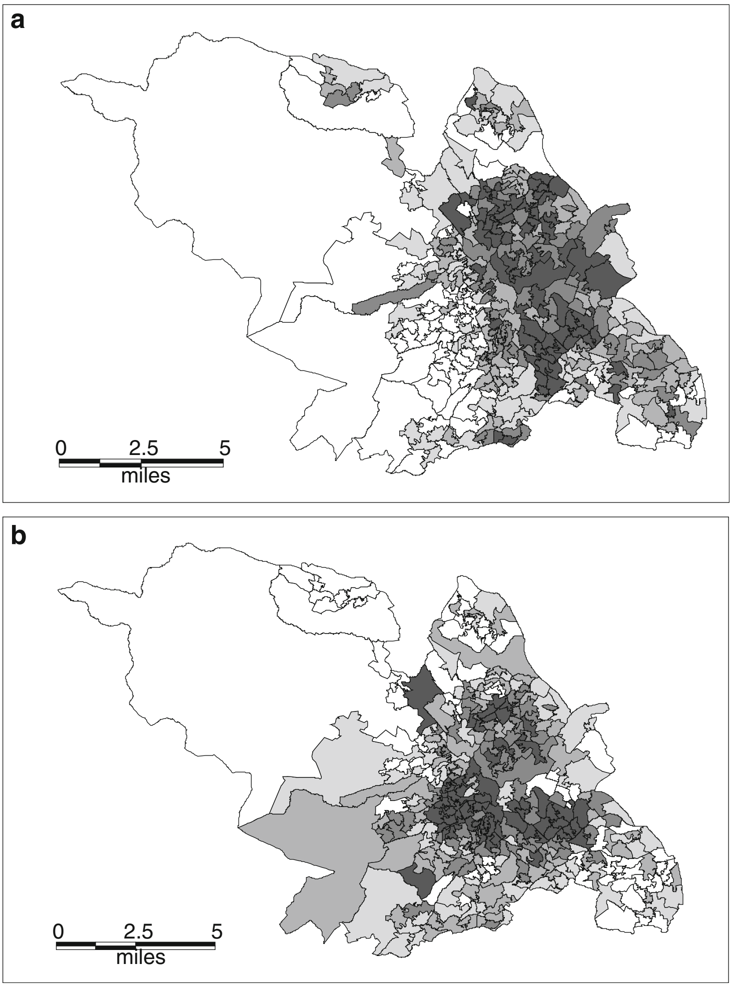
Overview

The study of the geography of crime has a long history, stretching back to the early nineteenth century. After a quiescent period in the middle of the twentieth century, it has now again become a field of strong research activity. However, the interests of scholars in this field have often been divergent: for example, some have been motivated by very practical (crime-preventive) concerns, while others are more interested in explanatory theory; some have mainly focused on neighborhoods, but others see greater merit in studying micro-locations. Not infrequently, work in these different traditions has been pursued in relative isolation, leading to some fragmentation of the field. However, there is now a growing interest in developing a more integrated understanding of geographical criminology (Bottoms 2012; Weisburd et al. 2012; Wikström et al. 2012). This chapter is written from that integrative perspective, with a special focus on arguably the three most important strands of research in the recent geography of crime, namely, the "hotspots approach," the "neighborhood effects tradition," and the "signal crimes perspective." The chapter is organized into three main sections, focusing respectively on space, social structure, and social action.

Three Research Approaches in the Contemporary Geography of Crime

The "hotspots" approach within criminology effectively began with a seminal paper by Sherman et al. (1989), which showed that 50 % of the crime-related calls made to the police in Minneapolis related to just 3.3 % of the micro-locations in the city. This degree of concentration of crime seemed to offer significant potential for targeted crime prevention programs, and such programs have subsequently been successfully developed by scholars and practitioners working in the hotspots tradition (Braga and Weisburd 2010; Weisburd et al. 2010). Indeed, it has been recently argued that "the police can be more effective if they shift the primary concerns of policing from people to places" (Weisburd et al. 2010, p. 7).

The "neighborhood effects tradition" is older and can be traced back to the work of the Chicago School of Sociology in the 1930s. The argument of the Chicagoans was that "socially disorganized neighborhoods" produced more juvenile delinquents than other residential areas with similar populations; in other words, that aspects of the social structures and the culture of certain neighborhoods could lead to the development of criminality in some individuals who would otherwise have remained crime-free. For a time, the existence of such "neighborhood effects" (as opposed to "individual effects" or "family effects") was challenged, but in light of further research evidence, they can now be regarded as clearly established (for a review see Bottoms 2012). For example, in a paper based on data from the Pittsburgh Youth Study, Wikström and Loeber (2000) showed that, after controlling for various individual "risk factors" for offending (such as impulsivity, poor parental supervision, and low school motivation), neighborhood factors remained causally important in generating adolescent criminality, at least in the poorest neighborhoods.



Geography of Crime and Disorder, Fig. 1 City of Sheffield: geographical distribution of offender residences and burglary victimizations, September 2004 – August 2006. (**a**) Map of offender residences (in quintiles, *highest rate darkest*) (**b**) Map of victimizations for offenses of residential burglary (in quintiles, *highest rate darkest*). Note: both maps are based on UK Census lower level super output areas (Source: Bottoms 2012, p. 459; maps prepared by Dr. Andrew Costello)

There are two important differences of empirical focus as between the hotspots approach and the neighborhood effects tradition. First, as their names imply, there is a difference in geographical scale: hotspots are micro-locational, while the study of neighborhoods entails a locationally wider research focus. Secondly, the dependent variable for hotspots researchers is the *criminal event located in geographical space*, while the neighborhood effects tradition, being concerned with potential neighborhood influences on the criminality of individuals, focuses particularly on the *geographical location of offenders' homes*. Yet despite these differences, in real-life research contexts the two approaches are empirically interconnected, because one of the best-established and durable findings in the geography of crime is that – for reasons to be discussed later – *many offenses are committed close to offenders' homes*. This is illustrated in Fig. 1 which displays data on the location of offender residences and of recorded residential burglary victimizations in Sheffield, England, a city with a population of half a million. Sheffield is well known as a "city of two halves," with the population of the eastern half being substantially poorer, and having a lower life expectancy, than those living in the western half. Figure 1a shows that offender residences are very disproportionately concentrated in eastern Sheffield. One might therefore suppose that many offenders intending to burgle might travel the short distance from east to west Sheffield to take advantage of the (on average) much more lucrative theft opportunities available in the houses in the west. However, although there is clearly some movement in this direction (see Fig. 1b), most of the areas with high victimization rates for residential burglary are, as with offenders' residences, found in the east. Given data of this kind, it is now well established that an important risk factor for a high area victimization rate is that the location lies close to an area of high offender residence. That simple fact is one of the most important reasons why a better integration of research from the "hotspots" and "neighborhood effects" traditions is desirable.

The third strand of research, "the signal crimes perspective," is the most recent. It draws in part from the field of study known as *semiotics* ("the science of signs and symbols"), which focuses especially on the operation of such symbols in communication. Semiotics is relevant to geographical criminology because the signs emitted at particular locations can send messages that significantly affect behavior; for example, research in the Netherlands has shown that signs of disorder in public places (such as uncleared litter) tend to encourage further breaches of norms (including theft), while norm-compliant behavior (e.g., someone sweeping up litter) can encourage other norm-compliant behavior (e.g., helping a stranger who has dropped fruit in the street) (Keizer et al. 2008; Keizer 2010). According to Martin Innes, the originator of the signal crimes perspective (SgCP), criminology lacks "a coherent explanation of the public understanding of crime and disorder and how such understandings are imbricated in the wider symbolic construction of social space." Substantively, SgCP proposes that "*some crime and disorder incidents matter more than others to people in terms of shaping their risk perceptions*" in visiting defined locations (Innes 2004, p. 336, emphasis added). Thus, for example, three spouse murders in a month in a medium-sized town would be very unusual, but would not necessarily create widespread fear, or a sense of threat, in the community at large, because they would be seen as "private matters." By contrast, the abduction and murder of a local schoolgirl on her way to school would almost certainly generate much more fear, and a sense of threat, in the area, because of the *signal* it would transmit about potential risks in the community. In light of this signal, ordinary people might freshly consider as "risky" certain places, people, or situations that they might encounter in their everyday lives; hence signals are seen in SgCP as social-semiotic processes by which particular crimes and disorders might have a disproportionate effect in terms of fear and perceived threat, often in relation to specific locations. It will accordingly be noted that the focus of this third theoretical approach is – by contrast with the first two approaches – on neither area crime rates nor area offender rates *as such*, but rather on the symbolic meanings that people might attach to specific locations as a result of certain acts occurring in or near them or the characteristics of people believed to be present in the location.

From the above account, it will be clear that the three research traditions described, while distinct from one another, are in no sense necessarily contradictory. Coherent synthesis of the approaches, within defined contexts, is therefore in principle certainly possible, and aspects of this complementarity will hopefully become more evident in the ensuing sections of this chapter. In these sections, research results on the geography of crime and disorder will be considered within the framework of the three core dimensions of research in human geography: *space*, *social structure*, and *social action*.

Space

Human beings exist only within physical bodies. Although, in the Internet age, an increasing number of activities can be undertaken in virtual space, physicality remains important for many human activities, notably travel and the use of public space. This first section therefore considers physical places and spaces and their relevance within geographical criminology.

The physicality of humans is, however, not their only characteristic. Uniquely within the animal kingdom, humans possess the gift of language, and the ability to be self-reflexive about the situations in which they find themselves. In considering humans' use of space, therefore, it is necessary to address *perceptions* of locations, as well as the physical context. Within this dual framework, three topics will be discussed, namely, crime opportunities, hotspots, and the meaning of space.

Crime Opportunities

It is now well established in psychological research that much behavior is situation specific, and that people often act differently if some aspect of a particular type of situation is altered. A striking demonstration of these points was provided by Ronald Clarke and Pat Mayhew (1988), who showed that the suicide rate had dropped suddenly in Britain in the 1970s when the source of domestic gas supplies was switched from coal gas (toxic) to natural gas from the North Sea (nontoxic) and that there was no plausible explanation of this decline other than the change in the nature of the gas supply. In other words, even people desperate enough to try to end their own lives often did not turn to alternative methods when the immediate situational context was altered. Given this and other similar evidence, Ronald Clarke and others have made a special study of the specific situations in which different offenses are committed, with a view to modifying those situations to produce a reduction in crime – an approach known as *situational crime prevention* (StCP). Typically, this might involve strategies such as making goods harder to steal by strengthening security at potential targets, reducing the availability of the means to commit certain crimes (e.g., by restricting sales of guns or knives), or environmental management (e.g., separating the fans of opposing teams at football matches). Such strategies have often led to beneficial results, and there are now many reports of successful StCP initiatives (Felson and Boba 2010: ch. 10). Some of these initiatives are explicitly locational, and a good example is the strategy known as "alley-gating." In working class residential areas in British industrial cities, a favored style of pre-Second World War housebuilding was "back-to-back terraces," that is, rows of terraced houses opening directly on to the street, with small yards or gardens at the rear, backing on to an identical set of terraces in the next street. Normally, a "back alley" is located between the yards/gardens of the two rows of houses. Crime analysts noticed that the entry point for house burglaries in such areas was very often from the rear, and this led to the prevention strategy of "gating" the entrances to the back alleys. Evaluations of such initiatives have shown them to be successful in reducing burglary; moreover – and congruently with the evidence from the gas suicide example – there was no evidence of displacement of burglaries to nearby residential areas (Bowers et al. 2004).

Closely related to the StCP approach is *routine activities theory* (RAT), whose central proposition is that "the probability that a [criminal] violation will occur *at any specific time and place* might be taken as a function of the convergence of likely offenders and suitable targets in the absence of capable guardians" (Cohen and Felson 1979, p. 590; see also Felson and Boba 2010). This approach, which incorporates a specifically spatial dimension (see the italicized phrase), usefully divides the concept of "opportunity" into two component parts ("targets" and "guardianship"), but more importantly, it draws attention to the fact that the routine activities of a population can – often unwittingly – create or restrict criminal opportunities in defined locations. To take an example from a British study, multistory parking lots at train stations used by commuters (where few owners visit the lot during the working day) were shown to have a higher victimization rate than similar parking lots attached to shopping malls (where shoppers are leaving and returning to their vehicles all day, providing a flow of natural surveillance or guardianship). Many examples of a similar kind are provided by Felson and Boba (2010); as they memorably phrase the matter, these examples show how "noncriminal realities give rise to criminal events" (p. 205).

It is therefore a serious mistake to see criminal opportunities as existing in a social vacuum. This point is further illustrated through Patricia and Paul Brantingham's seminal contribution to geographical criminology, first formulated 30 years ago (Brantingham and Brantingham 1981), and now incorporated within a broader *crime pattern theory* (Brantingham and Brantingham 2008). These authors postulated that most offenders, like most people, feel much more comfortable in areas that they know reasonably well; in consequence, even when – for example – potential burglars are engaging in a search pattern for a suitable target, it is hypothesized that they will usually not wish to venture into residential areas that are completely unknown to them. In other words, the suggestion is that offenders will usually commit crimes in areas already known to them through their routine activities. (Oddly, routine activities theorists until recently paid little attention to this point, being more interested in how targets and guardianship are influenced by routine activities.) Subsequent empirical research evidence has strongly supported the Brantinghams' hypothesis (see especially Wikström et al. 2012: ch. 7), and this body of work clearly helps to explain why many offenses are committed not far from offenders' homes (see above), as well as in other locations in which they regularly spend time, and where there are criminal opportunities (such as downtown areas and leisure outlets). These social realities therefore illustrate the point that a so-called opportunity for crime in a given area is, in the full sense, only an opportunity when it is perceived as such by someone who (i) might enter the area and (ii) is willing to consider turning the opportunity into an act of crime. Otherwise identical physical "opportunities," if located in different social contexts, might differ greatly in the number of passersby who would consider committing a crime at the micro-location, and such differences will almost certainly be reflected in their aggregate victimization levels.

Sometimes, even more complex narratives emanate from discussions of "opportunities for crime"; street lighting is an important example. Improved street lighting was originally advocated as a situational crime prevention strategy in the belief that better lighting would increase the number of people using the location at night (thus providing improved guardianship of the area) and would also make potential offenders more visible (thus making them more easily detectable if they committed a crime). Both these effects were thought likely to deter potential offenders from committing crimes in the relevant area, because the opportunities for successful lawbreaking had been reduced. However, the actual research evidence is more complex. A Campbell Collaboration review of relevant empirical studies has concluded that, while "improved street lighting significantly reduces crime," it was also the case that, in areas with improved lighting, "night-time crimes did not decrease more than daytime crimes" (Welsh and Farrington 2008, p. 2). This finding presents problems for a simple opportunity theory, because if enhanced deterrence were the only mechanism in play, one would expect crime reductions in better-lit areas during hours of darkness, but no difference in crime rates during daylight hours. Accordingly, the Campbell reviewers concluded that the daytime effect was possibly occurring because "improved lighting signals community investment in the area and that the area is improving, leading to increased community pride, community cohesiveness and informal social control." This interpretation therefore seems to embrace not only "opportunities" but also the more normative language of the signal crimes perspective (note the word "signal" in the sentence quoted above, although the SgCP approach is not explicitly mentioned by the reviewers). However, the temporal sequencing of possible "deterrent" and "signal" effects has been insufficiently studied, so – as the authors make clear – further research is needed. But the juxtaposition of the two approaches in the Campbell Review is of great interest.

Hotspots

Like those who have focused on crime opportunities, criminologists who have developed the "hotspots approach" have concentrated on micro-locations. Indeed, they have very usefully shown that the neighborhood level of analysis can be misleading in the geographical study of crime events, because – for example – what might seem overall to be a "crime-prone neighborhood" often contains micro-locations with very varied levels of crime, including some low-crime locations.

These findings have led to a justifiable emphasis on the desirability of using small units of analysis when studying crime events (Weisburd et al. 2009). Accordingly, in a major recent research study in Seattle, to be described later, Weisburd and colleagues (2012) adopted as their unit of analysis the "street segment," that is, both sides of a street between two intersections in a standard North American street grid.

A main motivating reason for the development of the hotspots approach has been crime prevention. However, before researchers could confidently recommend to policymakers a preventive strategy based on hotspots, several issues beyond the simple demonstration of crime concentrations needed to be explored. These included the following:

(i) Perhaps the identified hotspots were ephemeral, so that a different set of hotspots would appear if one were to conduct the analysis for a later year or a series of years.

(ii) Perhaps crime prevention initiatives targeted on specific places would not actually reduce crime at the hotspot.

(iii) Even if the crime prevention effort was successful at the hotspot, perhaps those committing crimes in that location would simply move their activities elsewhere ("crime displacement").

These were reasonable questions, but subsequent research has convincingly dispelled doubts. Briefly, longitudinal analyses have now shown that hotspots in given cities are usually enduring, not ephemeral; rigorous evaluative studies have demonstrated that "hotspot policing" crime prevention strategies can be effective; and displacement is rarely a problem (Braga and Weisburd 2010; Weisburd et al. 2010). This body of work constitutes an impressive contribution to scholarship by hotspots researchers. But in addition – and of great interest to the quest for integration under discussion in this essay – hotspots researchers have begun to pursue the question of the *legitimacy* of crime prevention initiatives at crime hotspots. (On legitimacy and criminal justice, see Bottoms and Tankebe 2012). For example, Braga and Weisburd (2010: ch. 6) have set out in schematic form three different models by which police could in principle seek to control crime at hotspots: these are the "traditional" (or "reactive") model, in which police respond to incidents as they occur; a proactive "strong enforcement" model (such as the widely discussed "zero tolerance" approach to policing); and a proactive "situational prevention" model, focusing crime prevention efforts on targeted micro-locations identified through prior crime analyses. The third of these is the authors' preferred model, and a principal reason given for rejecting the "strong enforcement" model is its potential for legitimacy deficits: "overly aggressive and indiscriminate arrest-based strategies are more likely to generate community concern and poor [police-public] relations" (Braga and Weisburd 2010, p. 229). On this view, therefore, when assessing the policy-relevant features of specific locations, it is necessary to consider not only objective matters such as the concentration of crime events but also more normative and perceptual issues such as the way in which law enforcement agents are viewed in the locality (which will include the historical legacy of past law enforcement, still present in the memories of current residents). Such matters will, however, very often relate not simply to the hotspot itself, but to the wider socio-structural context in which it is set (e.g., a particular policing approach might have been adopted for a whole neighborhood, not simply a specific hotspot). In such circumstances, it becomes necessary to widen the spatial scale of the issues to be addressed when considering policy responses to crime in the hotspot.

Despite the unquestioned importance of the hotspots approach as a development within geographical criminology, early research in this field was subject to some criticism, particularly concerning two alleged omissions: first, that (apart from the discussion of legitimacy) hotspots researchers had paid little attention to hotspots from the potential offender's point of view and, secondly, that they had largely failed to analyze a key explanatory question, namely, *why* do some micro-locations have high crime, while others do not? Fortunately, both of these omissions have been addressed in more recent research.

An important study of hotspots from the offender's perspective was undertaken by Peter St. Jean (2007) in a socially very deprived high-crime neighborhood in Chicago. In qualitative interviews, the researcher elicited persistent offenders' views about optimum micro-locations for drug dealing and robbery. A strong "opportunity" dimension to offenders' locational preferences was shown, and the most favored street blocks for committing crimes were busy road intersections containing commercial premises such as grocery stores, liquor stores, and check-cashing outlets, all of which bring together "people who can be clandestine clients of drug dealers or easy targets for robbers" (p. 197). In more residential areas, however, a further "opportunity" variable seemed to be in play, namely, the vigilance or otherwise of residents, since "watchful neighbors…sometimes serve as effective constraints against neighborhood robberies" (p. 208).

The issue of watchful neighbors brings into focus the theory known as *collective efficacy*, particularly developed by Robert Sampson. "Collective efficacy" is defined as *the institutional ability to achieve what a group or community collectively wishes to achieve*; and in criminological research it has been principally utilized in research in small residential areas. It is normally measured with survey items that tap into two linked matters: first, the willingness of residents to intervene for the common good in certain defined situations (such as children spray-painting graffiti on a building) and, secondly, the existence or otherwise of conditions of cohesion and mutual trust among neighbors (on the assumption that one is unlikely to take action in a neighborhood context where the rules are unclear and residents mistrust one another). Various empirical studies have confirmed that, in many local contexts, there is evidence for the crime-reductive effectiveness of collective efficacy (Sampson 2006).

The second main omission in early hotspots research (i.e., why do particular micro-locations have high crime?) has been principally addressed through two major research studies using different methodologies, one in the USA and one in England.

The American research was a multivariate correlational study using a unique 16-year dataset for Seattle for the years 1989–2004 inclusive (Weisburd et al. 2012). As previously noted, the unit of analysis in this study was the micro-locational "street segment." Congruently with earlier research, the study found (i) a strong concentration of crime in "hotspots" (5–6 % of street segments each year accounted for c.50 % of crime incidents) and (ii) with some exceptions, a "tremendous stability of crime at street segments over a long period of time" (p. 56). Eight "trajectory [crime] patterns" were identified. Four of these (comprising 84 % of street segments) were stable over time, ranging in level from "crime-free" to "chronic crime"; the remainder showed increasing (4 %) or decreasing (12 %) trajectories. A multivariate analysis was then undertaken, in an attempt to uncover the factors that would predict a particular trajectory pattern in any given street segment. A principal feature of this analysis was an assessment of the comparative explanatory strength of (i) variables measuring the "opportunity perspective" (roughly, the kind of variables utilized in StCP and RAT) and (ii) variables measuring the "social disorganization perspective" (roughly, variables traditionally used in "neighborhood effects" research). Principal findings in the Seattle research were (i) that both these sets of variables were important contributors to explaining differential crime trajectory patterns in street segments, (ii) that opportunity variables had greater explanatory power than social disorganization variables in predicting variations in crime between micro-locations at any one point in time, and (iii) that social disorganization variables had greater explanatory power than opportunity variables in predicting changes in crime levels in micro-locations over time.

The first author of the Seattle study (David Weisburd) has been one of the leading researchers within the "hotspots" tradition. It is therefore noteworthy that in this study he and his colleagues deliberately set out to "broaden and expand the [traditional] theoretical foundations of the criminology of place" (p. 13), particularly by including variables representing the "social disorganization" (or "neighborhood effects") tradition – a tradition that, as they observe, had previously been "virtually ignored" by hotspots researchers (p. 43). Moreover, the results of the Seattle analyses strongly support the view that both "opportunity" and "neighborhood effects" dimensions need to be included within any full answer to the question "why are certain micro-locations hotspots, and others not?"

The second piece of recent research that aims to explain "why hotspots are hotspots" is the Peterborough Adolescent Development Study (PADS+) (Wikström et al. 2012). This study, which was conducted in the medium-sized city of Peterborough, England (pop. c. 165,000), differs in three main respects from the Seattle study: it uses a different methodology, it is significantly more theory-driven, and – because it reports data from the early stages of a longitudinal study of criminal careers – it is restricted to juveniles. Despite these differences, its results in no way conflict with the principal conclusions of the Seattle study.

PADS+ was conducted within the theoretical framework of Per-Olof Wikström's "Situational Action Theory" (SAT). SAT postulates that to understand how criminality arises, one needs to consider two matters: first, an individual's *propensity* to commit crime (defined as consisting of both the person's morality and his/her ability to exercise self-control) and, secondly, his/her *exposure to situations of varying criminogenic potential* (where *criminogenic exposure* is defined as "encounters with settings in which the (perceived) moral norms and their (perceived) levels of enforcement...encourage breaches of rules of conduct...in response to particular opportunities or frictions": Wikström et al. 2012, p. 17). The theory therefore envisages a possible *interaction* as between criminal propensity and environmental (geographical) conditions.

Two main types of "criminogenic exposure," both with a strong locational component, were considered in the Peterborough study, namely, that a young person spent time "unsupervised with peers in an area with high public entertainment" or "unsupervised with peers in a residential area with poor collective efficacy." Both of these conditions, for different reasons, provide increased opportunities for offending. Using a detailed interview-based "time budget" methodology, and measuring crime by self-reported offending on the days for which time budgets were compiled, the researchers found that, overall, a substantially greater number of crimes were committed when young people were in conditions of hypothesized criminogenic exposure than when they were not. For those with a "strong" criminal propensity, the difference in the rate of crime commission when "in" or "not in" a criminogenic environment was particularly marked (for both exposure conditions). On the other hand, those with a low crime propensity committed no crimes whether or not they were in criminogenic exposure conditions; for them, their strong anti-crime dispositions were able to override any temptations offered in criminogenic exposure conditions. Thus, the results show a genuine interaction effect as between the propensity of individuals and the environmental contexts of these locations.

Interestingly, the Peterborough results also showed that those with a high criminal propensity tended to spend more time in conditions of high criminogenic exposure than other young people. This finding therefore emphasizes – as the research of the Brantinghams had suggested in a different way many years before – the particular importance for the geography of crime of the routine activity patterns of those with a high criminal propensity.

The Symbolic Meanings of Places

In developing the "signal crimes perspective" (see above), Martin Innes and his colleagues conducted detailed qualitative interviews in 16 neighborhoods in England and Wales, asking representative respondents what they would identify as the key *potential threats to neighborhood safety* in their area (described in the theory as *signal crimes* and *signal disorders*). Not surprisingly, there was a good deal of local variation in the perceived threats identified in different localities. Nevertheless, a striking and largely unexpected result (although see not dissimilar concerns raised by Wilson and Kelling 1982) was that various kinds of *physical and social disorders*, not all of which were criminal acts, featured particularly strongly as perceived threats in the public responses *in all areas*. (Examples of such disorders included youths hanging around in groups, drug detritus, litter/graffiti, vandalism, and public drinking.) Indeed, such items were, in almost all areas, perceived as a greater threat to the area than residential burglary. These results appeared to be mainly explicable by the fact that the listed disorders are *events occurring in public space*, often with a strongly repetitive dimension: such events therefore seemed to send a powerful message to residents that "my area is out of control." As one respondent put it to Innes (2004, p. 348):

> Yes, it is daft, it is almost daft, but graffiti is the thing that sort of bothers me more, because it is in my face every day. I mean obviously rape and murder are more horrendous crimes, but it is graffiti that I see.

Thus, even quite minor incivilities in public space can, especially if persistent, be perceived as significant threats to peaceable daily living. This evidence is consistent with more general social scientific research results showing that disruptions of people's everyday routines can be perceived as significantly threatening to their sense of ontological security. Such results accordingly suggest that some earlier scholars in geographical criminology have neglected an important dimension of lived experience by focusing exclusively on crimes, rather than on both crimes and disorders.

Social Structure

The most important social-structural topic of relevance for geographical criminology is that of *social disadvantage*. In some countries, including the United States, this topic has a strongly ethnic dimension, but for reasons of space the discussion here will focus on disadvantage more generally.

A consistent finding in geographical criminology is that offenders' residences are very disproportionately located in more socially disadvantaged areas of cities (see, e.g., Fig. 1a). Given that many offenses are committed close to offenders' homes, it is also the case that socially disadvantaged residential areas usually have higher crime victimization rates than richer areas (see Fig. 1b), and, at least in England, national crime surveys also show that they have the highest rates of repeat disorders. These facts seem to most geographical criminologists to require a serious engagement with issues of social structure, although this view is not universally shared (see Felson and Boba 2010, p. 206, final sentence).

Of these various indicators, the resident offender rate normally shows the starkest contrast between rich and poor areas, and this raises the possible existence of a "neighborhood effect" on offending in such areas. In considering this issue, great care in interpretation is required, as may be seen from the recent meticulous research on juvenile delinquency in the Peterborough study (Wikström et al. 2012). On the one hand, social disadvantage is not explicitly part of the explanatory model tested and affirmed in this research (see above: the model, based on Situational Action Theory, is focused on criminal propensity and criminogenic exposure). Moreover, by no means all of the young people with a high criminal propensity lived in deprived neighborhoods. Nevertheless, in this study the researchers found that "population social disadvantage was a particularly important predictor of the number of resident young offenders" in a given area and that "social disadvantage and its influence on the efficacy of key social institutions such as the family and the school are clearly implicated in the understanding of why some young people develop a stronger crime propensity" (Wikström et al. 2012, p. 239). Clearly, some complex social dynamics lie behind these important results, and the authors intend that future analyses from the Peterborough study will explicate the issues more fully.

From results such as these (see also Wikström and Loeber 2000), it seems a reasonable hypothesis that moving children and young people from very socially deprived areas to less deprived areas should reduce their criminality, as well as providing other benefits to their families. These matters were tested in a large-scale randomized controlled trial known as the "Moving to Opportunity" (MTO) experiment, which was conducted in five major cities in the United States (Baltimore, Boston, Chicago, Los Angeles, and New York). So far as juvenile criminality was concerned, the results were unexpectedly mixed – on the best available evidence, the hypothesis of reduced misbehavior was confirmed for girls/young women, but boys/young men moving to less disadvantaged areas appeared to become *more* delinquent (Kling et al. 2007; Briggs et al. 2010; Clampet-Lundquist et al. 2011). Possible reasons for this gender difference, and in particular the counterintuitive result for boys, are discussed at the end of this entry.

In considering issues of social disadvantage, it should not be forgotten that patterns of both informal and formal social control can vary in areas of differing social status and that these are of potential criminological significance. This point was drawn starkly to criminologists' attention in the pathbreaking book by Lawrence Sherman (1992) analyzing the results of a series of experiments on police responses to domestic violence. In these randomized controlled trials, six American police departments responded to nonlife-threatening domestic violence incidents (where the assailant was still at the home) *either* by arresting the suspect *or* by some measure short of arrest. The results were more complex than had been anticipated. In summary, Sherman characterized three cities (Minneapolis, Colorado Springs, and Miami) as having shown a deterrent effect following arrest, while in three other cities (Omaha, Charlotte, Milwaukee) arrest appeared to have produced what was called a "backfiring effect" – that is, it seemed to *increase* subsequent violence among arrested suspects, by comparison with controls. This pattern of results naturally raised the question: "what…factors might explain the differences between the deterrent and backfiring effect cities?" The data showed that the strongest single area difference was to be found "in the proportion of black suspects, which averaged 63 % in the three backfiring cities…compared to 36 % in the three deterrent effect cities" (Sherman 1992, p. 18). In other words, differing *community characteristics* (including social disadvantage) in the six cities seemed to be at least partially relevant to the explanation of the results. On an individual (as opposed to areal) basis, the study also found that arrest was most likely to suppress subsequent violence if the suspect had high "stakes in conformity" (= employed and married) and least likely to suppress it when he had no such stakes (= unemployed and unmarried). Aspects of the interpretation of these results remain tentative, but it does seem from this research that the familial and communal relationships within which a person is embedded can significantly affect the manner in which he responds to an arrest (in principle, from deep shame to resentment against unfair police practices), and that such differences could affect the probability of subsequent violence against a partner. Referring back to an earlier discussion, one might add that the extent to which the policing in a neighborhood appears to its residents to be *legitimate* also seems potentially relevant – and this also might vary by social-structural context.

Before leaving the topic of social structure, a word must be added on the subject of *housing markets*. Housing markets are of great importance for the study of crime and criminality in residential areas, because the mechanisms of such markets strongly frame both who enters a given area as a resident, and how easy or difficult it is to leave the area if and when one wishes to do so. Of course, housing markets are often strongly influenced by economic factors (the rich buy large houses in desirable areas; the poor do not). However, economic factors are certainly not the only variables in play in shaping the operation of a housing market in a given area, for example, cultural questions or the reluctance of older residents to move might be very important in influencing exit decisions, and in some countries the allocative rules of public (or social) housing authorities are also relevant. In consequence, it is even possible for two adjacent areas with nearly identical economic and demographic characteristics to have radically different victimization and resident offender rates, flowing from the direct and indirect consequences of housing market processes (Bottoms et al. 1989). In short, as Robert Sampson (2009a, p. 90) has rightly commented, “because housing markets act as a mechanism of allocation, . . .they. . .need to be better integrated into sociological and criminological theory.”

Social Action

The third and final conceptual dimension to be considered, *social action*, is by its nature more dynamic than the other two – social actions are, after all, usually taken in an attempt to achieve certain consequences. Accordingly, this section contains more discussion of longitudinal theorization and research than previous sections.

The most famous longitudinal theory in contemporary geographical criminology is the *broken windows hypothesis*, originally formulated by Wilson and Kelling (1982) albeit in a somewhat informal and discursive manner. Taylor (2001, p. 98) has usefully formalized the proposed sequential stages of the Wilson-Kelling thesis; slightly modified, these stages are:

(i) Unrepaired low-level signs of incivility (e.g., broken windows, graffiti) appear in an area.
(ii) The local residents tend to withdraw from public areas and become fearful.
(iii) Emboldened antisocial locals commit more petty crimes, signs of incivility grow.
(iv) Local residents become more fearful and withdraw more.
(v) [Frequently but not inevitably]: Serious offenders from other areas note the lack of guardianship in the area and move in.

Thus, according to Wilson and Kelling (1982, p. 32), “the citizen who fears the ill-smelling drunk, the rowdy teenager or the importuning beggar is not merely expressing his distaste for unseemly behavior, he is also giving voice to a bit of folk wisdom that happens to be a correct generalization – namely, that serious street crime flourishes in areas in which disorderly behavior goes unchecked.” As regards policy responses, for Wilson and Kelling (p. 36) “the key is to identify neighborhoods at the tipping point- where the public order is deteriorating but not unreclaimable.” But others have gone further, linking the “broken windows” approach to zero tolerance policing, as in the following statement by former British Prime Minister Tony Blair (2010, p. 493): “if you tolerate the low-level stuff, you pretty soon find the lawbreakers graduate to the high-level stuff. So cut it out at source: tolerate nothing, not even painting a street wall or dropping litter.”

Empirically speaking, the evidence about broken windows is mixed. On the one hand, the Dutch research previously cited shows that a breach of a social norm (such as uncleared litter) does indeed, in the short term, encourage the breach of other norms. On the other hand, those empirical studies that have attempted to evaluate the broken windows hypothesis on a long-term basis have found little supporting evidence for the proposition that “disorder leads to serious crime” (Sampson and Raudenbush 1999; Taylor 2001; Harcourt and Ludwig 2006; Sampson 2009b).

Although further research is needed, on present evidence two matters seem particularly likely to explain the apparent tension between the short-term and long-term effects of “broken windows.” The first is that the final stage of the proposed Wilson-Kelling sequence (“serious offenders from other areas move in”) might often fail to materialize. St. Jean’s (2007) Chicago research (see above) showed that such offenders were usually more interested in nonresidential than residential areas as attractive sites for their activities; moreover, physical (as opposed to social) incivilities in residential neighborhoods were of no special interest to them. Secondly, the suggestion made by Tony Blair and others that one must “cut [incivilities] out at source,” or a downward spiral to “the high-level stuff” will inevitably occur, is incorrect. On the contrary, the literature contains several case examples of communities acting successfully at a later stage to ameliorate a downward spiral.

One such example is described in research by Taub, Taylor, and Dunham (1984). These researchers showed that two Chicago neighborhoods *with high crime rates* not only received positive "satisfaction with safety" scores in a residents' survey but also had rapidly appreciating residential property values. How did this unusual combination of factors arise? In both the areas concerned, "there [were] highly visible signs of extra community resources being used to deal with the crime problem" (Taub et al. 1984, p. 172). This observation has to be set within the context of another finding in the study, namely, that, in evaluating local areas, people make a generalized, *gestalt* judgement, taking into account a range of positive and negative factors, of which crime (and, by implication, disorder) is one. Within such a framework, the injection of "visible signs of extra community resources" is clearly a potentially positive factor.

The term "visible signs," used by these authors, is highly congruent with the later development, within the signal crimes perspective, of the concept of "control signals" (used in SgCP alongside the concepts of "signal crimes" and "signal disorders" – see above). "Control signals" are acts (particularly those taken by officials or by informal community leaders) that communicate ("send signals") to the general public, in a way that helps to promote the general sense of order in a neighborhood. An example within the Taub, Taylor, and Dunham research concerned the neighborhood that includes the University of Chicago. Anxious about decline in the area, university managers invested heavily in the local urban infrastructure and helped to introduce various initiatives that directly addressed citizens' worries about safety in public space – such as a private security force, 24-h "safety buses" and emergency telephones (Taub et al. 1984, pp. 99–102). This whole package of measures seemed to send a strong "control signal"; for while crimes such as burglary remained high (pp. 21–22), as previously noted, the area was perceived by the residents as safe, with rapidly appreciating property values. Thus, utilizing the trilogy of concepts around which this chapter is structured (space, social structure, social action), this was a powerful example of how *social action* can help to shape the future of a neighborhood. It seems likely – although we do not yet have fully confirmed evidence of this – that less dramatic but not dissimilar kinds of social action are not infrequently taken in other apparently declining local areas, with positive effects; and perhaps the apparent effect of improved street lighting on daytime crime levels (see above) results from similar social mechanisms. If these suggestions are correct, they could of course help to explain the lack of long-term evidence in support of the broken windows hypothesis.

It is not accidental, however, that in the above example the University of Chicago is a *corporate actor*. It is much easier for a corporate actor than an individual resident to send successful control signals; indeed, as Taub and his colleagues point out, for an individual household in a declining area, the instrumentally rational course of action will usually be to try to make a fast exit from the area. Thus, effective social action to halt social decline will probably normally require a lead to be taken by a public agency, a major private institution, or an active community organization. Thereafter, however, it is likely that local citizens will respond positively to the lead and feel emboldened to play their part in neighborhood renewal: recall that Keizer's (2010) experimental research in the Netherlands suggests that actions to reinforce prosocial norms, as well as actions that breach such norms, can have a "contagious" effect on the behavior of others in a locality.

Yet a final caveat is required. Sherman's (1992) study of domestic violence showed that police actions such as arrest can sometimes "backfire"; and the same, it would seem, is true also of residents' social action. For various technical reasons, it is not easy to provide a definitive explanation of the strikingly different results for boys and girls in the MTO experiment (see more fully Bottoms 2012). The most plausible account of the counterintuitive result for MTO boys is to be found in a detailed qualitative study in two cities (Baltimore and Chicago: see Clampet-Lundquist et al. 2011). According to this research, one of the factors in operation in these cities was that the adolescent boys who moved to less poor neighborhoods continued, in their new environments, to practice the dominant leisure activity they had learned in their previous home area, namely, "hanging out" with one another in public places. But, in the changed context, they found themselves less accepted by the local residents (possibly because these residents were wary of adolescent males who were known to have moved from stigmatized public housing projects). Moreover, the new areas had higher collective efficacy than the baseline neighborhoods and therefore – see earlier discussion – more adult interventions with teens. In consequence, "a negative side of collective efficacy" seemed to be apparent, that is, adult interventions were made, but they led to resentment from the boys (Clampet-Lundquist et al. 2011, p. 1171). This example therefore once again illustrates the very complex social dynamics of neighborhoods – dynamics that need to be taken fully into account in the study of the geography of crime and disorder.

Conclusion

Within the broad field of the geography of crime, a great deal of excellent research has been completed in the last two decades. However, much of this work has been conducted in relative isolation from those working in other parts of the field. A strong case can therefore be made for the adoption of a more integrated approach. Such an approach should in particular seek to synthesize more fully the work in the "hotspots," "neighborhood effects," and "signal crimes" traditions, each of which has contributed powerfully to our overall understanding of geographical aspects of crime and disorder. Such a synthesis should lead to improved understanding of the very complex social dynamics in play within this field. Potentially, also, it could have an important payoff in improved crime prevention, given the persuasive case that has recently been made for "the importance of place in policing" (Weisburd et al. 2010).

German Police Until 1918

Herbert Reinke
Bergische Universität Wuppertal, Wuppertal, Germany

Overview

Federalism is, except for periods during the twentieth century (Nazi Germany and communist East Germany after 1945) a key characteristic of political systems in Germany throughout the nineteenth and twentieth centuries. Due to this focal pattern of the German political system, there had been polices of the respective federal units during these periods, but no national German police. Early nineteenth-century administrative and political reforms established the police in many German states as a state prerogative, which manifested itself by the establishment of Gendarmerie forces. In Prussia, this Gendarmerie was to police the countryside, but in relation to major cities, the Prussian state commissioned municipalities with the establishment and the maintenance of an urban police, establishing state police forces proper in a few cities only. A comparable mixed system was established in some other German states as well. A characteristic, which was shared by almost all the polices in Germany throughout the nineteenth century and even during the first decades of the twentieth century consisted of the continuity of a comprehensive notion of police and policing, deriving from the Ancien Régime notion of "Polizey," beyond a modern, on law, and order maintenance focused understanding of police. Attempts were made by different actors (the police, the courts, members of the legal sciences) to narrow this comprehensive notion, but did not really touch upon the reality of police and policing in nineteenth-century Germany.

Due to "order" being a core issue of policing in Germany during the nineteenth century, crime and crime control was not a major concern of the police during that period. Until the First World War, only a minority of the major German cities had specialized crime investigation units among their municipal police forces. Because of this situation, the crime investigation department of the Berlin police headquarter became a key institution, as it professionalized increasingly its expertise for investigating complex and spectacular criminal cases.

The emergence of a political police and of political policing at the beginning of the nineteenth century was a correlate of the continuity of monarchist, bureaucratically framed regimes after the Napoleonic wars. Political policing regained momentum with the rise of the organized labor movement during the second half of the nineteenth century, when industrialization did set in Germany. Although political policing was seen by contemporaries as a significant policing pattern, the application of a comprehensive notion of police remained a key strategy for policing the emerging industrial society.

Police and Policing During the First Half of the Nineteenth Century

During the first decade of the nineteenth century, the Prussian government, because of the necessities to modernize Prussia on the background of its defeat in the war against Napoleonic France, a number of institutional reforms and governmental reorganizations were inaugurated, which were to bring the Prussian state into a position of meeting the challenges posed by Napoleonic France. These reforms touched upon the police in Prussia as well. During the Ançien Régime period, the police had either been a matter of urban authorities or had been carried out in the countryside by noble estate owners as part of their privileges. The early nineteenth-century reforms established the police as a state prerogative. This state prerogative was put into practice by the establishment of a – quantitatively – large-scale Gendarmerie, which, in the Prussian case, was to police the countryside, while, as far as the cities were concerned, the Prussian state commissioned municipalities with the establishment and the maintenance of an urban police, establishing state police forces in a few cities only. During the first half of the nineteenth century, the Prussian state established state polices only in those cities, which were seen as hotspots of political opposition and dissent. While the state polices were on the budgets of the Prussian state, it were the municipalities themselves which had to pay for their municipal police. During the 1860s, the Prussian state withdrew its state polices from a number of cities, leaving it to the municipalities to police them with municipal polices, the reason for this withdrawal being a mixture of budgetary considerations and changed security evaluations by the Prussian government.

The installation of the Gendarmerie, following the French example, was meant as introducing the state monopoly of power in the Prussian countryside, where the police until the reforms of the early years of the nineteenth century had been in the hands of the estate-owning nobility. Gendarmerie forces were created – except for Austria and the Habsburg Lands – in most of the German states. The reasons were similar across the states: The central governments in these states, often with new boundaries as a result of the Vienna congress, wanted a penetration of their authority into the whole of the state, were seeing the Gendarmerie as an appropriate instrument for creating some sort of identity among the inhabitants of the respective state and were using this force for policing the vagrant rural underclass, which was seen by contemporaries as a major threat. In Prussia, the introduction of the Gendarmerie was answered by the estate-owning rural nobility with (in the end successful) large-scale protest and opposition, resulting in a massive decrease of the Gendarmerie force and a restitution of the Ançien Régime model of policing the countryside by combining property titles (estate ownership) and police functions. In Prussia, the figures for the Gendarmerie forces were, in comparison to Gendarmerie forces in other German states, extremely low: In 1848, there were 8 gendarmes per 100,000 of population in Prussia, 52 per 100,000 of population in Baden, 52 in Bavaria, 40 in 1839 in Brunswick, 23 in Hanover, 10 in Saxony, and 25 in Württemberg (Jessen 1991). When looking at these figures and when taking into account, that the Prussian state left the policing of cities in most cases to communal or municipal police forces, then it might look as if Prussia had been underpoliced during the first half of the nineteenth century. But that does not take into account the massive presence of the military in very many Prussian cities. The Prussian military, having garrisons in quite a number of Prussian cities, did have in the respective cities policing prerogatives. In 1840, 53 % of the urban population of Prussia lived in a city, which held a garrison. State and communal or municipal officials continuously relied on the military in any case they considered an emergency for public order and safety. The interventions of the military into everyday urban policing matters have been interpreted as a significant militaristic impact on policing in Prussia during the nineteenth century (Lüdtke 1989). Additionally, the Berlin police headquarters became a key institution for the policing of politics in Germany (Fricke 1962).

Political Policing in Nineteenth-Century Germany

The emergence of a political police and of political policing in Germany at the beginning of the nineteenth century is a correlate of the continuity of monarchist, bureaucratically framed regimes after the Napoleonic wars. During this so-called period of "restauration" after 1815, the monarchist regimes of the German states aimed at defending their regimes against the growing demands of the bourgeoisie for political participation. In order to control political opposition, the Prussian government established after 1815 a number of government commissions. A similar model for supervising the political opposition was adopted by the German Federation, which did set up interstate government commissions not only for controlling opposition movements, but for disseminating information among the governments of the German Federation. The strategies of these government commissions were rather retrospective, focusing on political incidents, which had happened already, although elements of proactive control patterns were introduced as well already during this period. One of the Prussian government commissions became charged with examining the political reliability of teachers, which were to be employed, and with examining the political positions of candidates for the clergy and the judicial professions. This cooperation was enforced after the defeat of the revolutionary movements in the German states in 1848/1849. During the 1850s, when it became visible, that the revolutionary initiatives of 1848/1849 would not gain ground and significance again, these control activities were gradually reduced.

Political policing regained momentum with the rise of the organized labor movement. Together with the introduction of repressive legislative instruments for suppressing the organized labor movement after the foundation of the German Empire, a specific state police commissioners were introduced, which were to supervise the organized labor movement and organized groups of foreigners, such as members of the Polish minority. Municipalities were reluctant to establish political police branches within their municipal police forces, but the Prussian government circumvented these problems by establishing this nucleus of a political police strictly as a state police, thus creating the first political police proper in Germany.

Policing Nineteenth-Century Industrialization and Urbanization

Prussia and other parts of Germany have been, in comparison with countries and regions in Western Europe, latecomers as far as industrialization and urbanization were concerned. In Germany, large-scale industrialization and urbanization did not set in but after the beginning of the second half of the nineteenth century. In Prussia, the major industrial areas with their rapidly growing urban conglomerations were mostly covered up to the first years of the twentieth century by communal or municipal police forces or by a few gendarmes only. It was only in 1909, that in some towns of the Ruhrgebiet area in the West of Prussia, the municipal police forces were transformed into proper state polices (Funk 1986; Jessen 1991; Spencer 1992). In the cities with municipal police forces, the police remained principally part of the state prerogative on the monopoly of power. In these cities, the mayor represented this prerogative by being the official head of the local or municipal police. While the mayor was the head of the municipal administration, elected by the city council he was at the same time, with respect to his duties as head of the police in the respective city, executing state functions and had thus to obey state orders. Due to these specific patterns of police organization, the Prussian state could theoretically intervene in everyday municipal matters, although in practice, the cities had many possibilities for diverting or impeding such attempts. But more important was that municipalities had police competences of their own. Prussian legislation in 1850 and legislation on the municipalities had given the municipalities in Prussia ample competences regarding police matters, as it had provided the legal frame for issuing police ordinances concerning local matters (Jessen 1991). The municipalities operated within this frame extensively by issuing thousands of police ordinances until the First World War.

The overall appearance and organization of municipal police forces in Imperial Germany, not only in Prussia, was connected to Ançien Régime model of the police, the "Polizey." Under this model, policing covered virtually the entire complex of local administration, control, and regulation. This global police model was most visible in the towns that had municipal police forces. By the middle of the nineteenth century, the police in Elberfeld, which had been by that time one of the early industrial towns in Prussia, comprised among others the night watch; the police of strangers and the police of pubs and inns; the health-police and the life insurance-police; the medical police; the police of the religious cults; the educational police; the police of morals and order; the trade's and business' police; the police of measures and weights; the building-police; the fire-police; the police of the roads; the market-police; the police of the hunt; the forest-, field-, and agricultural police; the river-police; and the police of the dogs (Reinke 1992, 1993; Spencer 1992). Shortly before the First World War, communal policemen still spent much of their time carrying out routine duties relating to these duties, such as distributing tax and registration forms, enumerating buildings and animals, keeping lists of children to be vaccinated, and men liable to military service, providing a variety of identity papers needed by citizens, making certain various fees were paid, and licensing and inspecting a wide range of enterprises and activities (Spencer 1992). By the beginning of the twentieth century, numerous older police responsibilities had either lapsed or been transferred to newly emergent, specialized agencies. Fire fighting and street lighting, for example, were removed from police budgets. As urban service providers became more diverse and specialized, social welfare workers began to assume some functions policemen had performed in the past. In some cities, female welfare workers were taking over from the police the placement and supervision of foster children as well as the counseling of "morally endangered" women and girls and of unmarried couples living together, hoping that this approach would prove more beneficial than a police intervention only. At the same time, however, that the police cooperated with the new social workers in regulating the behavior of those who were poor, transient, or otherwise outside the limits of respectable society, determining what behavior was permissible and what forbidden. All this meant that despite reassignment of duties, little overall narrowing of police functions occurred in the cities (Spencer 1992). The shedding of some older police assignments was counterbalanced by the imposition of new ones. Communal policemen remained deeply involved in many aspects of the daily lives of the city's inhabitants, especially when they were members of the working class. Among police responsibilities were those arising from official concern with public health and sanitation. Before the First World War already, more and more health-related supervising was transferred to technically trained specialized personnel, but much remained for the police to do. Policemen inspected latrines and monitored the removal of wastes. Continued police responsibility for the control of stray dogs was also in part a health measure, linked to prevention of rabies. Furthermore, concern with public health could be used as one justification for the inspection of housing, another major task for the police, even where specialized urban housing inspectors had been appointed. In Düsseldorf in 1909, the police inspected 16,828 dwellings, whereas the city's housing inspectors examined only 2,891. The municipal administration described inspections by the police as a service to tenants, making it possible for renters to bring pressure on their landlords to correct deficiencies (Spencer 1992). At the same time, however, inspections of rental housing provided the authorities with an excuse for increased police observation of the private lives of poorer citizens. Special attention was paid to households including boarders, since worried bourgeois observers of working-class life saw the presence of outsiders in a family setting as fraught with potential for increased immorality. However, efforts to prevent overcrowding and thereby presumably to lessen temptations to promiscuity often proved impossible to enforce because of the lack of alternative accommodations in rapidly growing industrial cities. Representative of the catchall nature of many responsibilities assigned to the police was the decision to entrust them with the maintenance of lost-and-found services. In Elberfeld, the police also took the initiative in establishing and staffing facilities enabling the public to call taxis, with operating costs being paid by the taxi owners. In their expanding regulation of markets, local transport, and insurance contracts, the police cast themselves as the guardians of consumer interests, often arousing the resentment of small traders, carters, and cab drivers in the process (Spencer 1992).

Among the most troublesome of requests for intervention that came to the police were those linked to master-servant relations. Until 1918, police remained responsible for monitoring contracts entered into by domestic servants. When difficulties arose, both sides to a dispute might turn to the police for support. The police could try to mediate or impose fines to force compliance with their decisions, but they could not really make someone work in a household who refused to do so. Disputes between landlords and tenants and among neighbors often proved equally intractable.

With requests for intervention and assistance coming from so many sources, the communal police tried to free themselves from some of their most menial and irksome tasks. But their successes remained limited. In Elberfeld in 1906, for instance, the police informed a local school that they could not, without detracting from "real police responsibilities," repeatedly delegate patrolmen to conduct truants to school. In that same year, however, Düsseldorf policemen accompanied 567 reluctant boys and girls to schools of various kinds (Spencer 1992). During the decades, which preceded the First World War, statistical figures for issuing fines against parents and for accompanying boys and girls to schools showed that these tasks were a main activity of municipal patrolmen (Reinke 1991).

As in the past, many new tasks were transferred to the police simply because they represented a widely dispersed body of public servants, available on an around-the-clock, 7-days-a-week basis, and with closer contact to the daily life of the general populace than most public employees had. In addition, utilization of the communal police for a wide variety of highly visible services helped legitimate their costly and intrusive presence in the eyes of city councilmen and local taxpayers. A considerable number of the nineteenth-century police functions remained effective until the end of the Empire in 1918, and Elberfed was not unique in this among the major industrial cities in the West of Prussia. However, the continuity of the "Polizey" approach should not be misconstrued simply as conservative administrative behavior. Often, the various police were the nuclei of service-orientated departments of the city administrations. Attempts to narrow and to concentrate police functions on the maintenance of law and order were launched in the decade before the beginning of the First World War, but they became decisive only at the beginning of the Weimar Republic.

Policing the Industrial Society

Policing industrial society implied two approaches for the Prussian police during the Empire: on the one hand, in the tradition of the old "Polizey" model of policing, it meant control of the consequences of industrialization, in terms of environmental damage, control of the conditions of labor, etc., with some of these police activities being executed by the so-called trade and business police ("Gewerbepolizei"). But in practice, the police restricted their activities in this field to controlling and supervising traditional crafts and enterprises rather than intervening in the structures and the development of industrial enterprises.

Policing the industrial society meant of course on the other side the control of the working-class population with its unions and political organizations, mainly the Social Democrats: In the industrial society of Imperial Prussia, they were the main object of the control and repressive activities of the police. The legal system of the German Empire allowed for an extensive control of the working class by the police. Repressive legislation against the Social Democrats ("Sozialistengesetz") constituted the basis for a real police war against the unions and the Social Democrats, which took place from the end of the 1870s to the end of the 1880s. But when this legislation did not find a parliamentary majority any more, other measures were applied: When used against the activities of the organized working class, the exercise of extensive police discretion was very often approved by court decisions; legislations on associations ("Vereinsgesetz") allowed all kinds of police interventions and repression of the political mobilization and organization of the working class; the "Gewerbe-Ordnung," the law that regulated business activities and labor conditions, provided possibilities for breaking strikes (Saul 1974).

The early 1870s after the Franco-Prussian war were the period, when industrialization accelerated its pace in Prussia, resulting in a period of cumulative developments. The economic boom immediately after the Franco-Prussian war was followed by a deep depression with all its economic and social consequences. During these years, there was not only industrial activity, but also the spread of moral panics, and the rise of moral entrepreneurs launching their campaigns. Fears of danger to law and order and the increase of criminality were major themes of public discussion in this period. Although not all the higher public officials in the Prussian state administration took the moral panics of this time at face value, the state police administration seized the opportunity for promoting an increase in the number of royal policemen at the beginning of the 1880s. Starting with a ratio of one policeman to 1,500 inhabitants in the 1870s, the Ministry of the Interior improved this ratio gradually to 1:700 by the beginning of the new century. The state administration put pressure on the municipal police forces to come up with an improved police-population ratio as well, and by the 1880s a ratio of 1:1,500 was recommended for municipal police forces (Funk 1986). The symbolic representation of police forces, which were to expand were often given expression by impressive new police headquarters buildings. Significantly, the police headquarters in Berlin was the second largest building after the royal palace. The rise in the figures of the police personnel did not match the figures for the growth of the population, in particular in the industrialized West, along the Rhine and in the Ruhr area, were the figures for police personnel per 100,000 of population fell or stagnated during the 1880s before rising steadily again in the 1890s after strike actions by the miners in the Ruhr area (Jessen 1991).

Another measure for coping with the threats, which were seen as endangering society during this period resulted in institutionalizing a separate crime investigation branch within the police, the Kriminalpolizei. The Berlin Kriminalpolizei engaged itself intensively into the scientific policing during the later years of the nineteenth century and became not only in Germany as police institution a celebrity. But the impact of the institutionalization of a separate crime investigation branch remained limited. It remained very much Berlin based with some follow-up establishments in other very large German cities. But only few police headquarters in other Prussian cities institutionalized similar crime investigations in their departments or did so shortly before the First World War only (Funk 1986).

A major test of the effectiveness of police control and intervention was the first big miners' strike in 1889. This strike, whose scale was without precedent in German history, caught the municipal and state administrations completely unprepared. The Prussian Army was called upon; the intervention of the military finally led to a breakdown of the strike movement. But because of the strict military logic, the Prussian army applied against the strike movement and because of complex and difficult Prussian state authority – Prussian military relations, Prussian state authorities refrained until the First World War from using extensively the military as police in industrial disputes (Johansen 2005). Instead, strategies for enhancing the presence of state police in Ruhr area were enhanced. One measure was the establishment of state police administrations in three cities in the Ruhr area in 1909 (Funk 1986; Jessen 1991). Up to that time, these towns had been policed by their own municipal police forces. To this point, the state administration had pursued very ambivalent policing strategies in the Ruhr area, the "Wild West" of the Empire. Before the outbreak of the strike in 1889, policing in this area was carried out at a very low quantitative level, as compared to other parts of Prussia. While the industrial and urban development in the Ruhr area was already progressing rapidly, the Prussian state administration maintained the previously appropriate rural-cantonal administrative organization of this region, with a state representative at its head and a few policemen and gendarmes for policing it. This led to administrative patterns such as industrial villages with more than 100,000 inhabitants. To cope with this insufficient situation, a second measure, besides introducing a state police in three Ruhr area cities, was discussed, which consisted of deploying more Gendarmerie in the area. This measure, which was never put into practice, included an increase of the gendarm-population ratio per 100,000 of population to 28 and the establishment of Gendarmerie barracks. But Prussian state administrators nevertheless headed for turning the Gendarmerie gradually into Prussia core police force for policing the industrialized society. Shortly before the First World War, 45 % of Prussia's Gendarmerie was based near to Prussia's major industrial centers, in the East in Silesia, around the heavily industrialized capital Berlin, and in the West in the Ruhr area and along the Rhine (Funk 1986).

The Recruitment and the Training of Nineteenth-Century Police Personnel

Who could become a member of the police force in Prussia? There are some resemblances to patterns to be observed in France during the nineteenth century. In theory, previous service in the Prussian army for 9–12 years was an absolute prerequisite for being recruited into the uniformed Police in Prussia. Thus, the ranks of the uniformed policemen on the beat were supposed to be filled with non-commissioned officers (NCOs). Military service as a prerequisite for admission to the police served several functions: the NCO policeman was supposed to represent king and state in the everyday life of the citizen. His superiors expected him to show his derived authority, and, if necessary, to compel compliance to this authority from the public. On the other hand, long training within the military hierarchy was supposed to have made him an obedient servant to his superiors and a reliable instrument for maintaining law and order. But in reality, this recruitment pattern worked partially only. Although the civil service did have a high social ranking, the position of a uniformed patrolman had a low ranking on this list. Getting a job in the police was not what an army NCO necessarily looked for after years of military service. For many NCOs, the job of a policeman was only a transitory phase on the way to a quieter existence in the civil service than the police service could offer. In Berlin, for example, whose royal police was to serve as an example for other polices in Prussia, more than 2,000 policemen left the police force during the 1890s. The Berlin police force totaled about 4,000 men in the middle of the 1890s. A quarter of those who left the police went into other positions within the civil service. Due to these turnover rates, a large number of police posts were permanently vacant. Not only in Berlin, but other Prussian cities also had to cope with this situation. During the 1890s and again during the first decade after the turn of the century, the Prussian state administration tried to solve the turnover problem by reducing the military service requirements for employment in the police force. As a result, more men were drawn into the police service. The 9–12-year's military service remained nevertheless the ideal requirement looked for when conceiving a real Prussian patrolman on the beat. Those policemen who had acquired their post on the basis of the reduced requirements were often considered as some sort of second-class policemen (Reinke 1991).

Vacancies in the civil service, the police included, were announced and advertized by state and city administrations in public lists and journals. But the police posts offered regularly outnumbered applicants from the NCO's ranks. Cities with municipal police forces therefore reduced their employment requirements by recruiting men for the police service who had only fulfilled their obligatory military service after conscription, rather than service as regulars. By the 1880s, and much more so after 1890, cities in the West of Prussia, along the Rhine and in the Ruhr did find it increasingly difficult to recruit candidates with the adequate military background. While some cities reported during the 1890s that they were still managing to staff the municipal police positions accordingly, other cities found the supply of candidates with the requisite military experience falling ever more short of their needs. By 1911, the police department in Düsseldorf, one of the largest cities in the Prussian West, with 46 patrolmen's positions to fill, reported that of 500–600 applicants, only 22 had the adequate military background. Thus, despite persistent pressure from the Prussian state to seek out NCOs for police service, the cities in the Prussian West turned increasingly to the local wage-earning population for recruits. Urban administrators usually did so reluctantly, sometimes continuing to see the ideal policeman not just as someone shaped by long years of military discipline but also as someone from the outside, preferably of rural or small town origin. But the reality was that most applicants were local residents with only minimal military experience. As a consequence, the possibility of recruiting of policemen having personal contacts with organized workers loomed ever more threatening (Spencer 1992).

The training of policemen was carried out on the job and was oriented along the practical requirements of the man's on the beat everyday activities. The patrolman had to get acquainted with his precinct and with the things he was supposed to look after when on the beat. A number of "formalities" were also briefly taught, such as some basic ideas about the penal code of the Empire, the police ordinances that had been issued for the respective city or community, etc. Apart from that, the writing of dictations was part of the training. Often this was essential because the men's ability to write seems to have suffered considerably during the long years of military service. But all in all, serious training did not take place. Around the turn of the century, the Prussian state government as well as municipal police administrations acknowledged an urgent need for an improvement in the policeman's qualifications. In order to ensure better-qualified personnel, police schools were set up. And additionally, the military habits of the ordinary policeman were no longer deemed sufficient for the handling the everyday problems the police encountered in the growing urban contexts. The more Prussian cities grew and the more complex urban society became, the more qualifications were required from the policeman beyond his authoritarian and military attitude. In 1899, the first police school was established in Prussia, as a school for the Gendarmerie. The Gendarmerie took the initiative, since for this force, which was still part of the military, the problem was the most urgent. In 1901, the first police school for municipal police personnel was set up in Düsseldorf. The costs of the schools were covered by those municipalities who sent their police men there. But usually these schools were relatively small and few policemen were sent to there. In general, municipal administrations accepted the necessity for improving the qualifications of their police personnel, but for financial reasons, they kept down the number of men they sent to these schools.

Similar institutions were being established in other Prussian districts as well at about the same time, beginning with Berlin in 1895. Police schools were intended not only to impart necessary knowledge and approved attitudes but also to raise police prestige. Increased formal training (whatever its content) would bridge the gulf between policemen and respected representatives of the Prussian state. In Düsseldorf, the course for patrolmen lasted 2 months and that for senior officers for 3 months. Students were required to live at the school so that its influence could prevail around the dock. The cities paid the costs for the patrolmen, fearing that if the men were required to use their own resources they would fall into debt, a situation the policemen were strongly encouraged to avoid. The senior officers, expected to come from somewhat more well-off families, had to pay for their own instruction. Cities tried to protect their investment in the candidates by stipulating that those who left their departments after less than 5 years had to repay all or part of the costs of their schooling. Also, attendance at the school was typically reserved for those recruits who had already completed 6–12 months of service. As justification for this fiscally prudent move, police administrators argued that schooling was more meaningful if it followed a substantial period of practical experience. By 1906, the state district administration in Prussia had stipulated that in cities of 10,000 or more, patrolmen either had to attend the police school or pass an examination before being confirmed in their posts. Supporters of the Düsseldorf school were dismayed to find that many communal police departments, to save the cost of instruction, either tried to hire recruits who had already attended a police school elsewhere or else encouraged the taking of the examination. To make certain that the Düsseldorf school had enough students to pay for itself, the Prussian provincial administration before the war was contemplating eliminating the examination option. As a step toward making municipal policemen more credible as rule enforcers by increasing the likelihood that they knew and understood the rules and what they were doing and for what purposes, the Düsseldorf police school represented only a hesitant beginning (Spencer 1992).

A Note on the Historiography of Nineteenth-Century German Policing

Police history had a late start in Germany. Except for a few legal history studies, police history was not part of a mainstream in German historiography but rather the exception until the end of the 1970s (for the exceptions see Koselleck 1975; Maier 1986). In the context of new thematic issues arising during the 1970s and 1920s within German historiography, emerging studies on the history of nineteenth-century police focused on the functions and the role of the police in eminent political issues, which were at the core of politics in nineteenth-century German states, such as the relationship between the police and the military in Prussia (Lüdtke 1989; Johansen 2005) or the emergence of political policing during the first half of the nineteenth century (Siemann 1985).

The first German study, aiming at a comprehensive historical analysis of the police within the economic, political, and social structures of this period, has been published in the mid-1980s by a political scientist (Funk 1986), relating organizational patterns of the police, its everyday practices included, and describing police development in Prussia as a correlate of the increasing economic, social, and political cleavages within Prussia. The author analyzes how the ruling old and the new Prussian elites sought to cope with the threats to the economic, the social and the social order, deriving from what was seen as an overall change, by trying to increase the quantitative and qualitative strength of the state police and the Gendarmerie. The working class and its organizations were among these threats, but urbanization created a major moral panic as well.

While these early studies of a renewed look at the police concentrated very much at the political systems level or did put a focus on Berlin (e.g., Funk 1986), more recent studies, focusing on the local level, in particular on urban policing in other Prussian and German cities, have described the complexities and the contradictions of nineteenth-century policing in Germany and the attempts to modernize and professionalize urban policing (Reinke 1991, 1992, 1993, 2000, 2000a; Spencer 1992; Jessen 1991; Roth 1997). This modernization and professionalization has been seen by the research as strategy for adjusting the police to the growing control requirements, originating from industrialization and urbanization patterns. But urban policing during this period meant not only the enhancement of what could be seen as modern control strategies: a major characteristic of urban policing during this period was the persistence of large-scale welfare functions as part of police functions, thus placing police practices at the turn of the nineteenth to the twentieth century to some extent into the continuity of Ancien Régime *Polizey* models. These patterns resulted in an overpolicing, being abolished only gradually. This continuity created a legacy, which lasted until after the Second World War, when "police" and "welfare" became separated during the occupation of Germany by the victorious Allied forces (Reinke and Fürmetz 2000b).

Overview

The Good Lives Model (GLM) is a strengths-based theory of offender rehabilitation. The purpose of this essay is to (i) briefly overview the desistance literature; (ii) describe the risk management approach; (iii) highlight its limitations, including its weak fit with desistance theory and research; and (iv) provide a detailed description of the GLM. The GLM incorporates the advantages of the risk management approach at the same time as addressing its limitations. It can be argued that it provides social workers and other professionals with a more comprehensive framework to guide their work with clients in the criminal justice system.

Introduction

The rehabilitation of offenders is a complex process and involves reentry, and ultimately reintegration, into social networks and the broader society. While offenders need to work hard at modifying their personal characteristics that are related to their offenses, the community also has a responsibility to support this personal work with social capital and resources. Once individuals have begun to serve their sentence, they are entitled to have a chance at redemption and reconciliation. The presumption of human beings' equal value is a cornerstone of a decent and just society. It applies to offenders as much as to all humans. Furthermore, the rehabilitation of offenders is a normative and strength-building process, and therefore, from a practice perspective, both science and ethics are equally important. It is only legitimate to inflict significant harm (i.e., compulsory treatment) upon others when all human beings are regarded as equal in dignity and moral standing (Laws and Ward 2011).

Practitioners need rehabilitation theories to help them navigate through the various challenges and problems that materialize when working with offenders. These rehabilitation theories function as a conceptual map and facilitate effective intervention. Ideally, these maps will provide guidance on important issues such as the overall aims of intervention, what constitutes risk, what the general causes of crime are, how best to manage and work with individuals, and how to balance offender needs with the interests of the community. In recent years, strengths-based or "restorative" approaches to working with offenders have been formulated as an alternative to the very popular Risk-Need-Responsivity model of offender rehabilitation. In short, risk management approaches primary practice focus is on the detection and modification of dynamic risk factors (i.e., criminogenic needs), while strengths-based perspectives aim to create competencies in offenders and reduce risk more indirectly.

Offenders *are* "people like us" (Laws and Ward 2011). It is necessary to start relating to them in ways that reflect this attitude to improve correctional outcomes and reduce reoffending rates. The desistance research is clear that offenders respond well to practitioners who show an interest in them and believe in their capacity to turn their lives around (McNeill et al. 2005). Treating offenders with respect and decency rather than as sources of contamination to be quarantined (not cured) is likely to reduce the risk of practicing an ineffective confrontational therapeutic style (RNR; Andrews et al. 1990). Most information in this text is drawn on the sexual offending literature; although equally applicable to general offending, the GLM was initially developed in reference to the sexual offending literature.

Desistance from Crime

In contrast to the forensic psychology literature's focus on individual factors implicated in offending and reoffending, the desistance literature seeks to understand the lifestyle change process associated with cessation of crime (e.g., Laws and Ward 2011; Serin and Lloyd 2009). To suggest that a reduction in dynamic risk factors solely explains desistance seems to be unconvincing. Such an explanation is arguably somewhat simplistic and does not account for the very nature of human beings. Rather than being passively determined by external circumstances, humans actively seek outcomes that are personally meaningful and valued. The desistance literature disentangles *how* offenders change in regard to dynamic risk factors. Therefore it provides a richness not captured by the forensic psychology literature (Laws and Ward 2011). Available evidence indicates that there are a number of social and psychological factors that assist the desistance process (Laws and Ward 2011). These factors were named, for example, as "turning points" (Laub and Sampson 2003), "hooks for change" (Giordano et al. 2007), a "change in narrative identity" (McNeill et al. 2005), or "making good" (Maruna 2001).

Perhaps the most significant contributions to the desistance literature in recent years are those of Laub and Sampson (2003) and Maruna (2001). Laub and Sampson conducted an extended and comprehensive follow-up of men from Sheldon and Eleanor Glueck's landmark research (Glueck and Glueck 1950). They were interested in factors that differentiated serious and persistent delinquent boys from a matched group of nondelinquent boys. Laub and Sampson found that conventional adult social bonds such as marriage and employment explained variations in crime. Other variables, like childhood adversity, did not predict these. Specifically, they found that strong social bonds, for example, strong marital attachment and job stability, could facilitate the lifestyle change required for criminal desistance. Their findings have been replicated throughout the desistance literature (e.g., Maruna 2001; see below), and similar findings have been reported in the forensic psychology literature (e.g., Hanson and Harris 2000). Laub and Sampson also replicated the long-standing finding in criminology that frequency of offending decreases with age. They furthermore acknowledged the role of human agency, noting that men who desisted played an active role in their desistance process through making explicit choices to disengage from crime. Maruna (2001) replicated Laub and Sampson's findings regarding the significance of social bonds but also found that human agency or cognitive transformation (i.e., creation of a new, conventional, more adaptive narrative identity) was a key element in desistance. In sum, both external factors (e.g., social support, access to employment opportunities) and internal factors (e.g., making a conscious decision to want a different life) are required to facilitate the lifestyle change process associated with desistance. Desistance is the central aim of offender rehabilitation. In the following paragraphs, the risk management approach and its failure to account for the desistance literature will be contrasted with a recent strengths-based rehabilitation model, the Good Lives Model of Offender Rehabilitation.

The Risk Management Approach to Offender Rehabilitation

The risk management approach to offender rehabilitation emerged from Andrews and Bonta's influential book, *The Psychology of Criminal Conduct* (PCC; Andrews and Bonta 2010). The PCC sought to explain criminal behavior through empirically derived predictors of recidivism using what Andrews and Bonta termed a *general personality and social psychology perspective*. The PCC provides three empirically based principles aimed at reducing offenders' risk of recidivism: *risk*, *need*, and *responsivity* (Andrews and Bonta 2010). Hence, an underlying assumption of the risk management approach is that offenders are primarily containers of risk for recidivism, and the sole aim of offender rehabilitation is to reduce this recidivism risk through adherence to the RNR principles. The risk principle states that the dosage or intensity of interventions should match an offender's risk level. Therefore, low-risk offenders should receive less intense or no intervention, whereas high-risk offenders should be subjected to very intensive treatment. The needs principle incorporates that interventions should target criminogenic needs, also known as *dynamic risk factors*. Those factors are causally related to offending and are changeable. Dynamic risk factors include antisocial attitudes and antisocial associates (Andrews and Bonta 2010) and in the case of sexual offending, deviant sexual interests and self-regulation difficulties (Laws and Ward 2011). The aim of treatment is to reduce dynamic risk factors and, according to the need principle, directing intervention efforts at non-criminogenic needs will prove ineffective. For example, non-criminogenic needs such as low self-esteem and a history of victimization should not be targeted in treatment, given they have not been linked with recidivism (Andrews and Bonta 2010). Finally, the responsivity principle informs the actual delivery of interventions in order to maximize their efficacy. The responsivity principle involves matching the style and mode of intervention to the offender's learning style and abilities (Andrews and Bonta 2010). General responsivity advocates structured cognitive behavior therapy (CBT) interventions, given their general acceptance as the best treatment currently available for sex offenders (e.g., Hanson et al. 2002). Enhancing specific responsivity requires considering cognitive ability, learning style, personality profile, culture, and other characteristics of individual offenders and delivering treatment accordingly. The RNR has been hugely influential in offender rehabilitation initiatives internationally, forming the basis of correctional treatment since its inception in the early 1990s.

Although meta-analyses have found support for the efficacy of RNR-based treatment programs in reducing recidivism among general and sexual offenders (e.g., Hanson et al. 2009, 2002; Lösel and Schmucker 2005), some researchers argue that the available evidence is insufficient to conclude current treatment programs are in fact efficacious (e.g., Marques et al. 2005). Research suggests that a considerable amount of treated sexual offenders recidivates (e.g., Hanson et al. 2002). Thus, substantial scope remains for improving sex-offender rehabilitation and reintegration initiatives. In this entry it is argued that the Good Lives Model (GLM) offers exciting promise for further enhancing the effectiveness of current efforts by addressing limitations of the risk management approach, which are expanded on in the following entry.

Limitations of the Risk Management Model

The most heavily cited criticism of the RNR model revolves around its failure to motivate and engage offenders in the rehabilitation process (e.g., Mann 2000). Attrition from sex-offender treatment programs is particularly high with reported rates as high as 30–50 % (e.g., Ware and Bright 2008), which have been attributed to poor treatment engagement (e.g., Beyko and Wong 2005). Consistent evidence shows that men who drop out of treatment are more likely to reoffend compared to treatment completers (e.g., Hanson et al. 2002; Marques et al. 2005) as well as untreated comparison groups (Hanson et al. 2002). Without addressing the problem of treatment attrition, current treatment programs fail to deliver to groups of sex offenders most requiring treatment (Beyko and Wong 2005) and therefore fail to adhere to the RNR risk principle. Thus, although empirically derived, in reality the risk principle is difficult to adhere to.

What is behind the failure of the risk management approach to engage clients in rehabilitation? At the outset, the risk management approach differs substantially from therapeutic models used with other client populations (e.g., in the treatment of mental health problems) in the orientation of treatment goals, limited collaboration between client and therapist, and limited attention to problems not causally related to the problem behavior (i.e., in the case of offending – non-criminogenic needs such as self-esteem or personal distress). Addressing the first issue, risk management interventions rely profoundly on *avoidant* goals. These treatments try to encourage hypervigilance to threats of relapse and the reduction of dynamic risk factors (Mann 2000). By contrast, *approach* goals provide an individual with direction toward his or her goal. It has been suggested that individuals focused on approach goals concentrate on positive outcomes and thus persevere longer than people motivated by avoidance goals, who tend to focus on threats (Ward et al. 2007). Reframing the overarching goal of treatment (i.e., reducing risk of reoffending) as an approach goal might be “to become someone who lives a satisfying life that is always respectful of others” (Mann 2000, p. 194). This approach goal remains consistent with avoiding relapse. The final goal of avoidance of reoffending can be separated into personally meaningful subgoals that provide offender clients with direction in life, for example, increasing confidence in socializing with adult partners. Thus, by using approach goals, treatment can help offenders live a better, more satisfying life, not just a less harmful one, in ways that are personally meaningful and socially acceptable – and risk reducing (Mann 2000). In fact, it is likely that the combination of approach and avoidance goals is implicated in successful desistance. A balance between something that is hoped for – a better life – and what is feared for, i.e., recidivism, is thought to be more effective in reaching one’s ultimate goal (Paternoster and Bushway 2009). The resulting motivation can be seen as additive, because it incorporates avoidance and approach goals. Indeed, Mann et al. (2004) showed that an approach-goal-focused intervention with sex offenders was associated with increased treatment engagement compared to a traditional avoidant-goal-focused intervention.

Secondly, treatment goals in the risk management approach are enforced upon offenders rather than mutually agreed upon in therapy (Mann 2000). This can compromise the therapeutic relationship. Marshall and his colleagues (e.g., Marshall et al. 2003) demonstrated that confrontational therapeutic styles had a negative impact on attitude and behavior changes. Displays of empathy, warmth, encouragement, and some degree of directiveness facilitated treatment change. This suggests that careful attention to the therapeutic relationship might increase treatment engagement. The didactic, strictly formalized nature of the risk management approach, however, allows limited scope for enhancing the therapeutic relationship.

Third, some researchers have convincingly argued that a sole focus on criminogenic needs obstructs treatment engagement. Sometimes attention to non-criminogenic needs is necessary to establish enhanced well-being and quality of life. This in turn is likely to enhance treatment engagement (Laws and Ward 2011). More specifically, targeting non-criminogenic needs might be a necessary precursor for targeting criminogenic needs through enhancing the therapeutic alliance (Ward and Stewart 2003). For example, attempting to tackle criminogenic needs in the context of personal distress or financial crisis (both non-criminogenic needs) will likely prove fruitless if the more acute issues are not sufficiently addressed.

Another general limitation of the risk management approach is its minimal consideration of reentry and reintegration issues (beside identifying and then actively avoiding high-risk situations). The desistance literature emphasizes the decisive role of environmental systems such as close, supportive relationships and employment in ceasing offending (e.g., Laub and Sampson 2003). Thus, building and strengthening environmental opportunities, resources, and supports should be as central to offender rehabilitation and reintegration endeavors as it is to psychological treatment. Moreover, in the case of treated offenders, environmental factors can facilitate or impede the continuation of treatment-related change to dynamic risk factors. Treatment effects can only be generalized to parole if the environment supports and reinforces newly learned concepts, such as the restructuring of offense-supportive beliefs. If an offender, for instance, is embedded in a criminal subculture, which endorses offense-supportive beliefs, it is unlikely that the effects of cognitive restructuring will last long.

The failure of the risk management approach to engage offender clients in the rehabilitation process is derived from its theoretical underpinnings, or mainly a lack thereof (for a detailed discussion, see Laws and Ward 2011), which ignore the nature of human beings as value-laden, goal-directed beings. The risk management approach seems to be too mechanistic and reductionist – that is, there is an implicit assumption that through fixing a malfunction offenders are (hopefully) restored to their optimal functioning state. Humans, on the other hand, are arguably not simply clusters of mechanisms but also persons with an array of values. Therefore, it is not simply enough to correct personal deficits, or reduce criminogenic needs, and expect individuals who have committed crimes to be rehabilitated. It is important to acknowledge that these crimes were often committed in a misguided pursuit of subjectively valued outcomes. In other words, the theoretical grounding in managing risk, rather than improving the lives of offenders, compromises client engagement and their capacity for change.

In summary, critics argue that the RNR approach commonly current in offender rehabilitation and reintegration endeavors constitutes a necessary, but not sufficient foundation for effective interventions (Ward and Stewart 2003). It is essential subjecting offenders to interventions that are empirically supported; however, there is still much to be done in the arena of correctional practice and that desistance theory and research can offer those working with offenders numerous good ideas and practices. It has been convincingly argued that offender rehabilitation endeavors require a dual focus: reducing risk but also promoting human needs and values through approach goals, thereby engaging offenders in the treatment process. The GLM was developed as an alternative, more comprehensive approach to rehabilitation which is able to accomplish a dual focus. In other words the very nature of the GLM addresses limitations of the risk management approach, by including motivating offenders to engage in treatment, by addressing desistance issues, and by considering offenders' environmental contexts (Ward et al. 2007; Ward and Stewart 2003). Although developed independently on a theoretical level, the GLM is a natural ally of desistance theory on a practical level. This is because of the overlapping nature of both perspectives' theoretical assumptions and their common stress on the importance of both offender agency and social resources (for a more detailed discussion of this point see Göbbels et al. (2012)).

The Good Lives Model

The Good Lives Model (GLM), first proposed by Ward and Stewart (2003) and further developed by Ward and colleagues (e.g., Ward and Gannon 2006), is a strengths-based approach to offender rehabilitation. It is a strengths-based rehabilitation theory, because it is responsive to offenders' particular interests, abilities, and aspirations. It also directs practitioners to explicitly construct intervention plans that help offenders to acquire the capabilities to achieve the things that are personally meaningful to them, however in a socially appropriate manner. It assumes that all individuals have similar aspirations and needs and that one of the primary responsibilities of parents, teachers, and the broader community is to help each individual to acquire the tools required to make our own way in the world. Ideally, this is achieved through socialization in childhood and adolescence. Criminal behavior results when individuals lack the internal and external resources necessary to satisfy their values using pro-social means. In other words, criminal behavior represents a maladaptive attempt to meet life values (Ward and Stewart 2003). Rehabilitation endeavors should therefore equip offenders with the knowledge, skills, opportunities, and resources necessary to satisfy their life values in ways that do not harm others. Inherent in its focus on an offender's life values, the GLM places a strong weight on offender agency. That is, offenders, like all human beings, actively seek to satisfy their life values through whatever means available to them. The GLM's dual attention to an offender's internal values and life priorities and external factors such as resources and opportunities give it practical utility in desistance-oriented interventions. In addition, the GLM as a theory has the conceptual resources to incorporate desistance ideas because it also stresses agency, interdependency, and development. In other words, there is natural resonance between desistance theory and the GLM because of their overlapping theoretical ideas and broad way of conceptualizing the relationship between human beings and their social world.

The GLM is a theory of offender rehabilitation that contains three hierarchical sets of assumptions: general assumptions concerning the aims of rehabilitation, etiological assumptions that account for the onset and maintenance of offending, and practical implications arising from the first and second sets of assumptions. Each set of assumptions will be detailed, followed by a summary of empirical research investigating the utility of the GLM.

General Assumptions of the GLM

The GLM is grounded in the ethical concept of human dignity (see Ward and Syversen 2009) and universal human rights. The GLM perceives human beings as agents, rather than passive recipients who are determined by external circumstances only. That is, the GLM is concerned with individuals' ability to formulate and select goals, construct plans, and to act freely in the implementation of these plans. A closely related assumption is the basic idea that offenders, like all humans, aspire to certain states of mind, personal characteristics, and experiences. These are defined in the GLM as *primary goods*. Following an extensive review of psychological, social, biological, and anthropological research, Ward and colleagues first proposed ten classes of primary goods. In more recent work (e.g., Ward and Gannon 2006; Ward et al. 2007), they separated the goods of friendship and community to produce 11 classes of primary goods: (1) life (including healthy living and functioning),

(2) knowledge, (3) excellence in play, (4) excellence in work (including mastery experiences), (5) excellence in agency (i.e., autonomy and self-directedness), (6) inner peace (i.e., freedom from emotional turmoil and stress), (7) friendship (including intimate, romantic, and family relationships), (8) community, (9) spirituality (in the broad sense of finding meaning and purpose in life), (10) happiness, and (11) creativity (Ward and Gannon 2006, p. 79). While it is assumed that all humans seek out all the primary goods to some degree, the weightings or priorities given to specific primary goods reflect an offender's values and life priorities. Moreover, the existence of a number of practical identities, based on, for example, family roles (e.g., parent), work (e.g., nurse), and leisure (e.g., rugby player), means that an individual might draw on different value sources in different contexts, depending on the normative values behind each practical identity.

Instrumental goods, or s*econdary goods*, provide concrete means of securing primary goods and take the form of approach goals. For example, completing an apprenticeship or university degree might satisfy the primary goods of knowledge and excellence in work, whereas joining an adult sports team or cultural club might satisfy the primary good of friendship. If offenders engage in certain personally valued activities, it is likely that dynamic risk factors are reduced in an indirect manner. Thus, the GLM targets approach goals directly and avoidance goals indirectly.

Etiological Assumptions of the GLM

According to the GLM there are two primary routes that lead to the onset of offending: direct and indirect (Ward and Gannon 2006). The direct pathway is implicated when an offender actively attempts (often implicitly) to satisfy primary goods through his or her offending behavior. For example, an individual lacking skill to relate to potential partners may try to acquire the good of intimacy by committing date rape. The indirect pathway is implicated when primary human goods are frustrated over and over again. This can lead to a ripple or cascading effect that culminates in a criminal offense. For example, conflict between the goods of intimacy and excellence in work might lead to the breakup of a relationship and subsequent feelings of loneliness and distress. Maladaptive coping strategies such as the use of alcohol to alleviate distress might, in specific circumstances, lead to a loss of control and culminate in sexual offending (Ward et al. 2007).

Four types of difficulties in offenders' attempts to secure primary goods have been proposed. First, and most common in the direct route to offending, is the use of *inappropriate strategies* (secondary goods) to achieve primary goods. For instance, a preferential child sexual offender might not be able to achieve the good of intimacy with an adult partner and consequently tries to secure the good by molesting a child. Second, an individual's implicit good lives plan might suffer from a *lack of scope*, meaning that a number of goods are neglected in his or her life plan. For example, an offender might neglect the good of excellence in work and may feel incompetent because of his lack of achievement. These feelings might accumulate to a high degree of life dissatisfaction and can cumulate to sex offending. Third, *conflict* in the pursuit of goods might result in acute psychological stress and unhappiness. Fourth, an individual might lack *internal and external capabilities* to satisfy primary goods in the environment he or she lives in. Internal capabilities include relevant knowledge and skill sets, while external capabilities include environmental opportunities, resources, and supports.

Empirically identified criminogenic needs are conceptualized in the GLM as internal or external obstacles that interfere with the acquisition of primary goods. Indeed, as outlined by Laws and Ward (2011), each of the primary goods can be linked with one or more criminogenic needs. Taking the primary good of agency as an example, impulsivity might obstruct good fulfillment. Similarly poor emotional regulation might block attainment of inner peace.

Practical Implications of the GLM

To reiterate, the aim of correctional intervention according to the GLM is the promotion of primary goods, or human needs that, once met, enhance psychological well-being and functioning. In applying the GLM, assessment begins with mapping out an offender's good lives conceptualization by identifying the priorities given to the various primary goods. This is achieved through (i) asking increasingly detailed questions about an offender's core commitments in life and his or her valued day-to-day activities and experiences and (ii) identifying the goals and underlying values that were evident in an offender's offense-related actions. Once an offender's good life conceptualization is understood, future-oriented secondary goods aimed at satisfying an offender's primary goods in socially acceptable ways are formulated collaboratively with the offender and translated into a good lives treatment plan. Treatment does not have a one-size-fits-all approach but is individually tailored to assist an offender implement his or her good lives intervention plan and simultaneously address criminogenic needs that might be blocking goods fulfillment. Accordingly, intervention might include building internal capacity and skills and maximizing external resources and social supports to satisfy primary human goods in socially acceptable ways.

Ward et al. (2007) outlined a group-based application of the GLM based on seven modules typical of current best-practice sex-offender treatment programs: establishing therapy norms, understanding offending and cognitive restructuring, dealing with deviant arousal, victim impact and empathy training, affect regulation, social skills training, and relapse prevention (RP). They highlighted that most modules were associated with an overarching primary good, consistent with the notion that dynamic risk factors can be considered maladaptive means of securing primary goods. For example, an overarching good in the understanding offending and cognitive restructuring module is that of knowledge, attained through providing offenders with an understanding of how their thoughts, feelings, and actions led them to offend. The social skills training module is associated with the overarching goods of friendship, community, and agency. Offenders' individual good lives plans should inform the nature of interventions provided in this module. Some offenders, for example, may value other primary goods such as excellence in play and work over the good of friendship; thus, basic social skills training will likely suffice. Other offenders, however, may highly value intimate relationships; thus, intensive therapeutic work on intimacy and relationships might be required. This illustrates that the GLM promotes tailoring or treatment to individual offenders.

Willis et al. (in press) give specific recommendations on how to integrate the GLM successfully into cognitive-behavioral and risk management treatments. The basic assumption of humans as active agents implies that intervention planning should be collaborative. In addition, clients should be informed about their risk assessment results and should be explained to them. The GLM promotes individualization of treatment. In treatment, appropriate secondary goods should be acknowledged, reinforced, and incorporated together with future-oriented approach goals. For instance, an offender may be particularly ambitious and hardworking and thereby be very successful in his or her profession. In contrast, he or she might not be able to meet the good of relatedness with appropriate secondary goods. The offender might express the desire to reconnect with his or her family, make more friends, and find an intimate partner, and so on. Due to the holistic orientation of the GLM, also these non-criminogenic needs are addressed. The GLM has a dual focus. It capitalizes offender well-being *and* reduction of recidivism risk. Therefore, the offender does not introduce himself with only with offenses, sentencing information, and criminal history. The offender as a person is acknowledged by the therapist and other group members, rather than being reduced to his criminal offense. Offenders are treated as "people like us" (Laws and Ward 2011). As a consequence, offenders are also informed about the GLM and links between treatment modules and the acquisition of a good life. In contrast, hostility, negative labeling of the client, and the use of confrontation are all inconsistent with the GLM approach. In addition, the therapist should not be seen as a teacher or as superior to the clients. Clients are fellow human beings, who are active participants in the therapeutic process. Another crucial aspect is the GLM's emphasis of the client's environment. The offenders learn to attain valued goods with appropriate secondary goods to assure an offense-free life. This involves the work of a multidisciplinary team (correctional workers, nurses, healthcare workers, therapists, etc).

Empirical Research Supporting the Utility of the GLM

The most commonly cited criticism of the GLM is its lack of empirical support (Andrews and Bonta 2010). However, the GLM is not a *treatment* theory, but is rather a rehabilitation framework that is intended to supply practitioners with an overview of the aims and values underpinning practice. It functions as a broad *map* which needs to be supplemented by specific theories smaller in scope concerning concrete interventions such as cognitive-behavioral treatment techniques (Laws and Ward 2011). Thus, the criticism that the GLM (itself) has not been empirically supported misses the point. Rather, it is intended to provide a more comprehensive framework for offender practice than currently exists. However, programs can be – and are – constructed that reflect GLM assumptions and these can (and should) be evaluated. But in this case they are best construed as GLM consistent programs and are not the GLM itself (Laws and Ward 2011). To reiterate, the GLM provides an overarching rehabilitation framework, but does not prescribe specific intervention content (Willis et al. in press). Importantly, treatments that are developed within the framework of the GLM have to adhere to its basic and etiological assumptions. If there is a lack in fidelity with the GLM, the treatment might not work or might be, in the worst case, not beneficial. Due to its individual, flexible, and holistic focus, the GLM does not provide clinicians with rigidly structured treatment manuals. However, structure is needed to assure that central treatment targets are addressed and risk of reoffending will be reduced.

Keeping these general points in mind, recent programs have incorporated principles of the GLM with RP-based treatment, with positive results. For example, Ware and Bright (2008) recently reported preliminary results following the incorporation of GLM principles into their sex-offender treatment program, concurrently with the introduction of open treatment groups, meaning offenders work through treatment modules at their own pace (in contrast to closed treatment groups whereby group members start and finish together). Since the implementation of these changes, the treatment attrition rate has reduced, and staff have reported feeling more effective and positive in their work, likely benefiting their therapeutic relationship with clients. In another study, Lindsay et al. (2007) demonstrated the incorporation of GLM and RP principles with sex offenders using two case examples. They reported the dual focus on improving quality of life and managing risk-enhanced treatment engagement and provided offenders with a pro-social and personally meaningful life focus. Both offenders remained offense-free 5 years following their referrals for treatment. Consistent with reports of the GLM's effectiveness with sex offenders, the GLM has also been successfully applied with a high-risk violent offender (Whitehead et al. 2007) reported that the implementation of GLM principles facilitated treatment readiness and promoted long-term reintegration goals.

Other studies have empirically examined the underlying assumptions of the GLM. Willis and Grace (2008) retrospectively coded child molesters' release planning and found that the presence of secondary goods (i.e., socially acceptable approach goals relating to one or more primary goods) was a protective factor against any type of recidivism (i.e., sexual, violent, or general recidivism), again implicating the importance of goods fulfillment in the desistance process.

Barnett and Wood (2008) investigated how imprisoned sex offenders had operationalized the primary goods of agency, relatedness, and inner peace at the time of their offending. A lack of scope in good lives conceptualizations (e.g., through neglecting inner peace) and problems and/or conflict in the means used to pursue each good were evident. This supports the notion that difficulties fulfilling primary goods are implicated in offending. More recently, the GLM was applied to a sample of released child molesters and showed that the majority of primary goods were endorsed with high importance, supporting the premise that the GLM primary goods represent a set of universally sought after human values (Willis et al. 2010). In addition, it was found that positive reentry experiences at 1 and 3 months post-release (in terms of accommodation, social support, and employment) were associated with increased primary goods attainment 6 months post-release, suggesting that positive reentry experiences provided external capabilities for the implementation of good lives plans and eventual realization of life values.

In sum, the GLM has demonstrated preliminary effectiveness in addressing key limitations of the risk management approach to offender rehabilitation. This was done by enhancing treatment engagement, fostering desistance, and paying increased attention to environmental contexts. Moreover, a growing body of research supports the GLM's underlying assumptions.

Conclusion

Individuals with a history of criminal offending are more than bearers of risk, and as such, rehabilitation and reintegration endeavors require more than managing risk. The risk management approach has been hugely influential, and the primary RNR principles should not be rejected. Rather, the principles of risk, need, and responsivity should be integrated within a broader, strengths-based rehabilitation theory, the GLM. Through acknowledging that offenders are people like all human beings, the GLM engages offenders in the process of desistance, thereby bettering their lives and the lives of people they come into contact with. A problem with risk management practice models is that they tend to be overly focused on individual offenders and lack sufficient theoretical and ethical resources to enlarge their vision to the broader social and cultural vista. In other words, if the ultimate aim is to help individuals to cease offending and stay on the straight road, it is necessary to have a just, caring, and mutually accountable society.

Green Criminology

Rob White
School of Social Sciences, University of Tasmania, Hobart, TAS, Australia

Overview

The term "green criminology" emerged in the 1990s to describe a critical and sustained approach to the study of environmental crime (Lynch 1990; South 1998). This chapter provides an outline of the distinctive features of green criminology, its main concepts and foci of analysis, and the continuing debates that mark its further and continuing development as a bona fide perspective within criminology.

Generally speaking, green criminology takes as its focus issues relating to the environment (in the widest sense possible) and harm (as defined in ecological as well as strictly legal terms). Much of this work has been directed at exposing different instances of substantive social and ecological injustice. It has also involved critique of the actions of nation-states and transnational capital for fostering particular types of harm and for failing to adequately address or regulate harmful activity. Given the pressing nature of many environmental issues, it is not surprising that many criminologists are now seeing environmental crime and environmental victimization as areas for concerted analytical and practical attention.

From a criminological perspective, any attempt to take up the challenge offered here will require rigorous and sophisticated analysis of the social dynamics that shape and allow certain types of activities harmful to the environment (including humans and animals) to take place over time. This sort of analysis, in turn, demands that environmental issues be framed within the context of a sociological and criminological imagination (White 2003). That is, study must appreciate the importance of situating environmental harm as intrinsically socially and historically located and created. Interpretation and analysis thus has to be mindful of how current trends reflect the structure of global/local societies, the overall direction in which such societies are heading, and the ways in which diverse groups of people are being affected by particular social, economic, and political processes.

The Foundations of Green Criminology

Green criminology refers to the study by criminologists of environmental harms (that may incorporate wider definitions of crime than that provided in strictly legal definitions), environmental laws (including enforcement, prosecution, and sentencing practices), and environmental regulation (systems of civil and criminal law that are designed to manage, protect, and preserve specified environments and species and to manage the negative consequences of particular industrial processes) (White 2008).

The key focus of green criminology is environmental crime. This is conceptualized in several different ways within the broad framework of green criminology. For some writers, environmental crime is defined narrowly within strict legal definitions – it is what the law says it is. For others, environmental harm is itself deemed to be a (social and ecological) crime, regardless of legal status – if harm is done to environments or animals, then it is argued that this ought to be considered a "crime" from the point of view of the critical green criminologist.

Specific types of harm as described in law include things such as illegal transport and dumping of toxic waste, the transportation of hazardous materials such as ozone depleting substances, the illegal traffic in real or purported radioactive or nuclear substances, the proliferation of "e"-waste generated by the disposal of tens of thousands of computers and other equipment, the safe disposal of old ships and airplanes, the illegal trade in flora and fauna, and illegal fishing and logging.

However, within green criminology there is also a more expansive definition of environmental crime or harm that includes (White 2011):

- Transgressions that are *harmful to humans, environments, and nonhuman animals*, regardless of legality per se
- Environmental-related harms that are facilitated by *the state*, as well as *corporations and other powerful actors*, insofar as these institutions have the capacity to shape official definitions of environmental crime in ways that allow or condone environmentally harmful practices

The definition of environmental crime is, therefore, contentious and ambiguous. Much depends upon who is defining the harm and what criteria is used in assessing the nature of the activities so described (e.g., legal versus ecological, criminal justice versus social justice) (Beirne and South 2007; White 2008).

For many green criminologists the biggest threats to environmental rights, ecological justice, and nonhuman animal well-being are system-level structures and pressures that commodify all aspects of social existence that are based upon the exploitation humans, nonhuman animals, and natural resources and that privilege the powerful over the interests of the vast majority. It is for this reason that assessment of environmental injustice requires critical scrutiny of how states themselves intervene with regard to specific environmental harm issues.

An eco-justice perspective refers to the broad orientation of green criminology which is largely directed at exposing different instances of substantive social and environmental injustice. From an eco-justice perspective, environmental harm is best seen in terms of justice, which in turn is based upon notions of human, ecological and animal rights, and broad egalitarian principles. A key issue is the weighing up of different kinds of harm and violation of rights that may involve stretching the boundaries of conventional criminology to include other kinds of harms than those already deemed to be illegal.

Most green criminology is informed by at least one of the three approaches that collectively make up an eco-justice perspective. These include *environmental justice* (where the main focus is on differences within the human population: social justice demands access to healthy and safe environments for all and for future generations), *ecological justice* (where the main focus is on "the environment", as such to conserve and protect ecological well-being, e.g., forests, is seen as intrinsically worthwhile), and *species justice* (where the main focus is on ensuring the well-being of both species as a whole, such as whales or polar bears, and individual animals, which should be shielded from abuse, degradation, and torture).

A major factor that influences the study of environmental harm, therefore, relates to the specific interests that count the most when conceptualizing the nature and seriousness of the harm. For example, when criminalization does occur, it often reflects human-centered (or anthropocentric) notions of what is best (e.g., protection of legal fisheries, legal timber coups) in ways that treat "nature" and "wildlife" simply and mainly as resources for human exploitation. The intrinsic value of specific ecological areas and particular species tends to be downplayed or ignored.

Nevertheless, recent years have seen greater legislative and judicial attention being given to the rights of the environment per se and to the rights of certain species of nonhuman animal to live free from human abuse, torture, and degradation. This reflects both the efforts of eco-rights activists (e.g., conservationists) and animal rights activists (e.g., animal liberation movements) in changing perceptions, and laws, in regard to the natural environment and nonhuman species. It also reflects the growing recognition that centuries of industrialization and global exploitation of resources are transforming the very basis of world ecology – for example, global warming threatens us all, regardless of where we live or our specific socioeconomic situation.

Studying Environmental Harm

Green criminology provides an umbrella under which to theorize and critique both *illegal* environmental harms (i.e., environmental harms currently defined as unlawful and therefore punishable) and *legal* environmental harms (i.e., environmental harms currently condoned as lawful but which are nevertheless socially and ecologically harmful). How harm is conceptualized is thus partly shaped by how the legal-illegal divide is construed within specific research and analysis.

There are a number of intersecting dimensions that need to be considered in any analysis of environmental harm (White 2008). These include consideration of who the victim is (human or nonhuman), where the harm is manifest (global through local levels), the main site in which the harm is apparent (built or natural environment), and the time frame within which harm can be analyzed (immediate and delayed consequences). Many of the main features pertaining to environmental harm are inherently international in scope and substance.

Indeed, the categorization of environmental harm is varied in that there are different ways in which environmental crimes have been conceptualized and sorted. For instance, Carrabine et al. (2004) discuss environmental crimes in terms of primary and secondary crimes. Green crimes are broadly defined simply as crimes against the environment. Primary crimes are those crimes that result directly from the destruction and degradation of the earth's resources, through human actions. Secondary or symbiotic green crime is that crime arising out of the flouting of rules that seek to regulate environmental disasters. The first set of crimes relates to the harm as being bad in itself; the second relate to breaches of law or regulation associated with environmental management and protection.

In recent years researchers have studied a wide range of environmental harms associated with both "green" issues and "brown" issues. In the former the work has been motivated by either a concern with species justice or an interest in conventional environmental crimes such as illegal fishing. For instance, work over the past decade has been carried out in respect to crimes such as lobster poaching (McMullan and Perrier 2002), animal abuse (Beirne 2009), the illicit trade in endangered species (Wellsmith 2010), and deforestation (Boekhout van Solinge 2010).

In regard to "brown" issues, the production and disposal of waste is a matter of significant concern to academic researchers interested in questions of environmental harm. Relevant examples of such research include the role of organized criminal syndicates in the dumping of waste (Ruggierro 1996), inequalities associated with the location of disadvantaged and minorities' communities near toxic waste sites (Pellow 2007), and the global trade in electronic waste (Gibbs et al. 2010a).

The range of substantive topic areas that green criminology is presently investigating is growing. So too, the complexities involved in studying environmental harm are likewise being acknowledged. For example, the detection and origins of some types of environmentally related harm may be unclear due to significant time lags in manifestation of the harm. Here it is important to acknowledge the notion of cumulative effects. For example, this could refer to the way in which dioxins accumulate in fish flesh over time. It could also refer to the cumulative impact of multiple sources of pollution as in cases where there are a high number of factories in one area (such as places along the US-Mexican border). Diseases linked to asbestos poisoning may surface many years after first exposure, and this, too, provides another example of long-term effects of environmental harm. Persistent use of pesticides in particular geographical areas may also have unforeseen consequences for local wildlife, including the development of new diseases among endemic animal species (as has been suggested has occurred in the case of facial tumor disease now rampant among the Tasmanian devil population in Australia).

As extensive work on specific incidents and patterns of victimization demonstrates, it is also the case that some people are more likely to be disadvantaged by environmental problems than others. For instance, studies have identified disparities involving many different types of environmental hazard that especially adversely affect people of color, ethnic minority groups, and indigenous people (Bullard 2005). There are thus patterns of differential victimization that are evident with respect to the siting of toxic waste dumps, extreme air pollution, chemical accidents, access to safe clean drinking water, and so on (Williams 1996). It is the poor and disadvantaged who suffer disproportionately from such environmental inequalities.

The kinds of harms and crimes studied within green criminology include illegal trade in endangered species (e.g., trade in exotic birds or killing of elephants for their ivory tusks), illegal harvesting of "natural resources" (such as illegal fishing and illegal logging), and illegal disposal of toxic substances (as well as pollution of air, land, and water). Wider definitions of environmental crime extend the scope of analysis to consider harms associated with legal activities such as clear-felling of old-growth forests and the negative ecological consequences of new technologies such as use of genetically modified organisms in agriculture (e.g., reduction of biodiversity through extensive planting of GMO corn) (see, e.g., Walters 2011). Recent work has considered the criminological aspects of climate change (see White 2012), from the point of view of human contributions to global warming (e.g., carbon emissions from coal-fired power plants) and the criminality associated with the aftermath of natural disasters (e.g., incidents of theft and rape in the wake of Hurricane Katrina in New Orleans).

Differences Within Green Criminology

There is no green criminology *theory* as such. Rather, as observed by South (1998), there is what can loosely be described as a green "perspective." Elements of this perspective generally include things such as a concern with specifically environmental issues, social justice, ecological consciousness, the destructive nature of global capitalism, the role of the nation-state (and regional and global regulatory bodies), and inequality and discrimination as these relate to class, gender, race, and nonhuman animals. The green criminology perspective, therefore, tends to begin with a strong sensitivity toward crimes of the powerful and to be infused with issues pertaining to power, justice, inequality, and democracy.

Green criminology has emerged in the last 20 years as a distinctive area of research, scholarship, and intervention. It is distinctive in the sense that it has directed much greater attention to environmental crime and harm than mainstream criminology and has heightened awareness of emergent issues such as the problems arising from disposal of electronic waste (e-waste) and the social and ecological injustices linked to the corporate colonization of nature (including biopiracy and imposition of GMO crops in developing countries). Within the spectrum of ideas and activities associated with green criminology, there are nonetheless several different kinds of analytical framework.

While the link between and among green criminologists is the focus on environmental issues, important theoretical and political differences have become more apparent over time. For example, some argue that green criminology must necessarily be anticapitalist and exhibit a broad radical orientation (Lynch and Stretesky 2003). Others, however, construe the task as one of conservation and natural resource management, within the definitional limits of existing laws (Herbig and Joubert 2006; Gibbs et al. 2010b). Still others promote the idea that the direction of research should be global and ecological and that new concepts need to be developed that will better capture the nature and dynamics of environmental harms in the twenty-first century (White 2011).

Typically there are important differences within green criminology around issues pertaining to the distinction between "harm" and "crime." These differences do not stem solely from disputes over the legal/illegal divide however. There are also profound disagreements with regard to victimization and varying conceptions of justice. For instance, there may be differences *within* a particular area of work, such as debates over "animal rights" versus "animal welfare" in the case of concerns about species justice (Francione 2010). There are also disagreements in terms of priorities, values, and decision-making *between* particular areas of green criminology (Beirne 2011). This is evident, for example, in debates over multiple land-use areas. This kind of dispute can involve those who argue that human interests should come first (from the perspective of environmental justice), or that specific ecological niches be protected (from the perspective of ecological justice), even if some animals have to be killed or removed from a specific geographical location. From the point of view of species justice, however, big questions can be asked regarding the intrinsic rights of animals and the duty of humans to provide care and protection for nonhuman species.

The hallmark of green criminology, regardless of diversity of opinion and the plurality of views, is that proponents argue that criminology ought to take seriously environmental crimes, and in doing so to rethink how it does what it does, and how it might conceptualize the relevant issues. It is interesting in this respect that a number of prominent criminologists are now utilizing their expertise from mainstream areas of criminology (e.g., situational crime prevention, general strain theory) to study specifically environmental issues such as illegal trade in elephant tusks and social problems arising from climate change (Agnew 2012; Mesko et al. 2010; Lemieux and Clarke 2009). Green criminology is not only expanding in its own right but simultaneously there is a greening of criminology more generally.

Differences within green criminology are not only apparent at the level of theoretical focus and orientation. They are also manifest when it comes to responding to environmental crime or harm. From a critical green criminology view, for example, environmental harm is related to exploitation of both environments and humans by those who control the means of production. Analysis of global capitalism provides answers to questions such as why it is that human societies simultaneously respect and protect certain creatures (especially animal companions such as dogs and cats) while allowing and even condoning the dreadful treatment of others (as in the case of factory farming of battery hens to produce eggs) (Beirne 2009). It also allows us to better understand why it is that we strive to preserve some environments (via creation of national parks) while at the same time ensuring the devastation of particular ecosystems (such as clear-felling of old-growth forests).

Environmental harm takes place within the overarching context of a distinct global political economy. Most writers within the green criminology perspective concentrate on exposing specific types of criminal or harmful environmental actions or omissions. In doing so they have provided detailed descriptions and analyses of phenomena such as the illegal trade of animals, illegal logging, dumping of toxic waste, air pollution, and threats to biodiversity. In many cases, the corpus of work identified within this field has highlighted issues pertaining to social inequality, speciesism, ecological and environmental injustice, and crimes of the powerful. What is less common, however, are examples of study that locate these harms, crimes, injustices, and corrupt practices within the context of an explicit theoretical understanding of the state or economic relations. In other words, it is rare to find a sustained political economy of environmental harm.

Yet, analysis of broad trends indicates that it is systemic imperatives and historical transformations associated with global capitalism that, in today's world, ultimately shape what it is that individuals do with their lives and their environments. Even a cursory examination of dominant world political economic trends reveals the close link between capitalism as a system and environmental degradation and transformation. The sphere of production is dominated by the production of commodities, the advance of technology and biotechnologies, and the exploitation of labor (particularly in so called Third World countries) in the service of mass production of goods and services that, in turn, demand a high turnover rate. Extensive and intensive forms of consumption are essential to the realization of surplus value – that is, profit depends upon a critical mass of buyers purchasing the mass-produced commodities. The link between production and consumption is found in the form of specific kinds of distribution processes (e.g., transportation of goods and services, retail outlets, storage, roads, railways, bridges, and ships) and exchange mechanisms (e.g., finance capital, credit availability) that sustain and contribute to extensive use of natural and human resources. Economic efficiency is measured in how quickly and cheaply commodities can be produced, channeled to markets, and consumed. It is a process that is inherently exploitive of both humans and nature.

In essence, the competition and the waste associated with the capitalist mode of production have a huge impact on the wider environment, on humans and on nonhuman animals (e.g., in the form of pollution and toxicity levels in air, water, and land). These same processes pose major threats to biodiversity and the shrinking of the number of plant and animal species generally. This is related both to the legal and illegal trade in species, as well as to mass industrial production and extensive use of genetically modified organism (GMO) technologies.

Differences in opinion over the nature of global political economy, and over the tactics and strategies most likely to bring about desired social and ecological transformations, manifest in different approaches to how responses to environmental harm are construed (White 2008). One approach is to chart up existing environmental legislation and provide a sustained socio-legal analysis of specific breaches of law, the role of environmental law enforcement agencies, and the difficulties and opportunities of using criminal law against environmental offenders. Another approach places emphasis on social regulation as the key mechanism to prevent and curtail environmental harm, including attempts to reform existing systems of production and consumption through a constellation of measures and by bringing nongovernment and community groups directly into the regulatory process. A third approach presses the need for transnational activism, with an emphasis on fundamental social change. What counts is engagement in strategies that will challenge dominant authority structures and those modes of production that are linked to environmental degradation and destruction, negative transformations of nature, species decline, and threats to biodiversity. Social movements are seen to be vital in dealing with instances of gross environmental harm.

By its very nature, the development of green criminology as a field of sustained research and scholarship, will incorporate many different approaches and strategic emphases. For some, the point of academic concern and practical application will be to reform aspects of the present system. Critical analysis, in this context, will consist of thinking of ways to improve existing methods of environmental regulation and perhaps to seek better ways to define and legally entrench the notion of environmental crime. For others, the issues raised above are inextricably linked to the project of social transformation. From this perspective, analysis ought to focus on the strategic location and activities of transnational capital, as supported by hegemonic nation-states on a world scale, and it ought to deal with systemic hierarchical inequalities. Such analysis opens the door to identifying the strategic sites for resistance, contestation, and struggle on the part of those fighting for social justice, ecological justice, and animal rights.

There are major political divisions within the broad spectrum of green criminological work (and indeed within green political movements), and these have major implications for whether action will be taken in collaboration with capitalist institutions and state authorities, or whether it will be directed toward radically challenging these institutions and authorities. Similarly, there are significant tensions between ecological justice and species justice approaches, as indicated in the following observation:

> The [green environmentalists] rarely champion the sites of their concerns with rights talk, whereas for [animal rights advocates] their very focus is the criterion for moral standing and holding of rights. This crucial deep-seated difference is already present in green criminology in environmentalist notions such as ‘fisheries’ and ‘harvests’ and ‘conservation’, all of which are the stuff and fodder of animal welfare and sustainability but mostly anathema to animal rights. (Beirne 2011: 354)

To put it differently, some green criminologists view nature instrumentally, and harm is viewed through the lens of legality; others view the exploitation of nature, particularly in relation to animals, as intrinsically bad and harmful. How or if this “moral fissure” can be overcome is of major interest to many currently working within the broad area of green criminology.

Conclusion

Green criminology has many different substantive contributions and theoretical dimensions. Debates will continue over how best to define concepts such as harm, crime, and victim; over the moral calculus that weighs up human, ecosystem, and animals interests and rights; and over which interventions will achieve what kinds of intended and unintended outcomes. Dialogue around these issues will ensure lively and healthy deliberations over environmental matters now and into the future.

The development of green criminology has led to new interests, new conceptualizations, and new techniques of analysis. This is because there is increasing acknowledgement of environmental problems and the relevance of this to traditional criminological concerns with social injury and social regulation. There is also greater awareness of the interconnectedness of social and environmental issues. For example, matters relating to poverty, health, indigenous people's rights, exploitation of nonhuman nature, corporate business wrongdoing, state corruption, and so on are seen in many instances to be inseparable. As well, there is recognition of the need for multidisciplinary approaches to the study of environmental harm, involving cooperation between different "experts," including those with traditional and experiential knowledge associated with culture and livelihood (such as indigenous peoples and farmers and fishers), as well as sensitivity to ideas and research generated in intellectual domains such as law, police studies, political science, international relations, zoology, biology, philosophy, sociology, and chemistry.

These kinds of observations and interrelationships are forcing a rethink of the social and natural universe and a reconceptualization of the relationship between humans and nature in ways that accord greater weight to the nonhuman when it comes to assessing issues such as environmental harm. In practical terms, this translates into new and overlapping domains of consideration within green criminology itself: hence, the concern with transgressions against humans, environments, and animals.

Group Characteristics and General Strain Theory

Stacy De Coster
Department of Sociology and Anthropology,
North Carolina State University, Raleigh,
NC, USA

Overview

Although general strain theory was developed to explain differences in offending across individuals (Agnew 1985, 2006), recent scholarly efforts suggest that the theory offers significant insight into group differences in offending. These efforts suggest that group differences in exposure to strain, emotional reactions to strain, and access to resources for dealing with strain and negative emotions contribute to different rates of offending across various groups. In applying this argument to sex differences in offending, the theoretical emphasis has been on how patriarchal structures inform gender socialization and gendered roles, which ultimately shape stress exposure, emotional and behavioral responses to stress, and the efficacy of legitimate coping resources for dealing with strain (Broidy and Agnew 1997). Explications of race differences in offending emphasize the role of additional structural arrangements and race discrimination in shaping the relationship between strain and offending (Kaufman et al. 2008). Cross-national research guided by general strain theory has been somewhat sparse, but explanations for research findings on samples of non-United States residents have emphasized that cultural values shape the strain process in ways that may contribute to understanding differences in offending cross-nationally. A particular strength of general strain theory for understanding group differences in offending is that it allows for consideration of how structural arrangements and cultural values coalesce to create group variations in crime and delinquency. An important direction for future research is to consider the ways in which the structural arrangements emphasized in the race literature and cross-national studies coalesce with the cultural beliefs about gender at the heart of the literature on sex differences to provide insight into variations in offending across groups and individuals situated at various junctures in gender-race-class hierarchies and race-gender-nationality locations.

Introduction

General strain theory is among the most prominent individual-level explanations of offending (Agnew 1985, 2006). The theory posits that strain leads to negative emotions – including anger, frustration, and depression – that promote offending when resources for legitimate coping are limited. Although the theory was developed to explain differences in offending across individuals, recent scholarly efforts indicate that the theory also offers significant insight into group differences in offending. Generally, theoretical and empirical efforts suggest that group differences in offending can be attributed in part to structural and cultural forces that shape group differences in exposure to strain, emotional reactions to strain, and access to resources for dealing with strain and negative emotions. This broad argument has been applied most commonly to understanding differences in offending across sex, race, and neighborhood groups but likely applies equally well to societies and to groups situated at various junctures at the intersections of race-gender-class and race-gender-nationality.

Sex Differences

A gendered extension of general strain theory offers that the theory can explain why males are more likely to engage in illegal behaviors than are females, positing that the strains most frequently experienced by females and males, emotional and behavioral reactions to strain, and the availability of legitimate coping resources are shaped by gendered roles and gender socialization (Broidy and Agnew 1997). The first hypothesis in this gendered perspective centers on sex differences in the types of strains most often experienced by females and males.

One of the crime-producing strains emphasized by general strain theory is failure to achieve positively valued goals. Drawing on gender research, Broidy and Agnew (1997) note that gender socialization emphasizes different goals for females and males. Females in patriarchal society traditionally are socialized to be concerned with maintaining relationships, finding meaning in life, and how people are treated in interactions; by contrast, males are taught to focus on economic success, personal achievement, and outcomes of interactions. As a result, females and males are likely to experience different types of goal-related strains. Relational strains – such as conflict in close relationships, network events, and suicide attempts of loved ones – align with feminine concerns, whereas, agentic strains – including economic failure, academic failure, mistreatment by others, and criminal victimization – are linked with masculine concerns. Consistent with these gendered concerns, adults often occupy gendered roles that require more emotion work and caretaking from females and emphasize the primacy of economic responsibilities for males (e.g., Kessler and McLeod 1984). Like gender socialization, the gendering of social roles in patriarchal society informs the types of strains – relational and agentic – to which males and females are most exposed and those they are most prone to experience as stressful (e.g., Kessler and McLeod 1984).

Broidy and Agnew (1997) propose that the differentiation of relational and agentic strains is pertinent for understanding sex differences in offending because agentic strains are more likely than relational strains to promote crime. For instance, criminal victimization and mistreatment may be particularly conducive to violent crime; failure to achieve economic goals can provoke property crime. Relational strains are less likely to encourage illegal behavior because such behavior can threaten social relationships or harm others.

Although some empirical evidence documents that females report more exposure to relational strains and males report more agentic strains (e.g., Kessler and McLeod 1984; De Coster 2005), there is little evidence that agentic strains are more criminogenic than relational strains (see Agnew 2006). This lack of evidence can be attributed to the fact that empirical assessments of general strain theory most often use composite scales of strain that do not separate relational and agentic strains. Studies that differential between types of strain typically include measures of either relational *or* agentic strains or include measures of both but do not examine which is more criminogenic.

The second hypothesis offered in Broidy and Agnew's (1997) gendered perspective proposes that emotional reactions to strain are shaped by gender socialization. Agnew (1985) has given primacy to the negative emotion of anger, positing that anger is the emotion most likely to lead to offending because it energizes individuals for action and leads to a desire for retaliation. Given that males and females are equally likely to respond to strain with anger, Broidy and Agnew (1997) emphasize that understanding sex differences in offending requires consideration of qualitative distinctions in the experience of anger among males and females. Specifically, they propose that female anger is more likely than male anger to be accompanied by depression, anxiety, and sadness because females are socialized to view anger as inappropriate and also may worry that their anger may jeopardize valued social relationships.

This distinction in how males and females experience anger is relevant for understanding why males are more likely to offend than females, according to Broidy and Agnew (1997), because the depression that accompanies female anger may mitigate anger's impact on law violation. Although research demonstrates that female anger is more likely than male anger to be accompanied by depression and sadness, limited evidence suggests that depression actually exacerbates the impact of anger on offending (De Coster and Zito 2010). Since the feminine experience of anger – concurrently with depression – is more conducive to offending than the masculine experience, the key to understanding links between gender, emotions, and illegality in general strain theory may reside in gendered expressions of emotional responses to strain rather than in gendered experiences of emotions.

An emphasis on expressions of emotional responses to strain is consistent with a large body of work on emotional displays and with Broidy and Agnew's (1997) proposition that illegitimate responses to strain and negative emotions may be shaped by gender socialization, gendered roles, and cultural beliefs about gender and emotional displays in patriarchal society. Consistent with much prior theorizing, they note that femininity is the antithesis of crime and violence but that masculinity is consistent with and may even promote illegality. In addition, feminine roles are more likely to limit access to crime as a coping strategy than are masculine roles. As such, males with limited access to legitimate coping resources are likely to respond to strains and negative emotions with illegal behaviors; similarly situated females may respond with eating disorders, suicidal ideation, distress, or other mental health problems. Indeed, empirical evidence demonstrates gender distinctions in the expression of problems (e.g., Horwitz and White 1987; Kaufman 2009).

The final hypothesis in Broidy and Agnew's (1997) gendered perspective offers that males are more predisposed to illegality and have fewer legitimate coping resources. That is, males are more likely than females to engage in crime without thinking (predisposition) and are more likely to lack the social skills necessary for legitimate coping and the maintenance of socially supportive relationships. These differences are linked once again to the fact that gender socialization emphasizes the development of relational concerns for females and agentic concerns for males. The expectation is that legitimate coping resources, social support, and noncriminal predispositions – buffering factors – protect females to a greater degree than males from offending in the face of strain and negative emotions. Although research often supports the claim that females possess more coping and social support resources than males (Thoits 1995), these resources do not buffer the impact of either strain or negative emotions on offending more for females than for males (e.g., Morash and Moon 2007; Jennings et al. 2009). However, criminal predispositions – captured with measures of aggressiveness and low self control – exacerbate the impact of strain on illegal behaviors more for males than for females (e.g., Liu and Kaplan 2004; Cheung and Cheung 2010).

Overall, Broidy and Agnew (1997) propose that general strain theory can effectively explain why males engage in more law violation than do females. Their overarching framework emphasizes that males and females occupy gendered roles in society and are socialized to have concerns and goals that are consistent with traditional expectations for their gender. This shapes their experiences of strain, emotional reactions to strains, and their coping resources, social supports, and criminal predispositions. Empirical studies support the propositions that the types of strains to which males and females are exposed, emotional responses to strain, and expressions of negative emotions are gendered. However, current evidence does not support the claim that the gendering of strains and emotional responses to strain are relevant for understanding sex differences in illegal behaviors. Instead, sex differences appear to emerge because males are more likely than females to *express* negative emotions illegally and because the effect of strain on offending is more likely to be exacerbated by criminal predispositions for males than for females.

Perhaps the greatest limitation of the empirical literature to date is the failure to differentiate sex from gender. That is, tests of the propositions specified by Broidy and Agnew (1997) typically have assumed that gender socialization is perfect, ignoring variability within groups of females and males with respect to how much traditional gender socialization and gendered expectations shape their goals, emotions, predispositions, and reactions to strain and negative emotions. Research that includes direct measures of the extent to which individuals embrace traditional definitions of gender would provide a more accurate assessment of Broidy and Agnew's (1997) hypotheses than what has been offered to date.

Race and Neighborhood Differences

Theory and research on race and offending in criminology most often emphasizes the broad structural forces that shape offending. Consistent with this, discussions of race and offending from a general strain perspective emphasize the role of discrimination and neighborhood disadvantage in the etiology of race patterns of offending.

Strain theorists highlight several mechanisms through which race discrimination can produce elevated rates of offending among Blacks in particular. Perhaps the most obvious argument is that discrimination is a form of strain – failure to achieve the valued goal of justice or presentation of a negatively valued stimulus – that produces negative emotions and criminal coping (see Kaufman et al. 2008). Indeed, Agnew (2001) defines race discrimination to be among the strains most likely to produce crime because it is likely to be seen as unjust and is high in centrality/magnitude because it threatens core values and identities. Consistent with this, research demonstrates a link between race discrimination and offending among Blacks that is mediated at least partially by anger and depression (Simons et al. 2003).

Race discrimination can also influence race patterns of offending by situating Blacks in neighborhoods where strains proliferate, they are exposed to angered/frustrated individuals, and access to legitimate coping resources is limited (Kaufman et al. 2008). Much research demonstrates that the racial segregation of disadvantaged urban neighborhoods arises in part from economic constraints (often produced by discriminatory practices in the labor market and discriminatory practices in housing markets). Given this, Agnew's (1999) general strain theory of neighborhood crime rates provides important insights into elevated rates of crime among Blacks, who often are concentrated in the most disadvantaged neighborhoods.

One mechanism through which disadvantaged neighborhoods create elevated crime rates, according to general strain theory, is through the generation of strain (Agnew 1999). Consistent with this, research shows that residents of disadvantaged areas are more likely than those in more advantaged areas to experience a wide array of strains, including harassment and threats, criminal victimization, and witnessing violence (e.g., Warner and Fowler 2003; Kaufman 2005). Importantly, studies demonstrate that the disproportionately high offending rates among Blacks can be attributed partially to their greater exposure to major events, such as criminal victimization and witnessing serious violence (Eitle and Turner 2003).

The concentration in disadvantaged areas of individuals who experience a wide array of strains translates into a high concentration of angered/frustrated individuals in these areas, which increases the chances of interacting with angry/frustrated people in what can be thought of as a "charged environment" (Bernard 1990; Agnew 1999). This, of course, is an additional source of crime-provoking strain for residents in disadvantaged neighborhoods. When confronted with this and other forms of strain generated by disadvantage and race, individuals are likely to blame their situation and their angry feelings on external factors, which increases the chances of illegitimate coping (Bernard 1990; Agnew 1999).

The likelihood of illegitimate coping is also increased by the fact that disadvantaged neighborhoods provide individuals and groups with few legitimate coping resources. For instance, retaliatory crime is a means through which groups can deal with victimization of self or loved ones, particularly when models of effective coping and access to police, court, and psychiatric resources are largely unavailable. Retaliatory crime, in fact, may become a necessity in these areas to help avoid the strains of future victimization and identity threats (Mullins et al. 2004).

In sum, general strain theory offers that elevated offending rates among Blacks may be explained both directly and indirectly by discrimination experiences. Race discrimination has been shown to be a source of strain that leads to negative emotions and offending (Simons et al. 2003), but it impacts crime also through the role it plays in concentrating minorities in disadvantaged urban neighborhoods. These neighborhoods are characterized by high rates of offending in part because they expose residents to strains – such as victimization of self and loved ones, mistreatment/harassment, and hostile interactions with angry people – that are particularly criminogenic. Limited access to legitimate coping resources in disadvantaged areas only exacerbates the criminogenic nature of these strains.

Although research supports the argument that strains emanating from disadvantaged neighborhoods help mediate the impacts of race and neighborhood disadvantage on offending (e.g., Kaufman 2005), much less emphasis has been placed on assessing whether legitimate coping resources interact with strain in the production of race and neighborhood crime patterns. Perhaps this is because some studies find that race differences in levels of exposure to strain are relevant for understanding racial patterns of offending, but differences in the likelihood of responding to strain illegally are negligible in explicating these patterns (Eitle and Turner 2003). This might imply that differential access to coping resources is not of primary importance for understanding race and neighborhood patterns of offending. Given that research on neighborhoods, race, and strains is relatively sparse, however, the role of coping resources – particularly at the neighborhood level – requires further exploration.

National/Societal Differences

Although cross-national research from a general strain perspective has been relatively sparse (see Agnew 2006), there is sufficient evidence to suggest that the theory has meaningful insights to offer for understanding variability in rates of offending across societies or nations. For instance, cross-national comparative studies show that nations with high rates of economic inequality – a structural source of strain – have higher homicide rates than nations characterized by less inequality (e.g., Messner 1989; Pratt and Godsey 2003). Importantly, the impact of economic inequality on homicide rates is tempered by national-level social support resources (see Pratt and Godsey 2003). This suggests that cultural values – the value of being supportive of citizens – may significantly shape the extent to which strain impacts offending across nations.

This suggestion bears out most prominently in studies of general strain theory on non-United States samples, which often invoke cultural arguments to explain why certain strains may be more or less criminogenic in other nations than in the United States. Research findings support the applicability of general strain theory in samples of Chinese, Philippine, South Korean, Israeli, and Ukrainian samples (Landau 1997; Maxwell 2001; Bao et al. 2004; Morash and Moon 2007; Botchkovar et al. 2009; Cheung and Cheung 2010). However, the conclusions of these studies generally suggest that cultural values shape the types of strains that may be most relevant for understanding offending within various nations. For instance, mistreatment by teachers appears to be a particularly important source of crime-producing strain among South Korean adolescents. Morash and Moon (2007) propose that the importance of this strain may be rooted in both South Korean cultural norms that emphasize emotional and physical punishment as achievement motivators and Confucian values that emphasize academic achievement as a prerequisite for success in social and economic realms.

Studies that fail to replicate links between specific strains and offending that have been established in American samples most often conclude that cultural differentiation provides the key to understanding why some strains are relevant in some nations and not others. For example, the strain of coercive parenting leads to delinquency among American adolescents but not among Chinese adolescents (compare Hay 2003 and Cheung and Cheung 2010). An explanation offered for this difference is that coercive parenting is consistent with the collectivist ideology of China, which encourages the subordination of the individual to family and community. In American society, where individualism is lauded, coercive parenting is likely to be experienced as a stressful infringement on individuality, thereby resulting in delinquent responses (Cheung and Cheung 2010). Youths from the Philippines respond to aggression between caretakers with delinquency but are not vulnerable to delinquency when faced with physical aggression by their caretakers. Maxwell (2001) explains this by offering that the general cultural acceptance of physical punishment in the Philippines may buffer the relationship between caretaker aggression and delinquency often reported in samples of American youths (e.g., Smith and Thornberry 1995). Finally, Botchkovar and colleagues (2009) conclude their study of general strain theory in Ukrainian, Greek, and Russian samples by noting that their general strain scale may have proven ineffective in the prediction of offending decisions among their Greek and Russian samples because it failed to consider that cultural values may shape the types of strains that are most relevant for understanding criminal intentions (Botchkovar et al. 2009).

Generally, these studies suggest that general strain theory has much to offer for understanding rates of offending across nations. To date, the majority of studies have provided ad hoc cultural explanations for why various strains are particularly relevant or irrelevant for explicating offending in different nations. Research on the applicability of general strain theory across societies would be strengthened by a theoretical framework that takes into consideration structural and cultural variations between nations and derives hypotheses about how these variations might shape the types of strains, emotions, and coping resources most relevant for understanding variations in offending across societies.

Conclusions

Despite the fact that general strain theory was developed to explain individual offending, recent scholarship demonstrates the theory's relevance for illuminating sex, race, neighborhood, and societal rates of offending. Explanations for sex differences in offending have focused primarily on gender socialization and gendered roles rooted in patriarchal structural arrangements; race differences have been discussed as emanating from neighborhood structural arrangements that are shaped by race discrimination and economic factors; and societal-level arguments have focused on economic structures and cultural values. A strength of general strain theory for understanding group differences in offending is in its ability to consider how structural arrangements and cultural beliefs coalesce to predict offending rates across groups. Given the emphasis on intersectionalities and crime in the broader literature on offending, an important next step for general strain theorists may be to further unite some of the cultural and structural arguments that have been offered in the literature to help explicate patterns of offending across race-sex-class or race-sex-nation groups.

One avenue for pursuing this goal would be to consider that some of the structural factors discussed as relevant for understanding race and neighborhood patterns of offending may shape the gendered roles and socialization that Broidy and Agnew (1997) propose shape strains, emotions, coping resources, and offending across sex groups. Intersectionality theorists propose, for instance, that race discrimination and economic disadvantage have made it such that the feminine roles and ideals lauded in patriarchal society have never applied to Black girls and women. As such, Black families socialize their daughters in ways that differ from how White families socialize their daughters. This means that Black females are less likely than their White counterparts to embrace the cultural form of femininity and feminine roles highlighted in Broidy and Agnew's (1997) discussion of sex and crime. This insight may prove relevant for understanding how race discrimination, community disadvantage, and gender socialization operate simultaneously in a general strain theory framework to help explicate patterns of offending across gender-race-class. One can also envision consideration of how variability across nations in cultural beliefs about gender may shape the strain process differently for males and females in different nations, thereby providing insight into variability in the size of the sex-gap in crime across nations.

Synonyms

Group-based trajectory modeling; Latent class growth modeling; Latent trajectory modeling; Semi-parametric group-based method

Overview

Group-based trajectory modeling is a powerful and versatile tool that has been extensively used to study crime over the life course. The method was part of a methodological response to the criminal careers debate but has since greatly expanded in its applications. The current state of the art of group-based trajectory modeling is complex, but worth becoming familiar with so as to recognize the variety of uses to which this tool can be applied. The method has attracted unusually robust criticism for a statistical tool. Researchers should aim to use it and other statistical tools as effectively as possible.

Introduction

Criminologists have long been interested in studying crime as a longitudinal phenomenon. Recent interest stems from vigorous debate surrounding the interpretation of the fact that criminal behavior bears a robust curvilinear relationship with age, quickly ramping up to a peak in the late teen years, and declining thereafter. Part of the criminal careers debate of the 1980s concerned the interpretation of this aggregate relationship. The peak around age 17 may reflect patterns of offending among all offenders, or it may reflect an influx of offenders with relatively short criminal careers around their teen years. In short, the question is whether individual criminal careers resemble the aggregate age-crime curve. This is one of the many questions that group-based trajectory modeling – a general statistical tool for uncovering distinct longitudinal patterns in panel data – can answer.

Group-based trajectory modeling can best be understood in contrast to its alternatives. The most common alternative to group-based trajectory modeling is hierarchical linear modeling, also known as general growth curve modeling. This alternative identifies the average trend over time and quantifies the degree of variation around this average. It is relatively parsimonious because it assumes a specific error distribution around the overall average, typically Gaussian. Group-based trajectory modeling, in contrast, makes no assumptions about the distribution of parameters. Rather, it assumes that the distribution can be approximated by a finite number of support points. Group-based trajectory modeling is related to hierarchical linear modeling in the same way a histogram is related to mean and standard deviation. The mean and standard deviation quickly provide information about the distribution of a variable, but a histogram can provide more detailed information on the shape of the distribution. Both are approximations of a more complex reality. Given a specified number of groups, group-based trajectory modeling attempts to discover a set of longitudinal paths that best represents the raw data. Group-based trajectory modeling is a powerful tool for uncovering distinct longitudinal paths, particularly when significant portions of the population follow a path that is very different from the overall average.

Group-based trajectory modeling is a versatile tool, not limited to revealing distinct longitudinal paths. Once the best group-based trajectory model has been chosen, the researcher may proceed by: (1) describing characteristics of the groups (i.e., characteristics of their growth patterns and covariates); (2) predicting group membership based on preexisting characteristics; (3) evaluating the group-specific effects of time-varying covariates and testing whether such effects vary by group; (4) using groups as independent variables to predict later outcomes; and (5) incorporating measures of group membership as control variables in regression models or propensity score matching protocols. Attesting to its utility and the ease of interpreting its results, although group-based trajectory modeling was developed to answer specific questions posed by the criminal careers model (Nagin and Land 1993), the method has been used to model trajectories of abdominal pain symptoms in pediatric patients (Mulvaney et al. 2006), fungal growth on the forest floor (Koide et al. 2007), and of course, extensive use in the study of longitudinal patterns of criminal activity (Piquero 2008).

This entry will proceed by first describing some of the theoretical background for the emergence of group-based trajectory modeling. The bulk of the entry will be devoted to describing the state of the art of the method including the basic components of the model, how to choose the number of groups, and several model extensions. Next, it will cover a number of controversies surrounding the method as well as some possibilities for further development.

Background

A central fact of criminology is that a small portion of the population commits a large share of crime. Goring (1913) found that just 3.4 % of the population accounted for about half of all convictions in England. This finding was repeated in a Philadelphia birth cohort: 5 % of the cohort accounted for over half of all police contacts (Wolfgang et al. 1972). This rediscovery of the concentration of offending occurred around the same time that the rehabilitative focus of punishment gave way to rationales of deterrence and incapacitation, creating demand for theoretical accounts and statistical tools that identified high-rate or “chronic” offenders as a distinct group

Alfred Blumstein and colleagues (1986) promoted a criminal careers framework that could be used to describe the volume of crime committed over an individual lifespan, including age of onset, rate of offending, age of termination (desistance), and career length. The criminal careers paradigm suggested that each of these parameters warranted investigation and, possibly, distinct theoretical explanations. It also provided a way to distinguish “career criminals” from others, through their long criminal career length. In opposition to this perspective, Travis Hirschi and Michael Gottfredson (1983) claimed that the criminal careers model did not provide any special insight into age and crime. They claimed the age-crime curve was invariant across social context and no sociological variable was able to account for it. They deemed longitudinal research a waste of resources since the correlates of crime are consistent across age. These two positions formed the basis for the criminal careers debate.

These developments set the stage for a number of theoretical and statistical advances in the 1990s. On the theoretical side, Robert Sampson and John Laub (1993) drew from Glen Elder’s life-course framework (1994) to develop an age-graded theory of informal social control. The life-course framework presents a way of thinking about individual development. Anything that can be measured once can be measured repeatedly, and stringing these measurements together over time creates a *trajectory*. Embedded within, and providing meaning to these trajectories are life *transitions*, which, if they redirect the trajectory onto another path, are called *turning points*. In contrast to Sampson and Laub's age-graded theory, Moffitt's (1993) typological theory of antisocial behavior posited that the age-crime curve is made up of two groups with distinct trajectories of antisocial behavior and distinct etiologies.

The criminal careers debate engendered several methodological advances as well. Rowe and colleagues (1990) used Rasch modeling to arbitrate between Hirschi and Gottfredson's parsimonious latent trait theory and the contention of the criminal careers model that each component of the criminal career may require distinct theoretical explanation. And in 1993, Nagin and Land introduced the group-based trajectory model to address several theoretical puzzles posed by the criminal careers model. This paper modeled longitudinal patterns of individual offending using a finite mixture model of time-varying rates of offending. This established the groundwork for a long line of statistical advances that have profoundly affected the field of criminology.

State of the Art

Overview

Any phenomenon or characteristic that evolves over age or time in an identifiable population may be an appropriate candidate for group-based trajectory modeling. This tool has the potential to draw out common patterns and help the researcher to make sense of the data. Group-based trajectory modeling produces a parsimonious summary of a complicated distribution of longitudinal developmental trajectories using a finite set of developmental trajectories and their estimated population prevalence. In contrast, hierarchical linear modeling and latent curve analysis summarize this complicated distribution even more parsimoniously, with a single developmental trajectory representing the average, and some characterization of the nature of variation around this average, obtained by imposing fairly strict distributional assumptions.

As opposed to these strict distributional assumptions, group-based trajectory modeling is agnostic on the nature of the distribution of growth parameters. It allows for the possibility for meaningful subgroups within the population that follow distinct developmental paths. The nature and definition of these "subgroups" has fueled a considerable amount of debate. It should be recognized that these groups may only be identified *after* the developmental paths that define them have already unfolded. That a distinct group is identified by the model does not speak to the issue of prospective identification of the group. Groups must be understood, like simple regression parameters, as useful simplifications and summaries of a complex reality.

Group-based trajectory models can be put to a variety of purposes. Once groups are obtained, description of each group's developmental paths and antecedents can be very useful. For example, if high-rate stable, medium-rate decreasing, and low-rate offending groups are identified by a particular model, the proportion of each group possessing certain risk variables can provide information of etiological significance. More generally, group membership may be treated as a dependent variable, something to be predicted as accurately as possible. Covariates may be added to the model to assess group-specific effects of certain conditions or life events on the developmental outcome of interest as well as whether these effects statistically differ between groups. Group membership can also be treated as an independent variable in a number of different ways. Variables representing group membership can be used in regression models to parsimoniously control for complicated developmental histories. Groups may also be used as the basis for matching or incorporated into a propensity score matching framework. These and other uses will be described below after first presenting data requirements, parameterization, and practical issues to address in choosing the "correct" model.

Practical Requirements

The group-based trajectory model requires panel data. There must be repeated measurements of a particular dependent variable within some unit of analysis. The unit of analysis depends on the purposes of the researcher and availability of data. To give a sense of the range of questions this method can be applied to, all the following units of analysis would be appropriate and several have been used in published research: person (delinquent, police officer, and academic), residence, street segment, journal article, sports team, gang, prison, terrorist organization, state, country.

There are currently three pieces of software able to estimate group-based trajectory models: MPLUS, the PROC TRAJ add-on to SAS, and the traj add-on for Stata. Estimation specifics in this entry will refer to PROC TRAJ, the most complete implementation of the method. Using this software, panel data must be structured in wide format: one line for each unit of analysis, with repeated measures of the dependent variable, time, and time-varying covariates represented using distinct variable names.

There are three broad distributional categories permissible for the dependent variable in PROC TRAJ: logit, censored normal, and Poisson. The censored normal distribution is flexible enough to incorporate cases of upper censoring, lower censoring, both, and neither. And the assumptions of the Poisson model can be relaxed using a zero-inflated Poisson parameterization. Categorical dependent variables and other distributions not listed here are not supported in PROC TRAJ.

Balanced panel data is not required. Any unit with one or more observations will be used in estimating the final model. Generally, at least three repeated measures within each unit are preferred to estimate a stable and meaningful model. The independent variable can be represented in units of age, time (years/months/ etc.), or other sequence. It is often desirable to create a meaningful zero value in the independent variable. For example, if estimating trajectories in young adulthood, age can be transformed so that zero represents age 18, and other ages are interpreted relative to age 18. This allows the estimated intercept of each group to quickly be interpreted as the predicted value at age 18. Centering the independent variable and scaling it down by dividing by 10 or 5 also helps the model to converge more readily.

It is worth thinking carefully about the scale of the independent variable, as transforming it can result in very different trajectory models. Consider, for example, the implications of a group-based trajectory model of marijuana use in adolescence with three types of age scales: untransformed age, age relative to the age of onset for marijuana use among those who ever reported using, and age relative to high school dropout among those who ever dropped out. The first scaling of age provides a model that characterizes longitudinal patterns of marijuana use in the population of interest. The second represents desistance/persistence patterns after initial use, and the third reveals marijuana use patterns relative to a potential turning point event.

Finally, it should be noted that the unit of time need not proceed in lock-step for each observation. For example, the model will estimate ideal group-based trajectories from age 14 to 22 even if one-third of the sample is observed only from ages 14 to 18, another third from 16 to 20, and the final third from 18 to 22. The final groups would have to be interpreted with great caution however, since they represent 8-year trajectories when no single individual is observed for more than 4 years.

Estimation

Equations used in this entry draw heavily from Nagin's (2005) detailed presentation in *Group-Based Modeling of Development*. Three subscripts will be used throughout: i refers to the unit of analysis, t to time or age, and j to group. Corresponding to these, N refers to the number of units in the model, T to the number of time periods, and J to the total number of groups in a particular model. The general form of the data used for group-based trajectory models is a set of longitudinal observations for each unit i:

$$Y_i = \{y_{i1}, y_{i2}, \ldots, y_{iT}\}$$

The set of parameters to be estimated for groups 1 through J represents a growth polynomial with respect to the unit of time. The order of the polynomial is specified prior to estimating the model, and can vary across groups. In SAS's PROC TRAJ implementation of group-based trajectory modeling, the polynomial order of each group's growth curve can range from 0 to 5. Below, for the sake of example, I present a cubic growth curve for each group j.

$$f(y_{it}) = \beta_0^j + \beta_1^j Age_{it} + \beta_2^j Age_{it}^2 + \beta_3^j Age_{it}^3 + \varepsilon_{it}$$
$$\pi_1, \pi_2, \ldots, \pi_J$$

$f(y_{it})$ refers to a link function for the outcome of interest. This can either be the censored normal, Poisson, or logit link. In all cases, we are modeling a polynomial on age/time that defines the shape of the trajectory for each group 1 through J. Although the TRAJ procedure lists group membership percents (π_j) among its parameter estimates, it actually estimates $J - 1$ parameters (θ_j) that are used to produce these probabilities. While group membership percents are bounded between 0 and 100 and must sum to 100, theta parameters are completely unbounded. This is useful in estimating the likelihood function. The two sets of parameters are related as follows:

$$\pi_j = \frac{e^{\theta_j}}{\sum_{j=1}^{J} e^{\theta_j}}$$

Because J − 1 group membership percents define the remaining group membership percent, only J − 1 parameters have to be estimated, and θ_j is set to 0, so that it equals 1 when exponentiated. This part of the estimation procedure is the same no matter which type of dependent variable is used.

The goal of estimation is to obtain a set of parameters that maximize $P(Y_i)$, the probability of observing $Y_{i,}$ the full set of individual developmental trajectories. The likelihood for each individual is obtained by summing the product of the estimated size of each group and the likelihood that the individual belongs to each group, J products for each individual. Estimates are obtained using maximum likelihood estimation with a quasi-Newton algorithm. As a by-product, if the assumptions of the model are sound, it benefits from known properties of maximum likelihood estimates.

Importantly, the model assumes conditional independence: conditional on membership in group j, deviations from the group-specific growth curve at time t is not correlated with deviations from the group-specific growth curve at time $t - 1$. In other words, conditioning on group membership, there is no serial correlation in the residuals. This is a stronger assumption than that made by standard growth curve models (CIA at the individual-level), but growth curve models also assume a multivariate distribution of parameters, which group-based models do not.

The three types of link functions entail additional parameters and modeling decisions. Censored normal models allow for censoring at either the upper or lower bounds and can also accommodate uncensored normal distributions. Lower and upper censoring limits must be provided to model this kind of distribution. If limits are set that are far outside the observed range of data, these limits do not figure heavily in the likelihood function and essentially the uncensored normal distribution is estimated. Otherwise, the model assumes the existence of a latent trait y^* that is observed only if the dependent variable is within the upper or lower censoring bounds. When y^* is outside the bounds, the observed value, y, is equal to the upper or lower bound. Additionally, censored normal models have the option of estimation of random intercepts and slopes, allowing one to estimate a hierarchical linear model with one group or growth mixture models with multiple groups. Other link functions do not provide this option in PROC TRAJ.

The logit distribution is appropriate for dichotomous outcomes such as arrest, conviction, incarceration, gang membership, high school dropout, etc. Similar to the censored normal distribution, the link function for the logistic distribution assumes the existence of a latent trait y* such that $y = 1$ if $y^* > 0$ and $y = 0$ if $y^* \leq 0$. If left untransformed, the growth curves from the logistic model are in terms of y* which is the log odds that $y = 1$.

When the dependent variable is count data such as number of arrests, the Poisson distribution may be appropriate. This distribution requires that the dependent variable take only nonnegative integer values. This type of model was in fact the first presentation of group-based trajectory models because "lambda" in the criminal careers model corresponds directly to lambda in the Poisson model: the rate of offending. Nagin and Land (1993) added a parameter for intermittency that doubles as a way to account for more zero counts than expected from the Poisson distribution. This zero-inflated Poisson (ZIP) model breaks up the probability of a zero count into two components: the probability of a zero count because lambda actually equals zero, and the probability of a zero count by chance when lambda is greater than zero. There are several options for how to specify this model using the "iorder" command in PROC TRAJ. The simplest is to estimate a single parameter for zero inflation across all groups. This can be relaxed in two ways: by estimating group-specific zero-inflation parameters, and by estimating higher order polynomials for the zero-inflation function. Additionally, exposure time can be incorporated into the model to account for different intervals between waves or across units.

Further details on the likelihood functions for these three distributions can be found in Nagin (2005, pp. 28–36).

Choosing the Final Model

PROC TRAJ does not directly reveal the best number of groups. Rather, given a set of data, a model specification, a predetermined number of groups, and starting values (optional), it obtains parameter estimates. There is a danger that these estimates represent local solutions, particularly with very complicated models. The only way to guard against this is to try different sets of starting values to determine if a better solution is obtained. But even the best solution for a specified parameterization and number of groups may not be the best overall solution. A major part of finalizing a group-based trajectory model is choosing the number of groups, tied up with this is the choice of polynomial order and other characteristics of the model.

The model choice set consists of the set of models considered as candidates for the final model. Nagin (2005) recommends a hierarchical decision-making process to reduce the number of models in this set, since it is impossible to try every possibility. The first step is to choose the optimal number of groups. Holding constant other modeling options, vary only the number of groups and assess model adequacy to determine the optimal number of groups. In the second step, specifications for each group are altered until the best solution is obtained, holding constant the number of groups. For example, in Poisson models, should zero inflation be modeled, and if so, should it be general or group-specific and should it be constant or vary over time? The optimal number of groups with general zero inflation may be different from the optimal number of groups with group-specific zero inflation, so this decision point may need to be included in the model choice set at Step 1.

There are a variety of criteria for arbitrating between models to choose the best solution. The most commonly used criterion is the BIC score, based on the log likelihood. The model with the higher BIC score (less negative) is preferred. Given a set of models, the probability that model j is the "correct" model is given by:

$$\frac{e^{(BIC_j - BIC_{MAX})}}{\sum_{1}^{J} e^{(BIC_j - BIC_{MAX})}}$$

While this may seem to provide a clear guideline for choosing the right model, it is sometimes ignored or downplayed, particularly when the optimal solution according to the BIC score is a very large number of groups. Other quantitative criteria can provide evidence of model adequacy as well.

After model estimation, the probability that each unit belongs to each group can be calculated using the likelihood function. These posterior probabilities are part of the PROC TRAJ output dataset. Each unit's maximum posterior probability is used to assign units to groups. The maximum certainty for group membership is 1, and the minimum is anything larger than 1/*J*. The mean posterior probability of group assignment conditional on assignment to that group (AvePP) is indicative of how well that group was identified. Nagin (2005, p. 88) provides a rule of thumb that these average posterior probabilities should be above .7 for each group. However, there is no formal test using this measure that indicates whether a model should be rejected. The minimum group-specific average posterior probability can be compared across models to get a sense of better-performing models. Additionally, an overall average posterior probability can be obtained by averaging every unit's maximum posterior probability, equivalent to a weighted average of group-specific average posterior probabilities, and a rough correlate of entropy, estimated in MPLUS.

Second, combining group-specific average posterior probabilities and estimated group sizes, one can calculate group-specific odds of correct classification. This essentially compares the ratio of the odds of correctly classifying individuals into group j based on the AvePP value, to the odds of correctly classifying individuals into group *j* based solely on the estimated proportion of the sample that belongs in group *j*. It is an odds ratio:

$$OCC_j = \frac{AvePP_j/(1 - AvePP_j)}{\hat{\pi}_j/(1 - \hat{\pi}_j)}$$

where AvePPj is the group-specific average posterior probability. Nagin's (2005, pp. 89) rule of thumb is that each OCC should be above 5. Again, however, this is not a formal test, but useful for comparing fit across models.

Nagin also suggests that estimated group probabilities can be compared to the proportion of the sample assigned to the group. Models with more divergent figures are less preferred. No hard limit or even rule of thumb is suggested however, other than "reasonably close correspondence" (2005:89).

PROC TRAJ also has the capability to produce confidence intervals for group membership probabilities and group-specific trajectories. These can also be produced using traditional or parametric bootstrapping. In general, as these confidence intervals widen, models are less preferred.

Finally, solution *J* + 1 may be rejected because the additional group is not substantively different from any of the groups in the *J* group solution, for example, when one group is split into two parallel groups. Sometimes a solution is rejected because it identifies an additional group estimated to comprise only a very small fraction of the population, which has limited external validity.

Focusing exclusively on the BIC score can lead to models with little utility. For example, when using a very rich dataset with large N and large T, the upper limit on the number of groups may outstrip their empirical and/or theoretical utility. A more reasonable approach takes into account a variety of model diagnostics to choose the best solution. Unfortunately, there is no ironclad rule for any of these diagnostics. Even the BIC, which seems to offer some certainty to the model choice problem, is highly influenced by the model choice set, and can lead to models which seem to capitalize on random noise. In the end, professional judgment must be exercised in choosing the best model. Taking all diagnostics into consideration, the most defendable and useful model should be retained.

Post-Estimation

As noted in the previous section, after the model is estimated, for each individual and each group, a posterior probability of group membership is estimated. In addition, a categorical variable is created based on posterior probabilities that classifies each unit in a group based on the maximum posterior probability. These are useful in many ways besides model diagnostics. First, they can be used to create group profiles. Second, they can be used as control variables in regression models. Finally, they can be incorporated into matching frameworks.

For each application, there are two options: classify and analyze vs. expected value methods. To illustrate, if we wish to determine the proportion of each group that are male, using the classify-analyze method, we would simply cross-tabulate the categorical group variable with the gender variable. The main shortcoming of the classify and analyze method is that it does not take into account uncertainty in group assignment. When average probability of group membership in a particular group is 75 %, for example, it does not seem advisable to take categorization into the group at face value. Using posterior probabilities takes this uncertainty into account. The expected value method requires a few extra steps to estimate the proportion male in each group. To estimate the proportion of group 1 that is male, calculate the mean for the "male" variable using posterior probabilities for group 1 as a weight. This is repeated for each group. Each person contributes to this group-specific mean proportional to the probability of membership in that group.

The same options are available when incorporating measurements of group membership into regression or matching models. One danger in this type of application, however, is that regardless of which method is chosen, estimation error in group classification is not taken into account. Failing to take this estimation error into account results in biased standard errors. This measurement error can be accounted for using bootstrapping methods.

Model Extensions

Since introducing the PROC TRAJ procedure (Jones et al. 2001), Nagin and colleagues have added a number of modifications and extensions to the model (Haviland et al. 2011; Haviland and Nagin 2005, 2007; Jones and Nagin 2007; Nagin 2005). The discussion here will focus on bootstrapping to obtain confidence intervals, testing equality of coefficients, trajectory covariates, and group membership predictors. Dual trajectory analysis, multitrajectory analysis and incorporating group-based trajectory modeling into matching protocols will be briefly touched upon as well, with reference to other sources for a full treatment.

We can place confidence intervals around any single parameter estimated via group-based trajectory modeling since standard errors are provided for every estimated parameter. However, certain values of interest are functions of multiple estimated parameters. Group membership probabilities are a nonlinear function of $J - 1$ theta parameters and the growth curves themselves are products of polynomials sometimes transformed through a link function or otherwise modified through extra parameters of the Poisson and censored normal specifications. There are several approaches that can be taken to address this problem and place confidence intervals around these estimates.

A typical approach to bootstrapping would create a large number (500, for example) of samples by resampling from the original dataset with replacement, and reestimate the trajectory model on each of the samples to generate a distribution of parameters, group membership proportions, and/or levels of each group's developmental trajectory to obtain a confidence interval free of distributional assumptions. While this approach is possible using PROC TRAJ, it can be very time intensive. Further, it's not clear that trajectory groups have consistent meaning across bootstrap samples.

Nagin (2005) suggests using parametric bootstrapping to obtain confidence intervals. Instead of resampling and reestimating the model, parametric bootstrapping simulates the exercise by using the means of the parameter estimates and the variance/covariance matrix. These are taken as values defining a multivariate normal distribution, for which a large number of draws are estimated, and then confidence intervals are obtained the same way they usually are, by appropriate percentile ranks. Because the multivariate normal distribution is well defined, taking even 10,000 replications is much easier than even 500 replications via traditional bootstrapping.

Jones and Nagin (2007) propose a third alternative for generating confidence intervals around growth curves. They introduced a "ci95m" option in PROC TRAJ that provides 95 % confidence intervals around growth curves using Taylor polynomial expansion to approximate the standard errors of combinations of parameters. These confidence intervals can be plotted using the "%trajplotnew" macro. Regardless of how confidence intervals are obtained, they are useful for establishing the precision of a group-based trajectory model. Distinct groups become less interesting if their confidence intervals overlap. Similarly, we change our assessment of a 5 % high-rate offending group if we learn that the confidence interval for the group's size ranges from 1 % to 20 % versus 4 % to 6 %.

Jones and Nagin (2007) also introduced an important macro add-on for PROC TRAJ that allows one to easily conduct Wald tests for equality of coefficients (%trajtest). This can be used to test equality of growth parameters across groups and has a number of important applications in combination with other extensions of PROC TRAJ described below.

The life-course paradigm organizes the study of human development around longitudinal trajectories, life transitions, and turning points. If a life transition shifts an individual's developmental trajectory onto a new path, it is a turning point. This suggests a counterfactual type of analysis, answering the question of what would have happened for individuals in situations which they did not experience. Group trajectories, because they represent a group of individuals that are similar with respect to their developmental path and related covariates, provide an important source of plausible counterfactuals to test for these kinds of effects. Group-specific trajectories can easily be generalized to accommodate *m* time-varying covariates (x_1 through x_m):

$$f(y_{it}) = \beta_0^j + \beta_1^j Age_{it} + \beta_2^j Age_{it}^2 + \beta_3^j Age_{it}^3 + \alpha_1^j x_{1it} + \alpha_2^j x_{2it} + \ldots + \alpha_m^j x_{mit} + \varepsilon_{it}$$

Trajectory covariates can test a wide range of hypotheses from life-course criminology. The specific interpretation of these covariates depends on how they are entered into the model. The simplest strategy is to enter a series of dummy variables reflecting being in a particular life state such as being married, in a gang, employed, etc. This results in group-specific estimates that are easy to interpret, but does not capture the dynamic element of turning points. It does allow for an easy test of whether the effects of that life state depend on group membership, using the %trajtest macro. It assumes constant effects over time/age and over years in the state. If marriage is introduced in this manner, it imposes an assumption that the effect of marriage depends neither on when a person gets married nor length of marriage. A more flexible method consistent with the life-course paradigm would enter a dummy variable for being in a particular state, age interacted with this dummy variable, as well as a counter variable for years in the state. This would allow the effect of marriage to vary according to when one gets married and to increase or decay depending on how long one stays married.

While posterior probabilities and group membership categories can be used to create group risk profiles, these profiles are of limited use because of error estimates biased due to lack of incorporation of group estimation error. But these risk variables can be incorporated directly into trajectory models, allowing all parameters to be estimated at the same time and with correct standard errors.

The trajectory model changes in several important ways when risk variables are incorporated into it. The shape of the trajectories in the optimal solution may change, and posterior probabilities depend not only on levels of the dependent variable but also on risk variables. Group membership probabilities are estimated conditional on a set of risk variables (x_1 through x_r, for *r* risk variables). Multiple thetas are estimated for each group. These are used to generate predicted group probabilities for specified sets of risk variables.

$$\theta_j = \sum_{r=1}^{R} \theta_{jr} x_r = \theta_{j0} + \theta_{j1} x_1 + \theta_{j2} x_2 + \ldots + \theta_{jR} x_R$$

With risk variables, the intercept theta estimates can be used to calculate group membership probabilities when all risk variables are equal to zero. If all risk variables are centered at their means before estimating the trajectory model, then the intercepts would represent theta estimates at the average. The differential impact of risk variables on group membership probabilities can be tested using the %trajtest macro, and confidence intervals around theta estimates or group membership probabilities for specific sets of risk variables can be calculated using bootstrapping.

When more than one dependent variable is of interest, either because of comorbidity of developmental trajectories, heterotypic continuity or a developmental predictor of a developmental outcome, a couple options are available in PROC TRAJ. Dual trajectory analysis (Jones and Nagin 2007; Nagin 2005, Chap. 8) is a very flexible extension of standard trajectory analysis. The basic requirement is that two dependent variables are meaningfully linked via the unit of analysis. Each unit should have repeated observations for both dependent variables. The dependent variables need not be distributed the same way, need not be measured at the same time nor have the same number of measurements, and the estimated number of groups need not be identical. The two dependent variables are linked through a shared variance-covariance matrix and a set of group membership probabilities for one series that are conditional on group membership in the other series. These allow the full set of unconditional, conditional, and joint group membership probabilities to be estimated. Conditional group membership predictors can be included as well.

When more than two dependent variables are of interest, the parameter space for extending the dual trajectory analysis quickly becomes unwieldy. But when the focus is on only two or three dependent variables, multitrajectory modeling is available in PROC TRAJ using the "MULTGROUPS" option (Jones and Nagin 2007). This type of model is constrained in that no cross-classification is estimated across dependent variable types. Instead, each group is defined by a set of trajectories across two or three dependent variables. This simplification greatly reduces the number of parameters that need to be estimated while still providing a rich portrayal of group heterogeneity. As with dual trajectory analysis, the distribution of the dependent variables, the number of observations (T) need not match, and the timeframe need not overlap. The main restriction is that the number of groups must be the same, and of course no cross-classification is estimated.

Recent work incorporates group-based trajectory modeling into a matching framework (Haviland and Nagin 2005, 2007). The basic insight of this work is that developmental histories can serve as important proxies for more complicated processes, and matching within developmental history group serves to balance numerous characteristics – not only the dependent variable of the trajectory model, but numerous related developmental trajectories and risk variables correlated with these trajectories. Haviland and Nagin (2005, p. 4) think of these groups as "latent strata in the data." Of course, the power of this method depends quite a bit on the extent to which the developmental history being modeled is linked to the selection process for the treatment of interest.

If treatment is random conditional on group membership, this method can provide a convincing measure of turning point effects, where estimated effects are group specific, but can be aggregated through a weighted average to obtain population average effects. Haviland and Nagin's method establishes developmental paths preceding potential turning points. Within each path, there are two possibilities, one might experience the turning point event, or not. Those individuals within the developmental group who do not experience the turning point event serve as natural counterfactuals for those that do. Assessing differences longitudinally after the turning point event allows us to see whether differences between the two groups emerge, and whether those differences increase, remain stable, or decay over time. To the extent that they persist, evidence for the existence of a turning point is shown. Life-course research also suggests that the response to a turning point event may depend on prior developmental histories. This method allows one to explicitly test that hypothesis. To the extent that groups do not balance important treatment predictors, the group-based trajectory model can be incorporated into a more general propensity score framework, either with propensity score models embedded within each trajectory group, or posterior probabilities of group membership incorporated into a single propensity score model.

Controversies

Group-based trajectory modeling has attracted an unusual amount of criticism of a surprisingly harsh tone. Objections to group-based trajectory models center around the meaning of "group" and the relative merits of alternative statistical models.

Since the concentration of offending was publicized by Wolfgang and colleagues (1972), the search for the high-rate offending group *before* they engage in the bulk of their crimes has taken up a great deal of resources. In fact, reliably prospectively identifying the chronic offender has been something of a white whale of criminology for decades. Blumstein and Moitra (1980) showed that retrospective identification of groups in Wolfgang et al. did not hold up prospectively, so that the "chronic offender" label was not useful for selective incapacitation of "career criminals." More recently, Sampson and Laub (2005) have shown that although retrospective offending groups can be identified in their Boston data, even very rich sets of theoretically based predictors cannot reliably distinguish between the groups prospectively. The central point is that even though high-rate offending "groups" can be identified retrospectively either through simple decision rules as in Wolfgang et al. (1972), or through more statistically sophisticated methods such as group-based trajectory models, clustering or other finite mixture models, prospectively, for policy and theoretical purposes, these "groups" do not exist. This is not to say that these groups have no significance, but that their identification in a group-based trajectory model is just the starting point. If the researcher wants to make the case that a specific group is important, that argument must be grounded in theory (Brame et al. 2012) and there must be some demonstration that the group exists outside a single group-based trajectory model.

Critics of this method either over-interpret the significance of groups or imply that because of the nature of the model, other less sophisticated researchers will reify the groups. But of course, the search for the "chronic offender" that Blumstein and Moitra (1980) debunked demonstrated that sophisticated models are not needed in order for reification of a high-rate offender typology to occur.

Many critiques of group-based trajectory modeling are premised on the notion that another statistical tool is superior. Generally speaking, there are three options for summarizing longitudinal developmental patterns: group-based trajectory models, hierarchical linear models, and growth mixture models. Each of these models simplifies a more complex reality in a different way. The differences boil down to how heterogeneity in developmental patterns is characterized. Hierarchical linear models characterize heterogeneity as a jointly normal distribution of parameters centered around the overall average. Group-based models characterize heterogeneity using a mixture of a finite number of growth curves that are support points of a complex distribution. Growth mixture models combine the two strategies, modeling jointly normal distributions of parameters around each group's average trajectory. Arbitrating between these choices depends on the nature of the research problem and the purposes of the analysis. Nagin (2005) points to complexity of the continuous distribution as an important guide when choosing between group-based and hierarchical linear models.

Future Directions

To date, although group-based trajectory modeling has been extensively employed in the criminological literature, its uses have usually been limited to descriptive exercises. More sophisticated applications such as Haviland and Nagin's matching method and correct modeling of standard errors using some form of bootstrapping have been less often employed. It is hoped that future work using the method will realize its full capabilities.

Despite the lack of uptake of these more sophisticated features, further development of the model has the potential to greatly benefit the field. The range of dependent variable distributions, although sufficient for most applications in criminology, could be expanded. For example, multinomial, categorical, and quantile group-based trajectories could have immediate applications. Advances such as multitrajectory modeling could be generalized to any number of dependent variables, allowing for complex characterizations of developmental history typologies and perhaps an even stronger basis for identifying latent strata in the data. And the problem of local solutions could be tackled and better understood by incorporating an automated start value algorithm, which is currently offered in the MPLUS implementation of the model.

Conclusion

Group-based trajectory modeling is a powerful tool that can be put to a very wide variety of uses alongside hierarchical and growth mixture models. Through careful, thoughtful use, it can test a number of important theoretical hypotheses (Brame et al. 2012).

Group-Based Trajectory Models and Developmental Change

Robert Apel
School of Criminal Justice, Rutgers University,
Newark, NJ, USA

Overview

The widespread availability of panel data on unlawful behavior has stoked criminological interest in statistical methods that are capable of quantifying developmental change. One such method is the group-based trajectory model of Nagin (1999, 2005; Nagin and Land 1993), which has become an essential tool for quantitative criminologists who conduct analysis with longitudinal data. It has been widely utilized to study the development of delinquent and criminal behavior in a variety of American and cross-national contexts.

The appeal of the group-based trajectory model stems from the fact that it explicitly allows for heterogeneous developmental pathways, without imposing any assumptions about the distributional properties of the heterogeneity. Instead, heterogeneity of unknown form is approximated using a discrete mixture of two or more distributions. This is in contrast to other conventional panel data estimators, which require the analyst to impose untestable (ergo, unfalsifiable) assumptions about the form of the heterogeneity, namely that it varies continuously in the population (usually in the form of a normal distribution).

This essay proceeds as follows. First, some background on the group-based trajectory model, as used in criminology, will be provided. Second, details on the estimation of the model will be given by way of an empirical illustration. Third, more flexible uses of the model, beyond quantifying developmental change, will be described. The essay closes with some concluding remarks.

Background of the Group-Based Methodology

The rationale of the group-based trajectory model is provided by Heckman and Singer (1984), in an analysis of the determinants of unemployment duration. They argued that insufficient attention had been devoted to *population heterogeneity*, or temporally persistent unobservables which underlie relative differences across individuals in spell length. The problem is that failure to adequately control for population heterogeneity produces bias in structural parameters of interest. They observed further that theory rarely provides guidance about the distribution of unobservables: “The choice of a particular distribution of unobservables is usually justified on the grounds of familiarity, ease of manipulation, and considerations of computational cost” (p. 272). In a parametric analysis of single-spell duration data, they demonstrated that structural estimates (for age, education, marriage, tenure of the previous job, unemployment benefits, unemployment rate, and unemployment duration) were extremely sensitive to the distribution chosen to model unobservables, each of which was *ex ante* theoretically plausible. Indeed, they concluded that "there are as many different 'structural models' as there are distributions of heterogeneity" (p. 276).

In an econometrically dense exposition, Heckman and Singer (1984) then proposed a non-parametric estimator intended to minimize the impact of (arbitrary) distributional assumptions on parameter estimates. Their method entailed the specification of a finite number of underlying distributions or "points of support" for the distribution of unobserved heterogeneity, each with unique location (mean) and shape (variance) parameters. Importantly, no single parametric distribution produced estimates that harmonized fully with the non-parametric estimator. Furthermore, their simulation showed that, while it did not reliably estimate the underlying mixing distributions, the non-parametric estimator was quite successful at recovering structural parameters and reproducing sample duration times.

In criminology, two developments had a more immediate influence on the origin of the group-based methodology: the criminal career paradigm of the 1980s and taxonomic theories of unlawful behavior of the 1990s. First, the 1980s gave rise to the criminal career perspective, which partitions the aggregate age distribution of crime into two distinct phenomena: the fraction of the population that is criminally active at any given age (participation), and the number of crimes committed per year by any given active criminal (frequency) (Blumstein et al. 1986). Crime prevention policies could then be classified as to whether their impact on the crime rate was through participation or frequency. This perspective led to the parameterization of the essential features of an individual's "criminal career," including age of initiation (A_0), age of termination (A_N), length of the criminal career ($T = A_N - A_0$), and offending frequency (λ, or lambda), or the number of crimes committed per year while criminally active.

The second major influence on the development of the group-based trajectory model was taxonomic theorizing about the unfolding of delinquent and criminal behavior over the life span, most prominently in the work of Moffitt (1993). She theorized that the population is comprised of two distinct groups or "taxons" that differ in meaningful ways in the causes, consequences, and developmental courses of unlawful behavior. The "life-course-persistent" pathway characterizes a comparatively small fraction of the population, but is distinguished by early onset, temporal persistence, and involvement in a large class of antisocial behaviors, originating in neuropsychological deficits that interact with environmental disadvantages. The "adolescence-limited" pathway, on the other hand, characterizes the lion's share of the population, and is distinguished by pubertal onset, acquisition from mimicry, maintenance through social reinforcement, and discontinuity as the maturity gap is successfully bridged. In short, the life-course-persistent pathway is pathological, whereas the adolescence-limited pathway is normative.

A key empirical requirement of both the criminal career paradigm and taxonomic theory is availability of long-term panel data on individual offending, along with a grouping procedure capable of identifying distinct classes of offenders. With panel data and latent class methodology, then, it becomes possible to answer a variety of unresolved questions: Is λ constant or age graded over the duration of the criminal career? Do all individuals follow the same basic criminal career, perhaps differing only in degree, or are there distinct groups in the population? How many groups exist in the population? Do different groups of offenders have distinct etiological pathways?

With the foregoing econometric and criminological developments as background, Nagin and Land (1993) introduced the group-based trajectory model to criminology. They applied the non-parametric approach of Heckman and Singer (1984) to panel data on criminal behavior, in the process providing preliminary answers to questions of interest for the criminal career paradigm and taxonomic theories. In their analysis, they used data on criminal conviction frequency spanning ages 10–30, from the Cambridge Study in Delinquent Development. They characterized their method as a non-parametric, mixed Poisson model. Their key findings are summarized below, but statistical details on their model are reserved for the next section.

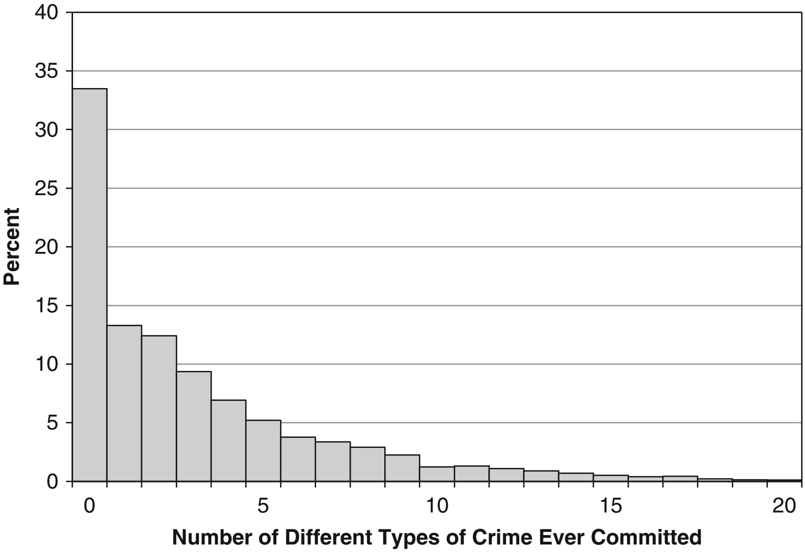
Nagin and Land (1993) settled on a four-group solution, producing a number of important findings. The first result concerned the form of λ over time, and revealed that conviction frequency has a pronounced relationship with age. When they constrained the sample to have a common age trajectory (i.e., a common peak age) that differed only in level, conviction frequency was shown to reach a single peak at age 18 and then decline by a considerable margin by age 30. The second result addressed heterogeneity in criminal careers, and revealed substantial differences across groups in the essential features of the age distribution of criminal conviction. Peak ages ranged from 14 to 22, and the groups varied considerably in the shape of the age-conviction curve, exhibiting a pronounced peak at an early age followed by a rapid decline ("adolescence limited"), slow acceleration and deceleration but the most frequent convictions at all ages ("high-rate chronic"), and a flatter, more chronic age profile ("low-rate chronic"). The third result concerned the differential predictability of group membership from a number of background risk factors, revealing a variety of differences in both degree and kind. For example, the high-rate chronic offenders were distinguished by the presence of delinquent siblings and more widespread involvement in antisocial behavior (e.g., lying, truancy, heavy drinking, marijuana use), while the low-rate chronic offenders were distinguished by unusually low intelligence. The adolescence-limited offenders, on the other hand, were distinguished from the chronic offending groups by more popularity among peers and better school performance.

The Nagin and Land (1993) study was closely followed by further efforts to explore the utility of the group-based trajectory model for studying the essential features of criminal careers (D'Unger et al. 1998; Land et al. 1996; Land and Nagin 1996; Nagin et al. 1995). Across numerous datasets, these studies have found that there is a general tendency to extract four–five trajectory groups, with some commonality in the basic contours of the trajectory profiles. One group can be classified as non-offenders or intermittent offenders, one group can be described as adolescence-limited offenders, and one group can be classified as chronic offenders. Oftentimes, the latter can be further stratified into two subgroups: a high-rate chronic and low-rate chronic group.

Estimation and Evaluation of the Group-Based Trajectory Model

The group-based trajectory model is a semi-parametric approach to modeling longitudinal outcomes. Described simply, the method groups subjects into more homogeneous latent classes based on their longitudinal sequence of behavior. It is in the class of finite mixture models discussed at length by McLachlan and Peel (2000). The group-based model is parametric by specifying a probability distribution governing the realization of the response variable (e.g., normal, logistic, Poisson), as well as by specifying the functional form of the response as a polynomial in age or time. The group-based model is non-parametric in terms of specifying the population as a multinomial mixture of two or more such distributions ("points of support"), with the parameters of each component of the mixture estimated freely. The group-based trajectory model has been shown to have desirable properties in applications where the components in the mixture are well separated (Brame et al. 2006; Loughran and Nagin 2006).

To walk readers through an empirical application, data on self-report offending from the National Longitudinal Survey of Youth 1997 (NLSY97) will be analyzed. The response variable is a variety scale composed of 20 dummy indicators, ranging in seriousness from minor offenses such as petty larceny (less than $50) and destruction of property, to more serious offenses such as aggravated assault and robbery. For each offense, respondents are coded "1" if they reported engaging in the behavior since the last interview (or ever prior to the initial



Group-Based Trajectory Models and Developmental Change, Fig. 1 Histogram of cumulative self-report crime variety (Note: $N = 8{,}984$. Percentages are weighted. This figure represents the distribution of delinquent/criminal behavior across the first seven waves of the NLSY97, using all available information from respondents. Source: National Longitudinal Survey of Youth 1997, Rounds 1–7)

interview) and coded "0" otherwise. These indicators are then summed at each interview, yielding a measure of the number of different kinds of criminal acts committed. A histogram of the cumulative distribution of the variety scale is provided in Fig. 1. To create this figure, a lifetime indicator (using information from all available interviews) for each of the 20 criminal acts was constructed for each respondent, and was then summed. Two-thirds of the NLSY97 sample (66.5 %) reports involvement in unlawful behavior at some point during the first seven interview waves.

Before proceeding with the analysis, Fig. 2 provides an illustration of the age-graded nature of delinquency/crime in the NLSY97 data. It exhibits the classic features of the age-crime curve, with a peak of almost 1.3 different types of crime per year during the 14–16 age range, followed by a steady decline through the late teens and a leveling out at under 0.3 in the early 20s. Basically, the group-based trajectory model will be used to ascertain whether this average developmental pathway characterizes all youth in the sample (to a greater or lesser degree, at least), or whether qualitatively distinct pathways are evident in the data.

To formalize the group-based trajectory model, Y_{it} represents a count of the number of different kinds of criminal behaviors (i.e., crime variety) reported by subject i (i = 1,. . .,N) in time t (t = 1,. . .,T). It is natural to presume that Y_{it} is a Poisson random variable with density:

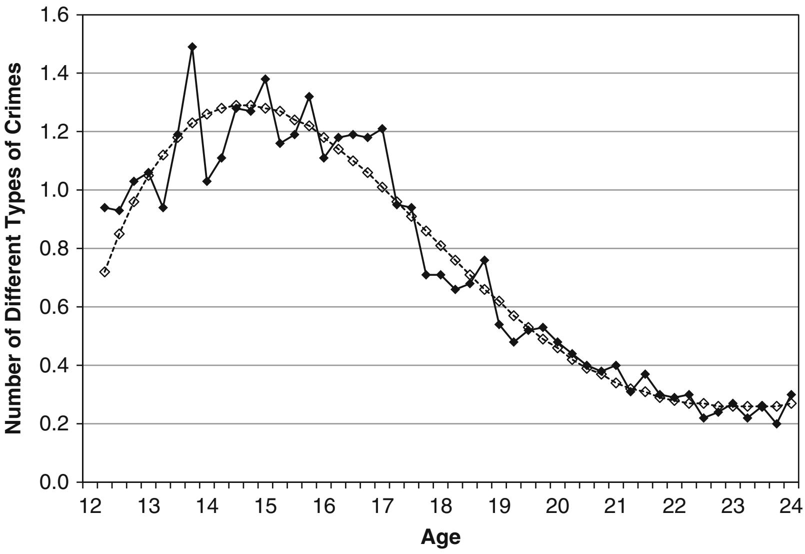
$$f(Y_{it}) = Pr(Y_{it} = y|\lambda_{it}) = \frac{e^{-\lambda_{it}}\lambda_{it}{}^{y}}{y!}$$

wherein λ_{it} represents an individual's underlying rate of offending, or the number of different kinds of crimes committed per unit of time (e.g., per year). An individual's (logged) offending rate, given membership in trajectory group j, is then modeled as a polynomial function in age:

$$ln\left(\lambda^{j}_{it}\right) = \beta^{j}_{0} + \beta^{j}_{1}Age_{it} + \beta^{j}_{2}Age^{2}_{it} + \beta^{j}_{3}Age^{3}_{it}$$

Here, age is assumed to follow a cubic functional form, although other polynomials are obviously possible. The parameters define the shape of the trajectory, and the j superscripts denote group-specific parameters for j = 1,. . .,M trajectory groups. So if a one-group model is specified, four shape parameters are estimated; if a two-group model is specified, eight shape parameters are estimated; and so on.

Estimation of the group-based trajectory model proceeds by way of maximum likelihood.



Group-Based Trajectory Models and Developmental Change, Fig. 2 Age distribution of self-report crime variety (Note: $N = 8{,}984$. Estimates are weighted but are not exposure adjusted. The *dashed lines* are predicted values fit from a fourth-order polynomial in a linear model with random effects. Source: National Longitudinal Survey of Youth 1997, Rounds 1–7)

Define a vector $\mathbf{Y_i}$ to represent the longitudinal sequence of individual i's self-report crime variety:

$$\mathbf{Y_i} = \{Y_{i1}, Y_{i2}, \ldots, Y_{iT}\}$$

Then let P($\mathbf{Y_i}$|j) represent the conditional distribution of $\mathbf{Y_i}$ given membership in group j, in other words, the probability of observing individual i's crime "trajectory" conditional on his being in group j. In the current example, this is constructed from the Poisson probability distribution. An important assumption of the group-based trajectory model concerns the conditional independence of the sequential realizations of Y_{it}, which allows us to write the conditional distribution of $\mathbf{Y_i}$ as:

$$P(\mathbf{Y_i}|j) = \prod_{t=1}^{T} f(Y_{it}|j) = \prod_{t=1}^{T} \frac{e^{-\lambda_{it}^{j}} \lambda_{it}^{j\ y}}{y!}$$

where

$$\lambda_{it}^{j} = e^{\beta_0^j + \beta_1^j Age_{it} + \beta_2^j Age_{it}^2 + \beta_3^j Age_{it}^3}$$

Now, let π_j represent the probability of membership in group j. Thus formalized, the unconditional probability of observing individual i's longitudinal sequence, or the marginal density of $\mathbf{Y_i}$, can then be recovered by aggregating across M conditional distributions:

$$P(\mathbf{Y_i}) = \sum_{j=1}^{M} \pi_j P(\mathbf{Y_i}|j)$$

Finally, in a sample of N independent individuals, the sample likelihood is formed by the product of N such marginal densities:

$$L\left(\pi_j, \beta_0^j, \beta_1^j, \beta_2^j, \beta_3^j | Y_{it}, Age_{it}\right) = \prod_{i=1}^{N} P(\mathbf{Y_i})$$

A SAS-based procedure, Proc Traj, has been developed by Jones et al. (2001; Jones and Nagin 2007) to estimate the group-based trajectory model as parameterized above. One practical challenge to estimation of group-based trajectories is model selection, specifically, decision making about the optimal number of trajectory groups. Nagin (1999) advocates use of the Bayesian Information Criterion (BIC) rather than the log likelihood, because trajectory models are not formally nested in the way required to conduct a likelihood ratio test. The BIC is estimated by:

$$BIC = ln(L) - \frac{1}{2} K ln(N)$$

Group-Based Trajectory Models and Developmental Change, Table 1 Model summaries from trajectory group solutions

Model summary	2-group solution	3-group solution	4-group solution	5-group solution
Parameter estimates	9	14	19	24
Log likelihood	−66,247.15	−62,187.58	−60,521.25	−59,388.47
BIC	−66,288.11	−62,251.30	−60,607.74	−59,497.71
2 × (ΔBIC)	–	8,073.62	3,287.12	2,220.06
Probability correct model	0.00	0.00	0.00	1.00

Note: $N = 8{,}984$. The models use information on self-report crime variety from the first (1997) to the seventh (2003) interviews. Although the coefficients are not shown, a cubic functional form in age is specified for each trajectory group. The first row from the bottom is the log Bayes factor approximation, and contrasts a model with j + 1 trajectory groups to a model with j trajectory groups. Values in excess of 10 are regarded as very strongly supportive of a model with j + 1 trajectory groups. The bottom row provides the posterior probability that the referent model is the correct model, when equal weight is placed on the prior probability that each model is the correct one

where ln(L) is the log likelihood, K denotes the number of parameters, and ln(N) is the log sample size.

Table 1 provides the BIC and other quantities of interest from models assuming two–five Poisson mixtures for the NLSY97 data. Computing twice the difference in BIC's between two models provides a useful guide to decision making about the number of components in the mixture (Jones et al. 2001), as does the posterior probability that any given model is "correct" when more than two models are being compared and equal weight is placed on their prior probabilities (Nagin 1999). The latter is estimated by the formula:

$$\frac{e^{BIC_j - BIC_{max}}}{\sum_j e^{BIC_j - BIC_{max}}}$$

where BIC_j is the BIC from the referent model, and BIC_{max} is the maximum BIC of all of the models under consideration. By both of these criteria, Table 1 shows that the preferred solution is the model with five trajectory groups. (Note that this example is not intended to be a formal analysis of the optimal number and shape of the crime trajectories. It is strictly intended to serve as an illustration. A formal analysis for this author would require sequentially adding more components to the mixture until the model can no longer converge, adjusting the order of the polynomials for the trajectory groups to identify the optimal fit, examining the utility of including an inflation parameter in the Poisson model, and experimenting with a variety of start values to evaluate the robustness of the final solution).

Results from the five-group solution are provided in Table 2. The output from Proc Traj includes the parameter estimates characterizing the shape of the trajectory for each group and the proportion of the population that is estimated to follow group j's pathway, as well as estimates of the probability that a subject belongs to each trajectory group. The latter are known as "posterior probabilities" (not to be confused with the posterior probability that a model is correct, as estimated from the formula above). To aid interpretation of the parameter estimates characterizing the shape of the trajectories, they are plotted against age in Fig. 3.

One of the first things to notice about the parameter estimates and plotted trajectories is just how heterogeneous the developmental pathways of delinquent/criminal behavior are in the NLSY97. The model suggests that about one-half of youth – Group 1 (49 %) – follow a non-offending pathway, or at least a highly intermittent one, as the offending rate is non-zero but quite low during the teenage years. One-third of youth – Groups 3 and 4 (25 % and 8 %, respectively) – follow an adolescence-limited pathway that peaks at 14–15 years of age, but at very different levels. Specifically, Group 3 peaks at about 1.5 different crimes while Group 4 peaks at almost 4.5 different crimes. (Substantively, a value of 1.5 on the variety scale translates into about 3.5 total crimes per year – one criminal act every 3.5 months – while a value of 4.5 on the

Group-Based Trajectory Models and Developmental Change, Fig. 3 Age distribution of self-report crime variety, by Trajectory Group (Note: Parameter estimates for this trajectory model are shown in Table 2)

variety scale represents about 23.2 total crimes per year – about two criminal acts per month. This was determined by mapping mean crime frequency onto crime variety.) A bit less than one-fifth of youth – Groups 2 and 5 (13 % and 5 %, respectively) – appear to follow a chronic pathway, but again at very different levels. Group 2 peaks at about 1.5 different crimes while Group 5 peaks at more than 4.5 different crimes. However, both groups continue offending well into their 20's, when all other youth have, for all intents and purposes, desisted from crime.

Having selected the optimal model and described the five trajectory groups, an important next step is to diagnose how well the model fits the data. Nagin (2005) outlines a variety of diagnostic criteria, including the discrepancy between the proportions of the population and sample in each trajectory group, the mean posterior probabilities of group assignment, and the odds of correct classification (OCC). Each of these criteria is shown in the bottom half of Table 2.

One diagnostic involves a comparison of the proportion of the population that is estimated to follow a given trajectory, with the proportion of the sample that is “assigned” to the same trajectory. The former proportion, π_j, is a component of the likelihood function:

$$\pi_j = \frac{e^{\theta_j}}{\sum_{j=1}^{M} e^{\theta_j}}$$

where the normalization, $\theta_1 = 0$, ensures identifiability (note, $e^0 = 1$). The sample counterpart is derived from the posterior probabilities, or the model-predicted probability that an individual is assigned to each trajectory group. Formally, the probability that any given sample subject is assigned to trajectory group j, given her longitudinal sequence of criminal behavior, is estimated by appealing to Bayes’ theorem:

$$P(j|\mathbf{Y_i}) = \frac{\pi_j P(\mathbf{Y_i}|j)}{\sum_{j=1}^{M} \pi_j P(\mathbf{Y_i}|j)}$$

The proportion of the sample assigned to each group is determined using the maximum posterior probability assignment rule, in which each subject is classified into the trajectory group with the highest posterior probability. The population and sample proportions shown in Table 2 suggest no major discrepancy between these two proportions.

A second useful diagnostic is an inspection of the mean posterior probabilities. These are determined by assigning subjects to trajectory groups using the maximum posterior probability assignment rule, and then computing the mean posterior probability among the individuals assigned to each group. Nagin (2005) suggests that a mean in excess of 0.7 is evidence of good classification. In the current example, shown in Table 2, the lowest mean posterior probability is 0.83 (Group 3), indicating good model fit by this criterion.

A third diagnostic is the “odds of correct classification” (OCC), which uses the mean posterior probability as well as the population proportions. It is computed for each trajectory group in the following manner:

$$OCC = \frac{\overline{\mathrm{P}}(j|\mathbf{Y_i})/(1-\overline{\mathrm{P}}(j|\mathbf{Y_i}))}{\widehat{\pi}_j/(1-\widehat{\pi}_j)}$$

Nagin (2005) indicates that an OCC in excess of 5.0 indicates good model fit. Among the estimates in Table 2, the smallest OCC is 11.9 (Group 1), confirming that the model provides good classification of sample subjects to trajectory groups.

Extensions of the Group-Based Methodology

There are manifold uses for the group-based trajectory model, beyond its clear descriptive capability as shown in the previous section. For example, the model can be used to quantify the degree to which the developmental history of crime modifies the causal effect of a nonrandom “treatment” on subsequent criminality (e.g., employment, school dropout, marriage, gang membership, incarceration). There are at least two pernicious problems in the estimation of treatment effects on crime from nonexperimental data, which the trajectory methodology is well positioned to remedy. The first problem is that treatment assignment may not be independent of the response variable of interest. The second problem is that the impact of treatment may not be uniform across the population of interest. Manski (1995) refers to the first as the *selection problem*, and to the second as the *mixing problem*.

The selection and mixing problems were demonstrated in a study by Apel et al. (2007), who were interested in quantifying the effect of first-time, formal employment at age 16 on delinquent behavior. They estimated trajectories of delinquency from ages 11 to 15 among those who had not yet transitioned into the formal labor market and identified four distinctive clusters of individuals – conformists, decliners, low-level risers, and high-level risers. The selection problem was evidenced by the fact that the low- and high-level risers were more likely to be employed in excess of 20 h per week at age 16, confirming the differential selection of highly delinquent youth into “intensive” employment. The mixing problem was illustrated by the fact that, whereas for most youth the treatment effect was zero, the high-level risers experienced a significant decline in delinquent behavior when they began working intensively at age 16. In this study, then, the developmental history of delinquency was correlated with selection into treatment and also modified the existence and magnitude of the treatment effect of employment on delinquency.

A study by Haviland and Nagin (2005) assessed the effect of first-time gang membership at age 14 on violent delinquency. Their trajectory model identified three groups of youth based on their history of violence from ages 11 to 13 – low, declining, and chronic. Consistent with the selection problem, youth in the chronic trajectory were much more likely to join a gang at age 14 compared to their non-chronic peers. Consistent with the mixing problem, the effect of gang involvement exacerbated violent behavior among all three trajectory groups, but did so particularly among the chronic group.

There are many more uses of the group-based trajectory model than estimation of treatment effects than can be fully described here. Many of these are outlined in Jones and Nagin (2007). First, time-invariant regressors can be introduced into a model of group assignment, which involves introducing covariates into the model for π_j. Second, time-varying regressors can be modeled, in addition to age, in order to allow the impact of such covariates to vary by trajectory group. Third, distinct but related (i.e., co-morbid) behaviors can be modeled using the dual trajectory methodology, in order to examine how such behaviors jointly unfold. Fourth, Haviland and colleagues (Haviland and Nagin 2007; Haviland et al. 2007) have demonstrated the utility of the group-based trajectory model in combination with propensity scores to study the impact of non-random treatments on antisocial behavior.

Conclusion

In criminology, the group-based trajectory methodology arose in response to a desire to provide answers to unresolved questions that arose from the criminal career tradition, and to evaluate the empirical validity of taxonomic theories of criminal offending over the life span. It has since evolved into a general analytical approach capable of answering a variety of questions of interest to behavioral scientists. Its use is widespread not only in criminology (Piquero 2008), but in other disciplines such as clinical psychology (Nagin and Odgers 2010).

The strength of the group-based trajectory model is the flexibility gained by approximating unobserved heterogeneity of unknown density using a discrete distribution rather than the traditional approach of assuming a single continuous density, usually the normal or gamma. Yet the model is not without controversy (see Eggleston et al. 2004; Sampson and Laub 2005; Skardhamar 2010). The view of this author is that most of this controversy stems from how the groups produced by the model are used in applied settings, namely, the tendency to label and reify the groups rather than treat them as the imperfect approximations that they are.

One particularly promising use of the group-based trajectory model is as a way to control flexibly for age in panel models of criminal behavior, a recent application of which is provided by Ezell and Cohen (2005). They showed that valid inferences about the impact of time-varying regressors on criminal behavior depend crucially on how one controls for age-graded developmental change. Models which imposed a uniform age distribution for their sample resulted in substantial overestimates of the impact of time-varying regressors. Their solution was two-pronged. In the first step, they estimated a group-based trajectory model. In the second step, they entered the posterior probabilities into a panel model (except one, for the group which served as a contrast), and interacted each posterior probability with age (as well as age squared and age cubed).

There is no doubt that the group-based trajectory model is an indispensible tool in the panel data expert's toolbox. At a minimum, Heckman and Singer (1984) advocated use of non-parametric estimators – the group-based trajectory model is one such estimator – to evaluate the plausibility of estimates from more conventional, parametric specifications of the distribution of unobservables. It is difficult to find fault with such advice. Panel researchers who are serious about causal models of criminal behavior would be well advised to follow it.

Overview

Motivated by the limited available literature on the treatment of longitudinal binary and ordinal outcomes in a growth modeling framework, the goal of this entry is to provide an accessible and practical introduction of this topic for a criminological audience. The parameterization of categorical latent growth models is explained by integrating aspects of the more familiar conventional latent growth models and generalized linear models. Emphasis is placed on the process of model building, evaluation, and interpretation. The entry contains an elaboration of how to include predictors of developmental change in the model for covariate-related hypothesis tests along with remarks regarding of the importance of auxiliary information for assessing model validity and utility. Finally, several model extensions including nonlinear change, generalized growth mixture modeling, and longitudinal latent class analysis are discussed.

Introduction

Criminologists typically encounter data on crime and deviance which is skewed and discrete, thus violating the assumptions of ordinary least square (OLS) regression models, which require that the outcome variable is continuous and is (conditionally) normally distributed. Many criminological studies involve binary outcomes, such as arrest versus no arrest, or unordered categorical outcomes, such as judge and jury consensus or disagreement on conviction versus acquittal. Other outcomes consist of categories, which represent a natural ranking or ordering, such as offense severity or self-reported attitudinal items measured on a Likert scale ranging from strongly disagree to strongly agree. Finally, some outcomes in criminological inquiries consist of counts of a particular event, such as the number of police contacts or the number of arrests. Generalized linear models (GLM), originally formulated by Nelder and Wedderburn (1972), represent a flexible generalization of OLS regression to accommodate skewed and discrete outcomes in a regression framework. In addition to classic textbooks (e.g., Agresti 2002; Long 1997), ample guidance exists on direct applications of GLMs for cross-sectional binary, unordered, and ordered categorical outcomes (e.g., Britt and Weisburd 2010) as well as for count outcomes (e.g., MacDonald and Lattimore 2010) in criminological research.

Beyond the explanation and prediction of cross-sectional outcomes, describing and predicting the developmental course of individuals' involvement in criminal and antisocial behavior is a central theme in criminological inquiries. It is well-known that only repeated observations of individuals across time allow for explicit modeling of intra individual change processes and enable the charting of interindividual differences in intra individual age-crime curves including the manifest features of onset, continuation, and cessation in criminal activity (Piquero et al. 2007). In particular, longitudinal data permits proper inferences about stability and change in individual trajectories, differences across individuals with respect to their trajectories, and the predictive effects of time-invariant risk and vulnerability factors as well as time-dependent life events on those trajectories (Piquero 2008). Given the ever-growing interest in not only describing but testing hypotheses related to individual differences in criminal behavior across the life course, more researchers have endeavored to collect longitudinal data on samples of individuals and are making use of statistical models that effectively and appropriately utilize those repeated measures data. In the last two decades, latent growth modeling (LGM; also known as growth curve modeling, latent trajectory analysis, hierarchical linear modeling, linear mixed models, etc.) has emerged as the preferred analytical choice. This preference is in part due to the fact that LGM is more flexible than repeated measures analysis of variance or observed change score analysis in dealing with missing data, unequally spaced time points, complex nonlinear developments, and, importantly, non-normally distributed and discretely scaled repeated measures (Curran et al. 2010).

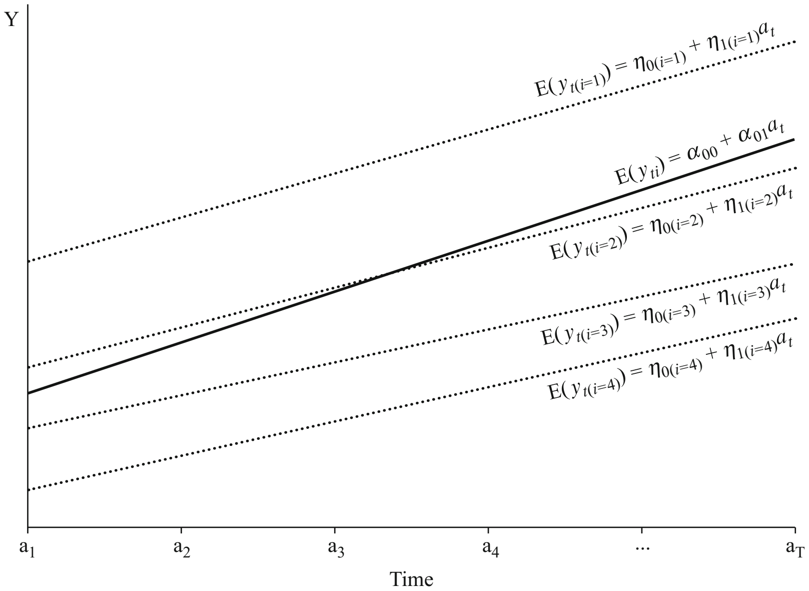
Along with their increasing popularity, vast resources have accumulated to instruct researchers in the application of LGMs with longitudinal continuous (e.g., Bollen and Curran 2006; Muthén 2004; Petras and Masyn 2010) and count outcomes (Kreuter and Muthén 2008; Nagin and Land 1993). With the exception of Feldman et al. (2009); Mehta et al. (2004); Muthén (1996); and Skrondal and Rabe-Hesketh (2004), the discussion regarding the treatment of binary and ordinal outcomes in a growth modeling framework is, by comparison, quite limited, especially for the applied criminology audience. Thus, the goal of this entry is to provide an accessible and practical introduction to the study of change using binary and ordinal repeated measures. The remainder of the entry is organized as follows: First, the conventional growth model for continuous outcomes is briefly introduced followed by a presentation of generalized linear models with binary and ordinal outcomes. Then the process of modeling repeated binary and ordinal measures in a latent growth modeling framework is advanced. This entry is concluded with a summative discussion including an overview of model extensions and alternatives.

Conventional Latent Growth Models

Modern growth models generally treat longitudinal outcomes in one of two ways: (1) as multilevel outcome data, where time or measurement occasions at "Level 1" are nested within persons at "Level 2"; or (2) as multivariate outcome data, where the repeated outcome measures are multiple indicators for latent growth factors values for each individual. Taking a multivariate approach, intra individual change is captured by the measurement model for the growth factors, describing the relationship between individual growth factor values and the observed outcomes over time, and interindividual differences are captured by the structural model, i.e., the mean and variance-covariance structure of the growth factors, describing the distribution of the growth factors in the population of individuals.

Although it is possible to specify analytically equivalent unconditional and conditional growth models across the multilevel and (multivariate) latent growth modeling frameworks, estimated via full-information maximum likelihood (FIML), utilizing the latent variable approach affords access to a variety of modeling extensions not as easily implemented in other frameworks, e.g., models that simultaneously include both antecedents and consequences of the change process, higher-order growth models with multiple indicators of the outcome at each assessment, multiprocess and multilevel growth models, and models that employ both continuous and categorical latent variables for describing population heterogeneity in the change process (for more on growth modeling in a latent variable framework, see, e.g., Bollen and Curran 2006; Muthén 2001, 2004). Given this greater flexibility, it is the multivariate approach to longitudinal data in a latent variable modeling framework that we focus on herein.

The latent growth model specification is a restricted form of a more general structural equation model (SEM; Kline 2010). In the SEM formulation of a latent growth model, there are T repeated measures, $y_t(t = 1, \ldots, T)$, that serve as the indicators or manifest variables, where T is the number of time points or waves during which study participants were assessed. For a *linear* latent growth curve model, there are two latent factors: an intercept growth factor, η_0, and a slope growth factor, η_1. The measurement and



Growth Curve Models with Categorical Outcomes, Fig. 1 Individual trajectories (*dotted lines*) for a hypothetical random sample of four individuals ($i = 1, 2, 3, 4$) drawn from a population with a mean growth trajectory given by the *solid line*

structural portions for an unconditional linear latent growth model are given by

$$\begin{aligned}
&\text{Measurement model:}\\
&\qquad y_{ti} = \eta_{0i} + \eta_{1i}a_t + \varepsilon_{ti},\\
&\text{Structural model:} \qquad\qquad\qquad\qquad (1)\\
&\qquad \eta_{0i} = \alpha_{00} + \xi_{0i},\\
&\qquad \eta_{1i} = \alpha_{10} + \xi_{1i}.
\end{aligned}$$

Here, y_{ti} is the observed outcome y for individual $i(i = 1, \ldots, n)$ at time $t(t = 1, \ldots, T)$, a_t is the time score at time t, η_{0i} is the random intercept factor (i.e., the expected outcome on y for individual i at time score $a_t = 0$), and η_{1i} is the random linear slope factor (i.e., the change in the expected outcome on y for individual i for a one unit increase in time, on the scale of a_t). The values for a_t are fixed to define the slope factor as the linear rate of change in y on the observed time metric; for example, in a panel study for which participants were assessed annually for T years, we might use $\mathbf{a} = (0,1,2, \ldots, T - 1)'$ so that one unit on the time metric defined by $\mathbf{a}$ is one year. Typically, the first time score, a_1, is fixed at zero so that the intercept factor can be interpreted as the expected response at the first time of measurement. The ε_{ti}s represent independent and identically distributed measurement and time-specific errors on the y_{ti}s at time t, and the ε_{ti}s are usually assumed to be uncorrelated across time. In the structural model, α_{00} is the population mean of the individual intercept factor values, α_{10} is the population mean of the individual slope factor values, ξ_{0i} is the deviation of η_{0i} from the population mean intercept, α_{00}, and ξ_{1i} is the deviation of η_{1i} from the population mean slope, α_{10}. The distribution of individual intercept factor values and slope factors values is assumed to be multivariate normal, as is the distribution of the ε_{ti}s; the growth factors are assumed to be uncorrelated with the errors. Figure 1 displays the expected individual trajectories (dotted lines) of a hypothetical random sample of four individuals drawn from a population with an overall mean growth trajectory given by the solid line. Intra individual change is represented by each of the individual-specific trajectories (each with person-specific intercept and slope values), and interindividual differences are represented by the variability in individual-specific intercept and slope values relative to the overall mean intercept and slope values.

Extending now to the conditional latent growth model, hypothesized predictors of the interindividual differences can be included in both the measurement model (for time-varying predictors and time-invariant predictors with unrestricted time-varying effects) and the structural model (for time-invariant predictors of the intercept and slope factors) as given by

Measurement model:

$$y_{ti} = \eta_{0i} + \eta_{1i}a_t + \pi_{1t}w_{ti} + \varepsilon_{ti},$$

Structural model: (2)

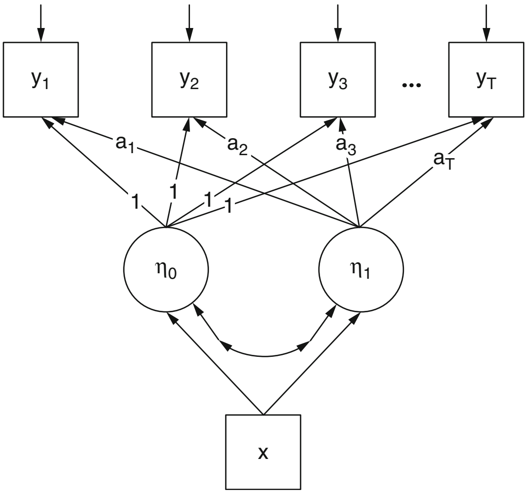
$$\eta_{0i} = \alpha_{00} + \alpha_{01}x_i + \xi_{0i},$$
$$\eta_{1i} = \alpha_{10} + \alpha_{11}x_i + \xi_{1i},$$

where π_{1t} is the difference in the expected outcome, y_t, corresponding to a one unit difference in the time-varying covariate, w, specifically at time t; α_{01} is the difference in the mean of the intercept factor corresponding to the one unit difference in the time-invariant covariate, x; and α_{11} is the difference in the mean of the slope factor corresponding to the one unit difference in the time-invariant covariate, x. The conditional growth model with a predictor for the growth factors is depicted in path diagram form in Fig. 2 using the following diagramming conventions: latent variables are represented by circles, observed variables are represented by rectangles, linear directional relationships are represented by single arrow paths, correlational relationships are represented by double arrow paths, and error terms are represented by unanchored single arrow paths.

Now that we have provided a brief overview of conventional latent growth modeling in a latent variable framework, we next introduce the foundations of binary and ordinal logistic regression followed by discussion of how repeated measures of a categorical outcome can be analyzed in this same latent variable framework.

Generalized Linear Models for Binary and Ordinal Outcomes

As mentioned in the introduction, categorical and limited dependent variables are quite common in criminology research. These types of outcome variables, be they cross-sectional or longitudinal, violate most if not all the assumptions of the linear models in standard use for continuous outcomes. Generalized linear models (GLMs) are a family of regression models that extend OLS regression to accommodate noncontinuous outcomes while still working with outcome predictors in a linear regression framework. There are different (often equivalent) approaches for parameterizing and estimating GLMs (Long 1997; Skrondal and Rabe-Hesketh 2004). For the purposes of this entry, we will introduce a somewhat less standard specification, known as the *latent response variable* (LRV) formulation for ordinal outcome variables. Our choice of the LRV formulation is based on the ease with which it enables the extension of the latent growth model specification given in the previous section to include categorical longitudinal outcomes.



Growth Curve Models with Categorical Outcomes, Fig. 2 Path diagram for a conditional linear latent growth model with continuous outcomes and a time-invariant predictor of the growth factors

In the latent response variable formulation, it is assumed that the observed ordinal outcome, y, is a discretized form of an underlying continuous latent response variable, y^*. For example, consider the binary (0/1) outcome of clinical depression, *depress*. One could imagine an underlying continuum of depression, $depress^*$, such that individuals whose values of $depress^*$

exceeded a certain level, or threshold, would all be observed with binary outcome *depress* = 1. In general, the relationship between a binary outcome, y, and the latent response variable, y^*, is given by

$$y_i = \begin{cases} 1 \text{ if } y_i^* > \tau_1 \\ 0 \text{ if } y_i^* \leq \tau_1, \end{cases} \qquad (3)$$

where τ_1 is the *threshold* for y^* and $\Pr(y = 1) = \Pr(y^* > \tau_1)$. As another example, consider the four-category ordinal outcome, *oppose*, measuring opposition to or disapproval of the death penalty for first degree murder with response categories on a Likert scale: *strongly approve/support* (0), *approve/support* (1), *disapprove/oppose* (2), and *strongly disapprove/oppose* (3). One could imagine an underlying continuum of opposition or disapproval, *oppose**, such that four different ranges of *oppose** defined by three cut points or thresholds map onto the observed values of *oppose*. In general, there are $J - 1$ thresholds that define the relationship between a latent response variable, y^*, and its J-category ordinal form, y, such that

$$\text{y}_\text{i} = \begin{cases} 0 \text{ if -}\infty < y_i^* \leq \tau_1 \\ 1 \;\text{ if } \tau_1 < y_i^* \leq \tau_2 \\ \vdots \\ J-1 \;\text{ if } \tau_{\text{J-1}} < y_i^* \leq \infty \end{cases} , \qquad (4)$$

where τ_j is the j^{th} *threshold* for y^*, delineating responses $j - 1$ and j on the scale of y. In this LRV formulation, $\Pr(y \leq j) = \Pr(y^* \leq \tau_{j+1})$ and $\Pr(y = j) = \Pr(y^* \leq \tau_{j+1})\text{-}\Pr(y^* \leq \tau_j)$, where $j \in \{0,1,\ldots,J\text{-}1\}$, $\tau_0 = -\infty$, $\tau_J = \infty$, and $\tau_0 < \tau_1 < \ldots < \tau_{J-1} < \tau_J$. The continuous latent response variable, y^*, is then expressed as the sum of a mean and error term given by

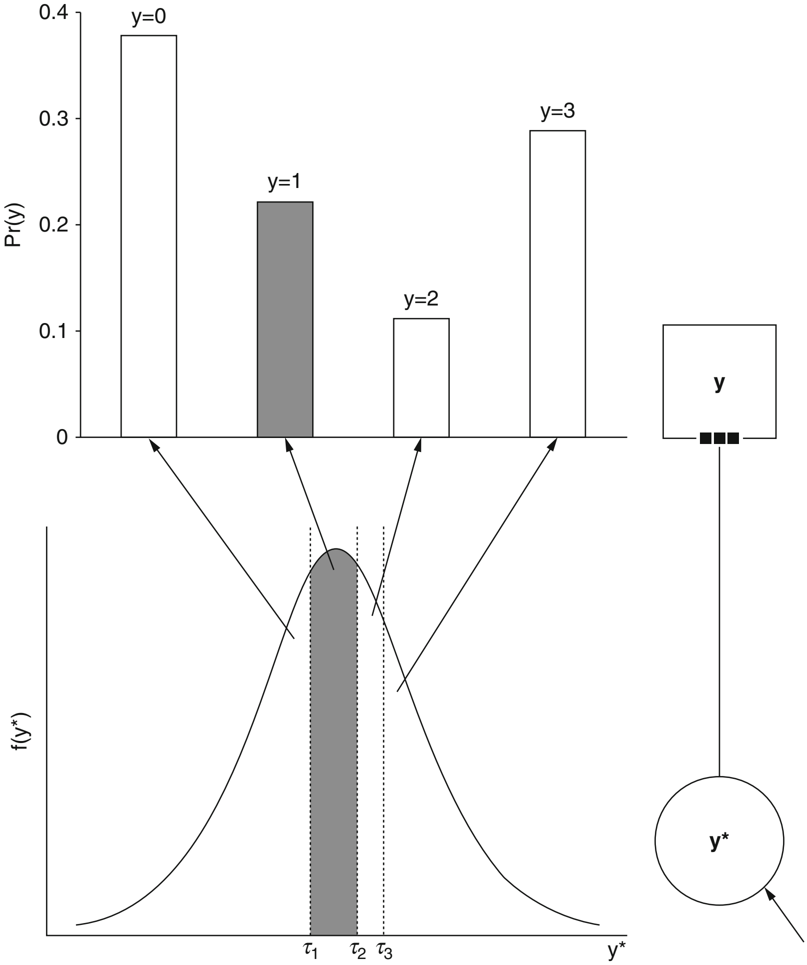
$$y_i^* = \mu_i + \delta_i. \qquad (5)$$

The distribution and scale of the error, δ, must be specified a priori by the analyst; the two most common distributions for δ are the standard normal distribution and the standard logistic distribution. Figure 3 provides a visual representation of the latent response variable formulation for an ordinal outcome with four response categories. The bottom portion of Fig. 3 depicts a standard logistic distribution for y^* with three corresponding thresholds, (τ_1, τ_2, τ_3). All individuals in the population with y^* values between τ_1 and τ_2 will manifest the response value $y = 1$, and the shaded area under the probability density curve for y^* between τ_1 and τ_2 is equal to the probability of the $y = 1$ outcome, as depicted in top portion of Fig. 3. Figure 3 also displays the path diagram representation of the relationship between y^* and y. The three solid squares at the point where the path from y^* meets y indicate the deterministic relationship specified between given values of y^* and resultant observed values on y defined by the three thresholds, (τ_1, τ_2, τ_3).

The conditional model for ordinal outcomes is specified so that the observed predictors of the categorical outcome are related to cumulative response probabilities via the latent response variables as follows:

$$\begin{aligned} y_i^* &= \mu_{i|x_i} + \delta_i, \\ \mu_{i|x_i} &= \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \ldots + \beta_k x_{ki}. \end{aligned} \qquad (6)$$

Figure 4 displays a plot of linear regression model of latent response variable, y^*, underlying a four-category ordinal outcome, versus a single predictor, x. As with a standard linear regression model, the expected values of y^* given x falls along the line, $\beta_0 + \beta_1 x$, and the distributions of y^* values in the population at each given value of x are the same in shape and variance (as shown in Fig. 4 by the probability density curves at the x-values, $x = x_1$, $x = x_2$, and $x = x_3$). For model identification, the intercept, β_0, is suppressed, i.e., fixed at zero. The linear model implies that the difference in the expected value of y^*corresponding to a one unit difference in x is equal to β_1 across the entire range of x. The conditional model given in Eq. 6 also makes the assumption of *threshold invariance*, that is, assuming that the thresholds defining the



Growth Curve Models with Categorical Outcomes, Fig. 3 Graphical and path diagram representations of the latent response variable formulation for an observed ordinal outcome with four response categories

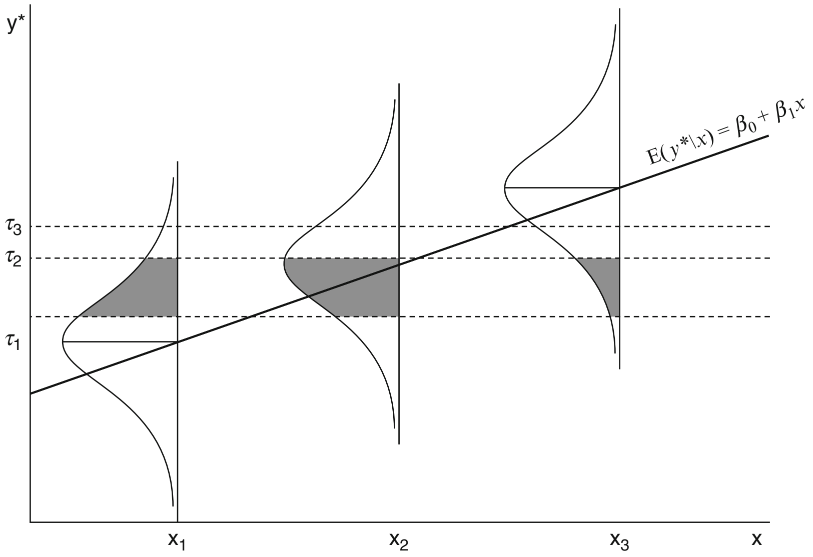
relationship between y^* and y do *not* depend on (i.e., are invariant) relative to x. To assist in visualizing how the linear functional relationship between y^* and x and the assumption of threshold invariance translate to the relationship between observed response probabilities of y and x, the three thresholds for y^*, which do *not* depend on x, are drawn as horizontal lines in Fig. 4. The area under the probability density function for y^* between τ_1 and τ_2, corresponding to $\Pr(y = 2|x)$, at $x = x_1$, $x = x_2$, and $x = x_3$, is shaded making it easy to see that even though the mean of y^* shifts linearly across the range of x, the response category probabilities do *not* change linearly or even monotonically.

Using a standard logistic distribution for δ, the linear regression for y^* on a single predictor (easily replaced with a linear combination of multiple predictors as given in Eq. 6) and the assumption of threshold invariance translates to the following relationship between the response category probabilities and the predictor:

$$\Pr(y_i \le j|x_i) = \frac{1}{1 + \exp\left(-\tau_{j+1} + \beta_1 x_i\right)}, \tag{7}$$

or, equivalently,

$$\log\left(\frac{\Pr(y_i \le j|x_i)}{\Pr(y_i > j|x_i)}\right) = \tau_{j+1} - \beta_1 x_i. \tag{8}$$



Growth Curve Models with Categorical Outcomes, Fig. 4 Plot of the linear regression line for a latent response variable, y^*, underlying an observed four-category ordinal outcome variable, y, versus a single predictor, x. Probability density curves depict the distribution of y^* values at three different values of x. Dashed horizontal lines show the threshold values for y^* delineating the four value ranges mapping on to the four response categories of y. Shaded areas of the probability density show the changing Pr ($y = 2|x$) across the three values of x

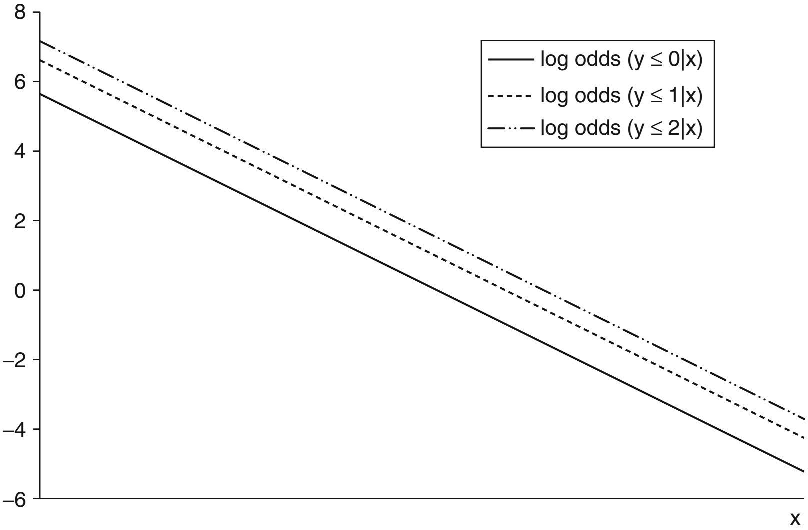
For a binary variable (with $J = 2$ categories), Eq. 8 reduces to the familiar logistic regression equation:

$$\log\left(\frac{\Pr(y_i = 1|x_i)}{\Pr(y_i = 0|x_i)}\right) = -\tau_1 + \beta_1 x_i. \qquad (9)$$

In Fig. 5 we can see the representation of the relationships between the cumulative response category log odds and the predictor as described in Eq. 8 – that cumulative log odds for the different response categories all vary linearly as a function of x and that the lines for each of the three cumulative log odds are *parallel* with the distance between them determined by the differences in the threshold values.

The functional form of each of the three lines in Fig. 5 and the fact that they are all linear is a direct consequence of linearity assumption for the relationship between y^* and x. Assuming a linear relationship between y^* and x constrains the relationship between y and x such that cumulative response category log odds differ identically and linearly for every one unit difference in x. Consequently, β_1 is interpreted not just as the difference in the expected value of y^* corresponding to a positive difference of one unit on x but also as the log odds ratio for responding at or below a given response category (rather than above) corresponding to a *negative* difference of one unit on x, i.e., the odds for a response less than or equal to category j differ by a factor of exp $(-\beta_1)$ for every one additional unit on x, for all $j = 0$, 1, or 2. Thus, the cumulative odds for each response category differ identically and proportionally for every one unit difference in x. The linearity assumption is also known as the *proportional odds* assumption.

The equidistance between each pair of lines in Fig. 5 across the full range of x is a direct consequence of assuming that the thresholds defining the relationship between y^* and y do not depend on x. Thus, the differences in the cumulative log odds across the response categories (i.e., the vertical distance between the lines) at any given value of x are constant across all values of x. The assumption of *threshold invariance*, meaning that the thresholds do not depend on x, is also known as the *parallel regression* assumption. Both the proportional odds assumption and the



Growth Curve Models with Categorical Outcomes, Fig. 5 Plot of the cumulative response log odds for *y* versus *x* based on a linear regression model of y^* on *x* with threshold invariance

parallel regression assumption can be relaxed (and tested), and this will be mentioned again in the growth modeling context in the next section.

Building upon the overviews of both conventional latent growth models and cross-sectional latent response variable models for binary and ordinal dependent variables, the intersection of these two modeling approaches that enables the study of change in binary and ordinal longitudinal outcomes is introduced next.

Latent Growth Models for Binary and Ordinal Outcomes

The specification for the latent growth model for binary or order categorical outcomes is built on the same latent response variable formulation used with cross-sectional data. It is assumed that there is a continuous latent response variable, $y_{ti}{}^*$, underlying the observed response on the J-category ordinal outcome, y_{ti}, for individual $i(i = 1, \ldots, n)$ at time $t(t = 1, \ldots, T)$ with the relationship between $y_{ti}{}^*$ and y_{ti} given by

$$y_{ti} = \begin{cases} 0 \text{ if } \; -\infty < y^*_{ti} \le \tau_{1t} \\ 1 \text{ if } \; \tau_{1t} < y^*_{ti} \le \tau_{2t} \\ \vdots \\ J-1 \;\text{ if } \tau_{(j-1)t} < y^*_{ti} \le \infty \end{cases}, \quad (10)$$

where τ_{jt} is the j^{th} *threshold* for $y_t{}^*$, delineating responses $j - 1$ and j on the scale of y_t. Usually, in the model building taxonomy, it is common to begin with models that make the assumption of *longitudinal threshold invariance*, meaning that the set of $J - 1$ thresholds, $(\tau_{1t}, \ldots, \tau_{(J-1)t})$, are the same at each wave; i.e., $\tau_{jt} = \tau_j, \forall t$. The longitudinal threshold invariance assumption can then be evaluated by testing the improvement in model fit when threshold invariance is relaxed.

The continuous latent response variable, $y_{ti}{}^*$, at each wave, t, is expressed as the sum of a mean and error term given by

$$y^*_{ti} = \mu_{ti} + \delta_{ti}. \quad (11)$$

As before, the distribution and scale for the error at each wave, δ_{ti}, must be specified a priori by the analyst – for the purposes of this entry, the standard logistic distribution for the error terms will be used. A latent growth model is then specified for the individual μ_{ti} values in a similar way as for observed continuous repeated measures. A linear latent growth model expresses the expected value on the latent response variable for individual i at time t as a function of the intercept and growth factors values; that is,

$$\mu_{ti} = \eta_{0i} + \eta_{1i} a_{\,t}, \quad (12)$$

or, equivalently, combining Eqs. 11 and 12,

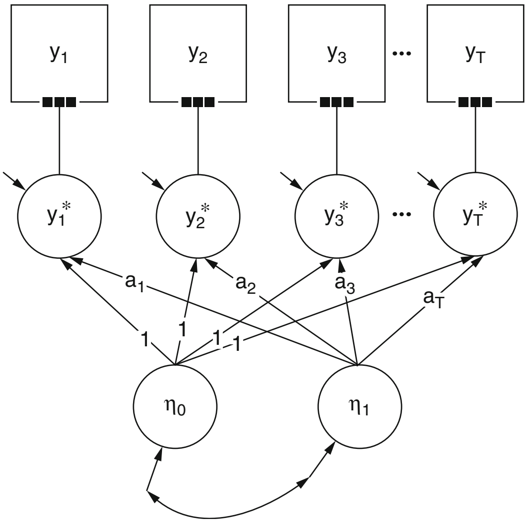
$$y_{ti}^{*} = \eta_{0i} + \eta_{1i}a_t + \delta_{ti}. \qquad (13)$$

The structural portion of the latent growth model is identical to the specification for observed continuous repeated measures; that is,

$$\begin{aligned}\eta_{0i} &= \alpha_{00} + \xi_{0i},\\ \eta_{1i} &= \alpha_{10} + \xi_{1i},\end{aligned} \qquad (14)$$

where $\xi_{\bullet i}$ s are specified to have a multivariate normal distribution. Since the location and scale of the latent response variable is indeterminate, an additional restriction must be placed, fixing $\alpha_{00} = 0$, similar to fixing $\beta_0 = 0$ for y^* in the cross-sectional model. The path diagram representation of an unconditional linear latent growth model for observed ordinal outcomes is depicted in Fig. 6. Although the above specification expresses the change in the latent response variable over time as a linear function of the time metric, the same approaches can be used as with observed continuous outcomes to investigate interindividual differences in curvilinear and other forms of nonlinear trajectories of change.

To gain a better understanding of what specifying a linear latent growth model for the latent response variable with longitudinal threshold invariance implies with respect to interindividual difference in intra individual change in the observed ordinal outcome, consider Fig. 7 which displays expected individual growth trajectories (dotted lines) on the latent response variable underlying an observed four-category ordinal variable for three hypothetical individuals, $i = 1$, 2, and 3, and the population overall mean growth trajectory (solid line). The time-invariant thresholds are shown by the horizontal dashed lines. Each individual in the population has their own expected y^* trajectory as given by Eq. 12. Each individual's cumulative response probabilities at each point in time are determined by the thresholds and the distribution of y_{ti}^{*} centered at μ_{ti}, as depicted by the separated density curves for each of the three hypothetical individuals at time points a_2, a_3, and a_4 shown in Fig. 7. Assuming that δ_{ti} are independently and identically distributed standard logistic, the relationship between the observed ordinal response and the growth factors is given by

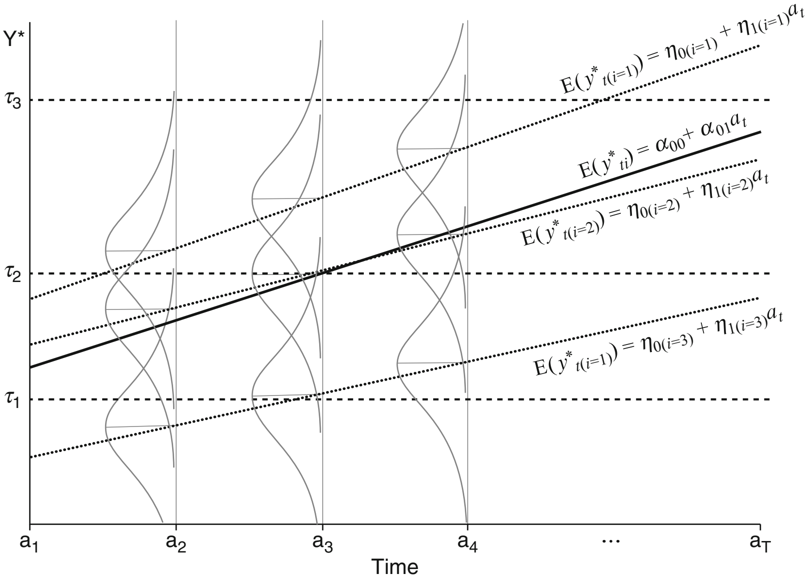


Growth Curve Models with Categorical Outcomes, Fig. 6 Path diagram for an unconditional linear latent growth model for the latent response variables underlying a set of observed longitudinal ordinal outcomes

$$\log\left(\frac{\Pr(y_{ti} \le j)}{\Pr(y_{ti} > j)}\right) = \tau_j - (\eta_{0i} + \eta_{1i}a_t). \qquad (15)$$

Thus, $\tau_j - \eta_{0i}$ is the cumulative log odds for response category j for individual i when $a_t = 0$, and $-\,\eta_{1i}$ is the change in the cumulative log odds (or cumulative log odds ratio) for response category j for individual i corresponding to a one unit increase in the time metric of a_t.

It can be seen from Eq. 15 that the longitudinal threshold invariance assumption (i.e., $\tau_{jt} = \tau_j, \forall t$) implies that the difference in cumulative log odds for any two response categories will be the same at any given fixed point in time, a_t, across the entire time span for a given individual i. Assuming a linear function for the intra individual change process in the latent response variable under the threshold invariance assumption implies that the change in the cumulative log odds for a given individual and for a given response category corresponding to a one unit difference in the time metric is the same across the entire time span and across all response categories. As mentioned



Growth Curve Models with Categorical Outcomes, Fig. 7 Individual trajectories (*dotted lines*) of latent responses to repeated measure of an observed four-category ordinal outcome variable for a hypothetical random sample of three individuals ($i = 1, 2, 3$) drawn from a population with a mean growth trajectory for y^* given by the *solid line* with *dashed horizontal lines* show the time-invariant threshold values for y^* delineating the four value ranges mapping on to the four response categories of y

before, both the linearity and threshold invariance assumptions can be relaxed and tested. However, in order for the structural portion of the latent growth model to be identified, *at least one threshold* must be held invariant across time. For a binary longitudinal outcome with only one threshold at each time point, complete threshold invariance must be imposed.

It is important at this point to make the reader aware of one critical difference between the latent growth model for observed continuous outcomes and the LGM for observed ordinal outcomes. For continuous outcomes, the mean growth trajectory for the population is just a linear function of the population mean intercept factor and population mean slope factor. This is only the case at the latent response variable level of the categorical LGM – it is *not* the case for the mean population responses for the observed ordinal variable across time. In other words, it is incorrect to just plug the means of η_0 and η_1 into Eq. 15 to get the population mean cumulative response probabilities because the average of the individual cumulative response probabilities is not the same as the cumulative response probability corresponding to the mean growth trajectory for the latent response variable. That is,

$$E[\Pr(y_{ti} \leq j)] \neq \frac{1}{1 + \exp\left(-\tau_j + (\alpha_{00} + \alpha_{10}a_t)\right)}. \tag{16}$$

To compute the mean cumulative response probability for the population at a given point in time requires calculating and then averaging the individual cumulative response probabilities for all members of the population, that is,

$$E[\Pr(y_{ti} \leq j)] = \lim_{n\to\infty}\left[\frac{1}{n}\sum_{i=1}^{n}\left(\frac{1}{1+\exp\left(-\tau_j+(\eta_{0i}+\eta_{1i}a_t)\right)}\right)\right]. \tag{17}$$

The above expression can also be written as a double integral equation, integrating over both η_0 and η_1. Obtaining model-estimated mean cumulative response probabilities for a specific response category at a specific measurement occasion requires numeric integration based on the model-estimated distribution of the latent growth factors which is a post-estimation option in some modeling software, such as Mplus V6.12 (Muthén and Muthén 1998–2011a).

It is straightforward to extend the unconditional ordinal LGM to include time-invariant and time-varying predictors, just as is done with observed continuous repeated measures. Time-invariant predictors can be included as predictors of the growth factors, or direct predictors of the expected latent response variable across time and time-varying predictors can be included as direct predictors of the expected latent response variable across time, as given by

$$\begin{aligned} y_{ti}^{*} &= \mu_{ti} + \delta_{ti}, \\ \mu_{ti} &= \eta_{0i} + \eta_{1i}a_t + \pi_{1t}w_{ti}, \\ \eta_{0\mathrm{i}} &= \alpha_{00} + \alpha_{01}x_i + \xi_{0i}, \\ \eta_{1i} &= \alpha_{10} + \alpha_{11}x_i + \xi_{1i}, \end{aligned} \tag{18}$$

where δ_{ti} are assumed to be *i.i.d.* standard logistic and α_{00} is fixed at zero for identification.

The unconditional and conditional ordinal latent growth models presented in this section can all be estimated using maximum likelihood estimation. These growth models can be more computationally intensive than the cross-sectional models for observed ordinal outcomes as maximizing the likelihood function with continuous latent predictors (i.e., the latent growth factors) for the ordinal responses requires numeric integration with one dimension of integration for each growth factor. Full-information maximum likelihood (FIML) is available for these models which allows the inclusion of cases with incomplete data on the longitudinal outcomes under the missing-at-random (MAR) assumption (for more about missing data, see, e.g., Enders 2010).

Discussion

This entry has discussed the application of latent growth curve modeling to categorical outcomes by integrating aspects of the conventional latent growth model with the generalized linear model. The unconditional growth model with respect to parameterization and estimation was presented, and concise guidelines were provided for how to conduct the model building and evaluation process. It was then elaborated on how to include covariates to evaluate hypotheses about the relationship between predictors and the developmental change process.

There are several interesting augmentations of and alternatives to these models that are currently available to applied researchers. Although in Eq. 18 the change in the expected latent response outcome was expressed as a linear function of the time metric, it is possible (with an adequate number of repeated observations on each subject) to investigate interindividual differences in curvilinear and other forms of nonlinear trajectories of change. The two most common approaches are (1) to freely estimate $T - 2$ of the time scores loadings for η_1 (fixing one loading at zero to define the intercept location and fixing one loading at unity for identification and to set the slope factor metric) or (2) to use additional growth factors (beyond the intercept and slope factors) to accommodate curvilinear polynomial functions of times (e.g., adding a third, quadratic growth factor with loadings fixed at the values ${a_t}^2$). Alternative specifications of time can also be easily accommodated, including piece-wise linear growth models as well as exponential and sinusoidal models of change (see, e.g., Blozis et al. 2007; Bollen and Curran 2006).

In this entry, the application of a latent growth model to repeatedly measured categorical outcomes was discussed. In this model intra-individual change over time is estimated by person-specific growth parameters (e.g., intercept and slope), and interindividual differences are modeled by allowing for individual variation around the estimated growth factor means. Notably, this model is somewhat restrictive in that it assumes population homogeneity in the growth trajectories, i.e., that the growth factors for all persons in the sample are identically distributed. However, etiological as well as prevention and intervention evidence exists to suggest that criminal and antisocial behavior in the overall population may be better represented by a mixing of unobserved heterogeneous subgroups of individuals characterized by differently distributed developmental trajectories, differential risk factors, and differential responses to behavioral and policy interventions. Fortunately, it is relatively straightforward to extend the categorical latent growth model to a generalized linear growth *mixture* model (Feldman et al. 2009). As is the case for continuous outcomes, different latent trajectory classes can be characterized by class-varying mean and variance structures for the growth factors. For example, the developmental change process for one latent subgroup may be perfectly captured by an intercept and a linear slope, while for another subgroup, an additional nonlinear slope is needed.

In addition to modeling nonlinear change and developmental heterogeneity, it is possible that developmental differences cannot be captured by continuous or discrete individual variability around a structured function of time (i.e., intercept, linear, and nonlinear slope). Longitudinal latent class analysis (LLCA: Vermunt et al. 2008; also known as repeated measure latent class analysis, RMLCA: Collins and Lanza 2010) can be used in such situations. LLCA is the application of latent class analysis to repeated outcomes, and unobserved heterogeneity in the developmental response profiles is captured exclusively by a categorical latent variable. In comparison to a growth model which models time-scaled change, LLCA models the longitudinal patterns of discrete states (see, e.g., Feldman et al. 2009; Liu et al. 2010; Liu et al., in press).

In the above-discussed three modeling extensions (nonlinear change, generalized linear growth mixture model, and longitudinal latent class analysis), the inclusion of antecedents and distal outcomes plays an important role. The use of such auxiliary information, potentially derived from substantive theory, is highly relevant to determine the concurrent and prognostic validity of specific growth factors and developmental trajectory profiles derived from a particular data set (Kreuter and Muthén 2008; Petras and Masyn 2010). That is to say, the inclusion of auxiliary information in these models is a necessary step in understanding as well as evaluating the fidelity and utility of the resultant trajectory profiles from a given study. In the simplest case, auxiliary information can consist of observed univariate or multivariate variables measuring predictors or distal outcomes. However, the auxiliary information could itself be a latent variable with its own measurement model and can consist of repeated measures which are observed sequentially or concurrently and modeled simultaneously with the change process of the outcome.

Clearly, these models hold great potential for aiding empirical investigations of developmental theories of normative and non-normative behaviors and risky outcomes across the lifespan. In no way is this more evident than in the marked increase in their use among applied researchers in criminology and other behavioral sciences. However, there is still much opportunity in the realm of methods development to capitalize on the potential of these models and extensions to better accommodate the complexities of developmental theories. And, as with any statistical tool, the research question, along with previous theoretical and empirical work, should guide these models' application in a particular study, with thoughtful and purposeful choices for model specification, selection, and interpretation.

Handwriting examination: the art and science

Overview

Handwriting is produced by finely coordinated and precisely articulated movements of the hand, finger, and arm, manipulating a tool which leaves a trace on a surface with the ultimate control being responsible – the brain. It is a very complex activity requiring intelligence that distinguishes human being from the rest of the animal species. By way of writing, the author can convey and preserve ideas or information. With the advancement of technology, the writing instrument changes considerably, but handwriting, being the most personal and immediate means of graphic communication, and the movements associated with it remain virtually the same since the creation of the strokes and the alphabets.

Ever since the invention of the "written language," the need for the verification of authorship started to exist. Nowadays, there is a widespread demand for the examination of handwriting, not only in criminal cases and civil litigations but also in historical and archaeological investigations, and handwriting examination is an important specialist subject in forensic sciences. Basic principles in handwriting identification are given in a number of books authored by authorities in the field (Harrison 1966; Osborn 1978; Hilton 1982; Ellen 1993), while forensic scientists continue to conduct research in the scientific examination of handwriting.

Writer Identification

Physiologically the ability to write is a "motor-perception" skill, involving psychological aspects, perception, and muscular coordination on the part of the author who is constantly under the influence of a variety of factors. These comprise both internal (or personal) and external (or circumstantial) influences. Because of the large number of variables affecting the writer, handwriting from one person on different occasions cannot be expected to be identical in each and every aspect of line quality, speed, pen pressure, shading, pen emphasis, slant, arrangement of strokes, proportionality, chronological sequence, and connecting components. This phenomenon of a "nonuniformity" in the handwriting of an individual is commonly referred to as natural variation.

That handwriting varies does not present serious problems to the task of identification. The skill to write is developed and practiced over many years and is largely a subconscious

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

and automatic activity of human beings. Thus, the handwriting of a person, despite not being 100 % precise, conforms to a distinctive and predictable pattern. The verification of handwriting, as to whether or not it was written by a certain individual, is based upon the fact that handwriting embodies various qualities and attributes which in combination are sufficiently unique to be individualized. The joint probability of a compound event comprising a number of mutually independent simple events is the product of the probabilities of the simple events. Hence, if the disputed handwriting contains a variety of personal characteristics that lie within the range of natural variation of the known writing and at the same time not even a single fundamental, or unexplainable, difference from the genuine specimens can be found, then the combined probability of occurrence of this set of characteristics present in the handwriting of another person selected at random from a population will be so small that it can be ignored. The argument is that it would not be reasonable to assume that the same combination of writing attributes, in sufficient numbers and weight, would accidentally occur in the handwriting of another person without showing even a single idiosyncrasy from the control specimens. This hypothesis forms the basis of identification.

Handwriting characteristics are the observable features generated by the movement of the author's hand. The act of writing involves not only two-dimensional movements of the pen but also variations in the pressure of the writing tip on the substrate. Minutiae of the landing movement when the writing tip approaches and finally "touches down" on the surface of the paper generate a large variety of shapes at the start of a stroke. Likewise the rehearsed motion at the conclusion of a stroke provides specific calligraphic attributes. Details of the habitual manners of utilizing the pen to write contribute toward much of the visual appearance which can be generalized by the terminology of line quality. The spatial relationship of strokes, the formation of the basic components of words or characters, the relative dimensions of two or more alphabets, and the ways of connecting adjacent strokes, in aggregate, constitute the writer's calligraphic profile. The determination of authorship therefore depends on the discovery, in the disputed script, of personal characteristic features that fall within the range of natural variation of writing habits of the author of the control material.

In practice, the process of identification must include a determination of the extent, kind, and significance of this resemblance as well as of the variation. It is necessary to determine whether the divergence is due to the operation of a different individual or is only the expected and inevitable variation found in the genuine writing of the same writer. It is also necessary to decide whether the resemblance is the result of a skilful imitation or is the habitual and characteristic resemblance which naturally appears in a genuine writing. When these two questions are correctly answered, the whole problem of identification is solved (Osborn 1978). Figure 1 gives a diagrammatic presentation on the process of handwriting examination.

For many years, document examiners have been practicing the empirical theory of handwriting examination. The US Supreme Court case, Daubert et al. v. Merrell Dow Pharmaceuticals, alongside with several other cases, namely, US District Court ruling, United States v. Starzecpyzel; US Supreme Court ruling, General Electric Co. v. Joiner; US Supreme Court ruling, Kumho Tire Co. v. Carmichael; and US 11th Circuit Court of Appeals, United States vs. Paul, have prompted the so-called Daubert Standard which refers to the following guidelines for admitting scientific expert testimony: (1) *Judge is gatekeeper*: The task of "gatekeeping," or assuring that scientific expert testimony truly proceeds from "scientific knowledge," rests on the trial judge. (2) *Relevance and reliability*: The trial judge is required to ensure that the expert's testimony is relevant to the task at hand and that it rests on a reliable foundation. The judge must find it more likely than not that the expert's methods are reliable and reliably applied to the facts at hand. (3) *Scientific knowledge = scientific method/methodology*: A conclusion will qualify as scientific knowledge

Handwriting as Evidence, Fig. 1 Diagrammatic representation of the handwriting comparison process

if the proponent can demonstrate that it is the product of sound "scientific methodology" derived from the scientific method. (iv) *Factors relevant*: The Court defined "scientific methodology" as the process of formulating hypotheses and then conducting experiments to prove or falsify the hypothesis and provide a test for establishing its "validity":

- Empirical testing: The theory or technique must be falsifiable, refutable, and testable.
- Subjected to peer review and publication.
- Known or potential error rate.
- The existence and maintenance of standards and controls concerning its operation.
- Degree to which the theory and technique is generally accepted by a relevant scientific community.

In 2000, the above rule was amended in an attempt to include the additional provisions which state that a witness may only testify if:

- The testimony is based upon sufficient facts or data.
- The testimony is the product of reliable principles and methods.
- The witness has applied the principles and methods reliably to the facts of the case.

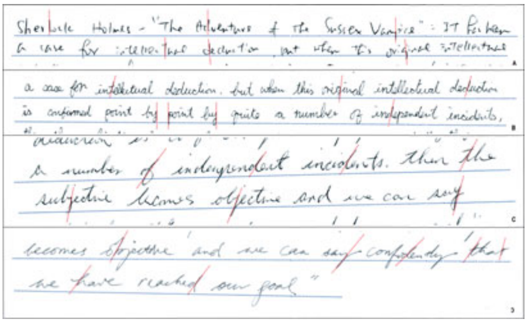
Although the Daubert Standard is concerned with legal requirements for scientific testimony in the United States, it is nevertheless important to assess the mandate of handwriting examination as a specialist forensic science subject.

Scientific Method and Handwriting Examination

Science is a branch of knowledge conducted on objective principles involving the systematized observation of, and experiment with, phenomena especially concerned with the material and function of the physical universe (Allen 1990). It stems from the curiosity of an observant mind, which generates impetus to the quest for an explanation. Observation is the primary scientific procedure of comprehending things; based on observation, scientists attempt to provide logical deductions that can plausibly explain the incident. A hypothesis is thus formulated.

The proposed explanation is tested by way of further observations and experimentation. The latter simulates the observed events under controlled conditions and the designer of the experiment attempts to draw logical inferences from the results thus obtained. Similar experiments, often using a variety of approaches and methodology, are performed by different workers to verify the results reproducibility. When a hypothesis cannot live up with the standard or is considered unsatisfactory, it is either modified or discarded. On the other hand, a hypothesis passing stringent scientific tests will be adopted into the framework of a theory which not only explains the observations in a reproducible way but also makes meaningful predictions.

Application of the scientific method often involves measurement which facilitates a more accurate description of the observed phenomenon in numerical terms and quantifiable units. Phenomena presented in the form of numerical data can be compared and correlated, and their numerical representations treated by mathematical and/or statistical procedures to generate more information which objectively explains the observations in a more detailed and profound manner. Handwriting embodies many parameters that can be measured, and in the Latinized writing – slant or slope – the angle of inclination of the axis of letters relative to the baseline (Hilton 1982) is an important measurable parameter. It varies between writers from backward slanting to a sharply inclined forehand slope. The wide range of variation in slant gives rise to good discriminating power among individual writers.



Sherlock Holmes – "The Adventure of the Sussex Vampire" : It has been a case for intellectual deduction, but when this original intellectual

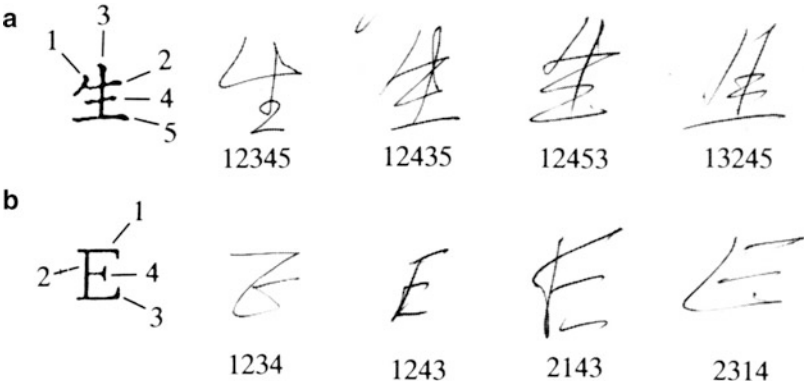
a case for intellectual deduction, but when this original intellectual deduction is confirmed point by point by quite a number of independent incidents,

a number of independent incidents. then the subjective becomes objective and we can say

becomes objective and we can say confidently that we have reached our goal"

Handwriting as Evidence, Fig. 2 Variability of slant in English handwriting

Figure 2 illustrates the variability of slant in the handwriting of four individuals: Writer A exhibits a habit of occasionally writing alphabets with a backward slant, for example, the *l* of *Sherlock*, the *p* of *Vampire*, the first *d* of *deduction*, and the *g* of *original*. But many of the other letters exhibit a near-vertical or slightly forward slant. On the other hand most, if not all, of the characters in sample B are forward slanting, for example, the *d* and the *t*, although a few of the letters are more vertically oriented, for example, the *p* of the two *point*s and *independent*, and the *y* of the *by*'s. Author C produces consistently forward-slanting alphabets in many of the *d*'s and *t*'s. While displaying natural variation, specimen D appears to be more consistently forward slanting. The diversity of slant in the handwriting of different individuals can therefore be utilized for the identification of authorship. Additionally, the slant of different alphabets in a sample of handwriting can vary considerably in magnitude, for example, as evidently shown in the writing of C, the *j* of *subjective* and *objective* and the *y* of *say* are less forward slanting than the other letters. It is generally observed that (1) while the slant of an alphabet in the handwriting of an individual generally conform with one another, different alphabets of the writings of the same individual can vary to a greater extent; (2) in some writings, the position of an alphabet in different words can display different slanting angles, for example, the initial *t* of the word *that* in sample D is much more slanting than the terminal *t* of the same word; and (3) the slant of an alphabet can also vary in accordance with the letters adjacent to, or flanking, it. Leung (Leung et al. 1987) noted the same phenomenon in Chinese handwriting and found that measurable parameters of the handwriting of a writer do not conform to a uniform value but may vary in accordance with the structure of, and the position of the strokes in, the character. The concept of "internal variability" was suggested which is attributed to the divergence of writing habits in relation to the position of the writing element and the overall structure of the written words or characters.



Handwriting as Evidence, Fig. 3 Classification of stroke sequence of the Chinese character *Live* and application of the concept to characterizing the capital letter *E*. (Reprinted with permission from Journal of the Forensic Science Society 1993; 33:9–19)

It was maintained that this calligraphic property can be utilized as an additional tool for handwriting identification (Leung et al. 1987; Leung 1994). To conclude, the numerical expression of depicted features enables the document examiner to characterize handwriting objectively and accurately and is especially useful when the similarities and/or differences are inconspicuous.

Another important facet of the scientific method is classification which simplifies the approach to a given problem by narrowing its broader elements and ramifications on the basis of categorical distinctions. Classification methods can be effectively applied to find out the relationship, if any, of certain observations so that general principles can be derived. It forms the basis of natural sciences such as biology, chemistry, and taxonomy. Apart from writing attributes which can be characterized quantitatively, there are other qualitative features that are equally useful for identifying the writer. Eldridge reported a scheme for the classification of a selected set of cursively handwritten letters comprising *d*, *f*, *h*, *k*, *p*, and *t* (Eldridge et al. 1984). These letters were treated in terms of three major structural components: the *staff*, the *base*, and the *crossbar*. Twelve features were chosen for classification, although not all features are applicable to all letters. They are as follows: (1) *construction order*, the order of construction of the base and the staff; (2) *number of strokes*; (3) *base direction*, the direction of the curvature from the uppermost part of the base to the beginning of the upstroke to the next letter; (4) *base closure*; (5) *top of staff closure*; (6) *top of staff direction*; (7) *bottom of staff closure*; (8) *bottom of staff direction*; (9) *preceding letter join*; (10) *following letter join*; (11) *crossbar position*; and (12) *crossbar curvature*. Each feature has at least two, and possibly as many as seven, distinct forms. It was found that the letter *k* best discriminates between writers in the sample of 61 subjects.

A systematic classification scheme not only provides valuable information on the variability of handwriting but also inspires objective interpretation on examination results. Leung conducted statistical studies into 98 selected Chinese characters written by 438 subjects (Leung et al. 1993). A classification system on the qualitative features of pen emphasis, sequence of strokes, stroke connections, and structural detail was established. Diversities of writing habits depicted among the subjects confirmed the belief that many of the classifiable handwriting attributes contribute toward the science of authorship verification. Figure 3 illustrates four chronological writing sequences in the Chinese character *Live* which comprises one slanting stroke, one vertical stroke, and three horizontal strokes. The possibility of applying the concept of classification by means of stroke sequencing on the capital letter "E" is demonstrated.

Individuality of Handwriting

The principles of handwriting examination have been laid down in classical treatise that the identification of authorship depends on the discovery in the questioned script of a combination of personal characteristics which lie within the range of variation of the control specimens accompanied by the absence between them of any idiosyncrasies that cannot be satisfactorily explained. However, as pointed out by Sugiyama and Kurauchi, the problem of the methods in practice relies on the basic task of determining and extracting a sample's distinguishing features, which have often been questioned for dependence of subjective judgment and intuition rather than on objectivity and empirical evidence (Sugiyama and Kurauchi 1986). The rapid advances in computer technology enable the practical application of statistical classification techniques to handwriting examination. Many forensic scientists reported positive results; to name just a few, Hardcastle, Thornton, and Totty reported a computer-based system for the classification of block handwriting on checks (Hardcastle et al. 1986), and Eisermann and Hecker described the Forensic Information System for Handwriting (FISH), which utilized an image-processing technique with statistical classification analysis for the identification of handwriting (Eisermann and Hecker 1986).

Motivated by several rulings in US courts concerning expert testimony in general, and handwriting testimony in particular, Srihari undertook a study to objectively validate the hypothesis that handwriting is individual (Srihari et al. 2002). They maintained that there are two variances of concern in handwriting comparison, within the handwriting of the same individual and between the handwritings of two individuals, and that the within-writer variance is less than the between-writer variance. The goal of their study was to objectively verify this common observation. A source document in English of 156 words capturing all characters (letters and numerals) and certain character combinations of interest was designed for each participant to copy three times. Handwriting samples of 1,500 individuals, representative of the US population with respect to gender, age, ethnic groups, etc., were obtained. Analyzing differences in handwriting was done by using computer algorithms for extracting features from scanned images of handwriting specimens. Two types of features characteristic of the handwriting were obtained: conventional and computational. Conventional features are the handwriting attributes that are commonly used by forensic document examiners which comprise 21 discriminating elements, namely, (1) *arrangement*, (2) *class of allograph*, (3) *connections*, (4) *design of alphabets and their construction*, (5) *dimensions (vertical and horizontal)*, (6) *slant or slope*, (7) *spacings (intraword and interword)*, (8) *abbreviations*, (9) *baseline alignment*, (10) *initial and terminal strokes*, (11) *punctuation*, (12) *embellishments*, (13) *legibility or writing quality*, (14) *line continuity*, (15) *line quality*, (16) *pen control*, (17) *writing movement*, (18) *natural variations or consistency*, (19) *persistency*, (20) *lateral expansion*, and (21) *word proportions* (Huber and Headrick 1999). Macro- and micro-computational features are those that can be determined algorithmically by software operating on scanned image of handwriting. The following set of 11 macro-computational features were used: (1) *entropy of gray values*, (2) *gray-level threshold*, (3) *number of black pixels*, (4) *number of interior contours*, (5) *number of exterior curves*, (6) *number of vertical slope components*, (7) *number of horizontal slope components*, (8) *number of negative slope components*, (9) *number of positive slope components*, (10) *slant*, and (11) *height*, while micro-computational features are computed at the allograph, character, or shape level.

Statistical analysis was conducted using the identification model and the verification model. In the identification model, given a questioned handwriting sample x and samples of handwriting of n known writers, the classification task was to pick out the writer of x among n writers. In verification model, given two unknown handwriting samples x_1 and x_2 and samples of handwriting of n writers, the objective was to determine whether x_1 and x_2 were written by the same person or by two different people among the n writers. It was found that writer identification accuracy was close to 98 % for two writers while the verification accuracy was about 96 %.

Using global attributes of handwriting and very few characters in the writing, the ability to determine the writer with a high degree of confidence was thus established.

Another study was made to show that the handwriting of an individual is so unique that by applying discriminant analytical methods on the parameters of width-height ratio, symmetry factor, slant, and tilt, the writer could be objectively indentified (Cheung and Leung 1989). In the above experiment, 25 Chinese characters were selected. A total of 376 handwriting specimens were collected from 21 subjects and after 3 months, 6 of the subjects were randomly selected to write once again the 25 characters which were then used as the "questioned samples"; each of the handwriting specimens was characterized by one or more of the 4 measurable parameters. Applying linear discriminant analysis, although the six "questioned" handwritings could not be correctly associated with their corresponding authors by using only one of the parameters, a perfect recognition rate was recorded using all four parameters. The findings are consistent with the hypothesis that verification of authorship is based upon the discovery of a number of divergent characteristic features which in combination become sufficiently personal for an identification to be made.

The above-mentioned two pieces of research have clearly demonstrated the uniqueness of handwriting, and it can be inferred that consideration of both measurable and qualitative parameters in handwriting gives rise to a powerful theoretical foundation for the scientific identification of authorship. Using this theoretical framework, identification of handwritings can be made, with objectivity occupying the center position.

The Art and Science of Handwriting Examination: An Epilogue

Successes in computational classification experiments on handwritings provide scientific support for the long-established (but not vigorously tested) practices of handwriting examination. However, these experiments were conducted on natural handwritings but were not directed to forgery, or any other examinations involving such complications as disguise, handedness, and influence of health and drugs. It is envisaged that for a long time, handwriting identification would have to be made by specialist document examiners instead of relying on computational software for verifying authorship. As such, the entailment of a certain degree of subjectivity would be inevitable in handwriting examination. The objective component of handwriting examination provides the most easily acquired skills of a document examiner, while the subjective reasoning processes require years of training to fully develop (Whiting 1986).

The initial stage of handwriting analysis is basically a comparison of morphological features between the questioned writing and the control exemplars. It depends on the ability, on the part of the document examiner, to find out the more subtle, personal writing attributes in the script. This exercise is *by and large* objective. Some degree of subjectivity is involved because the procedure relies on the expert's cognitive selection of handwriting features which he or she regards as *important* personal characteristics. While it is the author's personal experience that well-trained document examiners generally pick out similar assortment of characteristics from the same handwriting specimens, there are deviations, both in terms of numbers and the ways of how the depicted characteristics are described and comprehended.

The second stage of authorship determination is the interpretation of the depicted writing characteristics. The document examiner has to evaluate the relative significance of the writing attributes which he or she has discovered and consider the information related to the case, for example, the physical or mental condition of the alleged writer, the presence or absence of any external influences, and the possibility of disguise. This is a mental exercise which encompasses subjectivity to a larger extent. Handwriting experts can diverge considerably, especially for difficult cases, in their assessment of the relative importance of the depicted handwriting features. It is during this stage of the examination process that divergence of opinion among handwriting experts sometimes arises.

An element of subjectivity also relates to the expression of an opinion in that after assessing the evidence and forming an opinion, one has to transform the conceptual inclination into written words. Any findings or observations will be useless unless they are comprehended and their significance appraised. Based on the assessment of the examination results, the expert will have to come up with an opinion on the authorship. Inaccuracy and variability can occur. While a *wholly subjective* opinion will be the personal view on the subject matter without any evidential support which is undoubtedly inacceptable, an *entirely objective* opinion would be restricted to facts and figures only. In handwriting examination, a 100 % objective "opinion" will not meet the expectations of the parties concerned because the so-called opinion will only be a list of the similarities or differences that the expert has discovered without any interpretation as to what these findings indicate.

Opinion expressions used by handwriting experts vary among different schools of document examiners, both in terms of opinion expressions and meaning (Leung and Cheung 1989). Some of the more popular opinion expressions being adopted are as follows: *wrote or written by, highly probable or very high probability, probable or high probability, very likely, likely, could well have, consistent with, could have, inconclusive, no evidence, consistent with (not being written by), unlikely, highly unlikely, probably not, could not have, and did not write*. While not all of the above-mentioned expressions are used by a single document examiner, the choice of terminology depends on the reasoned *preference* of the individual expert. The levels of opinion also vary among different practitioners. A few document examiners, which can be described as the "all-or-none" school, believe that only three classes of opinion, namely, identification, elimination, and inconclusive, should be given (McNally 1979). However, the majority of document examiners who maintain that since facts of handwriting examination will vary in number and significance, the language selected to summarize different sets of facts must vary, some being in definite terms and some in qualified terms (Cole 1980). Nowadays, it is widely accepted that in order to reflect the *degree of certainty or belief*, a scale consisting of different levels of expressions should be used. Ellen described a scale of five ranges of opinion and proposed that a small number of divisions of a scale are advantageous in that the significance of each point on the scale can be easily defined (Ellen 1979), but an 11-point opinion scale was also suggested (Leung 1994). In 1991, the Questioned Documents Section of the American Academy of Forensic Sciences and the American Board of Forensic Document Examiners have adopted recommended guidelines in report and testimony which consist of a 9-point opinion scale (identification, strong probability, probable, indications, no conclusion, indications did not, probably did not, strong probability did not, elimination) based on the concept that probability, as used in handwriting opinions, is not a statistical measurement but a measurement of the examiner's confidence based on scientific principles and experienced judgment (McAlexander et al. 1991).

The divergence of the number of opinion scales and terminology used by handwriting experts clearly show that the process of expressing opinions does involve a certain degree of subjectivity on the part of the expert although the expressed opinion is based on scientific observations and experienced judgment. After examining the handwritings or signatures, the expert has to assign the opinion in ordinary language terms that he or she believes to be the most appropriate, and subjectivity comes into play during the transformation from abstract thinking – a degree of certainty or confidence in one's mind – into written words which is susceptible to vagueness and controversy when the readers of the report attempt to convert in their minds these same written words back to the abstract certainty of belief. The inherent difficulty in handwriting and signature examination is due to the fact that contrary to DNA profiling, basic statistical data in relation to frequencies of occurrence of handwriting characteristics, especially for signatures which are unique calligraphic entities of their owners, are unknown. By comparison, the chance match of DNA grouping of, say, one in a billion reported by two laboratories embodies the same meaning because the *entirely* objective opinions from both laboratories are the results derived from statistical data. Handwriting experts *cannot* provide explicit probability figures routinely appearing in DNA grouping reports but instead have to use such ordinary language terms as "highly probable," "probable," or "may" to represent the degree of confidence, or certainty.

The scientific validity of the methodology for handwriting examination has been well demonstrated and from the "utilitarian" point of view, testimonies in handwriting analysis do help jurors and judges make their own decisions, although occasionally expert opinions are criticized for containing a certain element of subjectivity. In this connection, Evett makes an interesting point ". . . that a so-called 'objective test' can only exist within a framework of assumptions and the validity of those assumptions in an individual case is a matter for subjective judgment. The objectivity is an illusion" (Evett 1996). A good enlightenment about the relationship between objectivity and subjectivity, which is aptly applicable to handwriting evidence, can be found in *The Adventure of the Sussex Vampire* where Sherlock Holmes said ". . . It has been a case for intellectual deduction, but when this original intellectual deduction is confirmed point by point by quite a number of independent incidents, then the subjective becomes objective and we can say confidently that we have reached our goal." Hence, the probabilistic principles of handwriting identification can, perhaps, be treated from a philosophical perspective.

Overview

This entry aims to lay out some of the key controversies developments in hate crime scholarship and practice in recent years. Specifically, it speaks to the dilemmas of defining and legislating hate and to the harms associated with hate crime. In addition, it enumerates “what’s hot” and “what’s not” in terms of current scholarship, identifying those areas that are well developed and those that have received little attention. It concludes with a discussion of emerging nonpunitive means by which to address hate crime in practice.

Key Issues

Sadly, the phenomenon we have come to call hate crime has a lengthy history in the west. History does indeed repeat itself as similar patterns of motivation, sentiment, and victimization recur over time. Just as immigrants in the 1890s were subject to institutional and public forms of discrimination and violence, so too were those of the 1990s; likewise, former black slaves risked the wrath of the Ku Klux Klan when they exercised their newfound rights in the antebellum period, just as their descendants risked violent reprisal for their efforts to win and exercise additional rights and freedoms in the civil rights era; and women who demanded the right to vote on the eve of the twentieth century suffered the same ridicule and harassment as those who demanded equal rights in the workplace later in the century. While the politics of difference that underlie these periods of animosity may lie latent for short periods of time, they nonetheless seem to remain on the simmer, ready to resurface whenever a new threat is perceived – when immigration levels increase, or formerly powerless groups are suddenly empowered, or when relationships between groups shift for other political, economic, or cultural reasons. Anders Breivik’s appalling attacks in Norway attest to this, as does the surge of Islamophobic violence in the aftermath of the September 11 attacks.

Nonetheless, it has only been in the past two or three decades that practitioners and academics have begun to take hate crime seriously. Most scholars trace the origins of the concept now known as hate crime to the 1980s. The first legislative recognition of hate crime in the United

States came in the form of a federal hate crime statute in 1969 and as state act in California in 1978. The real "flurry" began, however, with the signing of the Hate Crime Statistics Act of 1990. By the end of the 1990s, virtually all US states had hate crime legislation. Most other western nations seem to have followed suit, introducing their own variants during the late 1980s and early 1990s. Interestingly, while most explicitly used the umbrella term hate crime, the UK did not, opting instead for more directed legislation around racial hatred, and later religious hatred.

Oddly, scholarship in the field did not seem to keep pace with legislation. We were much slower to recognize this emerging construct (Shively 2005). Certainly, there were no major works with "hate crime" in the title prior to the mid-1980s. In fact, few references of any kind are to be found in the scholarly literature, until 1989 and 1990, which seemed to be watershed dates. The field really took off in the opening years of the 1990s, with the publication of such works as Kelly's (1991) *Bias Crime: American Legal Response*, Herek and Berrill's (1992) *Hate Crimes: Confronting Violence Against Lesbians and Gay Men*, and Levin and McDevitt's (1993) *Hate Crimes: The Rising Tide of Bigotry and Bloodshed*. This entry seeks to assess the current state of the art in the field.

The entry opens with traditional definitional dilemmas, moving then to identify emerging approaches to the consideration of the impacts of hate crime for the individual as well as the community(ies) at large. This is followed by a discussion of the tensions associated with legislating and policing hate crime. Focus is then turned to a consideration of "what's hot" and "what's not" in the context of hate crime scholarship. The entry ends with a call to consider the value of nonpunitive approaches to hate crime. The aim is to draw attention to areas in need of further development and to inspire a dialogue on how to move forward both academically and practically.

Defining Hate Crime

One of the greatest challenges facing the prevention and response to hate crime is the lack of a common definition and understanding of what constitutes hate crime. There are legal definitions which have generally followed the lead of the model legislation as set out by the Anti-Defamation League:

> A person commits a Bias-Motivated Crime if, by reason of the actual or perceived race, color, religion, national origin, sexual orientation or gender of another individual or group of individuals, he violates Section ______ of the Penal code (insert code provisions for criminal trespass, criminal mischief, harassment, menacing, intimidation, assault, battery and or other appropriate statutorily proscribed criminal conduct).

Slightly different are "hate incidents" which are

> expressions of bias, prejudice and bigotry that are carried out by individuals, groups, organizations and states, directed against stigmatized and marginalized groups or communities, and intended to affirm and secure existing structures of domination and subordination. (Hate Crimes Community Working Group (hereafter HCCWG) 2006: 18)

It is important to include these noncriminal incidents in our understanding of hate crime, since what appear to be relatively petty incidents are very common and thus wear cumulatively on the victim. That means that, from a scholarly point of view, legalistic definitions are too exclusive, relying as they do on violations of criminal law. They are also significantly limited in their ability to breathe life into the term. They provide little insight into the power dimensions that are inherent in the act of hate crime. Consequently, the preferred definition that has come to be used widely in the literature accounts for the politicized nature of hate crime and the role of hate crime in constructing the relative identities and subject positions of both the victim and the offender, individually and collectively:

> Hate crime, then, involves acts of violence and intimidation, usually directed toward already stigmatized and marginalized groups. As such, it is a mechanism of power and oppression, intended to reaffirm the precarious hierarchies that characterize a given social order. It is intended to simultaneously recreate the threatened (real or imagined) hegemony of the perpetrator's group, and the "appropriate" subordinate identity of the victim's group. It is a means of marking both the Self and the Other in such a way as to re-establish

> their "proper" relative positions, as given and reproduced by broader ideologies and patterns of social and political inequality. (Perry 2001)

Here, we see context, intent, and impact. Hate crime is embedded in relations of power and intended to reinforce extant relations. And its aim and effect – typically – is to intimidate a group of people who "hold in common a single difference from the defined norm – religion, race, gender, sexual identity" (Pharr, cited in Wolfe and Copeland 1994: 203). As such, hate crime is a "message crime," intended to remind not just the immediate victim but also his/her community of their "rightful" place in carefully crafted hierarchies of race, religion, gender, and sexuality, inter alia.

What's the Harm?

This notion of "message crime" has more recently given rise to more attention to the issue of the impacts of hate crime. In particular, scholars are beginning to assess the ways in which collective harm might derive from bias-motivated violence. Indeed, running through much of the hate crime literature – even through court decisions on hate crime – is the assumption that such offenses are, for that same reason, qualitatively different in their effects, as compared to their non-bias-motivated counterparts. Specifically, Weinstein (1992) identifies three potential levels of harm: "that racial violence causes injury to the victim above and beyond physical damage, that racial violence causes injury not only to the immediate victim but also to the victim's racial or ethnic group, and that racial violence has particularly pernicious ramifications for society as a whole." The first of these has been the subject of considerable scholarly attention. The empirical findings in studies of the physical, emotional, psychological, and behavioral impact of hate crime are beginning to establish a solid pattern of more severe impact on bias crime victims, as compared to non-bias victims (see, e.g., McDevitt et al. 2001).

When we move beyond the experiences of the immediate victim to the broader *in terrorem* effects, we enter the realm of speculation. Many scholars point to the "fact" that hate crimes are "message crimes" that emit a distinct warning to all members of the victim's community: step out of line and cross invisible boundaries and you too could be lying on the ground, beaten and bloodied. Consequently, the individual fear noted above is thought to be accompanied by the collective fear of the victim's cultural group, possibly even of other minority groups likely to be victims. Yet, there have been few studies that explicitly survey members of victims' reference communities to determine the veracity of this assumption (Lim 2009; Noelle 2002; Perry and Alvi 2011).

Another related area that has received scant attention has been the impact of hate crime on perceptions of national ideals. Hate crime throws into question national commitments to tolerance and inclusion. Speaking specifically of Native Americans over 50 years ago, legal scholar Felix Cohen noted that mistreatment – legal or extralegal – of minorities "reflects the rise and fall of our democratic faith." In other words, it is possible that the persistence of hate crime is a challenge to democratic ideals. It reveals the fissures that characterize its host societies, laying bare the bigotry that is endemic within each. As such, it may very well be the case that bias-motivated violence is not just a precursor to greater intergroup tension, but is an indicator of underlying social and cultural tensions. In this interpretation, hate crime is but one indicator that enshrined ideals of freedom and equality are illusory.

Alternatively, one possibility is that hate crime acts as a catalyst to positive change. That is, patterns of persistent violence, or highly publicized cases – like the 1998 Matthew Shepard or James Byrd cases – often have the unintended effect of mobilizing victim communities and their allies. For example, the racially motivated murders of Michael Griffith in Howard Beach in 1996 and Yusuf Hawkins in Bensonhurst in 1989 both inspired widespread demonstrations condemning the racism of the perpetrators' communities, as well as the racist culture of New York City generally. On a smaller scale, we've seen some evidence of this in Ontario in response to the alleged incidents of hate crime against

Asian anglers north of Toronto. Indeed, community outcry resulted in the establishment of an inquiry into those events (Ontario Human Rights Commission 2007).

Legislating Hate: Persistent Challenges

Debate continues to swirl over whether, in fact, we should even attempt to legislate "hate" crime as a distinct entity. For some, this springs from practical concerns with identifying motive. The argument is that it is exceedingly difficult to determine what may have motivated any particular incident, especially in the absence of offensive language or other direct indicators. Thus, officers are likely to be required to gather additional background information "proving" motive – such as ties to racist groups, or previous expressions of homophobic attitudes. It is this approach that raises the thorny issue of "hate thought."

The most strident critics of hate crime legislation are those who equate the regulation of hate crime with the regulation of hate "thought." Jacobs and Potter (1998) have been especially articulate in their charges in this respect. Writing of sentencing enhancement provisions, for example, they question how increased punishment for a bias motive could be interpreted as anything other than punishment for beliefs, that is, thoughts, rather than simply the actions. Often, this argument is expressed in constitutional terms, in so much as restrictive legislation is perceived as a violation of the freedom of expression.

Nonetheless, most western nations have responded to public concerns about bias-motivated violence with an array of policy interventions. As early as 1981, the Anti-Defamation League (ADL) developed model legislation aimed at confronting hate crime. The framework has proven popular not just in the United States but internationally as well, with nations adopting similar legislative structures.

The most momentous piece of explicit hate crime legislation at the federal level in the USA was the Hate Crime Statistics Act in 1990, according to which states and their respective law enforcement agencies were "required" to report hate crime statistics on an annual basis. With the passage of the act, the federal government appeared to have committed itself to the task of collecting "accurate" information on hate crime nationwide. The Act mandated that all law enforcement agencies report annually on reported and recorded hate crime in their jurisdictions. As of the 2008 reporting year, however, less than 20 % of relevant agencies were in compliance.

The limits of the US federal legislation are immediately apparent in S(b)(1) itself, especially with respect to the narrow definition of both the protected groups and the enumerated offenses. Only five grounds for motivation and eight offenses are to be counted in the UCR. This leaves a lot of ground uncovered. Other criminal offenses and equally injurious noncriminal offenses are left uncounted. Similarly, victimization on the basis of gender or political orientation, for example, is excluded. Moreover, this brings to mind the problem of inconsistency between reporting agencies. Not all states recognize the same categories of bias in their legislation. Some states do not include gender in their hate crime legislation; some don't include sexual orientation; yet others include such anomalous categories as "whistle blowers." In short, we have yet to resolve, either philosophically or legally, the question of the "boundaries" of protection.

This problem is, of course, exacerbated in the EU context where member states have diverse pieces of legislation, covering a wide array of different offenses, protected categories, and/or sentencing responses. Reports from the Office for Security and Cooperation Europe (OSCE 2009), for example, consistently bemoan the lack of standardization across EU states. In fact, some states have no specific provisions on hate crime (e.g., Greece, Italy and Portugal). A 2009, OSCE report on hate crime laws includes an overview of the different protected categories among member states, including the most commonly protected classes (e.g., race), frequently protected classes (e.g., gender), and rarely protected classes (e.g., political affiliation). Similarly, states vary on the nature of the legislation, ranging from genocide, to sentencing enhancement, to hate speech provisions. The UK is an interesting case. Policy guidance is largely derived from the Association of Chief Police Officers (ACPO) which holds a relatively inclusive definition of hate crime as an offense motivated by race, sexual orientation, faith, and disability. Yet prior to 2003, concrete legislation revolved around racially motivated crime (Crime and Disorder Act, 1998) and religiously motivated crime (Anti-terrorism, Crime and Security Act, 2001). With the passage of the Criminal Justice Act 2003, provisions were extended to include sexual orientation and disability. Protection is thus still limited to only four categories.

Policing Hate

The weaknesses associated with legislative efforts have had the effect of similarly limiting law enforcement's ability to investigate and respond to hate crime. In addition, Bell (2009: 35) identifies an array of structural limitations on police recording of hate crime including the presence of departmental hate crime policies, level of officer training, and administrative commitment to the issue. As with statutory provisions, there is wide variation among police departments in the extent to which any of above factors prevails. In the USA, for example, it appears that very few departments are effective in identifying or investigating hate motivated crime. On the contrary, very few acknowledge hate crime when it occurs. For instance, in 2005, only 16 % of agencies reported any hate crime; most departments in the Deep South reported no hate activity for the year, which many would find incredible.

In addition to the limitations imposed by law enforcement agencies are those presented by trends in public underreporting. In fact, some argue that hate crimes are even more dramatically underreported than other UCR offenses (Berrill 1992). Gay victims, for example, may fear that the admission of their victimization is concomitantly an admission of their sexual orientation. Reporting an anti-gay crime to the police is tantamount to "outing" themselves – an event for which they may not be prepared. Similarly, the undocumented laborer may fear the repercussions of his or her status being revealed. Moreover, victims may well fear secondary victimization at the hands of law enforcement officials. At the very least, they may perceive that police will not take their victimization seriously.

Most western nations have attempted to enhance their efforts around hate crime through the development of viable and engaged bias crime units, or in the case of smaller agencies, at least one or two personnel devoted to leading the effort to prevent and investigate hate crime. Most large regional police agencies in Canada, for example, Toronto, Edmonton, and Vancouver, have such dedicated units, generally comprised of 2–4 officers and occasionally civilian researchers and/or analysts.

What's Hot...

If there is a single field within hate studies that can be said to be highly developed it is in the area of violence against lesbian and gay communities, and especially the latter. Indeed, among the first book length publications in the 1990s were two that dealt explicitly with violence against gays and lesbians (Comstock 1991; Herek and Berrill 1992). Herek would follow this with a series of papers further detailing the "sequalae" of hate crime against gays and lesbians. Indeed, these two books seemed to open the floodgates for work on anti-gay violence, in that it dominated the substantive literature in the broader field of hate crime for most of that decade.

However, two key pieces were missing from the literature on sexualities and on gender. To this day, there has been very little scholarship on the experiences of lesbians specifically. It is as if scholars assumed that the dynamics and impacts of violence of gay men and women alike were equivalent. Indeed, simply glancing over journal titles makes this elision clear, in that they typically include the phrase "lesbians and gay men," rather than one or the other. Moreover, these pieces do not typically separate the differential experiences, dynamics, or impacts according for gay men and lesbians. This dismisses the fact that gender – and gender expectations – as well as sexualities play a significant role in motivating these crimes.

In the current lexicon, we generally speak of "the" LGBT community. However, the "T" – transgender community – has largely been invisible to hate crime scholars. While "trans violence" is on the surface concerned with gender identity, the emerging scholarship makes it clear that it, too, is often multifaceted, insomuch as sexuality comes into play, at least from the perpetrators' perspective. Shelley (2008) shares a number of victim narratives in which it is difficult to disaggregate the motivating factors in their assaults. He observes that "trans people are frequently subject to homophobia and heterosexism, whether or not they themselves are heterosexual in orientation" (Shelley 2008: 96). This suggests, then, that trans people are being punished for what is perceived to be inappropriate performance of both their gender and sexual identities. Available evidence is beginning to point to the fact that trans violence may be even more brutal than homophobic violence and more likely to involve sexual assaults. So, too, is it likely to be more dramatic in its impacts. This is perhaps part of the reason why trans people have higher rates of suicide than even their homosexual peers. Given the nascent stage of scholarship in this area, there is still much to learn.

Another long ignored class of targeted violence that has more recently come to the fore is what is typically referred to as disablist hate crime directed toward those with physical or mental disabilities. In the United States, this was the last protected class to be included in the reauthorization of the Hate Crime Statistics Act (HCSA) in 1996. With sexual orientation, it was only added to UK legislation in 2003. Disability has been a protected category in the Canadian sentencing enhancement provision since its inception. Regardless of its legal status, disablist hate crime has long been neglected by hate crime scholars. Hannah Mason-Bisch (2010: 62) suggests that this is because policy makers and scholars alike place disability at the bottom of the "victim hierarchy." In recent years, a number of scholars have turned their attention to documenting the extent, intensity, and impacts of anti-disability violence. Thus, it is becoming increasingly clear that people with disability are subject to the full spectrum of emotional and physical violence that characterize other communities (Sherry 2010; Lane et al. 2009). What distinguishes this group from others, however, is that they are much more likely to be victimized by people they know – especially caregivers – than is the case for others. Sadly, this dynamic, coupled with a common inability to recognize hate crime, means that disablist violence is dramatically undercounted. It is, thus, an area in need of deeper empirical examination.

The last decade has, for obvious reasons, seen increased attention to Islamophobic violence. Since the terrorist attacks in New York City and Washington DC and above Pennsylvania on September 11, 2001, ethnic minorities associated with Islam in most western countries have experienced increased negative attention from the media, from police and security forces, and indeed from agitated citizenry. There has been a concomitant increase in all such countries in the extent of anti-Muslim or "Islamophobic" hate crime, racial vilification, and discrimination (Poynting and Noble 2004; Welch 2006). This has been exacerbated by subsequent terrorist events, notably Bali in October 2002 and October 2005, Madrid in March 2004, and London in July 2005.

In addition to scholarship on particular victim categories, several other issues have captured the imagination of scholars and practitioners. Since the early days of the recognition of hate crime as a public concern, emphasis has been placed on the activities and rhetoric of organized hate groups. In recent years, more attention has been focused on the online activities of these groups. It is likely that this will only increase in the aftermath of Anders Breivick's attacks in Norway. He had made extensive use of electronic media to share ideas and especially to disseminate his manifesto. This was not something new, but rather something that a natural extension of the growth of the "Web of hate" initiated as early as 1985 when Donald Black created *Stormfront*, which is generally considered to have been the first white supremacist Web site.

The proliferation of hate-oriented and "White Power" sites has occurred at such a rate that it is virtually impossible to estimate the number of such Web sites. Such counting is made even more difficult by the fact that sites move and shut down on a frequent basis, often resurfacing on other servers with other names. Nonetheless, monitoring organizations have tried to quantify the problem. One 2005 estimate, from the Simon Wiesenthal Center, suggested that there were more than 5,000 Web sites advocating hatred at that time. A 2005 International Network Against Cyber Hate publication reported that "during the last 4 years, INACH members handled about 15,000 cases of online hate" (p. 7) among its network of 14 member organizations. It is difficult to assess the accuracy of such estimates. What monitors and scholars can agree on, however, is that the number of such sites has vastly increased over the past decade. Today, it is probably not an exaggeration to say that there are thousands of domestic and international Web sites marketing various brands of hatred and intolerance. For example, as of this writing (December 2012), the Hate Directory runs to nearly 200 pages and thousands of sites.

What's Not...

Generally speaking, hate crime scholars have not paid very close attention to the concrete experiences of discreet categories of hate crime victims. Comments above about new directions in victim research nothwithstanding, it remains the case that we have done insufficient empirical work with vulnerable communities. In light of this shortcoming, it is hardly surprising, then, that we have failed to take seriously the implications of intersectionalities for how hate crime is experienced. We simultaneously occupy multiple subject positions or identities. Kimberlé Crenshaw (1994) was among the first scholars to highlight academic neglect of the "intersection of racism and patriarchy." We might add other categories of difference to this equation, such that we attend to the intersection of racism and patriarchy, but also heterosexuality, class, religion, and disability. All black people do not experience their race in the same ways, but through the prisms of the other elements of their identity. Similarly, to be gay is to experience life differently depending on one's ethnicity, or religion, or sex. Our identities and life chances are dramatically affected not by one element of who we are, but multiple, cross-cutting, and sometimes contradictory positions. Yet this is not something that has taken up much space in the hate crime literature. A powerful exception to this is the work of Doug Meyer (2010). In a series of articles, he has explored empirically and theoretically how gay men and lesbians experience hate crime differently depending upon their class, race, and gender identities. This is a fruitful beginning to a new area of inquiry.

Even in light of the above assessment of the limited depth of research on vulnerable communities, it is clear that we still know more about victims of hate crime than we do about offenders. There are myriad reasons for this. First and foremost is that few such crimes are reported by victims. Where there is no documentation, there is no way to know about the offender. Additionally, even where police are involved, it is very likely that no suspect will be identified. Hate crimes are often random, anonymous events. Especially in incidents of vandalism or graffiti or other property crimes, there is no direct contact between the victim and offender that would allow identification.

Beyond these investigative problems lie academic limitations as well. We frequently speak to victims of hate crime, but rarely do we engage with offenders. In part, this is due to the difficulty in soliciting volunteers for interviews or surveys. Generally, offenders are not necessarily anxious to admit their wrongdoing. A dramatic exception involves members of organized hate groups – these typically young men are often quite happy to share their perspectives on why people of color, gays, or Jews, for example, "deserve" their victimization. However, the proportion of hate crime committed by such individuals remains a very small part of the population of offenders. Consequently, very little research has delved into the explicitly expressed motivations of the "typical" hate crime offender.

Across nations, it is clear that the typical hate crime offender is a young white male who is generally performing among a group of peers. Yet while perpetrators act in a group, it is nonetheless a myth that they are associated with organized hate groups. It is generally thought that less than 5 % of offenders have strong ties to white supremacist or other hate groups. Who, then, are the remainder? It is perhaps troubling to admit that, for the most part, they are probably "normal" young men, acting out cultural scripts of difference and superiority. Very early in the history of hate crime scholarship, Levin and McDevitt (1993), for example, argued that "hate crimes are more often committed under ordinary circumstances by otherwise unremarkable types – neighbors, a coworker at the next desk, or groups of youngsters looking for a thrill" (5).

Levin and McDevitt (1993) were also early to try to explicitly discern the motives provoking hate offenders. They created the now-classic typology of hate crime motives that included thrill seeking, defensive violence, mission/moral agenda, and retaliatory violence. While there have been attempts to replicate and refine Levin and McDevitt's categorization of offenders (Fisher and Salfati 2009), little work has been done with the typical hate offenders – rather the emphasis, noted above, continues to be on members of organized hate groups in spite of their relative underrepresentation as actual perpetrators of violence. This is especially the case in North America. In contrast, there have been a handful of powerful studies in the UK in recent years. Among these are Sibbit's (1997) study of racist offenders on two south London housing estates and Gadd and Dixon's (2011) study in the English North Midlands. Both provide important insights into the cultural and biographical histories that contextualize perpetrators attitudes and behaviors and are thus valuable starting points. Yet they may be limited geographically and culturally. We would do well to explore such violence in other contexts as well.

This suggests another limitation to our current understanding of hate crime. It might be said that we have been myopic, if not blatantly ethnocentric, in our study of hate crime. Attention is focused almost exclusively on the "western" experience of hate crime, with particular emphasis on the USA, the UK, Australia, and Western Europe. We know virtually nothing about racial or religious violence in Japan, or homophobic violence in Saudi Arabia, for example. There is some extant literature on the genocides of Rwanda, or the ethnic cleansing of the Balkan states, but we have not mined these tragic conflicts for lessons about the evolution of hate, or what the ADL might refer to as the pyramid of hate.

In 1998, two "international" anthologies on hate crime were published almost simultaneously. As strong as these were in many respects, they did little to expand our scholarly borders. Kaplan and Bjorgo's (1998) *Nation and Race* focused almost exclusively on European issues. Kelly and Maughan's (1998) *Hate Crime: The Global Politics of Polarization* strayed a little further afield, to address hate crime in India, ethnic cleansing in Colombia, and Palestinian persecution in the Arab world alongside the standard European and American fare. Subsequent to these two anthologies, however, little else has been done to examine bias-motivated violence outside of Europe and North America. And where attention is paid to racialized or other forms of bigoted violence, as in the Rwandan genocides, for example, this is not typically connected to the continuum on which hate crime falls. Interestingly, an exception appears to be emerging and that is consideration of anti-gay violence in the Caribbean (White and Gerke 2007).

Recent events, such as the 9/11 attacks and even Breivek's assaults in Norway, have raised the question of the links between terrorism and hate crime. Rosga (1999) and Hamm (1994) have separately articulated arguments that hate crime might, in fact, be understood as a form of terrorism, whereby "an attack motivated by prejudice targets not only its individual victim, but by its symbolic weight, effectively targets a whole group of marked individuals . . .. It functions, in other words, to reduce complex, multi-faceted individuals into one-dimensional, victimized identity categories" (Rosga 1999: 145).

Similarly, Mark Hamm (1994) champions the use of the term "domestic terrorism," by which he means violence – generally perpetrated by organized extremists – intended to reinforce a "putative norm." Typically, that "putative norm" refers to existing hierarchies along raced or gendered lines.

For obvious reasons, "terrorism" – especially now – is a powerfully evocative word. Both uses of the term capture the dramatic collective impact of bias-motivated violence. The term demands the recognition that "hate crime" is intended to reinforce the subordination – perhaps even the invisibility – of the targeted groups. The two phenomena are at least close cousins (Perry 2009). One might say they run along the same continuum of intimidation and fear, differing in scale more than kind. Yet how is this assessment useful? For one, it encourages us to take hate crime seriously. It could easily evolve into terrorism, as it does among organized hate groups, for example. Yet this point is typically obscured "when attacks on non-government targets, such as abortion clinics or members of unpopular or stigmatized religions, ethnic, racialized, sexual minorities, immigrants or gypsies are defined as 'hate crimes,' thus suggesting that such attacks are no more than expressions of personal prejudice" (Jaggar 2005: 204). As most would agree, however, the intent of hate crime is not only or even primarily intimidation of an individual, but of their community.

Countering Hate Crime

The majority of western nations have responded to hate crime punitively, opting for harsher sentences. However, we've learned in the last decade or so that harsher sentences don't necessarily make safer communities. Purely punitive responses have the potential to be counterproductive, in that they may "actually increase the social divisions they are designed to ameliorate" (Franklin 2002: 154). Moreover, hate crime offenders who go to prison often find themselves among peers who will reinforce their racist, or homophobic, or religious biases. Most offenders are youth, especially young men who are responding to what they see as a threat – to their community, to their neighborhood, or to their self-esteem. Often, these threats are more imagined than real. It has proven to be more effective, then, to challenge those myths and to thus "humanize" the victims and their communities. Incidents of hate crime can be taken as a starting point for education and healing rather than simply punishment. Consequently, community-based responses represent valuable alternatives. For the most part, however, these remain underdeveloped both conceptually and in practice. Indeed, Iganski and Smith (2011) recently canvassed a number of western nations, seeking evidence of programs for young hate crime offenders specifically. The findings were meager indeed, with nations like Australia, New Zealand, and Canada lacking any such programs, while promising US initiatives had been largely defunded. Germany, Sweden, and the UK seemed to be the only states boasting a commitment to anti-hate programming. While limited in number, the programs that were identified did seem to point to the importance of nonpunitive approaches. Alternative initiatives can be grouped into a number of categories.

Education. Rabbi Steven Moss, creator of New York City's Stopbias program stated that "I find most defendants are not bigoted in their hearts but are acting out, using hate words but often not knowing why they are hateful. You want to create an environment in which the [student] can grow from this." With this in mind, one option is to recommend an educational opportunity for hate crime offenders. This will make an impact on both the community and the offender. At the simplest level, the court could be asked to require that offenders take college or university courses on diversity, or on the community that has been victimized. Another, that is widely used in the United States, is for offenders to engage in community service within the victim's community. These alternatives are intended to deter further bias-motivated violence by teaching offenders the effects of their actions and by putting a human face on the victims.

Offender Counseling. Related to this are more formalized anti-bias programs that might be available in local communities, either through the justice system or through nonprofit agencies. Nearly two-thirds of all known perpetrators of hate crimes are teenagers or young adults. When appropriate, a victim-offender restitution program or offender counseling program can be an effective sanction for juveniles. Like the educational initiatives noted above, these are grounded in the understanding that young offenders, especially, often act out of ignorance and uncritical adoption of community norms of racism, homophobia, etc.

Counseling initiatives provide an opportunity to educate hate crime offenders about those who are the object of their violence. The goal is to alter and expand the offenders' perceptions of other cultures. These programs can consist of such activities as visits to places of worship or community centers, listening to guest speakers from other cultures, and listening to stories from victims of bias crimes. It might also include lessons on human and civil rights law, racism, anti-Semitism, and other forms of prejudice and a short history outlining the legacy of discrimination against minorities in America.

Victim-Offender Mediation. Recently, victim-offender mediation has been used in an increasing number of contexts, including hate crime. This option allows victims and offenders enter into a dialogue intended to enhance their understanding of one another: the motives of the offender and the effects on the victim. Part of the dialogue – which must be freely entered by both parties – is also the resolution of their conflict, generally by the offender admitting guilt and offering a sincere apology. Additionally, however, the two parties are meant to come to a mutually acceptable agreement about "what's next," typically, some kind of restitution. The goal in victim-offender mediation, then, is to empower the victim while evoking compassion and understanding on the part of the offender, so as to minimize recidivism.

Restorative Justice. In some cases, restorative justice may also be viable, particularly for low-level bias-motivated offenses and for juvenile offenders. The restorative justice model goes beyond victim-offender mediation to promote involvement of the victim, the offender, *and* the community in the justice process. In particular, restorative justice interventions help to restore victims' and communities' losses by holding offenders accountable for their actions by making them repair the physical and emotional harm they have caused. Such interventions also focus on changing the behavioral patterns of offenders so that they become productive and responsible citizens. The restorative justice model places emphasis on everyone affected by the crime – the community and the victim as well as the offender – to ensure that each gains tangible benefits from their interaction with the criminal justice system. This alternative, then, specifically addresses the community impact of hate crime, allowing any affected party a place at the table.

It is not enough to intervene at the level of the individual offender. Perpetrators are largely reflections of the communities within which they live, where sentiments are shaped by popular opinion as well as political rhetoric. We can expect little popular change in attitude without a corresponding – or even precedent – shift in government policies and rhetoric. In light of the rise of viable right-wing political parties across the west, this battle will not be an easy one. Hate-motivated vilification and violence can only flourish in an enabling environment. In most western nations, such an environment has historically been conditioned by the activity – and inactivity – of the state. State practices, policy, and rhetoric often provide the formal framework within which hate crime – as an informal mechanism of control – emerges. Practices within the state, at an individual and institutional level, which stigmatize, demonize, or marginalize traditionally oppressed groups legitimate the mistreatment of these same groups on the streets.

If political rhetoric fuels the flames of hatred, then it is also clear that a positive politics of difference expressed at the level of the state is vital if we are to temper, if not extinguish, those flames. First and foremost, politicians must assume a leadership role in condemning rather than embracing hate crime, organized hate groups, and other blatant expressions of intolerance. As leaders, they must express a commitment to social justice grounded in justice rather than injustice, inclusion rather than exclusion, respect for rather than resentment of difference. Just as the hate movement has piggybacked on the reactionary politics of the right, so too might a progressive movement exploit the windows opening up within more progressive parties.

Giving oppressed communities an opportunity to have a voice in such conversations is a first step in realizing social justice. Social justice revolves around participation and democratic representation in the home, in the workplace, and in political arenas. In other words, it consists of the ability to "do difference" without fear of violent reprisal. It frees women to make household decisions without fear of being beaten; it frees people of color to pass through or live in any neighborhood without fear of attack; it frees gay men and lesbians to demand equal treatment and recognition without fear of violence.

Affordable Care Act

Overview

The 2010 Patient Protection and Affordable Care Act (ACA), health care reform, comes at a particularly unique time in the criminal justice system – a time when mass incarceration policies are being scaled back and more prisoners are being released to the community. The ACA attempts to tackle weaknesses in the existing health insurance system and in the treatment delivery system through a variety of mechanisms. These changes could dramatically improve the health and justice outcomes of over five million US adults in the justice system.

The relative poor health of jail and prison inmates is well documented. Inmates have high rates of many chronic medical conditions, mental health disorders, and substance abuse disorders (Wilper et al. 2009). In addition, their rates of hypertension, asthma, and arthritis are higher than the general population even after controlling for race, education, and other socioeconomic differences (Binswanger et al. 2007, 2009), and rates of infectious diseases including current or chronic hepatitis C and HIV/AIDS are also high (National Commission on Correctional Health Care 2002; Maruschak 2010). Finally, sexual victimization rates in jail are higher than reported in community (Beck and Harrison 2008).

Justice-involved individuals are less likely than others to have insurance coverage. Working-age men in general have high rates of uninsurance. And, offenders' health status and constrained employment prospects after conviction and incarceration make obtaining health insurance less likely for them than for other adults.

Because they have relatively high rates of substance abuse disorder and low rates of insurance, offenders must rely on a part of the health care delivery system that is reliant on scarce and shrinking public financial support (Buck 2011). Offender surveys have found that addiction treatment services are underutilized; few community justice agencies integrated their services with substance abuse providers; and the quality of community treatment is frequently quality (Taxman et al. 2007).

This entry provides an overview of health insurance and challenges in securing coverage for offenders today. It then addresses the Affordable Care Act, including how prisoners and jail inmates are likely to be affected by the new federal health care reform law, as well as potential future impacts, challenges, and opportunities.

Fundamentals

Having health insurance means treatment will be less costly to individuals when they seek health care. Thus, insurance removes a financial barrier to care. Numerous studies have found that having health insurance is associated with obtaining more health services and having better health outcomes (Manning et al. 1987; Card et al. 2008). However, health insurance coverage can present a challenge for the justice population. For working-age adults in the United States, the primary source of health insurance is through employer-provided insurance offered to full-time employees (DeNavas-Walt et al. 2012). Very few nonelderly adults purchase coverage on their own. The justice population, particularly those reentering the community, may be disconnected from the workforce and need time to find housing, retool, and secure jobs. If their work is part-time, temporary, or low pay, then employer-based health coverage may not be available or affordable.

Medicaid is another important source of health insurance coverage for adults, primarily for adults who have disabilities and who have low incomes. In 40 states, poor, disabled individuals who receive Supplemental Security Income (SSI) also receive Medicaid. Medicaid has not traditionally covered childless adults who do not have disabilities. Only in 12 states does Medicaid coverage include poor adults, regardless of SSI. However, individuals who enter prison or jail may have their SSI benefits suspended, meaning they lose their Medicaid coverage as well. Both income and health benefits must be reinstated upon reentry into the community. Lacking health insurance criminal justice populations have traditionally relied on a web of safety net providers to meet their complex health care needs.

Health Benefits Covered by Insurance Today. Private insurance typically covers a range of medical services, but often with a share of the cost borne by the patient through deductibles, meaning the amount paid by the member before insurance begins, or through cost-sharing, meaning the amount paid by the patient when treatment is sought. Newer, so-called high deductible heath plans with a deductible of at least $1,000 ($2,000 for a family) have become more common in the United States and included 13 % of the privately insured in 2011 (Fronstin 2011).

Coverage for behavioral health care is often less generous for behavioral health than for general medical care, a consequence of longstanding concerns about the overuse of mental health services (Glied and Cuellar 2006). Consequently, behavioral health coverage traditionally has required greater financial contribution on the part of the patient and has placed limits on how much treatment would be covered. Efforts over many years to place mental and medical benefits on more equal footing ultimately lead to the federal Mental Health Parity and Addiction Equity Act of 2008. This Act required that mental health and substance abuse care be covered like other medical care, at least in large group health insurance plans. Under parity mental health and substance use, disorder coverage – if such benefits are offered – must be equivalent along co-payments and deductibles, maximum visits, annual and lifetime dollar limits, and out-of-network coverage. However, the law does not require that health insurance include any behavioral health benefits, only that they be equivalent if offered. The law also does not affect Medicaid unless Medicaid is offered to beneficiaries through privately managed care plans.

Research has found parity legislation to increase use of mental health and substance abuse services by removing significant financial barriers (Frank et al. 2001; Goldman et al. 2006; Dave and Mukerjee 2008). In light of high rates of mental health and substance abuse disorder, this is a potentially very important development for offenders.

Medicaid play s a unique role in coverage for low-income individuals with complex chronic conditions, as it covers many services that private insurance does not. Medicaid covers services such as targeted case management, personal care, and wrap-around services that are important for people with complex chronic conditions, such as HIV/AIDS or severe mental illness (Kaiser Family Foundation 2011). The same is not true for substance abuse coverage where coverage under Medicaid is frequently limited in amount and by type of provider (Kaiser Family Foundation 2011).

One particular challenge for Medicaid beneficiaries is the cumbersome application and renewal process. For inmates in particular, this process imposes onerous documentation, ongoing renewal, and identification requirements. Inmates who receive Medicaid by virtue of their SSI benefits have their SSI benefits are suspended while they are incarcerated or even in halfway houses that are under the auspices of the department of corrections. Additional restrictions apply to individuals with outstanding felony warrants or violators of parole or probation (Cuellar and Cheema 2012). Individuals who are incarcerated for longer than a year have a greater task, as they must reestablish the existence of their disability and wait for SSI determinations before accessing Medicaid.

Health Care Delivery Today. The justice system has the largest concentration of people with substance abuse disorders, and 50 % of those with substance abuse disorders have co-occurring mental health conditions (Taxman et al. 2007). Yet, the general substance abuse treatment system is arguably less robust than other parts of the delivery system, including mental health, in part because funding from insurance and Medicaid has been lacking. Of the 20 million individuals with alcohol and drug abuse disorders, only 10 % received treatment in the past year (Center for Behavioral Health Statistics and Quality, 2012). Among those not treated, 44 percent cited lack of insurance and cost as impediments to care and one quarter of the insured reported lack of coverage or affordability.

The general substance abuse delivery system is characterized by many small providers who are frequently understaffed. One third of addiction treatment settings do not contract with a physician or have one on staff and fewer than a half employ masters-level counselors or above (Buck 2011). Furthermore, substance abuse treatment is not well integrated with other medical care, such as HIV (Altice et al. 2011; Berg et al. 2011). Only 30 % of community substance abuse treatment programs offer HIV treatment and counseling. Lack of insurance coverage, staff training, and patient acceptance have been cited as barriers to the integration of HIV care into substance abuse treatment programs (Bini et al. 2011).

In contrast, mental health delivery has benefitted from expanded insurance coverage through Medicaid coverage of people with disabilities, insurance parity, and technology changes. Unlike substance abuse disorders, mental health disorders of sufficient severity are qualifying impairments under the SSI program which conveys eligibility for Medicaid in many states. This coverage, combined with state decisions to cover evidence-based mental health treatments, has led to greater insurance-based financing for mental health care.

Access to care by specialists remains a challenge in many communities (Cunningham 2009). The 2008 Community Tracking Survey of primary care physicians, e.g., family practice or internal medicine doctors, found that 42 % had trouble accessing high-quality specialty care for their patients and 59 % were unable to obtain specialty mental health services they thought were medically necessary for their patients. The relatively lack of mental health specialists, paired with innovations in pharmaceuticals and screening tools for common mental disorders, has led to more mental health care being provided in primary care settings than ever (Frank and Glied 2006).

Changes Under Health Care Reform. Health care reform, specifically, the Patient Protection and Affordable Care Act (ACA), has the potential to improve care for offenders, particularly those who live in the community, in several ways: (1) Most individuals must obtain health insurance. (2) Medicaid will be expanded significantly, particularly for childless adults who have income below 138 % of the federal poverty level. (3) Insurance exchanges will be created through which individuals can receive federal subsidies to purchase private coverage. (4) Numerous initiatives are created to address fragmented care for individuals with chronic conditions.

The ACA requires nearly every resident of the United States to obtain health insurance by January 1, 2014. Before the Supreme Court decision on the constitutionality of the ACA, the Congressional Budget Office estimated there would be 30–33 million newly insured individuals, with 17 million newly covered through Medicaid and 23 million covered through new health insurance exchanges, and a small reduction in employer-provided coverage (Congressional Budget Office, March 2012). These initial estimates assumed all states would expand Medicaid. However, the Supreme Court decision in National Federation of Independent Business v. Sebelius, 132S. Ct. 2566 (2012) held that states could choose whether or not to expand eligibility for coverage under their Medicaid program pursuant to the ACA and, despite strong financial incentives, not all states likely will elect to expand (Congressional Budget Office, July 2012). Further, some states may delay expansion until after 2014 and some may seek federal approval for partial expansions. As a result, the Congressional Budget Office scaled back its estimates concluding that seven million fewer individuals will be in states that expand Medicaid coverage by 2016 and four million more will be uninsured relative to prior estimates.

The Medicaid expansion is particularly important to criminal justice populations. Medicaid will become the primary source of health insurance for most low-income individuals, including childless adults. Medicaid is a shared federal-state financial responsibility, and states that expand coverage will pay proportionately less for the newly eligible Medicaid beneficiaries. The fact that states may not expand Medicaid will particularly affect criminal justice populations as they overwhelmingly represent low-income men. And, in those states where Medicaid is not expanded, there will be less financial support to bolster a treatment system that is fragmented and where low-income individuals frequently cannot find care when it is needed.

Cuellar and Cheema (2012) estimated that 21–34 % of prisoners released each year would be enrolled in Medicaid. Applying a similar methodology for jail inmates implies that a total of 2.4–3.6 million prison and jail inmates who are released would be eligible for Medicaid. The estimates are based on the average incomes of individuals with demographics similar to those of released prison and jail inmates and take into account a possible wage penalty from having a criminal record and the fact that some inmates will not have lived in the United States sufficiently long to qualify for benefits. In light of the more recent Supreme Court decision, these estimates should be scaled back by as much as 60 %.

Historically, states have found that fewer people actually enroll in Medicaid than are eligible, as few as 50–75 % of eligibles. This makes health care reform an opportunity only. It must be matched with substantial efforts to reach out and enroll individuals who are newly eligible for Medicaid and involved in the criminal justice system. To date, such outreach has not been particularly salient because so few nondisabled individuals met eligibility requirements. Going forward, outreach will require a new type of collaboration between criminal justice and Medicaid.

The criminal justice population that will be eligible for Medicaid is only a fraction of the estimated ten million newly covered Medicaid beneficiaries. However, their high health care needs and complex social conditions could pose new challenges for Medicaid health plans. Outreach, enrollment and education of providers, and health plans are key steps to improving health for the criminal justice population under reform.

Individuals not eligible for Medicaid can receive assistance obtaining health insurance through new health insurance exchanges under the ACA. The new health insurance exchanges will offer subsidies, on a sliding scale, to those with income up to 400 % of the federal poverty level who buy private coverage. The amount of the subsidy will depend on the enrollee's income relative to the federal poverty level and the cost of local plans. Cuellar and Cheema (2012) estimate that 50–54 % of released offenders would be eligible for a subsidy, based on their income if plan premiums are sufficiently high. In light of the Supreme Court decision, these estimates should be increased slightly.

Systematic outreach and simplified enrollment are emphasized under health reform, both in Medicaid and in exchanges. Federal assistance is available for states toward the design and implementation of the necessary enrollment technology. All states must engage in consumer information and outreach and related activities must be reported to the federal government. From the perspective of the criminal justice population, a strong enrollment system is one that can incorporate relevant corrections information when determining eligibility. Eligibility is determined based on vital, employment and income information and, therefore, correctional data can fill important data gaps for inmates. Inmates might also be handed key documents, including incarceration dates, to ease income verification and identification. Correctional facilities could also communicate release dates to eligibility offices. To smooth the transition from prison to post-release health care, community providers could be identified in advance. However, in some instances these steps may not be feasible as the average jail has a weekly turnover rate of over 60 %. Nonetheless, states can involve corrections, probation, and parole representatives in system design and include them in subsequent training programs.

Whereas health insurance today can vary considerably in terms of covered services and coverage limits, under health care reform the newly insured population will have insurance that covers "essential health benefits." The essential benefits must include mental health and substance abuse disorder treatment, as well as preventive and wellness services and chronic disease management, and behavioral health parity provisions will apply.

An increase in funding for behavioral health services is expected under health care reform, stemming from private insurance and Medicaid coverage. Providers of behavioral health services, including those who deliver care to individuals at risk of incarceration, must adapt to an environment where funds are tied to insurance, rather than grants from states or the federal government. This means greater adoption of financial information systems, professional credentialing to meet insurers' network requirements, and the ability to track the amount and quality of care delivered.

Over and above expanding health insurance, the health care reform law provides incentives to change how treatment providers coordinate care. Several provisions in the ACA promote new care delivery models for individuals with chronic conditions, including medical or health homes models. These models have enormous potential. Medical homes receive financial support specifically to manage chronic conditions and coordinate care across a range of specialists. For criminal justice populations, these medical homes will need strong ties to mental health and substance abuse treatment providers. Ideally, these medical homes will coordinate with corrections and probation departments around benefit enrollment, continuity of treatment from prison to community treatment, and have a basic understanding of probation terms and court orders.

Significant changes are likely for addiction treatment providers. Some anticipate that in the wake of the ACA, care delivery for substance abuse will shift away from traditional substance abuse providers (Buck 2011). Because the ACA emphasizes and rewards primary care–based models, more care may shift to primary care. This offers the promise that both the medical and behavioral health needs of offenders could be more comprehensively addressed and coordinated. Whether care improves will depend in part on how rapidly evidence-based care can be delivered in the traditional medical sector for this population. Another delivery model is to have the traditional behavioral health system integrate medical and chronic disease care. The success of either approach has yet to be determined on a wide scale, but considerable investment is being made, financial incentives are in place, and the intuitive appeal is strong.

Much of the burden of enrolling newly insured individuals through Medicaid and through health exchanges will fall on states. States face the practical challenges of orchestrating health insurance coverage for 30 million individuals, a fraction of whom are in criminal justice and have not only complex eligibility circumstances, but also complex health needs. Actively assisting inmates to enroll in health plans will remove financial barriers to treatment. Developing medical and health home models that can address offenders' complex health and behavioral health could be beneficial to both public health and public safety.

Overview

Incarceration has been used all too often as a solution for shortcomings in health and other social services. Medical and public health researchers are among those recommending that correctional facilities be used as a venue to improve individual and population health, since correctional facilities serve as health-care providers of last resort for the medically underserved (Freudenberg 2001; Rich et al. 2011). Reentry likewise constitutes a public health opportunity that is both often lost and problematic. Prison and jail inmates confront a range of challenges upon reentry into the community. The incarcerated carry a higher disease burden than the general population, and their health status and health care upon reentry have significant repercussions not only for their own post-incarceration lives but for public health as well. Correctional facilities can both serve as sentinels for the health of a disadvantaged population and implement care and transition services that ensure the continuity of medical care from prison into the community upon release, but they often fail to do so. There are complex challenges to the successful implementation of discharge planning and reintegration into society, but capitalizing upon such services to address mental health, substance dependence, and other medical needs has important consequences for both individual and community health.

Health Profile of the Incarcerated

Incarceration is concentrated in low-income communities, and health is strongly correlated with socioeconomic status. In addition, risk factors for incarceration and for poor health frequently overlap. As a result, inmates tend to have far more health problems than the general public. The United Nations and other international reviewers have documented that prisons and detention facilities in many world regions are not in compliance with international standards like the Standard Minimum Rules for the Treatment of Prisoners, established by the UN High Commissioner for Human Rights (UNHCR). Facilities are often overcrowded and unsanitary and thereby may have additional adverse health effects for an already ill population (Jurgens et al. 2011).

Public health practitioners have long been concerned with correctional facilities as repositories of infectious diseases, especially tuberculosis, HIV, and hepatitis C virus (HCV) (Hammett 2006). Despite gains since the 1990s, HIV prevalence in the USA remains about five times higher in state/federal correctional facilities than in the general public: 1.6 % among male inmates and 2.4 % among female inmates, compared with 0.36 % in the total US population for 2006 (Hammett 2006). Internationally, studies have found wide estimate ranges for HIV prevalence in prisons, especially in the former Soviet republics and Southeast Asia. For instance, a 2007 review found between 0 % and 26 % HIV prevalence in Ukraine and 4–22 % in Indonesia, reflecting the difficulties of establishing an accurate health profile even within individual countries. HIV prevalence could not be identified at all for 76 of 152 low-income or transitioning countries (Dolan et al. 2007).

Chronic diseases among incarcerated populations are gaining attention, given the simultaneous emergence of chronic conditions like diabetes among younger people and the aging of the incarcerated population. In the USA, between 39 % and 43 % of inmates are diagnosed with diabetes, hypertension, asthma, or another chronic condition, rates consistently higher than among the general population (Binswanger et al. 2009; Wilper et al. 2009). Moreover, comorbidity (i.e., the coexistence of two or more medical conditions) is high in this population. The risk behaviors for HIV – especially injection drug use (IDU) – put the same individuals at high risk for HCV, which is 9–10 times more prevalent among the incarcerated than among the non-incarcerated (Freudenberg 2001). Because patients coinfected with both HIV and HCV have also been found to have more comorbidities than HIV mono-infected patients, these inmates are likely to carry a greater overall burden of coexisting chronic and/or infectious diseases.

These physical conditions are frequently complicated by the mental health profile of the incarcerated. The emergence of prisons and jails as the largest institutions in the United States housing the mentally ill reflects the de facto criminalization of mental illness. Well over half of inmates at any given time have a DSM-IV (Diagnostic and Statistical Manual of Mental Disorders) mental disorder. In US jails, 63 % of blacks and 71 % of whites in a 2002 national survey self-reported symptoms or diagnoses of mental illness, with rates slightly lower in state and federal prisons (James and Glaze 2006). Women, who constitute a small minority of inmates, generally have much higher rates of mental illness, and posttraumatic stress disorder (PTSD) is common among incarcerated women, about one-third of whom were subject to physical abuse and one-third to sexual abuse prior to incarceration (Lewis 2006; Baillargeon et al. 2010). Because of differing research methodologies, it is difficult to determine whether the significantly higher rates of mental illness among US female inmates reflect a distinct US experience or whether they merely reflect different data collection practices. A systematic review of studies in 12 western nations also found disproportionately high rates of mental illness among inmates. Rates of personality and antisocial disorders were lower among women than among male inmates but were similar for women and men for psychotic illnesses and major depression (Brooker et al. 2007). Rates for other world regions are difficult to obtain, in part because both medical exams and surveys are not consistently conducted.

An important component of prisoners' mental health profile is substance dependence and addiction. Estimates of the number of the incarcerated meeting DSM-IV criteria for drug dependence or addiction vary widely but are well above 50 % and again substantially higher among female inmates (Freudenberg 2001; James and Glaze 2006; Binswanger et al. 2009). Comorbidity of substance abuse and mental illness is common among inmates. Addictions and other mental illnesses both increase the probability of engaging in behaviors associated with infectious disease transmission and complicate treatment for conditions such as HIV and HCV, which require a sustained adherence regime and careful monitoring for adverse drug interactions.

While incarceration may improve health conditions for some (e.g., by providing access to health care, stable shelter, and regular meals), it can worsen health outcomes in other respects. This may be the case especially with mental illness and addiction. Those with mental health issues are more vulnerable to placement in isolation, an environment particularly hazardous to mental health. Most facilities adopt a "cold turkey" approach to substance addiction, leaving the addicted subject to withdrawal during incarceration and more vulnerable to overdose upon release. Although drug use is technically forbidden in nearly all facilities, it remains common and the shared use of needles also contributes to the transmission of infectious diseases, especially HCV. Needle and syringe exchange programs exist in several European and Asian countries, but few facilities to date participate (Jurgens et al. 2011).

A number of national and international mandates exist regarding the provision of health care to inmates. In the United States, two key Supreme Court decisions have upheld the finding that correctional facilities must provide health care comparable to what might be reasonably attained in society. In 1976, the *Estelle v. Gamble* decision declared that the deliberate failure to provide health care constituted unconstitutional cruel and unusual punishment. Since *Estelle v. Gamble*, litigation or the threat thereof has greatly improved correctional health care, and in 2011, *Brown v. Plata* ordered the state of California to reduce overcrowding on the grounds of its interference with the due provision of health care. Despite these legal advances, a lack of standardized reporting and quality measures has made it difficult to know the quantity or quality of health care actually provided on a national basis. However, studies have indicated that many inmates in need of health care do not receive it or receive suboptimal care, whether for HIV, HCV, chronic conditions such as diabetes, mental illness, or substance abuse. There are some correctional facilities that are recognized as public health models of successful diagnosis and treatment of inmate health conditions. For the most part, though, there is still room for improvement in prison health services. Jails and pretrial detention centers diagnose and treat even smaller percentages of inmates, in part because of higher turnover and shorter stays. Since 95 % of inmates are eventually released, the inmate health profile follows them to reentry, with considerable implications for both their own reentry experience and community health.

Transitioning to the Community

Incarceration is a temporary situation for most inmates, and as recidivism rates are high, many people cycle repeatedly between the community and detention. In the USA, over seven million people leave jail and an additional 600,000 exit state and federal prisons annually (US Bureau of Justice Statistics 2003). They are largely a high-need, low-resource demographic: in addition to more than usual health needs that may interfere with daily functioning, as a group they have less education and fewer economic and social resources than the general population. Releasees also frequently return to the community in highly unstable circumstances, struggling to reestablish housing, employment, and relationships. In this context, attention to health needs often falls by the wayside, and high-risk behaviors such as unsafe sex and relapse to drug use are common. The overwhelming challenges of reentry are evident in mortality trends. Data in the USA and other nations have documented a spike in mortality in the first 2 weeks after release: in the USA, releasees were 12.7 times more likely to die in that period than the general public and 129 times more likely to die of an overdose (Binswanger et al. 2007). Similar postrelease mortality rates have been identified in other countries.

Correctional authorities are increasingly addressing this problem with discharge planning, a term that broadly refers to the process of helping prisoners to prepare to make the transition from incarceration back into the community, but the resources allocated to transition services have been steadily reduced in the last 20 years even as the correctional population has increased fourfold (Re-entry Policy Council, 2005). As a result, only about 10 % of releasees from US state prisons in need of discharge planning actually receive it, far less than was the case in earlier decades

(Mellow and Greifinger 2005). In general, the high turnover rates and short stays of jail inmates prevent discharge planning in jails altogether.

To date, there has not been any large-scale research examining the patterns of implementation or results of discharge planning, either across the USA or internationally. However, collaborative work focusing on HIV provides one basis for such research. A multicenter, Health Resources and Services Administration (HRSA)-sponsored Special Project of National Significance ("Enhancing Linkages to HIV Primary Care and Services in Jail Settings Initiative") was established in 2007 to test and evaluate models for linkage to care for people with HIV leaving jail. One linkage project under way makes use of new federal reporting requirements to link correctional and clinical data, thereby constructing an empirical basis for evaluating why some linkage succeeds and some fails. This HIV-specific work may be creating paradigms that can be used to evaluate the transition from correctional health care to community-based health care for other health conditions as well. It is clear that to achieve successful linkage to community-based health care, discharge planning must extend beyond the provision of information and even initial free services. A widely noted study in Texas found that only 5 % of HIV-positive releasees filled free prescriptions in time to prevent an interruption of treatment, suggesting the critical role of factors beyond the ability to pay (Baillargeon et al. 2009).

Discharge planners increasingly understand the need to view health within a broader spectrum of reentry needs. Because inmates are so often undereducated and lacking both financial and social resources, discharge planning is often unsuccessful unless it provides sustained, holistic assistance. On the one hand, untreated medical conditions will reduce the probability of successful reintegration into the community; on the other, the failure to address other reentry needs (especially employment and stable housing) significantly undercuts the probability of resolving health needs. Thus, medical discharge planning must occur in coordination with other transitional services targeting complex social needs.

Numerous guidelines recommend that discharge planning requires an ongoing, two-stage approach in order to be effective. Ideally, the process should begin shortly after admission into the correctional facility, though in general it is set in motion only a few weeks or months before the inmate's anticipated release. There is broad consensus among guidelines that the second stage should proceed to ongoing case management in the community upon reentry (Re-entry Policy Council, 2005). Randomized controlled trials have not yet confirmed the benefit of case management service; however, studies found an association between case management and positive health or behavioral outcomes (Springer et al. 2011). As a result, discharge planning requires the kind of sustained cross-agency collaboration that is frequently difficult for state and community agencies to coordinate and maintain. Only in rare cases do state health departments have any jurisdiction over correctional health care, so discharge planning requires Departments of Correction (or their non-US counterparts such as Ministries of Justice) to reach out to partners they are not ordinarily organized to work with.

Despite these organizational challenges, there are programs that provide more successful discharge planning results for health care and health behaviors, and there are examples of discharge planning being addressed by collaborations between corrections officials, cross-agency coalitions, and local community agencies. Many of the existing programs aim to build multi-sectorial collaboration with community-based organizations in order to prepare individuals for release and provide them with health care within a spectrum of other resources such as housing, employment, and social benefits. One such program is the Hampden County Jail in Massachusetts, which adopted a public health paradigm for its inmate health-care services (Conklin et al. 2002). The county sheriff's office partnered with the public health department, regional medical centers, and community health centers to provide continuous health-care delivery by assigning new inmates to care based on their zip code, in order to facilitate continuous care delivery by linking inmates to community providers prior to their release. Staff from community health centers provide health services inside the facility during incarceration and develop individualized discharge plans before release. Program evaluations are incomplete but indicate improved inmate and community health, reduced recidivism, and cost savings. Even in this closely coordinated system incorporating community providers into prerelease correctional care, however, releasees are frequently lost to follow-up care.

In light of generally insufficient resources, even where correctional authorities are concerned to support discharge planning, such services are often only provided for inmates with dedicated resources such as those with HIV or severe mental illness. HIV-centered reentry programs have been implemented in a number of states. Transitional services may be facilitated by two mediators: a small geographic range to work within and a close-knit, locally respected health professional community that works effectively with corrections authorities. (Thus, guidelines and best practices for discharge planners often warn not to "lift" programs from other communities, since what works in one setting may not work in another without adequately taking account of local circumstances.) In the Community Partnerships and Support Services for HIV-Infected People Leaving Jail (COMPASS) program, for instance, the Rhode Island Department of Corrections agreed to have jail staff notify community outreach workers when inmates with HIV were admitted or when inmates were newly diagnosed. Outreach workers then met with inmates in the jail to assess their postrelease needs and provided sustained case management upon reentry (Nunn et al. 2010).

Qualitative research with COMPASS care recipients revealed another complicating feature of transition services: their success relies to a great extent upon sustained personal relations. Successful initiation of community-based care upon reentry and ongoing treatment adherence was strongly associated with intensive case management, including home calls to remind participants to keep doctor's appointments, providing transportation to medical and other services, and assisting with processes like registering for Social Security or disability benefits. As the smallest state in the USA, RI has a highly centralized and compact service area and close ties among professional communities, advantages that may be difficult to replicate elsewhere. Participants also highlighted the importance of having an engaged and perceptibly caring doctor, the absence of which was identified as a barrier to treatment adherence in other studies (Nunn et al. 2010).

Because patients with HIV are six times more likely than those with other chronic conditions to identify a regular source of care after discharge, non-HIV postrelease continuity of care may be even worse. This is particularly relevant for those with addictions and mental illnesses who received insufficient treatment during incarceration, many of whom are incarcerated in the first place because community-based treatment was not available to them. Although more likely to receive discharge planning (66 % of state prisons provided some form of postrelease support to access community-based mental health services in 2000 (Baillargeon et al. 2010)), the proportion of releasees receiving needed mental health services is further reduced by incomplete identification of mental health needs among inmates prior to release. A 2008 study in Texas and Ohio found that self-reported mental illness was about one-third more common postrelease than during incarceration, which the authors hypothesized was due to inmates withholding information about mental health diagnoses from correctional staff (Mallik-Kane and Visher 2008). It is also possible that mental health deteriorates for some inmates as a result of incarceration itself.

For those inmates with mental health needs who are identified in time to arrange transition services, several sets of guidelines and best practices have been set out by the American Psychological Association, the Council of State Governments, and other entities. Even with such resources available to discharge planners, releasees with mental health needs often fail to link to community-based care and, even when they do, experience frequent treatment relapses, especially when there is an addiction or substance-dependence comorbidity. Mentally ill releasees are more likely to be homeless and usually exhibit patterns of health-care utilization for acute episodes (e.g., emergency department use or psychiatric hospitalizations) rather than ongoing mental health and medical treatment. Even though inmates with mental illnesses are generally given a supply of medications upon release, medication maintenance has been found to decline 8–10 months postrelease (Mallik-Kane and Visher 2008). The successful transition to community-based care upon reentry may be especially difficult when mentally ill inmates complete their sentences and are released without community-based supervision by a parole officer. Parolees may be subject to oversight and sanctions for failing to complete treatment (though this gives rise to possible ethical concerns about enforcing undesired medical treatment, which has more generally been found unconstitutional in the USA and elsewhere). Releasees who have completed their sentence, on the other hand, are not required to follow the recommendations of discharge planners; this scenario also eliminates the parole officer as a potential resource, albeit a coercive one, for releasees.

The specific mental health needs of people with substance dependence or addiction are subject to similar difficulties in effective discharge planning. Releasees with addictions are particularly prone to relapse and recidivism; many are returning to families or social groups with similar substance abuse habits, increasing the risks of relapse (Mallik-Kane and Visher 2008). In addition, enforced abstinence during incarceration contributes to both relapse and overdose upon release. Medication-assisted treatment (MAT) for opiate addiction has been found effective in reducing heroin use, criminal behavior, HIV-risk behaviors, and overdose deaths. For example, methadone, a synthetic opioid, has been used for several decades to treat opiate addiction, as it reduces the craving for shorter-acting opioids and with proper dosing blocks their euphoric effects. However, correctional authorities are generally reluctant to employ it. As a result, inmates with substance dependence or addiction are less likely to have methadone or other MAT as part of their discharge planning (Nunn et al. 2009). Interventions that follow in-prison drug treatment programs with postrelease treatment have been shown to reduce post-reentry drug use and its associated recidivism. Since the most recent developments in behavioral science emphasize the role of environmental triggers over individual motivation, though, such treatment is often undermined by a return to the original environment upon reentry.

Reviews of existing transition services suggest that discharge planning can provide critical assistance in linking releasees to continued health care upon reentry, with improved outcomes for both health and recidivism. However, discharge planning remains available to only a fraction of reentering prisoners with health needs. In many facilities, concerned staff receive little institutional support from administrators who may view continuity of care as extraneous to the facility’s function of punishment and/or public security. Even in facilities with supportive administrators, budgetary constraints frequently limit the amount of services available. It is also clear that even well-planned and well-funded transition services are undermined by other structural barriers that releasees encounter upon reentry.

Foremost among these is the problem of access to care. Unlike most other developed nations, the uninsured constitute a substantial percentage of the US public. Almost 80 % of former prisoners in a 2008 survey were without private or public insurance upon reentry (Mallik-Kane and Visher 2008). Because unemployment is high among releasees, Medicaid (state/federal coverage for those under 65 with income, family, or health qualifications) is particularly important. Although federal regulations require only that states suspend Medicaid during incarceration, most states terminate it altogether. As a result, releasees lack financial coverage and thus access to most health care during the critical reentry period. Since the reapplication process is cumbersome and often overwhelming for a low-resource population (e.g., low literacy hampers successfully completing paperwork, and the lack of stable housing interferes with the reception of notices from the Social Security Administration), resuming coverage can take months or occur not at all. This problem was exacerbated after 1996, when the Social Security Administration implemented a system of financial incentives to encourage correctional facilities to notify them upon incarceration of a Medicaid recipient, resulting in prompt termination of benefits including medical coverage.

Starting in 2014, the 2010 Patient Protection and Affordable Care Act (ACA) will expand eligibility for Medicaid for most reentering offenders, especially by targeting the low-income adult males that constitute the majority of inmates. Even the expansion of coverage under the ACA, however, will leave about one-third of the currently uninsured without coverage; thus, insurance can be expected to remain a critical factor in postrelease access to health care.

In addition to low rates of coverage, releasees are hampered by poor access to health care and often rely on emergency rooms for care. The successful transition to community-based care upon reentry is further hindered by poor communication among the various health-care providers involved. It is seldom possible for patients even among the general population to conduct their own medical histories from provider to provider, making inter-provider communication all the more critical for patients with complex health needs and low medical literacy. While discharge planning is far more frequent in prisons than in jails, state and federal prisons are also much more likely to be geographically distant from inmates' home communities and thus from the health-care providers to whom releasees must transition. Since a minority of US providers have transitioned to electronic health records (EHR), the successful communication of medical histories and treatment plans from correctional facilities to community-based providers is even more difficult to coordinate. As a result, information regarding health needs and service history can be fragmented and care correspondingly poorly coordinated.

Finally, releasees with health needs frequently reenter a social context that is poorly equipped to support their health needs and can undermine even the best discharge planning. Regardless of intent, releasees often have little choice but to return to networks and associations that support criminal activity and risky health behaviors. Family dynamics are especially critical upon reentry. Inmates with physical health needs are as likely to receive material support from their families as inmates without physical health problems, but they also appear to be more likely to be involved in domestic violence. In a 2008 survey, men with health problems were more likely to be victims of domestic violence than other men upon reentry, though their female counterparts were more likely to perpetrate domestic violence than women without physical health problems (Mallik-Kane and Visher 2008). Releasees with substance dependence or addiction are especially likely to return to families engaged in substance use and criminality; here too, men were more likely to suffer domestic violence than male inmates without substance dependence.

Reentry and Community Health

Correctional facilities do not often live up to their potential to link the medically underserved to health care. In a widely cited 2008 study of releasees in two US states, most of the prisoners returning to the community had received some health care for their physical conditions but one-third of men and a quarter of women had not (Mallik-Kane and Visher 2008); moreover, no studies are available that measure the sufficiency of care that is provided. As a result, most inmates return to their communities with unresolved health problems. This has repercussions not only for the postrelease health of prisoners themselves but for the community as well.

Research into incarceration's effects on community health has focused particularly on the transmission of infectious disease upon release. In the USA, the majority of HIV infections are acquired prior to incarceration, not while in prison or jail (Beckwith et al. 2010). However, incarceration makes a significant contribution to the spread of infectious diseases by means of the behavior it fosters upon reentry (Lichtenstein 2009). Because incarceration in the USA is concentrated in specific communities rather than being randomly distributed, it removes large numbers of young males from impacted neighborhoods and contributes to high-risk sex by leading to increased sexual relationship concurrency. Other studies have found that incarceration is associated with sexually transmitted diseases and teenage pregnancy by similarly affecting neighborhood social characteristics such as the ratio of males to females (Thomas et al. 2008). In addition, because HIV treatment is interrupted upon release in over 90 % of cases, releasees' heightened viral loads carry with them a greater infectiousness and likelihood of developing drug resistance, creating in turn the potential for reservoirs of drug-resistant HIV in communities most affected by incarceration (Baillargeon et al. 2009).

A second field of research has emerged regarding incarceration and family health, examining both the direct effects on the mental health of inmates' families and mediated effects on their physical health. For some, the imprisonment of a family member may represent a reprieve from a family member prone to substance abuse or domestic violence (Comfort 2007), and reentry can combine relief at the return of a family member with new stressors. Since the prison environment may foster psychological orientations like suspicion and aggression, release may have adverse effects on already-existing marriages, in addition to reducing marriage prospects in some communities by affecting the supply of marriageable men (London and Myers 2006; Massoglia 2008). These patterns are of public health concern because marital status is recognized as a key marker of health status, particularly for poor men. Moreover, committed relationships protect against sexual risk taking, so that the incarceration-based disruption of relationships contributes further to the spread of infectious disease.

There is increasing attention among US researchers to the effects of incarceration and reentry upon the children of inmates as well. Although some children's well-being has been found to benefit from the incarceration of a parent (i.e., where there is a history of domestic violence or violent crime), these cases are outnumbered by the adverse effects on mental health when the parent was incarcerated for a nonviolent offense, as is the case in the substantial majority of the increase in incarceration since the 1970s (Wakefield and Wildeman 2011). Parental incarceration is associated with both internalizing mental health problems (e.g., anxiety or depression) and externalizing problems (e.g., aggression or delinquency) (Wildeman and Western 2010). The magnitudes of these associations are small, but on a population level, they contribute 25–45 % of the disparities in behavioral problems between black and white children (Wakefield and Wildeman 2011).

Finally, it is important to recognize the health consequences of the economics of reentry. In addition to decreasing employment opportunities, in most states, a prison record eliminates eligibility for public assistance such as food stamps, public housing, and student loans. These restrictions have repercussions on life trajectories, health behaviors, and health outcomes. State and national policy also contributes to the community health effects of incarceration and reentry. The US Census counts prisoners as residents of the largely white, nonurban communities where prisons and jails are increasingly relocated. As a result, the public funding and political redistricting that utilize census data for distribution favor the latter over the communities from which prisoners come, and both political weight and funding for public health initiatives are diminished in the low-resource communities most releasees return to.

Conclusions

Both incarceration and reentry offer opportunities to improve the treatment and health of high-needs individuals who often lack financial and social resources to address their health needs independently. At the same time, incarceration has been associated with poor long-term health outcomes, and because people of color are incarcerated far more frequently than whites in the

USA, the experience may ultimately exacerbate rather than mitigate health disparities (Massoglia 2008; Wildeman 2011). Similar trends are visible elsewhere, for example, in the disproportionate incarceration of Australian aboriginals. Correctional authorities work regularly with the public health, medical, and social services professions to establish transitional services for releasees with health needs, but the highly complex individual and social challenges of reentry coupled with scant resources have made effective discharge planning rare. Although *Estelle v. Gamble* and similar international mandates do not extend to reentry, significant improvements in postrelease individual and community health are possible with substantial intervention and advocacy by the public health and medical communities.

High Policing

Gary T. Marx
Massachusetts Institute of Technology,
Cambridge, MA, USA

Overview

What is "high policing?" The term does not refer to the euphoria police may feel after an adrenalin generating challenge is met, nor does it refer to policing while high, although both might accompany the activities falling within the concept's broad meaning. In its original meaning, it referred to the use of political intelligence to preserve the power of the ruler, in particular as this involved stealth, spying, espionage, and intrigue. Yet, like barnacles that become attached to a ship, over time the concept has evolved and layers of meaning have been added. The original ship is long gone, but parts of it endure in new forms and settings throughout society.

High policing can refer to the *location* of an agency such as those attached to the highest levels of governance, to an *ethos* involving intelligence collection and prevention of threats to what is now called national security, and to *methods* of information discovery and subsequent action swathed in secrecy and deception, some of which are at the edge or over the bounds of conventional morality and are supported by an end-justifies-the-means perspective (and sometimes the reverse). The latter is illustrated by a police official's statement – "if we have the technology, why not use it?"

High policing grew out of the late seventeenth- and eighteenth-century ideas and practices associated with the appearance of the modern policed society and police state. The modern police state has high policing at its core. Yet it also is a legitimate and (sometimes illegitimate) feature of democratic societies. Elements of high policing are found in all states, and the use of intelligence (as broadly defined) to protect the organization and to further its goals (and to varying degrees the private goals of leaders) is a characteristic of all modern organizations.

The tools of high policing can thus be seen as either an overarching mushroom cloud or as a rainbow. Society must possess a police force governed by law, but the police force must not possess the society, nor be beyond the law, nor create the law. As ideal types, states vary along multidimensional continua from full-fledged, totalitarian police states that are a law unto themselves where citizens have no rights to democratic societies under the rule of law where citizens in principle have full rights. In democratic societies, the activities historically associated with high policing involve a challenge central to any hierarchical social organization: how to grant authorities the resources to effectively govern and serve the public or the organization's interest while ensuring that the use of those resources is not abused for the private interests of those governing. In democratic societies, this requires differentiating those who wield power from the social institutions they are supposed to serve. Contemporary leaders would never say as popular myth claimed the absolutist French king Louis XIV did, "I am the state" (L'etat, c'est moi").

This entry considers the emergence of high policing as a developing form in Europe over recent centuries concomitant with modernization; following the work of Jean-Paul Brodeur, its key components are noted and some elaborations of these are suggested. The entry concludes with a discussion of some enduring trade-offs and tensions of high policing in a democratic society.

Fundamentals

Emergence of the Policed Society and the Police State

In 1970, political scientist Brian Chapman offered a succinct primer defining the characteristics of the police state over several centuries. He observes that the words police, politics, and policy share common roots in *politeia*, the Greek word for tribe or community. In contemporary usage, polity refers to a politically organized You +1'd this publicly. Undo unit. Such units are administered and regulated by designated government agents.

Chapman discussed but did not offer a formal definition of high policing. But from his historical examples, it involves police directly attached to the head of government with a goal of maintaining the sovereign or a single political party in power above all else. Some of the agents and the means they use may be moral and supported by laws developed through genuinely democratic procedures. However, pragmatism, rather than morality, was historically the guiding principle. For a series of reasons, deception and what, in contemporary terms, are called intelligence and counterintelligence "dirty tricks" – whether involving coercion or deception – were major tools. The ironically named high police of European empires operated in the shade (Brunet 1990) and often used shady practices, although not always for nefarious purposes. From another perspective, the tactics were anything but high. Livres

In the fifteenth century, given the intertwining of the state and the church, religious surveillance of the public was the prominent form. Indeed, it could be indistinguishable from political surveillance. It built on the watchful and potentially wrathful eye of the biblical God. This involved the search for heretics, devils, and witches, as well as the more routine policing of religious consciousness, ritual, and religiously based rules such as those involving adultery and wedlock. Religious officials kept records involving births, marriages, baptisms, and deaths.

However, as individuals gained new rights and the demand for religious orthodoxy weakened, religious surveillance gradually declined. The state took over keeping traditional records on the population (such as birth and death), additional data was recorded, and identity documents and dossiers became more prominent.

In the sixteenth and seventeenth centuries, with the appearance and growth of the embryonic nation-state, which had new needs as well as a heightened capacity to gather and use information, political surveillance gained in prominence. New concerns over political loyalty appeared, along with more strident demands by the public for democratic citizenship rights. The search for political dissidents gained in prominence relative to the search for religious dissidents. Not surprisingly, monarchs sought more sophisticated means of ruling – including dealing with threats to their regimes, at first from their aristocratic peers and later from the public. A silent (and sometimes not so silent) Praetorian Guard developed to protect the sovereign.

Wider domestic political surveillance is a natural corollary of the centralization of power and the increased heterogeneity, scale, and mobility associated with the emerging modern society. Concerns over possible links between internal and external security become more evident.

Over the next several centuries, we see a gradual move to a broadly "policed" society in which agents of the state, industry, and commerce come to exercise control over ever-wider social and geographical areas. This was done in a world rapidly becoming more economically and socially interdependent and in which societal scale and complexity markedly increased. The tactics of high policing served to usher in the seemingly evermore powerful, centrally administered state. Modern, presumably rational, even supposedly scientific, ideas were applied to the administration of an emerging "policed society." In building on the work of Bentham, Marx, Nietzsche, and Weber, many later scholars have elaborated on these developments (e.g., Silver 1969, Shils 1975; Foucault 1977; Nisbet 1977, and Cohen 1985). A brief history of high policing forms will be considered next.

In prerevolutionary France, Cardinal Richelieu (1585–1642) created an explicitly political police unit with a very broad mandate to find conspiracies among elites. This helped consolidate royal power and squashed opponents. Steeped in secrecy and the mystique that can be associated with it, they sought to create the impression that they were omniscient (which they weren't) and omnipotent (which they pretty much were).

The "high police" (high because they were the direct agents of the sovereign and also gave special attention to threats posed by rival aristocrats) were among the first modern intelligence agencies. They looked to the future and to the larger picture. This contrasted with the more visible "low police" who came to regulate everyday affairs such as those involving markets, street crime, and sanitation.

Chapman locates the first modern police state in the highly militarized society of Prussia under Frederick William (1688–1740) and Frederick II (1744–1797) and in Austria under Emperor Joseph II (1741–1790). Joseph Fouche (1759–1820), Napoleon's ruthless, innovative, and intelligence-driven minister of police, made extensive use of high policing tactics, building on the early French efforts of Cardinal Richelieu. He reorganized and centralized the French police and made extensive use of criminals as informants. His police kept order but also operated as a domestic intelligence service spying on citizens to keep the emperor informed. His legacy has endured both internally and internationally. The French political intelligence system is one of the world's most developed and extensive.

The omnipresent police system that Emperor Joseph created watched government officials to be sure they carried out the reforms he sought and enforced the state's expanding rules. His police magistrates had a responsibility to report on, and regulate, a wide range of public behavior. But he also created a less (or non-bureaucratic) secret police group that made extensive use of informants and investigated potentially, or actually subversive groups (defined as being in opposition to the emperor). These police reported directly to the leader.

While hardly beacons of freedom or the city on the hill, the eighteenth-century societies of "enlightened absolutism" were not the draconian, tyrannous places described by Aristotle nor those of twentieth-century fascist and communist societies. Drawing on Plato's idea of benevolent despotism that filtered through to Hobbes and Rousseau, leaders believed that a strong state was needed to protect the emperor and the public (their interests were assumed to be synonymous). In complicated matters of governing, leaders were presumed to know what was best. It was not so much that the ideas they applied were new but that the capability of acting on them had improved and the perceived need to do so in the face of a growing urban society and more internationalized world was felt to be great. Intermittent reliance on the military for policing was no longer sufficient.

A more penetrating and comprehensive societal regulation from a central government source was necessary relative to the more decentralized, episodic, laissez-faire control regimes of the feudal period. As Max Weber noted, the state developed a self-perpetuating, hierarchal bureaucracy to administer an ever expanding set of minutely defined rules. These were applied to the economy, public welfare, and morals and were dependent on the systematic collection and management of information about the populace.

In the seventeenth and eighteenth centuries, threats to those in power were most likely to come from other elites – sometimes presumed to have ties to foreign countries. There was less concern with political surveillance of the unruly and sometimes riotous masses. However, after the French Revolution and with the coming of the nineteenth-century industrialization and increased resources for challengers (including modern means of communication and new political rights), the high police mandate broadened to greater concern with average citizens and threats from other countries.

Over the last several centuries, police intelligence agencies became much more systematic, organized, and specialized. Their resources vastly expanded and continued to expand, their tools became evermore sophisticated (from agents in balloons to satellites), and new goals and forms of organization appeared. An expanded census, improved record keeping, police registers and dossiers, identity documents (including those based on crude biometrics such as the shape of the head), and inspections offered data. Personal information came to be collected for taxation, conscription, law enforcement, and border control (both immigration and emigration) uses and also to determine citizenship and eligibility for democratic participation and to improve social planning and public health. And as a corollary, the line blurred between direct political surveillance and a more modern and in some ways more benign or at least neutral governance or administration, even while containing the seeds of twentieth-century totalitarianism and beyond.

The Work of Jean-Paul Brodeur

In a classic article, with the memories of the 1960s and the early 1970s protests and police actions in the USA and Canada still vivid, along with the Watergate scandal, Canadian criminologist-philosopher Jean-Paul Brodeur (1983) expanded on the concept of high policing. He continued to work on the topic (as both a scholar and government advisor) over the remaining decades of his all too short life (Manning 2012). This work helped open up an interdisciplinary and international field (culminating in his monumental book *The Police Web 2011*).

Brodeur saw high policing as consisting of political surveillance and low policing as law enforcement (holding apart the overlaps between the two). In 1983, he identified four features of the former:

1. It was absorbent in the sense of casting a wide net (what it absorbed was information).
2. It conflated legislative, judiciary, and executive or administrative powers.
3. The preservation of the existing political regime was its primary goal.
4. A major tool was the use of informants from throughout the society.

   In 2011, he noted five additional characteristics implicit in the above:

5. The state as intended victim
6. The utilization of criminals
7. Secrecy
8. Deceit
9. Extralegality

This comprehensive list can be expanded to note that such policing is not only absorbent like a sponge soaking up all information it encounters but is also laser-like in its ability to focus. These attributes may be combined as the agent moves from a general search (often using automated data) to a focus on specific profiles suggesting subjects and suspects of interest. The reliance on the new surveillance (e.g., computer surveillance, matching and profiling, satellites, drones, video cams, DNA, and other biometric measures) is central here. The ratio of human intelligence (humint) to signals intelligence (sigint) has shifted markedly toward the latter in recent decades.

Extralegality can be expanded to include gray policing and intelligence (Hoogenboom 2010) which blur the borders between the public and the private and takes creative advantage of value conflicts and the ambiguity of laws and policies, sometimes avoiding restrictions by delegating activities to organizations or countries not bound by restrictions and by working in areas that are not (yet) regulated but should be, given the standards of the society.

A significant change involves the emergent, complex, breaking, reconfiguration, and hybridization of a variety of high policing borders. Some of the traditional distinctions between "us" and "them" and inside and outside of a society change with globalization under the sway of new threats, technologies, and economic arrangements.

Organizations that were previously more distinct show increased commonalities – whether in the means used, intelligence-based and risk assessment goals, and in the shifting of personnel among federal and local police, police, among military, and national security agencies, between national and international agencies, and between government agencies and the private sector. There are new fusion centers where different agencies work together and an increase in task forces for specific investigations. There is some merging or convergence of military, national security, domestic police, and private sector security into a new multifaceted professional field (Bigo 2006). In the struggle with stateless terrorism and global crime, high policing mixes with traditional law enforcement as well as the military.

There are also increased overlaps between groups engaged in drug dealing and other crimes, violent political groups, and failed states. To varying degrees, national security agencies in democratic societies also covertly work with such groups. The secrecy and the multiplicity of agencies sometimes mean they work at cross-purposes.

There is increased cooperation between state and private sector actors and significant growth of national and international private sector agencies. Private police groups in pursing the goals of their corporate sponsors, or being delegated piece work by government agencies, are increasingly proactive rather than reactive and are far less accountable even than the public sector in its use of secret tactics. Lubbers (2012), for example, has documented many cases of private sector intelligence and provocation activities against protest groups.

For North America, empirical documentation on efforts to harm movements is widely available (e.g., Donner 1990, Cunningham 2004, Greenberg 2011). Such efforts were intensified and took new forms after 9/11 and with the worldwide anti-globalization protests (O'Harrow 2005, Chesterman 2011; Starr et al. 2011 and Earl 2011).

Beyond trying to hurt opponents, significant resources go into covertly helping allies such as by providing funds and propaganda. The Iran-Contra affair is an example. In a domestic context, Marx (1979) identifies a number of actions including giving allies intelligence, building leaders, creating a positive image of a movement, aiding recruitment, and providing money and supplies. In the United States during the 1960s, the CIA provided funds to the National Student Association, a group seen to be supportive of its goals, while the FBI and local police through programs such as Cointel sought to damage other student groups that were protesting. Similar actions on the part of the Royal Canadian Mounted Police under its Disruptive Tactics program were seen in Canada.

Brodeur emphasizes secrecy and deceit as means of piercing informational borders. Given the importance of finding information that is itself often secret, the turn to stealth is to be expected. Creating the myth of an omnipresent and omnipotent surveillance can itself be a form of control. But secrecy and deception may also be used on behalf of coercion and violence because rulers wish to hide their responsibility for the actions taken and to avoid reciprocal actions by opponents. Subterfuge may mask the identity of those sponsoring and carrying out violence. New forms based on secret intelligence collection such as armed drones and cyber-attacks became prominent in the twenty-first century.

Whether it is called the policing of politics, political intelligence, or regime (or societal) protection, high policing with respect to both its goals and its means is a pillar of social control in modern society – nationally and, even more so, internationally (although not the only pillar). It involves organizations, an ethos, and a set of activities that are most commonly associated with, and developed by, national security (as broadly defined) agencies but in fact goes beyond this wide domain to many social control settings in which organizations protect their flanks, try to anticipate or orchestrate events, and attend to actions, persons, and contexts seen as threats.

Security and intelligence agencies engage in wide sweeping information gathering activities for strategic planning and for preventive and preemptive purposes. Depending on the kind of society, this may be to protect the public interest by protecting the state's interest (including but going far beyond protection of the sovereign), to protect the sovereign or the ruling party alone, or even to only serve the interests of the police agency.

High police remind us that the police are above all political actors. Two meanings of this can be noted. The low police on the street were concerned with protecting individual victims and with order maintenance. High police, in contrast, were concerned with protecting a corporate entity – the political regime. A major question is whether in protecting the sovereign, police are also protecting the broader (civil) society. In a democratic setting when police protect the leader, they ideally are also protecting the society's democratic constitution and institutions. In an authoritarian or totalitarian setting, high police act as a private police ensuring the power of the rulers (whether a king or political party) apart from the broader society. That does not preclude disingenuous legitimating claims about acting on behalf of the people.

Policing that puts knowledge at its core often has a macro and longer-time frame focus. In addition to specific groups, persons, and behavior, sources of possible insecurity are sought far beyond the traditional cabal. The CIA, for example, has a Center on Climate Change and National Security.

A country's economic well-being and the economic activities of rival countries are also presumed to relate to national security. National intelligence agencies routinely gather open source economic information on their rivals and are sometimes suspected of industrial espionage in order to help their domestic economy. France's DST (Direction de la Surveillance du Territoire) through its unit for the Security and Protection of National Assets was well known for the attention it devoted to supporting French economy and technology in an array of fields.

Given the number of variables associated with high policing, there is no single theme that characterizes all activities and agencies. Tasks such as intelligence collection, analysis, and operations may be internally divided or allocated among different agencies. Organizations may be centralized or decentralized. The work may involve a single or (most often) multiple agencies, have responsibility for foreign and/or domestic matters (as with Britain's MI6 and MI5), be national or local (as with the FBI and urban police), be distinct or attached to other branches of government, and if the latter be part of the military, state, or justice departments, emphasize technical (as in the USA) or human (as in France) information collection sources. But however the activity is organized; accountability themes are an enduring concern in democratic societies.

While some activity is overt and involves open source information (see the CIA's World Factbook on its webpage www.cia.gov), agencies and agents whose identity, location, and activities are clearly known much remain secretive and hidden. These activities are buffeted to varying degrees from the conventional accountability of government and direction and control by legislatures, the judiciary, and even the executive. High police may be a law unto themselves, partly because some activities are not controlled by law (being neither required nor prohibited by a legislature but tolerated if done discretely). There will likely be different degrees of control, oversight, and review at different stages for domestic and international actions and for citizens and noncitizens.

A vital question is what the limits should be in an age of globalization where traditional borders are weakened – even as new borders appear and weapons of unimaginable horror are present and formal war has not been declared. Should (or can) there be common standards of law and ethics for these methods across national borders? Should noncitizens within a country have the same rights and protections as citizens? Should citizens have any special protections from their own government if they are in another country and behave as enemies of their government? The United Nations Universal Declaration of Human Rights suggests that basic rights must transcend national borders or citizenship status. But can standards be enforced internationally when mechanisms for compliance are weak or absent, when adversaries do not honor these standards, and when another standard argues for respecting differences among local cultures that give less emphasis to human rights in the western tradition?

In democratic societies, there is an ebb and flow of efforts to rein in or unleash high police activities (and even to acknowledge them), depending on the gravity of perceived threats, crisis, and scandals. Some data gathering techniques are simply too new to have been given much legislative control such as drone and satellite surveillance. The laws that do regulate can be vague and provide for maximum discretion and for states of exception. Plausible deniability may also be offered by the delegation of prohibited or controversial tactics to private contractors or to countries with fewer inhibitions (a practice known as a "functional equivalent").

Even when the laws and regulations are adequate, the scale of intelligence gathering, the shrouds of secrecy protecting the behavior, and the "national security justification" work against implementing the kind of accountability found with other government agencies. In the United States, for example, in 2011, there were 16 agencies concerned with national security with a budget of over 75 million dollars, 200,000 employees, and extensive private contracting. The activities of these secret agencies (including specialists in misinformation) are classified and often exist within an insulated culture of incipient crisis distrustful of outsiders. Secrecy feeds on itself, whether out of caution or self-protection, and there is a point at which it becomes highly dysfunctional and makes democratic dialogue impossible.

Such factors make it difficult for citizens and researchers to know what is going on, let alone most specialists. In 2012 in the United States, an estimated 4.2 million persons had access to classified documents. But information access was highly compartmentalized and limited to the narrow task at hand. Given such factors relatively little is known about the agencies, often even by government oversight committees, let alone by citizens and researchers.

Claims about high policing must be carefully assessed given the deception and secrecy surrounding the topic and the vested interests of the parties involved (police do not wish to reveal operational tactics or behavior that might create bad public relations or harm a prosecution and opponents often have an interest in painting agents in a negative light). Yet information is sometimes available as a result of government hearings and court records, first person accounts from agents who publicly disavow their actions, leaks, Freedom of Information Act requests, archives, police training materials, and investigative journalists.

Ideal types call attention to broad differences yet obscure crosscutting dimensions that may unite what seems different and separate what seems similar. As an ideal type, covert high policing organizations usefully contrast with the overt low policing organizations largely involved with the immediate policing of everyday life such as traffic control, property crimes, or domestic disputes. In these settings, uniformed personnel have a narrow focus on local incidents that occurred, or are occurring, and that involve order maintenance or law enforcement. Law plays a more significant role in their activities, and their actions are distinct from (but not independent of) those of the judiciary.

For some purposes, broad contrasts between high and low police organizations are helpful, but the variables built into the ideal type can also be unpacked and seen as dichotomous or continuous factors. The latter take account of degrees (just how secret is the organization, to what extent is it controlled by law and policy?). Apart from any particular organization, high policing can be defined as an ethos and a set of activities found to varying degrees in any control organization – national or local, police or nonpolice, and public or private.

The elements of high policing can be used to analyze social control settings. Viewing high policing in terms of its component parts provides a systematic way to identify variation and to think about explanations and consequences of the different ways of doing policing. This approach emphasizes policing as a process or function rather than as an organizational structure. It also calls attention to cultural themes which may be widely shared in a society such as systems thinking and an interest in dealing with root causes, rather than only with consequences and in technical developments associated with the information age which provide new resources for analysis and planning.

Thus, many of the elements of high policing are seen in current policies such as intelligence-led (database-based) and community policing and specialized police units such as those involving intelligence, undercover, internal affairs, and planning. Detectives, and even uniformed police, make use of traditional (informers) advanced tools of surveillance (thermal imaging). The reverse is also the case – high policing units are involved in activities associated with law enforcement – reacting to events rather than only trying to prevent them locating suspects. Over centuries, the mission of high policing, at least in democratic societies as an aspect of modernization, has in principle broadened beyond protecting those in power to ensuring the security of civil society and protecting citizen's rights. As noted, this is part of modernization. Secret police may occasionally even help create a democratic state in opposition to the wishes of a country's leaders, as to some degree was the case of Poland's velvet transition in 1989 (Los and Zybertowicz 2000). There can also be significant formal limits in the discretion lower level operational units have in doing intelligence investigations (Lowe 2011).

Some Ethical and Practical Issues

Those using the less morally elevated tactics of high policing offer many justifications. Police cannot be everywhere, and the frequent resort to secrecy and deception on the part of their adversaries creates informational borders. Self-defense – whether by states or individuals – is in general morally and legally defensible. A US judge said, "the Constitution is not a suicide pact." Yet fighting fire with fire may burn and even destroy the fighters.

Simmel observed that in conflict settings, adversaries come to resemble each other. The secrecy, discretion, and minimal accountability often found with the policing of politics can result in abuses by the state that are difficult to document. The uneasy alliances between intelligence agents and criminals may result in criminals who are even less subject to restraints coming to control the agents. Such associations and the use of tactics perceived as dirty may taint the agents. As the history of the British police suggests, police are moral actors and their behavior has symbolic meaning.

What happens to this elevated image of police (and of government more generally) when they resort to the dirty tactics of deceiving, lying, spying, infiltrating, and relying on informers and criminals? Is the state then indistinguishable from its genuine enemies who may use the same tactics indiscriminately?

Using citizens who are not criminals as informers (apart from alliances with criminals) greatly extends the eyes and ears of police and avoids some problems. From one standpoint, this is even democratic and honors the British tradition that police are simply citizens with no powers beyond those of other citizens. The fact that the first modern British police were unarmed reflects this community orientation in which police were dependent on the good will of those they served. Citizens would obey the law out of respect for it, not fear, coercion, or deception. Citizens were seen to have a responsibility to contribute to the policing of their communities. This "low" police force was self-consciously created in opposition to the high police of the European continent who served the sovereign not the people. Yet in widely cultivating informers among citizens (as was done in the former East German Republic where over 2 % of the public were registered informers and many more unofficially participated), privacy, trust, and community are difficult to sustain.

High police efforts emphasize prevention. This impetus has been increased by the astoundingly destructive potential of modern weapons, whether nuclear, chemical, and biological or cyber-attacks, in an evermore interdependent world. Prevention can be approached from a standpoint of big picture hard or soft engineering efforts to avoid problems (e.g., improved infrastructure protection as with enhanced security of bridges or computer networks or institution building in an effort to win hearts and minds), through deterrence via means of identification and severe sanctions, or through direct interventions to thwart planned attacks.

The latter efforts often draw upon undercover means as when agents substitute fake for real dynamite or gather evidence to prove charges of conspiracy. Such efforts may also backfire as agents lose control of events. There is also a trade-off here since in preventing an unwanted event agents risk giving away their sources of information and other tactics. There is often a conflict between those involved in intelligence collection who wish to protect their sources and those involved in operations. There also is the hoarding and failure to share information among rival intelligence agencies as was the case with the FBI and the CIA in the 9/11 case (9/11 Commission 2004).

Information collection can feed upon itself generating the need for evermore information and to wait to use it until the last moment. The idea of risk management on a broad scale requires large amounts of data across many cases (Ericson and Haggerty 1997) and lends itself to profiles and statistical judgments, rather than emphasizing the unique individual. The latter is a condition of due process which assumes that there will be some grounds for suspicion before a citizen is subject to state intervention.

The advantages of prevention are obvious. Yet resources should not go into preventing things that would be unlikely to occur or things which are a result of agent provocation. The line between speech and action is easily blurred; speech is of course a kind of action, but it does not offer the kind of definitive evidence of intent, nor the harm, that results from actually carrying out a destructive act. Yet to wait until after the fact can mean failing to protect the society. But under conditions of law, the need to prevent may conflict with the need to have adequate evidence to proceed and that may require waiting and involvement with suspects. Prevention and facilitation may conflict.

Yet assuming that the internal and external threats that high police tactics are directed against are genuine and not orchestrated by police themselves through dissimulated media campaigns and agent provocateurs or based on vindictive or erroneous informers, some distinctions can be noted. The legality and desirability of both means and ends and the procedures followed need to be considered. Using the tactics to protect a legitimate democratic government is very different from using them to overthrow such a government or to protect the private interests of those with power (as was the case in much of nineteenth-century Europe and with former president Nixon and Watergate).

Attention as well needs to be given to the relationship between dissent and crime. A robust democratic society encourages questioning and guarantees citizens the right to protest. At the same time, pressures to criminalize dissent are always present, and some laws, such as those involving conspiracy and sedition, lend themselves to elastic interpretations.

When the goal is legitimate, questions still need to be asked about the availability of other more desirable means and the consequences of not acting, the creation of a precedent, the ability to control events, the impact on agents and third parties, and the symbolic message of using a tactic. Using tactics that are legally sanctioned through a democratic process and subject to independent review and challenge (whether by a judge, an oversight committee, an inspector general, or supervisors) brings a degree of accountability and is distinct from their use in an unregulated fashion – whether by agents of the state or opponents. Oversight by the mass media and interest groups also has an important role here.

Yet even when legal and procedurally wise, the decision for a democratic state to sanction use of the tactics must be done reluctantly given the risks and an understanding of how easily secret power can be abused. There are no easy answers to what Klockars (1980) called, after the film of the same name, the "Dirty Harry" problem regarding means and ends. Awareness and caution are continually required.

When police states fail as in Eastern Europe in 1989, among the first demands is for the abolition of the secret police. However, while particular leaders may be punished, their organizations destroyed, and extreme tactics prohibited, secrecy and many of the information gathering tactics endure as a functional necessity, and agents pop up elsewhere. No modern state is without security agencies concerned with internal and external threats, and in a global environment with geographical mobility, the lines between these can be blurred given sleeper agents and the recruitment of citizens on religious, ethnic, or ideological grounds to violent international causes. Few societies will favor moral purity over self-protection more than once.

But how should a democratic society control high police tactics? Most states prefer to keep these means in the shadows – neither unleashing nor prohibiting them. They are seen to fit within the category of necessary evils – means which may occasionally be justified, but certainly not preferred. When present, the laws, regulations, and reviews that legitimate them are often shrouded in secrecy, leave considerable wiggle room, and change as conditions do. Thus, in the United States, many of the reforms limiting surveillance that followed the Watergate scandal and earlier abuses were undone following 9/11 with the Patriot Act and other legislation. Similar loosening occurred in Canada and in Europe.

Some domestic tactics may be banned outright, e.g., torture, lengthy detention without due process. Others such as wiretapping require a warrant, review by a secret court, or are permitted only temporarily under emergency conditions (the challenge is to permit such states of exception from becoming permanent and not to keep policy discussions about them secret as with a tendency to overclassify in the name of security). Other tactics such as undercover means in the United States are subject to internal organizational policies and reviews rather than legislation, in contrast to much of Europe (Ross 2004).

Regulating (rather than outright banning) the tactics via the law and policy may lessen problems but, ironically, can also lead to their expanded use since they are officially sanctioned. In contrast, without a formal mandate legitimating and acknowledging such tactics, agents may be unduly passive and hesitate to use them because of uncertainty about where to draw the lines and whether they will be sanctioned for going too far. Yet to formally ignore the tactics is an invitation to abuse. Careful supervision and subordination to the executive is necessary, but that power can ironically lead to the executive misusing police powers. Critics often do not realize that police committed to the rule of law may face political pressure from the executive to break the law.

What kind of regulation then is appropriate? Democratic societies walk an uneasy and ambivalent line here, particularly domestically. Regulation and transparency can bring accountability, but if too detailed and formulaic, these can become straightjackets that eliminate organizational discretion, flexibility, and innovation and stifle personal questioning, honest communication, and experimentation. On the other hand, if they are too open-ended and permissive of discretion, they invite abuse. Too much visibility regarding the limits and operations of security agencies can be a resource for those who would destroy the state.

In an important sense, a democratic police is a politically neutral police even as it may have legitimate resort to secrecy, coercion, and deception. In democratic societies, police are to behave in a universalistic fashion and strive for equal law enforcement. Should their personal attitudes depart from the demands of the role they are playing, this must not affect their behavior. They are not to act in an explicitly political fashion, such as by spying on, or disrupting groups they disagree with, or failing to enforce the law against groups they support. Nor are they to serve the partisan interests of the leader or the party in power (or the party they would like to see in power). Their purpose must not be to enforce political conformity. Police show neutrality if they simply enforce the rules in equivalent contexts regardless of the beliefs or characteristics of the persons or group involved (e.g., their race, gender, age, ability-disability status, or social class). With this ethos, police are better seen as referees or umpires than as conventional political actors pursuing self-interest. From this perspective, given freedom of the press and association and the legal toleration (indeed even protection) of dissent, it is sometimes asserted that in democracies there is no policing of politics, only of crime.

But apart from the ideal in the above paragraph, there is a second sense in which police are not neutral and *all* policing is political. Police are agents of a particular state and enforce the laws of that state. In that sense, any policing is "political" (in and of itself that does not imply that it is right or wrong). Police have a mandate to legally use force and to deprive citizens of their liberty. To those who disagree with those laws, police tactics – whether high or low – will not appear neutral since they are on behalf of the regime in power and the status quo. As a result, police, even in a democratic society, are likely to be much more controversial than other agencies of government. Yet the line between speech and action can be hazy, and definitions of crime can be elastic.

There is an enduring unease in sustaining a democratic society partly through coercion and secrecy in the face of civil liberties protections and in the absence of traditional criminal violations. While national security efforts may be legally sanctioned and ultimately draw on criminal law, prosecution plays a very minor role, and the implementation of legal oversight is a continual challenge – both because of agency resistance and resources and, not infrequently, the reluctance of regulators to probe. The unease may be dealt with by outright denial, obfuscation, illusion, and rules and policies that maximize discretion. The public is often told by agency leaders, "trust us because we carefully choose, train and supervise agents and rigorously review actions to be taken." Less often heard is the refrain, and besides, "you don't want to know."

Conclusion

A thread running through all systems with an ethos of total control – whether totalitarianism in a state, a prison, or a demanding cult – is for the authority to deny individuals the right to control information about themselves and to restrict their liberty. At the same time, in such societies, those with power seek to maintain full control over information about themselves with few or no restrictions on what they do. The importance given to the end of staying in power and otherwise pursuing their interests overwhelms concern with the morality of the means used and full concern with the public good in which the end of official power is to serve citizens.

It has been said that a civilization's nature can be seen in how it treats its prisoners. It might also be seen in the respect it shows for the informational borders and liberty of the person and the ability to form groups independent of the state. Central here is the kind of social structure and culture within which power is embedded.

As de Tocqueville argued (after his nineteenth-century visit to the United States), a democratic society requires that individuals be free to come together in associations apart from the domination of the state or other all-powerful organizations and that there be significant sharing of power and the acknowledgment of the legitimacy of different, often conflicting, interests. When restrictions upon liberty are appropriate, this must be under conditions of law, due process, and accountability.

In his argument, Tocqueville drew on the classic insights of Aristotle regarding how tyrannical regimes maintained their power. The latter's characterization anticipates the modern police state (not to mention the society George Orwell and other dystopian novelists depicted). Tyrannical regimes seek to perpetuate themselves through the creation of atomistic populations, the blocking of private communication, a prohibition on the forming of private associations, the elimination of borders to visibility, and the sowing of suspicion and discord among their subjects.

Aristotle, drawing from his knowledge of the great tyrannies of the ancient world, argues that to remain in power the tyrant, "...must not allow common meals, clubs, education, and the like; he must be upon his guard against anything which is likely to inspire either courage or confidence among his subjects; he must prohibit literary assemblies or other meetings for discussion, and he must take every means to prevent people from knowing one another (for acquaintance begets mutual confidence). Further, he must compel all persons staying in the city to appear in public and live at his gates; then he will know what they are doing: if they are always kept under, they will learn to be humble..... A tyrant should also endeavor to know what each of his subjects says or does, and should employ spies..." Eavesdroppers should be sent to "any place of resort or meeting; for the fear of informers prevents people from speaking their minds, and if they do, they are more easily found out. Another art of the tyrant is to sow quarrels among the citizens; friends should be embroiled with friends, the people with the notables, and the rich with one another."

In contrast, the democratic leader must do the opposite. The state must ensure that its rules are fairly enforced and that citizens are protected from each other and from internal and external threats (who defines these, and how, are vital questions). It must guard its own guards to be sure they act appropriately. Finally, the democratic state has an obligation to protect itself as the representative of the civil society it serves. That contrasts with using its vast resources to protect the narrow, personal interests of those who are in power at the moment. The police (and government more broadly) must belong to the society. The society must not belong to the police. Any complex democratic society must be a policed society within a framework defined by law for reasons of administration and protection.

A supportive culture, appropriate checks and balances, accountability, and visibility are central to countering the abuses that unequal power and secrecy invite. Unfortunately, no complex society can do without police secrecy – a factor that can be independent of a secret police. There is an eternal tension between protecting the public from itself (as well as from other country's publics) and from those entrusted with doing the protecting. The "Dirty Harry problem" of means and ends and related questions of "good people and dirty work" (Hughes 1962) can never be resolved. But they can be acknowledged and must be continuously wrestled with. Within appropriate limits, legitimate authority must have the power to act coercively and deceptively. Societies are messy affairs awash in moral dilemmas, value conflicts, and trade-offs. Desirable as well as dastardly deeds can occur under cover of darkness; sunlight can illuminate as well as blind; those in positions of authority sometimes do the wrong thing in order to do the right thing. While Dr. Faustus may sometimes be granted a place at (or under) the table, he must be invited reluctantly and only with adequate oversight. It is vital to confront, rather than deny, the ironies and challenges this brings. Therein lies the central paradox of government, and indeed of any authority – so well put by James Madison in the Federalist (Paper 51), "You must first enable the government to control the governed and in the next place, oblige it to control itself."

Historical and Comparative Perspectives on Incarceration

Matthew DeMichele[1] and Janet P. Stamatel[2]
[1]Justice Center for Research, Department of Sociology, Penn State University, University Park, PA
[2]Department of Sociology, University of Kentucky, Lexington, KY, USA

Overview

The US incarceration rate is exceptional in a number of respects. First, the USA has the highest number of people imprisoned (over two million) and the highest imprisonment rate in the world (730 per 100,000 national population) as of 2010. The number of people imprisoned in the USA is almost double that of China, which is ranked second on this measure, and more than ten times that of most Western countries. Other countries ranked highest in the number of people incarcerated include Russia, Brazil, India, and Iran (International Centre for Prison Statistics 2013). There is certainly something paradoxical about the USA, a democratic country that is a global hallmark of freedom and civil liberties, imprisoning more citizens than authoritarian regimes that are often criticized for human rights abuses.

This US exceptionalism has received a great deal of attention in the criminal justice literature as researchers have tried to explain mass incarceration in the USA in terms of political, economic, and cultural conditions specific to the USA (Christie 2000; Garland 2001; Tonry 2011). However, much less research attention has been given to comparative analyses of imprisonment that can situate the US experience within a broader global context. Such analyses bring greater attention to macrolevel historical, cultural, and institutional factors that are often overlooked in case studies.

One criminological axiom is that punishment trends are a reflection of structural forces and not simply a function of crime rates (Christie 2000; Garland 2001; Tonry 2011). Despite the research supporting this claim, the misperception persists that incarceration is driven by crime levels. This does not suggest that crime is completely unrelated to incarceration, but rather that there are several steps between crime commission and incarceration at the microlevel and numerous macrolevel factors that influence incarceration levels. For example, if you compare homicide rates internationally, which is often argued to be the most reliable indicator of cross-national crime differences, the US homicide rate is much lower than many other countries that have lower imprisonment rates (United Nations Office of Drugs and Crime 2011). This is because punishment is shaped by historically embedded preferences, values, and norms that are durable, yet malleable. Comparative research offers unique insights into the historical, structural, and cultural contexts of punishment. This entry illustrates how historical and comparative research on incarceration can shed light not only on US exceptionalism but more broadly on understanding why countries differ in their types and levels of punishment.

The Historical Context of Incarceration as Punishment

Formal punishment serves multiple purposes, including the direct punishment of an individual (i.e., inflicting pain), as well as the indirect demonstration of public definitions of acceptable social behavior. For much of human history, rulers relied on overt forms of brutal physical punishment to control populations, including whipping, ear cropping, branding, and other excruciating practices, as well as execution. Punishing the body left a physical mark (e.g., cut ear, missing finger, brand) so that others could easily identify and stigmatize the criminal. Additionally, physical punishments took place in public to send a message to other potential law violators that they too would receive a similar torture.

The brutality, corruption, and arbitrariness of early modern punishment fueled an egalitarian backlash demanding fairer treatment of individuals. Changes to the labor market also contributed to shifts in social control mechanisms. Specifically, brutal physical punishment no longer met emerging nineteenth-century economic demands for a large, able-bodied workforce that was needed to fill the factories emerging throughout the Western world (Rusche and Kirchheimer 1968). This new economic reality fostered the development of houses of corrections that were responsible for more than just punishing inmates. They were designed to correct and shape modern citizens through a reflective incapacitation process.

The USA was an early adopter of imprisonment, and the first prisons of the nineteenth century in New York and Pennsylvania emphasized this reflective incapacitation approach. Silence, separation, and introspection were seen as tools to teach pro-social values and compensate for the poor upbringings and lack of discipline that were believed to be the causes of criminal behavior.

However, structural changes in the late twentieth century brought about another shift in penal strategies. Many Western countries experienced changes in economic, social, and cultural frameworks that served as the *cultural preconditions* necessary for the development of a "culture of control" characterized by a growing reliance on criminal justice responses to more behaviors and longer prison sentences. These preconditions were accompanied by increasing crime rates that fostered a new perception of crime as a common occurrence that residents need to take proactive steps to prevent. The state was seen as incapable of protecting citizens from everyday predations because crime was now an embedded feature of the late modern social fabric. In the face of deindustrialization, growing unemployment rates, and inflation, the once flourishing central business districts of many cities experienced capital and human flight. These departures left only the most disadvantaged and marginalized groups behind. Instead of strengthening the social safety net, the US criminal justice system stepped in to regulate the resulting social disorganization and poverty (Garland 2001).

This historical context explains how incarceration became the primary means of punishment and social control in the USA, and it illustrates how social structural and cultural forces shape policy decisions regarding punishment. However, it does not explain how the USA became such an extreme outlier in the implementation of this form of punishment. How did the USA come to punish more people for longer periods of time? Comparative scholars began to recognize that there are unique legal institutional differences that shape different penal outcomes. Whitman (2003) provided an erudite historical analysis of punishment in France, Germany, and the USA to explain why three democratic, egalitarian, and capitalist nations sharing numerous cultural values could produce such different types of punishment. Interestingly, Whitman (2003) was not concerned with explaining the differences in the amount of punishment; rather, he focused on the differences in the types of punishment. The USA had distinctively harsh forms of punishment with many jurisdictions now using chain gangs, military-style boot camps, and double-bunking inmates, not to mention the forms of civil and social exclusion related to a criminal status. US inmates, for the most part, face felony voting restrictions, employment bans, and limited educational opportunities, such as being ineligible to receive financial aid to pursue a college degree. Whitman (2003) contrasts these exclusions with the Continental experience in which inmates maintain their privacy and dignity as they are housed in single-occupancy cells where guards must knock on doors before entering.

The crux of Whitman's argument is that French and German punishment mechanism consciously – yet slowly – moved away from stigmatizing responses. Criminal justice officials recognized the need to reduce the emotionally laden approach to crime control. Although there is much rhetoric among US policy makers of adopting evidence-based models of punishment, there are structural differences that make such attempts difficult. French and German prosecutors and judges are civil servants; they are experts that possess knowledge of human behavior and principles of behavior change. They have extensive and specialized training specifically related to their position, and the judiciary must act within a tightly bound system of accountability checks to ensure that punishments prepare inmates for normal life, not strip them of humanity. In contrast, prosecutors and judges in the USA have broad discretionary power regarding whom to charge, what to charge these individuals with, and what sentences to apply. The US plea bargaining system is relatively unthinkable in other countries due to the amount of prosecutorial discretion that it involves. Further, the US adversarial system is one that provides the judiciary with few boundaries during the sentencing phase of a trial; no doubt, sentencing guidelines do exist but these are presumptive. These distinctions were summarized by Weber (1967) as differences between types of legal thinking in which the Continental law relied on formal rational mechanisms and the common law relied on substantive rational mechanisms. To summarize these differences briefly, formal rational law attempts to eliminate individual discretion and subjectivity, whereas substantive rational law encourages legal actors to inject morality and ethics in legal decisions.

Tensions Between Modern Capitalism and Incarceration

The shift to an industrialized, capitalist economy not only changed labor market demands but also increased inequality and poverty, creating a marginalized class that could be potentially disruptive to social order. Governments have used a variety of tools to maintain order under such conditions. According to Bourdieu (1999), the left hand of the state controls the citizenry through less overt forms of coercion (e.g., education, welfare, and public healthcare), and the right hand of the state delivers direct control through police, courts, and prisons. At least since the end of World War II, Western nations have developed welfare programs to protect citizens from the inherent negative effects of capitalist production and have simultaneously bolstered criminal justice apparatuses to control the poor.

Beckett and Western (2001) argued that within the USA "penal and social welfare institutions comprise a single policy regime aimed at the problems associated with deviance and marginality" (Beckett and Western 2001, p. 44). The tremendous growth in US incarceration necessitates pondering who is occupying these prisons. Western (2006) provides an illuminating empirical analysis that shows how incarceration is driven by poor, uneducated, African-American males. This punishment trend is situated within a context of deindustrialization, stigmatizing subsistence-oriented welfare mechanisms and limited opportunities for the growing underclass left behind. Changing structural realities were embedded within a criminal justice culture lacking any real institutional blocks to increasing punishment. That is, US criminal justice actors did not push for rational and proportional sentences; rather, austere measures were the typical response because crime and criminals were seen as social pariahs, misfits, and incorrigible individuals. This is contrasted with Continental and Nordic perceptions of punishment in which criminals are a part and product of their social landscape – not disembodied from it. Criminality and crime control mechanisms fit within an inclusive context that provides a safety net from inequality as well as placing institutional barriers on criminal justice actors that prevent the reliance on overly emotional sorts of punishment. This is not to say that punishment lacks an emotive element. Rather, punishment takes a scientific, rational, and bureaucratic form. This form differs from the US response by recognizing that unpleasant features of social disorganization cannot be eliminated with incarceration nor can the rare, sensational, and highly publicized criminal events be prevented with new policies or longer sentences.

Comparative researchers demonstrate that the context in which governments, employers, and workers negotiate is consequential for incarceration rates. In particular, the ways in which governments set wages and determine labor arrangements to buffer the negative effects of capitalism – deindustrialization, unemployment, and underemployment – affect incarceration rates. Comparative research has shown that countries with corporatist bargaining, strong unions, and powerful left-oriented political parties have significantly lower incarceration rates than countries lacking these policies, such as the USA (Cavadino and Dignan 2006; Jacobs and Kleban 2003; Sutton 2000, 2004). Sutton (2000, 2004) concluded that across the advanced capitalist world criminal justice and welfare policies are historically intertwined as subthemes within a larger policy discourse about the management of social marginality. Furthermore, countries with a collectivist orientation have political-economic institutions in place that keep popular punitivism in check. Decentralized governmental structures increase the likelihood that the public's emotional desires for more punishment will creep into legal actor decision making (Whitman 2003).

Strong centralized efforts to protect labor interests keep incarceration rates down in at least two ways. First, the presence of collective bargaining and other political-economic frameworks that protect the working class from unemployment, underemployment, and universalizing welfare demonstrates interclass solidarity. Countries with such characteristics have a smaller gap between classes, an emphasis on full employment, and a social philosophy focused on diminishing inequality. Second, political-economic frameworks that protect the working class from economic uncertainty provide actual monetary benefits that prevent the development of the durable underclass that many have shown are driving the US mass incarceration movement.

This research clearly demonstrates that incarceration is not simply a response to crime. Instead, incarceration must be situated within a broader fabric of social control. This fabric is complex and varied and sometimes merges contradictory elements. Governments have varying preferences regarding diminishing gaps in inequality with wage bargaining and worker solidarity situated within left-political power, producing serious reductions in the reliance on incarceration as a social control mechanism in some countries. The USA, conversely, is a context in which policy makers, the public, and the media interact in a cyclical process of defining crime as something committed by the underclass, and criminals are in need of the state's "iron fist" through crime control policies centered on longer sentences, harsh treatment, and civic exclusions upon release. This approach fosters a path-dependent process creating policy inertia that makes it difficult to change course to more rational crime control responses that actually might reduce social inequality.

The Influence of Legal Traditions on the Use of Incarceration

The emphasis on state-labor relations in the comparative incarceration literature needs to be situated within historical legal traditions. The three legal families of the Western world – common law, Roman law, and Nordic law – codify and define enforcement strategies in different ways that reflect social preferences about state intervention that affect variations in the use of incarceration. Common law is a legal system that emphasizes common knowledge of facts brought to the court by private individuals. The contemporary adversarial system emerged from a private form of law that excluded defense attorneys from trials, lacked a public prosecutor, and did not allow judges to decide on guilt or innocence (Langbein 2005). The Roman legal system dates back to the Roman Emperor Justinian during the fifth century in which he commissioned legal scholars to devise a "gapless legal system" (Weber 1967). This system was institutionalized as an inquisitorial, code-based approach to eliminate legal actor discretion and lay influence in legal matters. The Nordic law combines elements of substantive (i.e., common law) and formal (i.e., Roman law) types of legal thinking with a cultural imperative focused on social solidarity and limited inequality. The shared histories and unique development of each legal family delineate legal theories, philosophies, and varying levels of discretion to legal decision makers.

Countries fitting into a specific legal family will adopt similar institutions to define and enforce state authority. This is not to suggest that all common, Roman, or Nordic law countries will be identical to one another; rather, these countries will have a high degree of interfamily similarity and high degree of intra-family variation. Simply, the USA and Australia, as common law countries, have similar legal practices that differ from their Roman law counterparts, say France and Germany, or from Sweden and Norway as Nordic law countries. It may seem out of place to discuss legal family or legal origin when explaining contemporary punishment outcomes, but this approach builds upon comparative economic research that shows how macroeconomic outcomes vary across countries according to their type of legal family (Hayek 1960).

Legal families define legal actor roles and structure financial markets in the form of rules of corporate ownership, stockholder protection, and private property rights that influence contemporary economic outcomes (Glaeser and Shleifer 2002, p. 1193). Legal institutions vary by legal family to reflect a country's use of law to protect property owners, enforce private contracts, and regulate the relationship between employers and employees. For example, Roman legal families use institutions that diminish legal actor discretion, rely on codified law, and prefer government intervention in financial markets. The common law approach, alternatively, uses institutions that favor judicial flexibility, case-based law, limited regulation, and private market solutions (Glaeser and Shleifer 2002). Comparative economic researchers find that the judicial flexibility of common law situates corporate actors within a context in which laws can be changed quickly according to social and economic preferences. This, essentially, shapes individual's willingness to rely on legal mechanisms of conflict resolution as there is a high expectation that legal decision makers will rule on the side of corporate interests.

This macroeconomic research is discussed because it – along with ample sociological literature (e.g., Weber 1967) – suggests that the rules defining and providing meaning to legal actor roles are consequential for punishment outcomes. Recently, (DeMichele & Janoski 2010) argued that similar legal institutions important for macroeconomics are consequential for criminal justice policies as well. Analyzing data from 1960 to 2002, he found that the common law countries had the highest amount of incarceration with average rates hovering between 125 and 150 per 100,000 in the population. The Roman law countries, composed of Continental European nations, had average incarceration rates between 80 and 100 per 100,000 in the population. And the Nordic law countries had the least incarceration with average rates ranging between 40 and 70 per 100,000 in the population. The unique blend of legal actor discretion, lay participation in the legal system, sentencing rules, and alternatives to incarceration coalesced to produce varying levels of incarceration. This research concluded that just as there are three types of capitalist welfare systems (Esping-Anderson 1990), there are also three types of Western punishment. Different legal systems produce environments that make possible the adoption of specific legal practices that reflect dominant definitions of the relationship between the state and individuals.

What Does Historical and Comparative Incarceration Research Tell Us About US Exceptionalism?

Historical research has put current incarceration patterns and trends in a larger context to understand how a confluence of economic, political, and cultural factors encouraged the use of incarceration as an important form of punishment and social control. Additionally, comparative research has shown how modern capitalism changed labor relations and exacerbated poverty and inequality in ways that also favored incarceration as a tool of social control. But why was this tool used more extensively in the USA relative to other advanced capitalist societies in the West? Criminologists have searched for institutional variation that differentiates the USA from other common law countries to point to the peculiarity of using popular elections to appoint many criminal justice and legal actors. That judges, prosecutors, and others are elected by the public may seem to be an inconsequential fact. However, it is well-known that during election cycles prosecutors and judges are found to implement longer sentences. Therefore, the common law relies on substantive practices that are more susceptible to public punitivism, and in the USA legal decision makers lack the bureaucratic protection found in other countries from these public desires for punishment. For example, consider the emotional reactions to sensational cases and how laws are created in the name of victims to gain public support. These institutional arrangements are situated within a US political-economic culture that favors individual responses to inequality, right-oriented politics, limited union strength, and decentralized wage bargaining – features known to correlate with increased incarceration. Mass incarceration, essentially, resulted from a social landscape that relies on formal punishment as the primary response to inequality embedded within a type of legal thinking predicated on the insertion of individual subjectivity and public emotionalism.

Future Directions

Although the literature explaining cross-national differences in the use of incarceration has not been extensive, it has certainly provided some important insights to explain US exceptionalism and also to delineate macrolevel forces that shape decisions regarding the tools of social control. Nonetheless, several questions regarding cross-national variations in incarceration rates remain unanswered. In particular, the prevailing focus on the use of incarceration in Western European countries provides a fairly narrow view of the question of why countries vary in their use of incarceration as punishment. The focus on the West is a common pattern in cross-national crime and justice research (Stamatel 2006) that has been exacerbated in the punishment literature because of the extreme US exceptionalism with respect to incarceration.

While Western European nations are natural points of comparison for the USA due to similarities in political and economic development, other countries outside of this region could provide interesting points of comparison for other reasons. For example, consider the fact that many countries with the highest incarceration rates per 100,000 population are former colonies, particularly British colonies, such as St. Kitts and Nevis, Anguilla, the Virgin Islands, or Bermuda (International Centre for Prison Statistics 2013). Are there commonalities in the colonization experiences of the countries, and the USA, that would explain similarly high usage of incarceration as punishment? Are their historical trajectories with respect to social control and punishment different from other formerly colonized countries with lower incarceration rates?

Another factor that is noticeably missing from the historical and comparative research on incarceration is religion. Tonry (2011) argues that Protestant fundamentalism is key to understanding harsh punishments in general in the USA. To what extent is this a common feature among other countries with high imprisonment rates? Is the type of dominant religion important for explaining cross-national differences in punishment or is fundamentalism the relevant explanatory factor regardless of type of religious foundation? The moral dimension of punishment that was so central in research on nineteenth-century practices seems to have been put on the back burner in the twenty-first century.

Lastly, the lack of diversity in comparative incarceration samples means that some types of legal systems have not been considered, most notably the socialist legal system that still has a strong influence on many Eastern European countries despite the fall of communism in that region or the hybrid legal systems that encompass much of the world, particularly countries with a history of colonization. These countries are interesting comparatively for two reasons. First, several countries with a socialist legacy have high incarceration rates, such as Russia, Belarus, the Ukraine, and Kazakhstan. Second, most socialist and hybrid systems, particularly in Eastern Europe and South America, have been undergoing significant changes in their legal systems (Newman 2010), raising questions about whether these changes will bring about more or less punitiveness.

Historical and comparative research is uniquely equipped to answer these types of questions. By contextualizing the historical, structural, and cultural contexts of punishment, we can identify and explain the macrolevel forces that affect punishment decisions and ultimately create cross-national differences in incarceration rates. Existing research has already shown how macroeconomic changes in labor markets, the creation of a permanent underclass, political configurations regulating state-labor relations, historical legal traditions shaping degrees of state intervention, and accompanying cultural perspectives regarding state strength, social control, and emotional gratification have contributed to different levels of incarceration across countries. This line of inquiry is still fairly new and many questions remain unanswered. Future research in this area has the potential not only to further explain US exceptionalism with respect to incarceration but also to situate the primacy of incarceration as punishment in a global context. This knowledge would be beneficial to other areas in criminology and criminal justice as it speaks to a number of important issues in the discipline, including social control, state control, cultural values, and the interrelationships among the criminal justice system and other social institutions.

History of crime

Overview

Historical criminology brings methods and concepts from history to the study of crime and criminal justice. This entry covers the differences between criminologists and historians, leading theoretical frameworks in historical criminology, methods of historical research, and the role of time in criminology theory and research.

Key Issues/Controversies

Criminologists and Historians

There are well-established areas of research that overlap history and criminology.

Manuel Eisner (2003) and Hans van Hofer (2011) analyze levels of crime over time. The study of crime trends makes intuitive sense to criminologists, particularly when these trends are examined from the Second World War. Trends in crime and imprisonment during the late twentieth century are readily interpreted using criminological models, so readily that criminologists do not regard this as "history." Criminologists are also interested in the history of criminology. This research examines the founding assumptions, theoretical traditions, and methods of criminological inquiry. Mary Gibson and Nicole Rafter have led the examination of Cesare Lombroso and biological criminology. They have explored the emergence of biological positivism in nineteenth-century Italy (Gibson 2002) and the popularity of criminal anthropology in the United States (Rafter 1992). Their work has advanced our understanding of Lombroso as more (and less) than the originator of the "born criminal" concept and raised new questions about criminology as a science of the human condition.

Nevertheless, there are real differences between criminologists and historians. For criminologists, historical research must do more than reveal the past. To be of use, history must be relevant to the present, meaning, there must be a clear statement about a present concern. In a sense, there is a commitment to "futurism." Criminologists try to build models that are good enough at explaining the present to anticipate what is likely to happen, and this provides a basis for advising crime policy (Lawrence 2012, p. 8). Historians are reluctant to comment on the present. They are more concerned with understanding the significance of past events against wider currents of human experience. They are happy to correct misrepresentations of the past (by politicians or others), but do not feel the need to offer policy recommendations.

Criminologists are committed to theory-driven research. They are particularly troubled by "empty empiricism," an assemblage of facts presented outside a clear conceptual framework (Loader and Sparks 2005, p. 14). While there is ample room for theory construction, and new theories of crime are always welcome, leading journals appreciate research developed within a theoretical tradition of criminology. Mathieu Deflem's (2002) investigation of international police cooperation deals with history, except that as a sociological criminologist, he constructs his book different than an historian would. He declares from the beginning that his work draws on the framework of Max Weber and that he will explore several propositions. Historians rely on theories to organize their facts, but do not specify them in the same way. Theories are not stated in the tradition of scientific research, but are rather weaved into the fabric of the narrative. Historians refer to concepts in the course of presenting their research material. They engage the arguments of other historians along the way: sharpening arguments, questioning evidence, and weighing interpretations.

Because the research training criminologists receive does not include historical research, most criminologists are not in a position to provide historical background into their topic of interest. The curriculum may include an option concerning the history of crime, but methods' requirements, even at advanced levels, do not include the craft of historical research and writing. Further, as social scientists, criminologists are suspicious of anecdotal data and wonder whether a few historical events can be stretched far enough to become social processes. In contrast, historians can choose crime as a topic of study rather more easily, and in fact, many have turned to crime in recent years. In Britain, there has been an "explosion" of scholarship concerning the history of crime (Godfrey et al. 2010, p. 18). The British Crime Historians have met every 2 years since 2008. Further, the American Social Science History Association and the European Social Science History Association operate networks for historians engaged in the study of criminal justice and legal history. Historians of crime, who are familiar with the aims and techniques of social history, are receptive to social science concepts.

And then there is the matter of style. Criminologists question the value of description. Historical material makes sense provided it is organized around criminologists concepts.

The sequence of events is secondary to the explanation of concepts and their connection to the criminological literature. Historians are more comfortable with narrative. Not all historians rely on chronology to organize their work, but they adhere to the belief that the sequence of events matters. Historians would not frame a research question as a "test of a hypothesis," so their writing does not follow the familiar sequence of literature review, research questions, data analysis, findings, and discussion. The technique of historical argument can be compared to constructing a dry stone wall. The builder fits all the available stones into a shape that holds together. In the same way, the historian must fit all the known evidence into a coherent pattern.

Theoretical History

Historical criminology could not have developed without the contribution of several theoretical frameworks which have built bridges between history and criminology. In the 1970s, the work of several British historians crossed over to criminology. The British Marxist historians, as they became known, pursued a "history from the bottom up" or "history from below," that is, the experiences of working class and ordinary people. *Primitive Rebels* (1959) and *Bandits* (1969) by Eric Hobsbawm, *Albion's Fatal Tree* (1975) by Douglas Hay and others, and *Whigs and Hunters* (1977) by EP Thompson examined the response to crime in the context of class structure and the emergence of industrial capitalism. Because these works engaged a conceptual vocabulary drawn from Marxist social theory, they found a ready reception among criminologists pursuing "radical" and "critical" approaches. Criminologists brought historical arguments about the rule of law and maintenance of social order to the contemporary critique of criminal justice policies. The British Marxist historians had excavated deep into the foundations of Anglo-American legal heritage. They offered insights into the administration of English criminal law in the eighteenth century that could apply to the policing of street crime in American cities of the late twentieth century.

About this same time, another influential book appeared: the English version of Michel Foucault's *Discipline and Punish* (1977). It was, ostensibly, a book about how Europe had come to rely on imprisonment. It inspired a great academic discussion about the "birth of the prison." But it was also more than this. In this book, and other work that followed, Foucault wielded an arsenal of images that captured the imagination of criminologists. Criminologists retold his examples (the execution of Damiens, Bentham's panopticon) and added his words ("discourse," "surveillance," and many more) to the lexicon of criminological terms. Historical studies framed as a: "history of the present" or "genealogical account" began to appear in criminology books and journals. Foucault made "appalling" mistakes about what happened, when, and where. But none of this mattered to criminologists who, particularly when it comes to history, prefer an entrée of ideas with only a small serving of historical details, perhaps as the apéritif. Foucault did not write a history of criminal justice; he turned criminal justice history into a worthy intellectual project.

Foucault even inspired further research by what he did not say. Foucault did not address the confinement of women, nor, for that that matter, did other widely-read historians of the prison. Nicole Rafter (1985) pointed out that it was a mistake to regard the history of women's imprisonment as an extension of the history for men. She presented the women's reformatory movement, the rise of custodial prisons for women, the legal and social characteristics of imprisoned women, and the effects of "race" and class on treatment of women (Rafter 1992). Work by Zedner (1998), and others, confirmed that gender could not be explained away as a lighter or softer version of men's experience. Historical research into institutions for women opened the doors to a parallel world operating according to its own logic, moving at its own pace, and leading to its own consequences.

David Garland took the "history of the present" to another level. In a series of influential books and articles, Garland produced an intricate history of changes in crime policy from the late nineteenth century. He examined institutional practices within wider social and cultural contexts with a particular eye for “moments of transition.” In *Punishment and Welfare* (1985), he examined how science entered legal culture before the First World War, and in *The Culture of Control* (2001), he analyzed the displacement of rehabilitation by security as the characteristic response of governments in the late twentieth century. Garland’s research opened up new issues for analysis: changes in prison practice, the origins of criminology, the role of the state, and convergence of welfare policy and penal policy. He generated a new conceptual vocabulary for historical study in criminology, such as “penal welfarism,” “mass imprisonment,” “the crime complex,” and “the culture of control,” and in the process, opened up new tracts of real estate for development by historical criminology.

The social theory of Norbert Elias has also been influential. In *The Civilizing Process* (1939), Elias recovered the transformation of European society from barbarism to civilization. Drawing on an interesting set of archival documents, commentary about manners, he charted the emergence of polite society. Through a process of cultural change so gradual as to seem invisible, control of violence shifted from external force to internal restraint. Elias’s theory of social change, sometimes called “process sociology” has been especially important in studies of penal policy and practices. Pieter Spierenburg (1984) and John Pratt (2000), two of Elias’s leading interpreters, have brought the civilizing process to punishment practices in the Netherlands and New Zealand. Mucchielli (2010) points to recent crime trends in France as evidence of an overall decline in violence. Crime figures in recent decades suggest Elias’s concept of the “civilizing process” at work, a fall in violent crime owing to the stigmatization or delegitimization of violence.

Archival Methods

Historical criminology borrows the methods historical research. Research in historical criminology relies on primary sources, documents, and materials that originate in the time period of interest, such as prison registers, police reports, and court records. Digitization has made significant material accessible for the historical study of crime such as the Old Bailey online project. The proceedings of the Old Bailey, London’s central criminal court, are available via the internet for 1674– 1913. Internet access has also made available an increasing number of books and periodicals, government documents, and newspapers from the nineteenth century and earlier. The vast majority of archival material, however, remains accessible only through traditional search strategies.

One of the challenges is avoid a narrow administrative history. Making a historical portrait from documents left by prison managers, police authorities, and so on presents a particular view, that is, a managerial or institutional view. The “usual suspects” – the poor, immigrants, the crowd – did not produce their own written records. To interrogate the deeper purpose and wider impact of institutions and practices, it is necessary to get beyond official records. It is true that much of the institutional record is “limited for anything other than administrative history” (Bosworth 2001, p. 434). Diaries of prisoners, letters from the accused, and the like are rare. But the official view can also be reframed with reports of visitors, commissions of inquiry, courtroom testimony, newspaper accounts, and even novels.

Another challenge is moving beyond the nation state. Criminal justice is a national or local project, and not surprisingly, much of the historical record concerns the response of national governments and city authorities. For the history of human trafficking, terrorism, drug trafficking, and other cross-border crimes, the records and materials left by nongovernmental organizations are particularly useful. These include organizations such as the Jewish Association for the Protection of Women and Girls, founded in 1885 in response to concerns that women emigrating from the Pale of Settlement were vulnerable to the white slave traffic (Knepper 2009) Other intergovernmental organizations, such as the League of Nations, also provide valuable material. The League of Nations led major campaigns concerning human trafficking and drug trafficking in the early twentieth century.

The archives in Geneva contain minutes of meetings, correspondence, field reports, photographs, and other materials (Knepper 2011).

Recent interest in "globalization" has invited new questions about the past, including an awareness of the legacy of empires. On paper, the British Empire represented one of the largest criminal justice systems in world history, with colonies, territories, and possessions extending from Australia to India, Ireland to Singapore. The Colonial Office attempted to coordinate police, prisons, and legal measures, and the influence was felt not only in the colonies but within Britain itself. Looking back yields insight into the diffusion of police and practices, and opens up new lines of inquiry, including the conditions for successful "policy transfer" and the influence of colonial practices on domestic institutions (Godfrey and Dunstall 2005).

Criminologists can gain a sense of history from published work by historians, but they cannot answer the questions they pose through secondary sources alone. Historians are interested in different questions, and the nature of historical research means that choices need to be made about sources and interpretation. Criminologists need to conduct historical research for themselves; they cannot proceed as if theory is all that really matters. Imposing a particular theory on the past yields a dull and pointless project, something like bringing one's own food to eat while on a holiday tour of several countries. As in social science, there is an interaction between theory construction and empirical findings. The historical researcher needs a theory to judge the significance of documents; the documents lead to new evidence, leading in turn to revising theories (Knepper and Scicluna 2010).

The Criminology of Time

Before Foucault, another French intellectual challenged social scientists to think about history. In the 1950s, Fernand Braudel encouraged social scientists to situate the objects of their inquiry in time. It was a mistake to believe that the significance of time could be gauged with a questionnaire or a few months of observation. Each social activity, he proposed, operates according to its own particular time, so that any historical moment is moving at multiple speeds.

In his history of the Mediterranean, Braudel presented three levels of historical time. He saw the natural environment, the mountains, deserts, and the sea, as the source of constraints on behavior that persist across generations. These behaviors produce the "almost immobile history" of geographical time. He described the "slowly rhythmic history…of groups and groupings," shaped by long-term trends in trade, transport, empire, and forms of war. This he referred to as social time. And, he narrated "history of short, nervous, rapid oscillations" brought about by political and military leaders. The "history of events" unfolded in individual time; individual time "has the dimension of their anger, dreams and delusions." (Braudel 1980, pp. 3–4) The fact that Braudel came up with his idea of multiple time while in prison during the Second World may suggest a particular relevance for criminology.

Criminologists have been interested in discontinuities, so much so that "paradigm shift" has become a cliché. Continuity, as suggested by geographic time, may be more important than we have realized. Media and crime affords one example. Given the development of electronic media since the Second World War, and the internet, satellite communication and so on in recent decades, it is easy to believe that the media has a powerful effect public understanding of crime, leading to particular crime policies. The influence of media on policy making about crime has been described as part of the "challenge of our times" (Garland and Sparks 2000). But as Robert Shoemaker points out with a look back at the eighteenth century, crime was a recurring topic in every form of print. As print become more available, popular understandings of crime were shaped more by what people read than by what they knew from personal experience or reports from friends and relatives. Pamphlets from social reformers exaggerated the extent of crime to justify particular projects. Newspapers overemphasized crime both in the frequency of reports and tone of coverage. Printed reports of trial proceedings distorted understanding of crime and justice, as much by what we left out as what was said. Edited versions of trials portrayed English court procedures as more coherent than they actually were. Eighteenth-century readers approached this surfeit of information with a skeptical eye; they knew that crime problems were more complicated than reformers, journalists, and the authorities made it appear (Shoemaker 2009). So, aside from the technology, what has really changed?

Braudel was interested in trends or cycles that occur over several decades, or what he referred to as "conjunctures." This is what LaFree had in mind when he urged criminologists to pursue historical analysis. There should be more emphasis on historical data and historical interpretation because theoretical insights cannot be obtained through cross-sectional designs that compare within a single moment of time. Crime events, such as the rise in crime during the 1960s and fall in the 1990s (in the United States), can be understood by recognizing that crime occurs within "distinct historical periods," and one of the goals of criminology is to understand factors behind the transition from one era to another (LaFree 2007). A recent example can be seen in theory of "crime waves." Periodization is a familiar idea to historians, and criminologists, who are accustomed to thinking about the importance of social context, are well-positioned to pursue it. Martin Killias (2006) examined fluctuations in crime rates across Europe with reference to "breaches," the way in which social developments surrounding technological advances open up new opportunities for crime. He combined the historical idea of periodization with the criminological idea of opportunity structure.

One of the criticisms of Braudel's approach, and particularly his emphasis on "structural history" grounded in continuity, is the absence of human agency. The agency-structure problem is well known to social science, and in examining biographies, criminologists have provided an interesting solution. In what must be the "longest longitudinal study," John Laub and Robert Sampson (2003) interviewed men some five decades after they had been selected for a study of delinquency. The interviews confirmed how individuals construct their own lives through the actions they take within the constraints of historical and social context. Criminal activities did not correspond with historical events, such as economic downturn, or social conditions, such as substandard schooling. Rather, in looking back over the course of their lives, the men saw the significance of choices they had made. Sampson and Laub (2005) encourage a view of time that balances structural constraints with human agency. Some historical events affect people very deeply. Others pass over, like a cloud across a quiet lake.

Concluding Thought

Criminologists have produced significant historical scholarship over the past few decades and, in recent years, have taken several steps toward incorporating historical criminology as a subfield of inquiry. Two presidents of the American Society of Criminology – John Laub in 2003 and Gary LaFree in 2006 – have used the annual presidential address to emphasize the value of historical perspectives (Laub 2004; LaFree 2007). In 2011, the Crime, Criminal Law and Criminology in History network was established with support from the Scandinavian Research Council for Criminology, and in 2012, the European Historical Criminology working group was established within the European Society of Criminology. It may be a step too far to suggest that historical criminology represents a recognized subfield. Criminologists and historians ask their own questions of the past, cultivate expertise in their own methods of inquiry, and organize their inquiries in different ways. But, from what has been done so far, one thing is clear enough: The most interesting criminology arises at the point that history and criminology meet.

History of Bail

Amanda L. Russell and Robert G. Morris
The University of Texas at Dallas, Richardson, TX, USA

Synonyms

Pretrail detention; Pretrial release

Overview

Although not traditionally viewed as a function of corrections, bail is an integral mechanism within the system that can allow a defendant to avoid the confines of jail in the early stages of the criminal justice process (i.e., before trial). However, the bail system – particularly in the United States – is frequently viewed as punitive for those who are denied bail as well as for those who cannot secure bail through financial means. In particular, individuals who are denied bail are immediately thrust into the correctional system despite an entitlement to a presumption of innocence. Meanwhile, indigent defendants are penalized for their inability to pay the requisite bail amount. In both scenarios, the punishment (of pretrial detention) occurs before guilt has even been determined.

Bail is commonly defined as the temporary release of an arrestee secured by a bond or promise to appear at future court hearings. Bail, as it is utilized today in the United States and other countries, is rooted in the long-standing practice of using personal sureties as an alternative to pretrial detention.

The term is a derivative of the French word *baillier* – a denotation of the verb "to deliver." In historical practice, it refers to the pretrial custody transference of an arrestee, from the court, to others who then become responsible for that individual's fulfillment of his responsibilities to the court ("Indemnification Contracts" 1949). These individuals are typically referred to as sureties because they function as guarantors of the arrestee's appearance. In some cases, financial stipulations are attached that must be satisfied by the arrestee, a personal surety, or third party. These monetary provisions may be required up front before bail is granted or may be later required from the arrestee or surety in the event that the individual fails to appear in court. Despite the many nuances of bail systems from one country to another, the practice has not changed significantly since its reported inception in the seventh century as a mechanism of pretrial release. A review of the extensive history of bail, for example, reveals that the theoretical basis underlying bail has essentially remained the same even into the twenty-first century. In other words, bail continues to be used as a deterrent to pretrial flight. Sureties, in particular, are believed to be motivating elements that ensure a person's appearance in court. What has changed, however, are the conditions in which bail is granted, the types of bail and the means to obtain it, and the purposes to which bail is intended to serve.

In the United States, specifically, the bail system has evolved into one that must reconcile conflicting objectives. In particular, the system must protect the presumption of innocence while also ensuring that individuals who are released return to court, abstain from crime, and maintain the sanctity of the case (Devine 1991; Goldkamp and Gottfredson 1979). Bail in the United States has also developed into an institution that emphasizes financially based means to obtain pretrial release. These are commonly referred to as secured bonds. In cases such as these, the judge or magistrate sets a bail amount to be paid by the arrestee. Here, the assumption is that the individual will opt to return to court rather than to forfeit the money or collateral posted to obtain release before his trial (Ryan 1967). Secured bonds, in fact, are one of the most widely used mechanisms of pretrial release in the United States. A report provided by the Bureau of Justice Statistics (BJS) indicates that of those released between 1997 and 2004, 48 % of felony defendants in state courts were released through secured bail, including surety, deposit, and collateral bonds. The remaining 52 % were released without the requirement of financial conditions (e.g., release on own recognizance, conditional release, unsecured bond) (Cohen and Reaves 2007). While the extensive use of secured bonds in the United States is contrary to how bail systems operate in other countries, such as England (Bottomley 1968), Norway, Denmark, and Germany (Foote 1965), the exchange of money or property for pretrial release is not unique to the United States or to modern-day systems of bail. Court reports from medieval Elton, Huntingdonshire (England) suggest that many arrestees provided payments to their sureties, or pledges, in return for their services (Pimsler 1977). Moreover, countries like England and Canada may impose financial conditions of bail in certain cases. The United States, however, is particularly exceptional in terms of its use of commercial bail bonds (Devine 1991), in which bail is secured through an arrangement between a professional bail bond agent and the arrestee for a fee – a development that reportedly occurred in the nineteenth century and has since become a standard of the American bail system.

This increasing reliance on secured bonds in the United States has raised a number of concerns, of which a majority has been voiced in the last century by individuals seeking bail reform. Critics suggest that the American bail system has strayed from the intended purpose delineated by the country's founders and has deviated from the criminal justice system's traditions of the presumption of innocence and equal protection under the law. Yet, despite its opponents, bail in this country continues to drift from its long-standing principles, whereas bail systems in other countries remain focused on nonfinancial factors and the use of personal sureties.

Early Origins of Bail

Bail is considered one of "the most ancient of Anglo-American criminal justice traditions" (Advisory Commission on Intergovernmental Relations [ACIR] 1983, p. 54). Its roots in Anglo-Saxon history serve as a common denominator that brings together the laws and systems of several countries, including England, the United States, and Canada (Metzmeier 1996). Although the precise origins of bail are unknown, many scholars concede that it originated at some point in medieval England. Some have traced it as far back as to the time of Charlemagne in the eighth century and the practice of hostageship. Hostageship was used as a tactic of war in which a person was held captive until the "principal" appeared. If he did not show up, the hostage suffered the fate intended for the principal ("Indemnification Contracts" 1949). DeHaas (1940), however, suggested that bail stems from Anglo-Saxon laws during the reigns of King Hlothaere and Eadric in the late seventh century. During this time, the accused had to pay a "bohr" to the victim's family; the money was returned, however, if he was found innocent of the crime. The use of this early form of pretrial release was not the consequence of forward-thinking sovereigns, but rather it stemmed from the realization that imprisonment was an expensive and problematic way to deal with accused criminals (Duker 1977). Others believed that the modern system of bail began in the ninth or tenth century due to the problems experienced in England's early criminal court system. At that time, the sheriff assumed primary responsibility for the detention of the suspect after the individual's arrest. It is likely that in some cases, the suspect had to stay in jail for considerable periods of time – even years – because of geographical issues and the judicial district assignments of the traveling judges ("Bail: An Ancient Practice" 1961). As such, the sheriff would allow the accused to pay a cash bail or utilize personal sureties in return for the suspect's promise to appear for trial, and, in some instances, he would release the accused on his own recognizance (Pollack and Maitland 1898).

The use of sureties, as noted previously, was reported to have existed some time before the Norman Conquest of 1066 in which individuals agreeing to be sureties were subjected to a formal contract of payment, in which the price was set at the value of a free man's life (Hazeltine 1910). Sureties were also used in the medieval practice of pledging. In this case, pledges were responsible for the assurance of other behaviors aside from appearance at trial, such as payment of court fines and repayment of a debt. Even still, it appears that the typical function of pledges was the equivalent of the modern-day bail bondsmen; in return for their services, it is likely that the pledgees paid their sureties (Pimsler 1977).

Generally, most writings on the history of bail attribute its modern-day traditions to the time of William I after the Norman Conquest. Prior to the thirteenth century, sureties were bound "body for body" by the court ("Indemnification Contracts" 1949). This meant that if the defendant did not appear at trial, the surety was then subjected to the punishment that would have been inflicted upon the suspect (e.g., enslavement or execution). In later years, however, this requisite was relaxed, such that the surety was responsible for a financial penalty if the accused did not appear in court, thus combining the older tradition of the responsibility of the surety with a different method to impose it (Pollack and Maitland 1898). Bail, therefore, developed into a formal bond by which the accused became the custody of the surety, and the surety promised to pay the penalty if the accused fled.

Statute of Westminster, 1275

Perhaps the most notable turning point in the evolution of modern-day bail was the Statute of Westminster in 1275. Prior to the thirteenth century, sheriffs had sovereign powers in the release or detention of accused individuals. Any dealings between the sheriff and the accused were not circumscribed by law. Consequently, they could use whatever factors they wanted in making this determination of pretrial release. The Statute of Westminster, therefore, endeavored to institute a standardized practice of bail. Yet, rather than providing a general schema to guide all decisions about bail, Parliament defined which crimes were bailable and which crimes were not subject to bail (Bottomley 1968). The statute also limited the authority of the sheriff by delineating under what conditions release was sanctioned. Interestingly, sheriffs' authority to determine bail amounts remained intact.

The provisions of the Statute of Westminster persisted for nearly five centuries thereafter. Although several statutes were passed between that time, they did not bring about any significant modifications to the fundamental principles of when or when not bail should be granted. Instead, the statutes subsequent to that of Westminster affected the processes and procedure underlying the granting of bail (Bottomley 1968). For instance, following the Statute of Westminster, a law was passed in 1487 due to issues in the release of nonbailable suspects. In response, Parliament required the use of two magistrates in bail granting proceedings. This law, however, did little in terms of correcting the problem, as it was realized that one judge was releasing suspects without the second judge's knowledge of the case. Therefore, in 1554, Parliament reaffirmed the previous statute's requirement but mandated that the bail decision be made in open session with both magistrates present and that the evidence considered in bail decisions be documented on paper.

Although these events document the historical use of bail, it is unlikely that bail was extensively utilized because pretrial detention itself was used infrequently (Pollack and Maitland 1898). As mentioned previously, imprisonment was an expensive and troublesome method of dealing with suspects, and to avoid responsibility of the accused, the sheriff would often entrust him to a friend or relative. Even when individuals were initially jailed, but could not produce the necessary surety, there is evidence that the accused was released. In short, there was a likely disconnect between what was written in law and what was actually practiced (Foote 1965).

Beginnings of Major Bail Reform in England

Although progress had been made in terms of bail reform, the restrictions placed upon sheriffs via the Statute of Westminster 1275 were not applicable to judges until the late 1600s in "Darnell's Case." In 1626, King Charles I sought and failed to obtain money from Parliament, thereby demanding loans from his subjects. After refusing to provide him with funding, numerous individuals were imprisoned without notification of the charges by the King. Of these, five knights responded by filing a *habeas corpus* petition, claiming that their imprisonment was unlawful and violated not only their right to bail but also their right to trial. Citing "sovereign prerogative," the court upheld the King's decision (Duker 1977). Darnell's Case, consequently, served as the impetus for the Petition of Rights later passed by Parliament in 1628. The Petition acknowledged the rights guaranteed under the Magna Carta and attempted to provide assurances that individuals could not be imprisoned without due process of law nor could they be detained before trial without being informed of the specific charges. Despite Parliament's efforts, problems persisted, eventually leading to the passage of the Habeas Corpus Act of 1679. The act was intended to protect an individual from unlawful detention; it did not, however, address the issue of excessive bail. Thus, judges were using undue financial conditions of release to detain individuals for indefinite periods of time. As a result, Parliament enacted the English Bill of Rights of 1689, famously mandating that "excessive bail ought not to be required." Together, the Petition of Rights, Habeas Corpus Act, and the English Bill of Rights formed the modern-day safeguards against pretrial imprisonment (Foote 1965). These concepts were later translated into American colonial law and eventually adopted by the Founding Fathers in the United States Constitution.

Bail in Colonial and Early America

English bail laws of the seventeenth century were considered "important matrices" that greatly informed subsequent American criminal law and procedures (Foote 1965, p. 973). As such, it is hardly surprising to find that the issue of bail was not one of contention at the time of the American Revolution. In fact, the prohibition of pretrial imprisonment was already in place in several colonies even before the English Bill of Rights. Massachusetts, for example, had enacted the state's Body of Liberties in 1641, considered by Foote (1965) as a "major benchmark in American bail history" (p. 975). This statute was the first in colonial America to delineate a number of individual rights and liberties, many of which were later referenced in the US Bill of Rights. Regarding bail and pretrial detention, the Body of Liberties states that an individual should not be detained by a judge "before the law hath sentenced him thereto, if he can put in sufficient security, bail, or mainprise, for his appearance and good behavior in the meantime, unless it be in capital crimes...." Therefore, unlike in England, where the Statute of Westminster determined which crimes were bailable, this statute provided the right to bail to all individuals not accused of capital crimes.

The value of liberty and the presumption of innocence in early America were evident not only through the Massachusetts Body of Liberties but also through the Frame of Government of Pennsylvania and the New York Charter of Liberties and Privileges of 1682 and 1683, respectively. The Pennsylvania law, in particular, had a major impact in later years as it reemerged in North Carolina in the late eighteenth century and largely found its way into many state constitutions in subsequent decades. This law was particularly important given its advisement of the right to bail in all noncapital cases (Foote 1965). Pennsylvania's Frame of Government also was the archetype for the bail provisions delineated in the Northwest Ordinance of 1787. With only slight modifications in verbiage, the ordinance stated, "All persons shall be bailable, unless for capital offenses, where the proof shall be evident, or the presumption great." By 1789, the absolute right to bail movement was well under way (Foote 1965), and by 1850, most state constitutions included the right to bail (Metzmeier 1996).

The significance of early English and American colonial law is observable not only in state constitutions but also in the US Constitution. Interestingly, the federal provisions of bail were addressed in "separate legislative packages" in 1789 (Foote 1965, p. 971). Following the English Bill of Rights and the Virginia Declaration of Rights in 1776, the excessive bail clause prohibiting high bail amounts was proposed as a part of the Eighth Amendment of the Constitution, whereas the right to bail was addressed in Section 33 of the Judiciary Act. The Eighth Amendment references only the use of excessive bail amounts and the prohibition thereof; it does not, however, grant an absolute right to bail in all cases nor does it define which crimes are bailable. In Foote's (1965) extensive analysis of the historical context of bail, he concluded that this omission was accidental and one that went unnoticed by Congress. Nevertheless, the Judiciary Act accounted for the omissions in the Constitution regarding bail. Specifically, the act established which offenses were nonbailable (e.g., capital crimes). In capital cases, judges were left to determine whether the suspect must be detained prior to his trial. Through the act, Congress also limited judicial discretion in setting bail. These collective efforts of the first Congress remained largely intact for nearly 150 years thereafter.

Bail in the Nineteenth and Early Twentieth Centuries

Though major developments occurred in eighteenth-century America in terms of bail reform, little changed occurred to the bail laws in England after the Bill of Rights of 1689, that is, until 1826. At this time, a law was enacted that mandated the right to bail in cases where the likelihood of the suspect's guilt is slight, but that bail should be avoided in cases where the probability of guilt is significant. Only 9 years later, this statute was repealed in place of a new law that granted bail for any crime, regardless of the presumption of guilt. This change in statute was particularly important because it reduced bail decisions to the sole determination of risk of nonappearance (Bottomley 1968). The court in *R. v. Robinson* (1854) not only substantiated this purpose of bail but also provided a guideline from which determinations of pretrial flight risk could be made. This included three questions that pertained to the nature of the offense, the likelihood of conviction, and the punishment that would be required if convicted. The "Robinson factors" were used in making bail release decisions until bail reform efforts in 1976 (Metzmeier 1996). The nature of the offense was also determined to be an important factor in bail decisions through the ruling in *United States v. Lawrence* (1835). In this case, the Supreme Court contended that the judge should consider the seriousness of the offense and the accused's ability to post bail. This statement of the court also reveals two other important elements: judicial discretion in bail decision making and consideration of the individual's capacity to obtain bail.

The Emergence and Proliferation of Commercial Bail

Before the nineteenth century, bail in both the United States and England was obtained primarily through the use of sureties with lesser concerns about cash bail. In England, personal relationships were considered to be of great importance in assuring the appearance of the suspect ("Indemnification Contracts" 1949). In the United States, however, cash bail later became the primary means of obtaining release. It is likely that several events converged to bring about the extensive use of this type of bail. First, the social context of that time had changed. Urbanization and the mobility of the population increased, thereby leading to a weakening of community ties. The American frontier presented issues as well. Personal sureties were not easy to come by for a suspect in a new location with few acquaintances and people willing to become sureties (Ryan 1967). Furthermore, it is likely that the expansive and transitory aspects of the frontier provided an incentive to flee, especially if the likelihood of conviction was great ("Bail: An Ancient Practice" 1961). Overall, the old surety system in the United States was rendered impractical for a mobile population. Collectively, these factors, therefore, gave rise to the role of the commercial bail bondsman as an alternative to the personal surety.

In general, commercial bail is an arrangement between a bail bondsman and the accused. For a fee, usually between 5 % and 10 % of the bail amount, the bondsman acts as a surety on behalf of the accused. In theory, if the suspect fails to appear, the bondsman forfeits the bail amount required by the court. Eventually this type of bail all but replaced alternative forms of bail (e.g., surety bond and release on recognizance), such that even well-connected individuals were being released in this manner (Ozanne et al. 1980). The prevalence of money bail and the bondsman were further realized after insurance companies began to serve as underwriters to the bondsmen ("Bail: An Ancient Practice" 1961). The changing climate of the bail system was noted by Justice Holmes in *Leary v. United States* (1912) who stated, "The distinction between bail and suretyship is pretty nearly forgotten. The interest to produce the body of the principle in court is impersonal and wholly pecuniary."

Not long after its inception, the commercial bail bond system was the subject of numerous accusations, including collusion, bribery of public servants, and conducting illegal business (Paulsen 1966). Moreover, some individuals grew concerned over the power and authority readily bestowed upon bondsmen. Although the judge sets the bail amount, often times it is the bondsman who ultimately makes the release decision. In other words, he decides whether or not he will "act as surety" for those considered a good risk (i.e., individuals who are able to pay the requisite fee); thus, those who cannot pay the fee remain in jail (Paulsen 1966, p. 115). Given the power of the bondsman, therefore, it is argued that suspects can effectively thwart the purpose of bail (Ozanne et al. 1980). Additionally, the commercial bail bond system was criticized for its ineffectiveness in ensuring that the accused was returned to court. Even though it would appear to be in the best interests of the bondsman to ensure his client's appearance as a means to avoid forfeiture of the bail amount, it was found that in some cases, the court waived the bondsman's forfeiture or even refunded a portion of the forfeited amount. In these instances, the court claimed that the bondsman used "reasonable diligence" in his efforts to produce the suspect ("Bail: An Ancient Practice" 1961, p. 968). Yet, in spite of the numerous complaints of the commercial bail bond system, this system's use was substantiated in *Nicholls v. Ingersoll* (1810) and *Taylor v. Taintor* (1873) in which the powers of the bail bond agent and bounty hunters were delineated by the court.

Inequities of Bail

As the reliance on money bail began to take shape, injustices throughout the bail system also began to emerge. Indigent defendants, in particular, were perhaps hardest hit – oftentimes detained before trial for periods of time that likely would have exceeded their imposed sentence had they been convicted (Metzmeier 1996). Three early studies on bail exposed the inequity in the bail system, demonstrating that bail decisions were based more often on financial means as opposed to the individual's risk of flight. Consequently, poorer individuals were more likely to be detained than wealthier individuals (see Beeley 1927; Foote 1954; "A Study of the Administration of Bail" 1958). Paulsen (1966) later described the bail system in the United States as "a costly failure, pressing hardest on the poor" (p. 125).

Bail Reform in the 1960s

Prior to the 1960s, several scholars had already begun to question the efficacy and fairness of the bail system in the United States. In the 1920s, Pound and Frankfurter (1922) protested the use of commercial bail bonding, arguing against its tendency "to prostitute the administration of justice in the inferior courts" (p. 292). Yet, the use of commercial bonds persisted. Shortly thereafter, Beeley's (1927) study of bail in Chicago revealed the extensive use of surety bail as well as a number of problematic issues, particularly in terms of bail decision making – which often excluded financial and social factors. In their place, judges were making decisions based on the nature of the crime. This study also shed light on bail-setting amounts, which appeared to be largely indiscriminate. Follow-up investigations into the bail system were conducted in Philadelphia and New York in the mid- to late 1950s. Researchers found similar results to the Chicago study, despite these studies taking place decades later. Moreover, they observed differences in the outcomes between pretrial detainees and individuals who were able to obtain release. Specifically, they found that pretrial detainees were more likely to be found guilty compared to those released on bail; in addition, they were less likely to receive lighter sentences, such as probation or a suspended sentence (see Foote 1954; "A Study of the Administration of Bail" 1958).

Despite these findings, little change occurred. Friedman (1976) suggested that the lack of change was due partly to the nonexistence of major research organizations working as part of a coordinated criminal justice system; thus, there was no central agent or organization to put together a plan of action or to effectively lobby for change. Equally problematic was the "wholly passive role" of the courts regarding bail despite the mounting evidence of the system's inequities (Foote 1965, p. 959). However, in the Supreme Court case of *Stack v. Boyle* (1951), Justice Jackson addressed this issue, stating that "the spirit of the procedure is to enable them to stay out of jail until a trial has found them guilty." Further, he wrote, "In allowance of bail, the duty of the judge is to reduce the risk by fixing an amount reasonably calculated to hold the accused available for trial and its consequence."

Nevertheless, it was perhaps due to the changing social climate in the 1960s that a concerted effort toward bail reform began to emerge. During this time, scholars, particularly those in the legal realm, grew skeptical of the bail system (Kennedy 1980). Not only were they concerned with the prevalence of money bail and the role of the bondsman, they also voiced concerns in regard to the seemingly disparate applications of bail and the detrimental effects of pretrial detention upon the indigent (e.g., the individual's loss of freedom, loss of job, and inability to help with his defense). Although bail was originally intended to serve as a means of release, it was argued that the bail system worked in such a manner that it proved more effective in detaining suspects rather than in freeing them (Foote 1965). The reality was that many bail decisions were based on an incomplete, if not absent, assessment of the defendant, despite claims that the following factors be considered in the bail decision making process: a person's ties to the community, likelihood of guilt, and financial ability to post bail. Instead, these decisions were frequently based on the nature of the offense. Consequently, a significant number of individuals were detained before trial regardless of their risk of flight.

The reality of this situation served as the impetus for the Vera Foundation and the Manhattan Bail Project and the emergence of pretrial service agencies in the 1970s. The Vera Foundation and the Manhattan Bail Project, specifically, were intended to address the issue of pretrial detention of impoverished defendants in New York City (Friedman 1976) but eventually inspired the major bail reforms that occurred during this decade. At a cocktail party in 1960, Louis Schweitzer – a chemical engineer and businessman – was surprised when he discovered that thousands of people in New York City were imprisoned before they had even gone to trial. After a tour of the jail facilities in the city and discussions with key players about jailed suspects who could not afford to post bail, Schweitzer offered his friend, Herbert Sturz, the task of developing a strategic plan (Friedman 1976). Thus, the Vera Foundation was created in 1961, followed shortly that same year by the commencement of the Manhattan Bail Project. Underlying this project was the assumption that nonfinancial factors were an effective alternative to money bail in terms of deterring the accused from flight (Ryan 1967). Therefore, the Vera Foundation, along with assistance from New York University law students, implemented one of the first control group experiments conducted in an American court. The Manhattan Bail Project was devised to first gather information about the individual's background and community ties from the accused and, second, to provide the judge with recommendations as to who would be a good candidate for release on personal recognizance. By the study's end in 1964, the court had granted release on personal recognizance to 60 % of the defendants recommended by the Vera Foundation. Only 1 percent of these defendants failed to appear.

The success of the Manhattan Bail Project sparked national interest and prompted a number of subsequent bail projects in other cities across the country. In light of the study's findings, Attorney General Robert Kennedy formed the Allen Committee to serve as an advisory board to the United States Department of Justice. In 1963, the Allen Committee published a report, recommending that the federal system broadens its use of release on personal recognizance. Yet, the report failed to include decision making guidelines addressing who should be released in this manner (Friedman 1976). Later that same year, efforts were made to conduct the first National Conference on Bail and Criminal Justice. Attended by over 400 policymakers, criminal justice officials, attorneys, and practitioners in May 1964, the conference focused on specific alternatives to money bail, keeping in mind the findings from the Manhattan Bail Project. According to Friedman (1976), there was a significant correlation between the conference and the rate at which other bail agencies grew. After the bail study in New York, 89 bail projects had been implemented.

The impact of the Manhattan Bail Project also spreads to other countries, including Canada and England. Inspired by the project, Canadian reformer Martin Friedland took to task the study of bail in Toronto's court system. Additionally, reform efforts in England eventually led to the Bail Act of 1976 (Metzmeier 1996). In the United States, Congress enacted its own bail reforms through the Bail Reform Act of 1966. This act reaffirmed what had been addressed in previous statutes but went a step further to "order" that the accused in a noncapital case be released under minimal conditions (e.g., personal recognizance or personal bond) unless it was decided by the judge that either method would be insufficient in guaranteeing the accused's return appearance. The statute also advised against the consideration of community safety in noncapital cases. Instead, this element should only be considered in capital cases or after the individual has been convicted.

Additional Reform Efforts

Although not as popular, the Manhattan Summons Project borrowed largely from its predecessor. This study, however, focused on an earlier stage in the process, particularly at the stage of arrest. In this case, release was to be determined by the police. The Summons Project commenced in the spring of 1964 at the New York City Police Department's 14th precinct. The study was designed in such a way that an individual arrested for a summonable offense was first interviewed by a member of the research team. Information, similar to that of the bail study, was collected and verified, and then recommendations were made to the precinct's desk officer. It was recommended that either a summons be issued (with instructions to appear in court 14 days later) or that the individual proceeds through the traditional criminal justice process (i.e., arraignment). The results of the three-month study were so successful that the project was eventually expanded to three precincts and then expanded to all of Manhattan. In the first 2 years of the project, over 36,000 summons were issued. Of those, only 5.3 % of the individuals who received a summons failed to appear in court (Friedman 1976).

Additional efforts to reform the bail system were undertaken in Illinois. In 1963, Illinois enacted the state's Ten Percent Deposit Plan as an alternative to financial surety bonds. Rather than going through a third party to gain release, individuals pay ten percent of the bond amount to the court, thus eliminating the need for bond agencies. The Illinois Code of Criminal Procedure was also amended to emphasize that criminal sanctions, rather than financial penalties, be used to guarantee a suspect's appearance (Paulsen 1966). Since that time, three other states have followed suit and eliminated commercial bonding (e.g., Kentucky, Oregon, and Wisconsin); others have experimented with similar deposit bail systems, such as in Massachusetts.

Setbacks in Bail Reform

While strides were being made in terms of bail reform to (1) reduce the reliance on money bail and (2) make bail decisions based only on flight risk, other events were taking place that contradicted these reforms. In *Hinton v. United States* (1965), for example, the court provided justification for the use of money bail, stating that "it has been the Court's experience that indigent defendants are often in the community on bond, having obtained the means therefor [sic] from family or friends." The court further argued that the bond provided by the suspect's kinship served as a deterrent to flight because the accused has an "obligation" to those ties as well as to the court.

Setbacks were also experienced in 1969, with efforts to amend the Bail Reform Act of 1966. Despite observations by the 1967 President's Commission on Law Enforcement and Administration of Justice that too many people were being detained and that release decisions were not based on fact, the United States Department of Justice submitted a proposal to Congress to amend the Bail Reform Act of 1966. The proposal recommend that federal courts be permitted to detain suspects for up to 60 days, particularly individuals accused of certain violent crimes and those who are deemed dangers to the community despite the strictest conditions of release imposed. Furthermore, for individuals not subjected to this provision, it was recommended that the court be allowed to consider the suspect's dangerousness to the community when making decisions regarding pretrial release conditions (Mitchell 1969).

The proposal by the Department of Justice was only one of many attempts in 1969 to amend the 1966 Bail Reform Act to include a provision of preventive detention. None of these bills were passed by Congress (Kennedy 1980). However, growing concern was being voiced regarding the possibility of dangerous suspects being released into the community under the act. Congress, in turn, allowed for the inclusion of a preventive detention provision in the District of Columbia Court Reform and Criminal Procedure Act of 1970. Suspects meeting any of the three criteria for pretrial detention were subject to a pretrial detention hearing. At the hearing, the judge must make a determination that no release conditions will "reasonably ensure" the community's safety. He must also find that there is a significant likelihood of the suspect's guilt. Finally, if pretrial detention is imposed, the case must be tried within 60 days.

The "Get Tough" Movement in the 1980s

Despite the bail reform efforts in the 1960s, the 1980s "get tough" movement in crime control stalled its progress. This time was marked by increased crime rates and the public's diminishing confidence in the justice system's rehabilitative model. As a result, policymakers and criminal justice officials responded with a number of sentencing reforms and statutes in an effort to curb the crime problem. The bail system did not remain unaffected for long, however. Members of Congress grew concerned about the possibility that suspected felons out on bail were committing crimes. Additionally, they recognized that judges were setting high bail amounts and imposing excessive conditions of bail for individuals they believed were dangerous (Metzmeier 1996). In light of these events, Congress repealed the Bail Reform Act of 1966 through the passage of the Bail Reform Act of 1984 – a statute that allowed for the consideration of the accused's perceived dangerousness to the community and permitted preventive detention. Critics argued that a preventive detention provision, such as the one in the Act of 1984, "pits the fundamental common law principle of the presumption of innocence against the desire by police and judges to protect the public from purportedly dangerous defendants" (Metzmeier 1996, p. 399–400). In addition, some scholars believed that it violates the suspect's constitutional rights and undermines a system based on the presumption of innocence. Finally, others recognized the issues preventive detention poses because of the difficulty in predicting who will endanger the community (Kennedy 1980). Nevertheless, in *United States v. Salerno* (1987), the Supreme Court upheld the statute, claiming that "Congress formulated the detention provisions not as punishment for dangerous individuals, but as a potential solution to the pressing societal problem of crimes committed by persons on release." Therefore, they believed that this was a "legitimate regulatory goal."

Criminology's Increasing Role in the Study of Bail

Up until the 1980s, a majority of the literature on bail in the United States was generated and advanced by legal scholars. Legal scholars played a particularly active role in the discussions on bail reform due to the constitutional issues surrounding the bail system. In the 1980s, however, more criminologists began to conduct studies akin to the research carried out decades before in the early part of the twentieth century. Of interest were the factors related to bail release decisions, risk of flight, and the outcomes of pretrial detention (e.g., conviction). One such study found that due to the timing of bail hearings, which oftentimes occur shortly after arrest, judges are not equipped with sufficient information on which to base their decisions. Consequently, there are many inaccuracies in predicting which subjects will commit crimes during their pretrial release (Gottfredson and Gottfredson 1988). In the examination of the factors related to release, some researchers found that the offense charge and type of counsel affected the likelihood of a suspect's release (e.g., Fleming 1982; Holmes et al. 1987). Although the study of bail is an area that has remained relatively underresearched since that time, the role of the criminologist has increased in subsequent decades.

Bail in the Present Day and Future Trends

Goldkamp (1993) contended that the American bail system has experienced at least two generations of major bail reform in the United States. The first generation occurred in the 1960s, as substantial efforts were made to move the system toward bail processes that emphasized pretrial release through nonfinancial factors. This generation was followed by major bail reform efforts in the 1980s, which in many ways, propagated the principles of bail that reformers of the 1960s were attempting to eliminate. Nevertheless, both generations of reform were marked by conflicting ideas as to what should be the underlying purposes and functions of the bail system specifically, the presumption of innocence versus community safety – a conflict that has pervaded the American criminal justice system as a whole.

The conflicts and issues of the American bail system in the past continue to persist today. More specifically, dissension remains as to the factors weighted in bail decisions and the types of bail that are utilized. Regardless, the current trend in the bail system is one that has reverted back to a reliance on surety bonds provided by a bail bondsman and a system that still considers community safety as an important requisite for release. The former is reflected in national-level statistics of felony defendant pretrial releases in state court which indicate that approximately 33 % of the releases between 1990 and 2004 were obtained through surety bonds (Cohen and Reaves 2007) and that this trend has continued upward through 2006 (Cohen and Kyckelhahn 2010). Drawing from data collected by the Bureau of Justice Statistics (BJS), Clark (2010) suggested that the increased use of money bail is inversely related to the reduction of individuals on pretrial release. In fact, the number of pretrial detainees in jail has been on the rise since 1998, thereby further contributing to the jail crowding problem. The latter is manifested in statutes such as the 2001 Anti-Terrorism Act and the 2002 Patriot Act. Both statutes have extended the crimes for which pretrial detention is applicable in the federal system. In addition, most states have amended their laws to reflect the consideration of public safety in the decision to grant bail.

The present state of the bail system in the United States, therefore, has sparked the attention of politicians, scholars, lobbyists, and the public once again, with staunch proponents on both sides of the bail issue, including efforts by some to privatize the system. Lobbying groups, such as the American Legislative Exchange Council, are increasing their efforts to further privatize the criminal justice system through a post-conviction release strategy that mimics the commercial bail in pretrial release. Other groups, such as the American Bar Association and the Pretrial Justice Institute, however, continue to urge that the bail system should impose the least restrictive conditions and rely on personal recognizance and other nonfinancial forms of bail (e.g., conditional releases and unsecured bonds). Interestingly, there remains a lack of empirical research as to which approach works best in terms of appearance rates and cost-effectiveness. Even still, it has been suggested that a third generation of the bail system is underway (Schnacke et al. 2011), concerned primarily with the use of empirically based screening tools in making pretrial release decisions and evidence-based decision making in release decisions through the use of pretrial service agencies. Assessments of some pretrial screening tools have already produced positive results (e.g., Lowenkamp et al. 2008). However, such initiatives remain arguably highly nuanced compared to the more common and generalized commercial bond practice. In fact, one rather robust empirical study found that defendants from 75 of the largest counties in the USA who were release via a surety bond (bail bondsman) were considerably less likely to fail to appear in court (28 % less likely) compared to similar defendants released on personal recognizance (Helland and Tabarrok 2004). Further, absconders released via a bondsman were 53 % to be at large for long periods of time compared to absconders released on personal recognizance. Moreover, national efforts reminiscent of those in the 1960s, including the National Symposium on Pretrial Justice, have taken place as recently as 2011 with the intent to further advance America's system of bail. Whatever the course, the objective remains clear – finding the balance between community safety and minding the long-standing constitutional presumption of innocence. In the end, there is a paucity of quality research on "what works" in regard to pretrial release practices. Few quantitative studies are generalizable to the criminal justice system as a whole, and scholars have only recently begun to such important questions with solid criminal justice data and advanced empirical research designs. Qualitative inquiries into the issue are altogether absent from the scholarly literature surrounding bail release in the United States.

History of Boot Camps

Ojmarrh Mitchell

Boot camps; Shock incarceration; Intermediate sanctions

Overview

Correctional boot camps are programs modeled after military basic training. Just like basic training, boot camps emphasize drill and ceremony, and physical activity. Generally, boot camps target young, nonviolent offenders with limited criminal history. Boot camps are almost always short-term programs lasting 90–180 days. Inmates who successfully complete these programs are released under supervision back to the community; however, inmates who drop out or are dismissed from the boot camps often are required to serve longer terms of incarceration in traditional correctional facilities.

Correctional boot camps in the United States emerged, proliferated, and receded with remarkable speed. In the early 1980s, boot camps emerged in two states. Soon thereafter, boot camps became a national phenomenon with at least one boot camp operating in the majority of states by the mid-1990s. Near their peak popularity, the boot camp bubble burst and their popularity plummeted in the new millennium. Thus, in a span of a little more than 25 years, boot camps went from programs in a few states to being widespread back to obscurity. All the while, boot camps remained controversial.

This entry traces the history of the rise, fall, and controversies of boot camps in the United States. In short, while many factors fueled the rise of boot camps, undeniably boot camps' growth was driven by growing correctional populations and boot camps' fit with prevailing political sensibilities. Conversely, their demise was driven by a combination of research inconsistent with the goals of boot camp and prominent cases of abuse. These factors served to erode boot camps' political support. In all of this, there is a larger cautionary tale that warns against latching on to the latest criminal justice fad without some reasonably rigorous empirical support for that intervention.

The Boot Camp Model

The term "correctional boot camp" is a generic term referring to various correctional programs that utilize a militaristic style and atmosphere. Boot camps programs are sometimes called "shock incarceration" programs, "leadership camps," "accountability programs," and so forth. While program names may vary, the military style that is at the core of each makes them a boot camp.

The environment of boot camps resembles military basic training. Inmates typically live in barrack-style housing, are dressed in military uniforms, and are supervised by correctional officers with military titles (e.g., drill sergeant, corporal, captain). Inmates ("cadets") refer to correctional staff as “sir” or “ma’am.” Cadets enter the boot camp in groups called “platoons.” Each platoon lives and works together as a group throughout the period of confinement.

The daily routine at a boot camp is filled with planned activities and idle time is rare. Cadets are required to wake early, typically 5 am. They dress quickly and then march to an exercise area. There, they engage in strenuous physical exercise (“physical therapy”) and perform military drill and ceremony. After an hour or two of physical therapy and drills, boot camp cadets march to a dining area for breakfast. Breakfast and all meals are orderly ceremonies. Cadets stand with their meals in hand until commanded to sit. Meals are eaten quickly and with minimal conversation. Generally, when breakfast is complete, cadets either attend school or leave the camp to engage in community service such as road cleanup. Afterwards, cadets are required to complete more physical therapy and military drills.

Cadets progress through three or more stages. Program activities vary by stage and there is usually decreasing emphasis on physical therapy and increasing emphasis on performing manual labor, work in the community (e.g., road cleanup), and treatment activities. The total length of stay in a boot camp is 90–180 days but can be extended by misbehavior that causes an inmate to repeat a stage.

At all times, boot camps require inmates to adhere to a strict code of conduct. Deviations from these rules are met with verbal reprimands, punishments involving physical exercises (e.g., push-ups), or the removal of privileges. Serious cases of misbehavior can result in an inmate being required to repeat a stage, and continued serious misbehavior can lead to expulsion from the program. Those expelled are usually placed in other correctional facilities and required to serve longer periods of incarceration. Conversely, those who complete boot camp programming are honored at a formal graduation ceremony which family members are encouraged to attend.

Those eligible for boot camp programs are almost always young and most often nonviolent offenders. Because of the physically demanding nature of boot camps, inmates are required to be youthful; thus, boot camp inmates are juveniles or young adults (typically, less than 30 years old, and very rarely more than 35 years old). Further, those eligible for boot camp participation are required to complete health screenings to ensure that they are capable of engaging in taxing physical activities.

Outside of this military atmosphere, boot camps vary widely. Some programs have little to no time allotted for treatment activities, while others devote considerable portions of the day to these activities. Some programs require offenders to volunteer for the programs; others allow judges and/or corrections officials to mandate boot camp participation. Another important variation is in the manner and intensity of post-release community supervision; some programs offer offenders limited community supervision, while other boot camp programs offer intensive supervision.

It is also important to note that boot camp programs appeared to evolve over time towards a rehabilitative focus. Early boot camps heavily emphasized military training. Later boot camps still kept the military model as a core component; however, these later programs included high levels of rehabilitative programming, especially drug treatment (Gransky et al. 1995).

Above and beyond these programmatic differences, at its core, the boot camp model is premised on the notion that an austere correctional environment combined with military style training will reduce crime through two mechanisms. First, the boot camps’ harsh environments deter crime by showing young, nonviolent offenders that crime is met with strict punishment. Second, boot camps instill discipline in program participants, which presumably is lacking, and this self-discipline allows participants to resist criminal temptations in the future.

The Rise of Boot Camps

Modern correctional boot camps emerged in the early 1980s. Boot camps, however, have clear predecessors. Perhaps, the earliest forerunner is New York’s Elmira Reformatory, which implemented military training in 1888 under

Zebulon Brockway's leadership. This militaristic approach was adopted in an effort to instill discipline and to keep inmates active – the same goals as modern boot camps. The latter goal was particularly important at the time, as recent legislation restricted the use of inmate labor for commercial purposes, which had been the norm. This military atmosphere remained in place at Elmira until 1920 (Anderson et al. 1999). Thereafter, the "rehabilitative ideal" reached its peak popularity and the military training used at Elmira was adopted only sporadically at other correctional institutions until the 1980s.

Military training was most systematically and thoroughly implemented in the modern boot camps that emerged in the early 1980s. Oklahoma opened the first correctional boot camp in 1983. Later in the same year, Georgia opened a boot camp at the Dodge Correctional Institution. Thereafter, boot camps spread rapidly across the United States. By 1993, just 10 years after their emergence, 59 camps were in operation in 29 states. In 1995, this number expanded to 75 state-operated boot camps for adults and 30 more for juveniles were in operation, as well as another 18 adult boot camps operating in county jails. Boot camps even spread to the federal correctional system, where three correctional boot camps were in operation. These numbers surely underestimate the actual number of boot camps in operation, as many boot camps, especially those for juveniles, were privately run. Thus, at one point before the turn of the new millennium, the majority of states, the federal system, and some counties had at least one boot camp in operation.

This explosive growth in boot camp programs was driven by many factors but three factors appear most important. The first of these factors is the dramatic growth of correctional populations. Correctional populations increased rapidly in the 1980s and 1990s, which caused overcrowding in many prisons and jails. Some of the offenders caught in this tidal wave of offenders were marginal who were deemed too serious for standard probation but too minor for prison. Boot camps, along with other "intermediate sanctions" (i.e., correctional sanctions in between standard probation and prison), provided courts with options suitable for these marginally serious offenders.

A second factor driving the popularity of boot camps was their purported ability to simultaneously reduce prison populations and costs, while reducing recidivism. As discussed above, boot camps involved short-term confinement. Proponents argued that these short periods of confinement were less costly than prison sentences, and consequently, boot camps would reduce prison costs and prison populations. Further, the harsh environment of boot camps were touted as effective in reducing recidivism via specific deterrence and perhaps more broadly via general deterrence. Thus, boot camps were advertised to be lower cost and more effective than traditional prisons.

The third, and perhaps most important, factor was that boot camps were a perfect fit to the "get tough on crime" political sensibilities of the time. In this era, increasingly policy-makers rejected correctional interventions based on "soft on crime" rehabilitative approaches and instead asserted the effectiveness and appropriateness of punitive sanctions based on just deserts, deterrence, and incapacitation. Policy-makers recognized boot camps' fit to this new correctional paradigm and responded by allocating millions of dollars for boot camps. Specifically, Congress in the Violent Crime Control and Law Enforcement Act of 1994 allocated $24.5 million for boot camps, and this money was used to fund 44 grants for boot camp planning and construction in 1995. This allocation was relatively small in monetary terms, but it served as an important, symbolic endorsement of the boot camp model.

Controversies

While boot camps became popular in the mid- to late 1990s, they were not without controversy. Proponents touted the utility of boot camps as intermediate sanctions, as well as their effectiveness in reducing recidivism, prison populations, and prison costs. These claims proved controversial as empirical research addressing these issues was in its infancy prior to the period of boot camp growth.

Most fundamentally, critics contended that because boot camps did not address the underlying individual and contextual risk factors for criminal behavior, such programs would be ineffective. According to these critics, the boot camp model fails to address the known correlates and causes of offending and instead focuses on factors such as self-discipline and physical fitness, which are not strong correlates of offending. The gap between the attributes targeted by boot camps and the attributes known to predict criminal behavior is so vast that Latessa et al. (2002) offer boot camps as an example of "correctional quackery."

Further, given that history demonstrated most intermediate sanctions draw offenders from probation – not prison – boot camps were unlikely to reduce prison populations and costs. Other critics went a step further and argued that boot camps may actually be harmful. For example, Mathlas and Mathews (1991) argue that boot camps not only widen the net (i.e., lead to more offenders being incarcerated) but also the offenders drawn into boot camps are more likely to be ill-suited for these environments and, as a consequence, they are more likely to be harmed by the experience.

Still other critics contended that boot camps confrontational and unsupportive environments would cause damage to young offenders, especially offenders with histories of abuse. These critics predicted that youths with histories of abuse would have difficulty adjusting to the boot camp environment.

Likewise, Morash and Rucker (1990) argue that boot camps are abusive and dangerous environments. These authors provide one of the earliest, most critical, and, in some regards, most prescient critique of the boot camp model. They argue that boot camps are steeped in images of masculinity and power. These "ultramasculine" environments encourage aggression by staff and inmates, and thus boot camps are dangerous.

In short, few criminal justice-based interventions have been simultaneously as popular and as controversial as boot camps. These controversies stimulated research on boot camps and the popularity of these programs facilitated this research.

Analyzing the Controversy

Central to the disagreements between boot camp proponents and critics is the assumption that boot camps and traditional correctional facilities are vastly different. Thus, a fundamental issue concerns the similarity between these two kinds of correctional facilities. Research studying the environments of these facilities finds that boot camps and traditional facilities do in fact differ in many regards. The most prominent research comparing the environments of boot camps and traditional facilities is the work of Doris MacKenzie and colleagues (MacKenzie et al. 2001a). These authors surveyed juveniles and correctional staff at a large number of boot camps and traditional correctional facilities. These survey data revealed that both staff and juveniles indicated that boot camps are more structured/regimented and boot camps keep juveniles more active than traditional facilities. Interestingly, both staff and juveniles indicated that boot camp environments exhibited greater safety in regard to inmate-to-inmate aggressive behaviors but boot camps exhibited somewhat greater danger to juveniles from correctional staff. This latter finding is explained by the fact that boot camp correctional staff typically used more confrontational disciplinary practices such as verbal reprimands and physical therapy as punishment. These confrontational and sometimes aggressive disciplinary tactics, according to Lutze and Brody (1999), raise concerns about Eighth Amendment violations and make boot camps susceptible to civil, and perhaps criminal, litigation. The above findings are largely consistent with popular perceptions of boot camps and were largely confirmed in later research conducted in adult facilities.

The research, however, does not support certain popular perceptions about boot camps. Most notably, boot camps exhibit more rehabilitative programming than is typically assumed. In fact, research finds that boot camps have similar or greater amounts of rehabilitative programming as traditional correctional facilities. This finding contradicts the critique that boot camps will be ineffective because they fail to address the underlying risk factors for criminal behavior, as boot camps contain the same kinds and amounts of rehabilitative program as non-boot camp facilities.

Another important, but much less well-known, finding is that when asked about their perceptions of overall correctional experience, boot camp inmates reported more positive perceptions about their experiences than inmates in traditional facilities (Lutze 2001; MacKenzie et al. 2004). In other words, inmates confined to boot camps found their experiences less onerous than inmates confined in traditional facilities. Why this is so is unclear, but some portion of this finding appears to be related to the high activity levels found in boot camps. One of the negative aspects of correctional confinement is the sheer boredom of having lots of idle time. Boot camps solve this problem for inmates, and, therefore, instead of perceiving boot camps negatively, inmates actually preferred their experiences to those confined in traditional facilities! This finding undermines the notion that boot camp inmates will be deterred by the harshness of these facilities' correctional environments; in that, one would expect boot camp inmates to have more negative perceptions of their correctional experience in comparison to inmates confined in other institutions, if the boot camp environment were truly aversive.

Considerable research also has been given to describing and assessing offender adjustment to the environments of boot camps. These studies generally find that boot camp inmates adjust to the correctional environment as well or better than inmates in traditional facilities (Lutze 2001; MacKenzie and Shaw 1990). However, juveniles confined in boot camps with histories of abuse adjusted less favorably to these environments than similar kids in traditional facilities (MacKenzie et al. 2001b). Somewhat similarly, other research finds that inmates who perceive the boot camp environment as more masculine adjusted more poorly than other inmates. And almost universally, research finds that a substantial minority of offenders cannot either conform to boot camps' strict rules or handle the physical rigors, and as a result, they either drop out or are dismissed. These offenders tend to perceive the boot camp environment more negatively, have greater indicators of criminal tendency, and have lower self-efficacy than other participants. Thus, once again, the research fails to fully support the caricature of boot camps in that inmates typically adjust to their environments quickly – contrary to a common criticism of boot camps. However, there is a nontrivial minority of boot camp inmates for whom adjustment is difficult, if not impossible.

Without a doubt, the most controversial issue surrounding boot camps is whether or not they reduce recidivism. Boot camp proponents assert that boot camp inmates will have lower rates of recidivism than other inmates, whereas some boot camp critics contend that boot camp inmates will have higher rates of recidivism. Taken as a whole, the research supports neither of these claims. The research comparing recidivism rates of inmates confined at boot camps and other correctional institutions can be summarized accurately and succinctly with just two words: no difference. While there are a small number of evaluations that find statistically significant differences between these two groups' recidivism rates, the great majority of such evaluations find highly similar recidivism rates. In fact, a large and sophisticated meta-analytic review of boot camp evaluations found no statistically significant difference in the average recidivism rates from these evaluations (Wilson et al. 2005). This finding held regardless of the evaluations' methodological rigor and sample features (e.g., adult or juvenile sample). Interestingly, they found that boot camps that had greater emphasis on treatment or had an aftercare component did significantly better than their comparison groups. This conclusion was further supported by a recent evaluation by Kurlychek and Kempinen (2008) that found boot camp participants who received a mandatory aftercare component have significantly lower recidivism rates relative to the control group.

Despite the fact that boot camps in many jurisdictions were adopted at least in part to ease prison overcrowding and reduce costs, relatively few studies have addressed these issues. Most studies focuses on these issues conclude that boot camps have minimal effects on correctional populations and costs. This finding is attributable to the fact that most boot camp inmates appear to be drawn from probation, not prison populations. Further, a substantial proportion of boot camp inmates are expelled for noncompliance, and as a result, they are sent into the very incarcerative settings from which they were supposed to be diverted. As an example, the work of Parent is instructive (Parent et al. 1999). These authors analyzed prison populations from three jurisdictions. They found that even if boot camp participants are drawn from prison-bound offenders, boot camp graduates are given large reductions in sentence length, and few boot camp participants are kicked out of the program, cost savings are likely small. Thus, even in the ideal set of circumstances, boot camps save few prison resources.

Taken as a whole, the empirical research fails to fully support boot camp proponents or critics. Contrary to claims of proponents, boot camps do not lower correctional costs or prison populations, and boot camp inmates do not perceive their experiences as particularly aversive in comparison to inmates at other institutions. Contrary to the claims of boot camp critics, most inmates quickly adjust to boot camps, boot camps have as much or more treatment programming than traditional institutions, and boot camps do not experience greater inmate-to-inmate aggression than traditional institutions. Perhaps, if the controversies discussed above were the only factors affecting boot camps' popularity, these programs' popularity may have tapered off slowly or perhaps remained stable. Instead, however, the popularity of boot camps was dramatically altered by growing evidence and dramatic cases of staff-to-inmate abuse.

The Fall of Boot Camps

Between 1995 and 2000, the number of state-operated boot camps dropped by more than 25 % and the number of inmates confined in boot camps dropped 30 %. Thereafter, national figures do not exist, but it is clear that the number of boot camps continued to decline sharply in the new millennium.

Boot camps' popularity diminished rapidly in the face of three factors: (1) lack of empirical support for boot camps' effects on recidivism and prison costs, (2) numerous and prominent cases of inmate abuse, and (3) the erosion of their political support due to the above factors. The lack of empirical support for boot camps' claims of effectiveness in reducing recidivism and costs undermined their reason to exist. However, given policy-makers historical reluctance to modify criminal justice policy and practice in response to empirical research, it seems unlikely that boot camps would have fallen out of favor so rapidly if this were the only issue.

A more important factor leading to the abandonment of boot camps was the growing evidence of inmate abuse at the hands of boot camps' correctional staff. As a collective, boot camps were plagued by complaints of abuse. These complaints received media attention beginning in the late 1990s and continuing into the new millennium when several deaths of juveniles confined in boot camps occurred. In 1998, Nicholaus Contreraz died at a privately run boot camp in Arizona from an untreated infection in his lungs. Despite Contreraz's reports of feeling ill, correctional staff did not seek medical attention for him. Instead, correctional staff, believing that Contreraz was faking his illness, reportedly ridiculed him and made perform exercise as punishment. The infection in his lungs worsened and eventually led to his death. An investigation of this death revealed approximately 100 previous complaints about the facility. As a result of this investigation, the facility and several similar facilities in Arizona lost their licenses to operate and were closed in 1998.

Similar cases of abuse occurred in other boot camp facilities in the following years including the deaths of Gina Score, who died after a forced march in a juvenile boot camp located in South Dakota; Anthony Hayes, who died of dehydration in an Arizona juvenile boot camp; and Roberto Reyes, who died from an untreated case of rhabdomyolysis, probably caused by a spider bite.

In all of these cases, despite complaining of feeling ill, these juveniles were forced to perform physical exercise until they died. Further, the autopsies in many of these cases revealed widespread bruising – suggesting that these juveniles were beaten prior to death.

The videotaped case of Martin Lee Anderson's death at a juvenile boot camp in Florida is the most well-known and infamous case. Within hours of arriving, Anderson was forced to exercise including a run. When he complained of fatigue, he was physically forced to continue to run and denied medical treatment. Eventually, Anderson collapsed. He died one day after being admitted to the juvenile boot camp. The force used against Anderson was captured on video, which eventually became public and created a public outcry. Just as in the cases discussed above, there had been numerous complaints of abuse made against the boot camp. As a result of the public outcry concerning Anderson's death and the ensuing investigation, the Florida Legislature closed all of the state's juvenile boot camps.

The closure of Florida's juvenile boot camps is a sure sign of the third factor that leads to the demise of boot camps: eroding political support. Florida had once been the nation's leader in juvenile boot camps. Currently, Florida has none. Thus, even in a famously "tough on crime" state like Florida, boot camps are no longer a correctional option for juveniles (the state still operates at least one boot camp for youthful adults). This is just one prominent example of the eroding political support for boot camps. Another sign is the fact that no federal funds dedicated to the planning and implementation of boot camp have been made available after the mid-1990s. In fact, in 2007, Congress held a hearing concerning abuse at boot camps and other juvenile residential treatment facilities. This hearing and an accompanying GAO report detailed many cases of abuse at boot camps, and the witnesses featured in this hearing uniformly testified against the boot camp model. The overall message was clear: federal policy-makers no longer endorse boot camps and the boot camp model is obsolete.

Boot Camps: A Cautionary Tale in Criminal Justice Interventions

Boot camps burst onto the scene touted as effective interventions for offenders in the early 1980s. Their popularity was fueled by their fit to the political sensibilities of the era, and the Violent Crime Control Act of 1994 endorsed boot camps as worthy crime control programs by providing federal funds for these programs. All of this occurred without any reasonably sound empirical support for their effectiveness and safety. In short, politics trumped science.

The moral to the history of boot camps is obvious: proceed with caution. Policy-makers should not have invested millions of dollars in boot camps. Federal policy-makers should not have spurred state and local jurisdictions to develop boot camps. At the time, the effectiveness and safety boot camps were not established. Instead of proceeding with caution, policy-makers latched onto the latest criminal justice fad. A more reasonable approach would have been to fund and carefully evaluate a handful of boot camp demonstration projects before endorsing them by making funding available for such programs.

Given the history of corrections, the cautionary tale of the rise and fall of boot camps is likely to be forgotten. Likewise, the common sense advice of proceeding with caution in promoting and adopting correctional interventions is likely to go unheeded. As a consequence, the next criminal justice fad of the day is only a short series of serendipities away.

History of Corporal Punishment

G. Geltner
University of Amsterdam, Amsterdam,
The Netherlands

Synonyms

Flogging; Physical punishment

Overview

In the gallery of penal practices, corporal punishment, or the dispensing of bodily harm in response to or as a deterring measure against crime, occupies a stable position as a marker of cruelty, especially when condoned by a central authority such as a state. From Cesare Beccaria to Émile Durkheim to Max Weber, and especially under the more recent and diverse influences of social philosophers Norbert Elias and Michel Foucault, modern students of punishment have construed cultures that allow physical pain to be legitimately, let alone publicly, inflicted as out of step with the process of civilization and as retaining a relic of an unenlightened past. Corporal punishment, however, has a far more complex history than a long and steady fall from grace, an inverse trajectory as it were to the progress of humanity (Scott 1938; Yelyr 1941). For, fluctuations in frequency aside, the past uses of corporal punishment were never devoid of reason, at least in the sense that it was mostly meted out proportionately, gradually, and with a view to achieving social goals far beyond individual suffering, such as shaming and paving the way to an offender's reintegration. And, on the other, it is still used today: openly in certain milieus and surreptitiously in others, with some indications that it is nowhere near to being abolished. Indeed, some scholars have recently argued for an expansion of corporal punishment as a solution to the crisis of modern penology (Newman 1983; Moskos 2011).

Fundamentals

For the purposes of this discussion, corporal punishment will encompass the licit infliction of intentionally nonlethal bodily pain, temporary or lasting, including physical impairment or aesthetic alteration meant to reduce capacity and create social disability. So defined, and observed from a broad geographical and historical perspective, corporal punishment appears to be a common measure that, moreover, rarely serves as an exclusive penalty typifying any particular civilization, be it modern or premodern; usually, it was one option among several practiced in a given context, and different cultures made recourse to it in different judicial environments and with changing frequency and goals.

Antiquity

Corporal punishment, like most current penal measures, can be traced back to the earliest civilizations whose records have come down to us, such as the early law "code" of Ur-Namma, ruler of the Sumerian city of Ur (2112–2095 BCE) and founder of its third dynasty. This casuistic text addresses a host of cases, running the gamut from labor to civic to criminal law, and in doing so not only attests the degree of judicial sophistication attendant upon a complex society but also denies the ubiquity of ancient corporal punishment specifically and of physical *lex talionis* ("eye for an eye") in general. The vast majority of the text's 85 surviving promulgations prescribe monetary penalties or rewards, and a mere handful order the death penalty. On three occasions alone is the infliction of nonlethal physical harm considered meet: "If a man fractures another man's skull in a fistfight, they will flog him 180 times" (§22); "If a freedman beats a slave, they will whip him sixty times with a strap and sixty times with a belt" (§26); and "If a slave girl insults someone who is acting as her mistress they will rub her mouth with one *sila* of salt" (§30). To be sure, legal texts do not always convey penal realities, but at least at the normative level it appears that Ur-Namma's policies more often than not aimed at sparing the rod. Even in cases amenable to the employment of the *lex talionis*, monetary fines are often preferred. Thus, for instance, "[i]f a man breaks another man's nose with his fists, he will pay forty shekels of silver" (§19), and "[i]f a man causes the loss of another man's eye, he will pay thirty shekels" (§23).

Contrary to the common view that sees punishment as becoming physically milder over time, the subsequent and more famous and elaborate Laws of Hammurabi (*c.* 1780 BCE) illustrate a "reverse" trend of increased brutalization. Whereas physical and even capital punishments in Ur were scarcely decreed, in Babylonian law they become all but ubiquitous. Yet, rather than expressing a knee-jerk response to any and all violations, Babylonian prescripts for corporal punishment were undergirded by several distinct rationales, which would remain influential for centuries to come. The first was to target the "offending limb," an approach already underlying the fate of the misbehaved slave girl mentioned in the previous paragraph. Thus, if the son of a paramour or a prostitute disowns an adoptive parent, he would have his tongue cut off (§192); a nurse concealing the death of an infant by obtaining and suckling another child will have her breasts cut off (§194); a reckless surgeon would lose his hands (§218); and so forth (see also §§193, 195, 226, 253). A further model prescribed retaliations according to the injury inflicted ("classic" *lex talionis*), as when a man putting another man's eye out or breaking his bone or teeth would suffer the same fate (§§196, 197, 200). Last, offenders were to be maimed in body parts less immediately tied to their crime, but in ways that nonetheless branded them as offenders of a particular sort: a false accuser was to be marked on his brow (§127), and a slave disowning his master would have his ear cut off (§282), as would a slave striking the body of a freedman (§205). Beating, by comparison to these three penal modes, was uncommon in Babylonian law. Only on one occasion is it prescribed, namely, when a man strikes someone of a higher social rank, in which case he is to be publicly subjected to sixty blows "with an ox-whip" (§202).

In Ancient Egypt, by contrast, beating appears to have been less common as a form of summary justice already during the Early Kingdom (2686–2181 BCE), while a papyrus from the reign of the Pharaoh Thutmosis IV (late fourteenth century BCE) records the case of a soldier by the name of Mery who was subjected to 100 blows for false litigation. Here as elsewhere in the ancient Near East, time brought more rather than less frequent recourse to corporal punishment (VerSteeg 2002). A royal decree issued under Seti I (late thirteenth century BCE) orders the infliction of 200 blows, five open wounds, and a monetary fine against civil administrators who illicitly requisition free personnel or slaves, or detain a boat or its crew belonging to a foundation for Osiris of Abydos. Anyone encroaching upon the boundaries of the same foundation or stealing an animal from it was to be punished by having his or her nose and ears cut off and then being put to work as a cultivator (Lorton 1977). Brutalization there may well have been, yet here as well as in other contemporaneous documents, there is an explicit proportionality between the offense, the number of blows, and the monetary fine or status change to be imposed upon the offender. Maiming, to take another example, is clearly meant to go beyond the infliction of pain: it is used to deter and shame by associating mutilation with and thus defining what is a major transgression. Practically, moreover, such disfigurement made escape more complicated.

These and other strategies were associated with physical punishment in early Vedic India (1700–1100 BCE), although here disabling the culprit appears to have been paramount. The range of punishments is also somewhat broader as well as more clearly gradated. Measures included whipping, beating with a broken bamboo cane, driving iron nails into the body, dripping hot oil into orifices, starvation (also an extremely painful form of capital punishment), branding, and various forms of maiming. More consistently than elsewhere in the ancient world, dismemberment in India was linked functionally and symbolically to the offending limb. For instance, someone who urinated in a forbidden place would have his penis cut off, a blasphemer would have his lips cut out, a thief his hand, and so forth. Most of these penalties, however, were never used summarily or gratuitously, but rather had to follow proper admonition, reprove, and fines. At least in principle, only when these failed to deter or prevent recidivism could a judge resort to corporal punishment. And even then certain and telling limitations were put in place, which served to reinforce social hierarchies and boundaries. For example, the more flexible (and thus potentially more lenient) punishment of whipping was meant by default for women, infants, the mentally ill, the poor, and the sick, and hot oil and iron could only be used against (and in turn defined) major offenses, such as blasphemy by a Sudra against a Brahmin or a king. A distinct feature of ancient Indian branding, finally, was that it was usually carried out on one's forehead and indicated the type of crime committed: female genitalia signified incest, a dog's foot the theft of gold, and so on. A branded person was often also banished from his or her city (Doongaji 1986).

While Egypt, India, and other early civilizations employed various principles to regulate the use of corporal punishment, no uniformity in its actual application seems to have emerged. A collection of some 200 early Hittite prescripts from the thirteenth century BCE, for instance, contains but a single unambiguous reference to penal amputation, namely, the practice of cutting off the nose and ears of a slave who burglarized a house (Hoffner 1997, §95). One other reference, which may or may not allude to beating a thief with a spear (§101), mentions it as a past practice, to be replaced by a monetary fine. Ancient China is another case in point. While Chinese law had no qualms about using physical torture to obtain confessions, and despite the common use of capital punishment, attitudes toward corporal punishment throughout that long period were discerning and even ambiguous. Under the Han Dynasty (206 BCE–220 AD), mutilations such as tattooing and cutting off the nose and feet were thought to be cruel and were commuted to extensive beatings ("bambooing") and various forms of hard labor. The shift from permanent to temporary harm had unexpected consequences, however, as the abuse of bambooing could and apparently often did end with death. To amend this situation, later Han ordinances repeatedly reduced the number of blows and defined the specific manner in which they were to be administered in order to ensure culprits' survival (Hulsewé 1955). The marginalization of corporal punishment and especially of maiming continued under later dynasties. The *T'ang-Yin-Pi-Shih*, a popular compendium of 144 legal cases stretching from *c.* 300 BCE to *c.* 1100 CE (van Gulik 2007), contains only three instances of flogging, one following a son's unintentional killing of his mother in the context of an attempt to prevent her from hurting a thief just apprehended (48A), another after the death of a food thief killed by his victim (48B), and a final one in response to a youth's entry into another's house at night (70A). The farther we look in time and space, then, the more diverse and complex the use of corporal punishment in antiquity becomes. Nor can we trace a steady decline over time in the application of this group of punishments or its commutation into seemingly milder measures such as incarceration or fines.

Greece and Rome

The quantity and variety of evidence surviving from Ancient Greece allows us to explore new or perhaps heretofore-hidden aspects of premodern crime and punishment. Authors such as Isocrates (436–338 BCE), in his *Areopagitus* (7.39–42), and Plato (d. 347 BCE), especially in Book 9 of *The Laws*, attained a high degree of theoretical abstraction in discussing the goals of punishment and even challenged its very legitimacy as a social institution. As far as corporal measures are concerned, the process we can detect in Classical Antiquity is not so much a reduction in usage as a sublimation and gradual disappearance of such penalties from the public sphere, accompanied by their proliferation in the private sphere, especially as regards non-free members of society. The same process characterizes Roman penal history to an even greater extent, as we shall see.

Written around the eighth century BCE, and possibly reflecting an earlier tradition, Homer's *Iliad* and *Odyssey* portray a society heavily reliant on self-help (private vendetta), where often harsh punishments were determined and meted out quite simply by the party that could. Subsequent centuries saw a gradual transition from private vendetta; to ad hoc, third-party arbitrators; to judicial assemblies; and finally to quasi-professional courts, which decided cases on the basis of increasingly detailed protocols, the most celebrated instances of which were produced under Draco in 621 BCE and Solon in 594 BCE (Saunders 1991). Within this process, corporal (but not capital) punishment largely fades from the public domain as it becomes associated with summary justice carried out in the domestic sphere, especially against offending slaves. Free citizens, the audience of most new laws and legal procedures, considered corporal punishment as particularly demeaning. According to Demosthenes (384–322 BCE), “the body of a slave is made responsible for all his misdeeds, whereas corporal punishment is the last penalty to inflict on a free man” (*Speeches* 24.167; and see 8.51; 22.55). Indeed, nothing could portray a ruler in more shocking terms than reporting that he had flogged free men. Accordingly, Thucydides (*c*. 460–400 BCE) observed how efficiently one exiled soldier incited his comrades by reporting (or in this case, misreporting) that under a certain regime “all were punished with stripes” (*History* 8.74.3). And in the *Athenian Constitution* (35), Aristotle (384–322 BCE) ominously describes the oligarchic Thirty’s rise by pointing out that they began ruling the city with three hundred “lash-bearers” before violently crushing their opponents.

Thus, the relative absence of flogging in particular and corporal punishment in general from most contemporary records, including legal and narrative sources, is not necessarily an indication of these measures’ decline (Robinson 2007). Under the radar of officialdom, but with the latter’s consent, corporal punishment crystallized into a highly effective mechanism for social othering, a measure particularly suitable for foreigners and non-free members of society. By and large this remained the case under Roman law, which consciously drew on ancient Greek law here as in numerous other matters. The Twelve Tables (449 BCE), a foundational text in Roman jurisprudence, prescribes beating prior to enslavement for anyone caught stealing in daylight. Slaves perpetrating the same offense are also to be scourged and then thrown off the Tarpeian Rock (II.5). Beatings are to precede execution for intentional destruction of property or grain and public verbal abuse or insult (VII.6 and 8). Last, a child shall be beaten at the discretion of the praetor if caught destroying or appropriating another’s crop at night and then forced to pay double the value of the damage (VII.4). Yet, as a sole punishment to be meted out to free adult citizens, beating became taboo: as in Greece, so in Rome, accusing a ruler of causing bodily harm as a form of punishment against free men was a sure way to taint his reign as especially, indeed extraordinarily, vicious (see Suetonius, *Caligula* 27). A similar point was implied in Late Antiquity by several Christian authors who described the bodily suffering of their brethren during the anti-Christian persecutions, which entailed beating as well as forced prostitution (*Acts of the Christian Martyrs*, Agape 5-6 and Pionius 7).

Status continued to serve as a determining factor in the application of corporal punishment throughout Roman history. Rome’s transition from kingdom to republic to empire, and the immense territorial expansion accompanying this process, culminated with the formal extension of citizenship to all free men under Roman rule. Yet while the Edict of Caracalla (212 CE) grew the political base of Rome, it also prompted a closing of the ranks among members of the elite citizenry. In the third and fourth centuries CE, a distinction between a class of *honestiores* (nobler) and *humiliores* (baser) men restricted the latter’s access to numerous legal privileges, also in the realm of penal law. In theory, flogging remained a licit penalty only as a form of summary justice reserved for foreigners, slaves, and children, and various offenses by these groups would have been punished in private by a *paterfamilias* or in public by the organ known as the *tresviri capitales* (Cascione 1999). Yet there is strong evidence to suggest that *humiliores* could be collapsed into the latter group for penal purposes. Claudius Saturninus, a Roman jurist probably writing in the early third century CE, authored many of the passages relevant to corporal punishment now preserved in Justinian’s *Digest* (early seventh century CE). Among his durable prescripts is one declaring: “All those whom it is not permitted to punish by whipping are persons that should have the same respect shown them that decurions have” (48.28.5). In other words, it was not or rather no longer enough to be a free citizen in order to avoid this humiliating form of punishment; the massive expansion of Roman citizenship prompted at best only a minor reduction in the use of corporal punishment.

Judaism, Islam, and Christianity

In and beyond the physical and chronological boundaries of Greek and Roman civilizations, three distinct religious traditions developed their own approaches to social control, including the application of corporal punishment: Judaism, Islam, and Christianity. Tracing these religions' pertinent ideas and practices, while not exhaustive of long-term trends, nonetheless offers a palpable link between antiquity and the medieval period, and their joint and individual legacies at present.

Mosaic and, later, Jewish law espoused corporal punishment via the early adoption of the *lex talionis*: "Eye for eye, tooth for tooth, hand for hand, foot for foot, burning for burning, wound for wound, stripe for stripe" (Exodus 21:24–25; and see Leviticus 24:19–20). Yet it is with particular respect to the latter measure – flogging – that Jewish jurists stand out in terms of the attention they paid to it and the high degree to which they promoted its practice (Goldin 1952). Operating under changing political fortunes and a generally declining autonomy, and eventually spread across the Near East and Europe, Jewish legislators turned flogging into a staple penalty, despite the measure's minor presence in the Old Testament. Indeed, flogging is explicitly prescribed only once in the Bible, in a passage specifying a limit of 40 blows to which a culprit may be subjected for a single offense (Deuteronomy 25:1–3). However, by the time of its completion in the early third century CE, the *Mishnah* expanded the use of penal whipping as applicable to some 168 offenses, including transgression of dietary, agrarian, and Passover laws (Makkot 3.1). Nor, apparently, and in contrast to earlier and contemporaneous cultures, was flogging directed at any specific social group or class, despite the claim by Flavius Josephus (*c*. 37–100), possibly influenced by a Greco-Roman tradition, that the measure "is the most ignominious for a freeman" (*Antiquities* 4.8.21 and 23). While corporal punishment proliferated, however, it did so at the expense of measures such as capital punishment and *kerait* or death by divine intervention. Perhaps reflecting a greater need for social cohesion under gentile rule, the authors of the *Gemara* (*c*. third to fifth centuries CE) and later commentators offered numerous exemptions from whipping. Still, at least at the normative level, corporal punishment remained common throughout and beyond the Middle Ages. The highly influential medieval Jewish physician and legislator, Maimonides (d. 1204), dedicated three whole chapters in his *Mishneh Torah* (Sefer Shoftim, Sanhedrin 17–19) to enumerating offenses punishable by flogging and to defining the terms of the measure's licit use (Jacob and Zemer 1999). And by and large this discussion was integrated into Jewish Halacha through its reception by Joseph Karo's *Shulchan Aruch* (1563), which remains until this day the most authoritative prescriptive text in and beyond Orthodox Judaism.

Unlike their Jewish counterparts, Islamic jurists dealt with punishment in general and corporal punishment in particular mostly within the context of a hegemonic culture; and in contrast with their Christian counterparts (see below), they did so in the absence of an identifiable separation between church and state. The Koran (mid-seventh century CE) enjoins the use of corporal punishment, and especially flogging, on several occasions as either a mandatory (*ḥadd*) or a discretionary (*ta'zīr* and *siyāsa*) penalty for a range of offenses, including slander and sexual misconduct. Subsequent oral and written traditions, however, glossed and at times supplemented such verses, giving rise to different schools of interpretation. For instance, while Koran 24:2 states that a "woman or man found guilty of sexual intercourse – lash each one of them with a hundred lashes," a later *ḥadīth* or oral tradition attributes to Mohammed a sentence of death by stoning against the woman and 100 lashes and banishment for one year against the man (Ibn Rushd, *Bidāyat Al-Mujtahid* 56.6.2). And while Koran 5:90 prohibits the consumption of wine, a corporal penalty for drinking alcohol was only devised much later, also on the basis of an oral tradition (Ibn-'Asqālani, *Bulūgh Al-Maram* 1064–66). Islamic law's adoption of the *lex talionis* facilitated the use of dismemberment in several cases, although in some instances, especially under Shiite law, the penalty could be commuted into a fine. Dismemberment was also prescribed to fulfill the social goals of incapacitation and deterrence, as in the case of theft: "[As for] the thief, the male and the female, amputate their hands in recompense for what they committed as a deterrent [punishment] from Allah" (Koran 5:38). Last, Koran 5:33 lists cutting off the opposite hand and foot (cross-amputation) as one among several penalties that can be imposed upon anyone found guilty of corruption. Beyond these contexts, corporal punishment in any form could be applied as a discretionary punishment whenever a defendant was awarded *ta'zīr*. Depending on the inclinations of a particular legal school, this could in theory be frequent, but in practice was subject to Islamic law's strict rules of evidence. As in Judaism, so in Islam, corporal punishment consolidated its status as a staple penalty in the Middle Ages, and so it remained throughout the early modern period, for instance, under the Ottoman Empire. In some Muslim countries, colonization by Western powers as well as independent state-building brought pressure upon legislators and judges to mitigate corporal punishment by its commutation into fines, especially in the case of women, and by replacing penal amputation with incarceration. Today corporal punishment continues to be practiced in several Muslim countries, especially wherever Shari'a law prevails as state law, for instance, in Saudi Arabia, Yemen, Sudan, northern Nigeria, Iran, and Pakistan (Peters 2005).

Early Christianity's blanket rejection of capital and corporal punishment (*sine vi humana*) in favor of, for instance, abstinence and incarceration, was to some extent at odds with hitherto prevailing notions of retributive justice, both Jewish and pagan. Yet physical pain did not disappear from the ecclesiastical penal landscape altogether. Church leaders and, later, canon lawyers promoted the use of, inter alia, severe fasts, flagellation (also self-inflicted), and exposure to extreme weather as ways to foster discipline and "medicate" against sin, first within ascetic and monastic milieus and later among laymen (Hillner 2009). From the perspective of a Greco-Roman class-based penal tradition, there surely was something deeply humiliating in free people's willingness to submit to physical pain, and this perspective was not lost on early church leaders, who, on the one hand, construed such afflictions as a "sweet inversion" of a pagan cultural taboo and, on the other, emphasized continuity with a biblical tradition (albeit one concerning the discipline of children rather than the punishment of criminals). Either way, throughout the Middle Ages, corporal punishment within the church appears to have been mostly limited to the regular clergy (monks) and rarely practiced among the secular clergy (priests) unless their punishment also involved cloistering. The church's capacity to apply its own range of penalties among lay people in this period varied widely across space and time, but some records suggest that corporal punishment was occasionally used as a main or additional measure (Plöchl 1955). From a broader cultural perspective, the notion that spiritual purgation involves physical pain continued to have wide purchase, as did the perceived causal relation between sin and divinely inflicted physical suffering, both of which were articulated and popularized throughout this period reaching an apogee of sorts in Dante's *Comedy*, published in the early fourteenth century.

The end of Roman Catholic hegemony in sixteenth-century Europe, along with the rise of the absolutist state, led not, as is often thought, to the overall contraction of religious law, including the regulation of corporal punishment. For, while the early modern period saw an increased policing of public morals by secular powers (the so-called criminalization of sin), it also witnessed an intensification of congregationally based discipline, especially (but not exclusively) where state churches were absent, as in the Dutch Republic (Schilling 1987). Neither process entailed a significant change in the role of corporal punishment, despite criminal law's renewed commitment to bloodless penalties under Protestant influences. Flogging and the stocks, for instance, remained minor and thus largely stable measures employed in a Christian penal context (Pihlajamäki 2006).

Premodern Europe

While Europe grew increasingly more homogeneous since Late Antiquity in religious terms, it also came to be characterized by political fragmentation and a concomitant legal pluralism. Different polities, occasionally conquering one another, operated under an array of traditions, including Roman and customary laws, which, juxtaposed with a more centralized church, shaped a diverse legal and penal landscape (Berman 1983). Contrary to popular opinion on the matter, the role of corporal punishment among these regimes was quite limited (Dean 2001); nor, once again, is it possible to trace a general decline in its use as a legal punishment throughout this period. The early medieval statutes contained in *Rothair's Edict* (643), for instance, display a typically strong preference for monetary compensation according to social rank (*wergild*) and functional damage, while later collections of German and French customary laws such as the *Sachsenspiegel* (*c.* 1220) and Louis IX's *Etablissements* (*c.* 1254) appear to have no qualms with dismemberment and branding. Among the Italian city-states in the fourteenth and fifteenth centuries, on the other hand, branding, amputations, and flogging were rare, and punishments tended to be overwhelmingly pecuniary (Dean 2007; but see Piasentini 1992), while in England, by the mid-thirteenth century, mutilations practiced under Norman rule had all but disappeared, only to rise again to prominence under the Tudors in the late fifteenth and sixteenth centuries (Bellamy 1973). The latter trend found a chronological parallel in the Netherlands, where branding and, more commonly, whipping were carried out both secretly and in public, and often accompanied by exposure on the scaffold (Spierenburg 1984). Last, throughout the Habsburg Empire, the enacted *Constitutio Criminalis Carolina* (*c.* 1532) paved the way for a broader use of judicial torture and corporal punishment (§§101, 104, 196–98), as was the wont of ever more powerful monarchs in France (Langbein 1974).

Modernity

It was thus perhaps more in response to the penal realities of the early modern period, rather than to any perennial premodern or even medieval state of affairs, that Enlightenment figures such as Cesare Beccaria (1738–1794), Jeremy Bentham (1748–1832), and others developed their revisionist views on punishment. Overall, these reformers rejected physical pain as a licit form of retribution or as a means to affect real psychological and behavioral change in favor of the more malleable punishment of incarceration. In the long run, the development of penal incarceration in Europe, and later in the US, was accompanied by dramatically reduced recourse to overt corporal punishment (Andrews 1994), although imprisonment itself entailed (and continues to pose) numerous physical risks and hardships. Ironically, while these reforms gradually contributed to the reshaping of Europe's penal landscape, Western colonial powers abroad remained quite tolerant and often even promoted the use of corporal punishment among indigenous populations across Africa, Asia, and the Americas, whether or not such measures predated their arrival (Benton 2002; Peters 2005). Judicial caning in present-day Singapore, Malaysia, and Brunei, for instance, can be traced back to British rule, although the measure has since become both a mandatory and a discretionary penalty, and its application has accordingly experienced a sharp rise. By the early nineteenth century, certain forms of corporal punishment such as amputation and branding had become a marginal measure in Western penology, as against a rise in the use of, on the one hand, imprisonment and, at least for a while, capital punishment (Weisser 1979). From a global perspective, however, flogging and beating still occupy a prominent role as a main or additional penalty in numerous countries, whereas in others they have been only recently banned. The last documented public whipping that took place in Delaware, for instance, dates to 1952, but the law allowing it was cancelled as recently as 1972.

There are other indications for the longevity of corporal punishment, which, as we have seen, for thousands of years has been a staple of summary justice and discipline in the semipublic and professional spheres, to say nothing of the private and domestic ones. Child psychologists and psychiatrists employ the term corporal punishment mostly to the chagrin of crime and punishment scholars (Ellison and Sherkat 1993; Straus and Donnelly 1994), who argue that transgressions in these environments rarely constitute crimes and consequently their desserts cannot be construed as punishments. Whipping a child for uttering profanity is a disciplinary measure meant to foster a certain behavioral norm that may or may not be strongly frowned upon outside the school or home, and slapping a spouse for sexual infidelity has less to do with enforcing a law than with expressing shame or frustration over a given situation. Conversely, and by comparison with the treatment of slaves in earlier periods, the law in many countries does not consider such measures as a form of summary justice. However, in certain domains such as the home and the school and in the religious and professional spheres, disciplinary action reflects (and in the past has certainly informed) mechanisms, procedures, and power structures in the world outside. In this sense nonpublic disciplinary action, including the use of corporal punishment, offers a political education and helps shape new generations' ideas of licit and illicit penalties. Moreover penalties meted out by the state are often in tune with those employed in domestic, religious, and professional contexts. Thus, a broad consensus regarding the need to protect children from domestic violence, for instance, is more apparent than real. As of January 2012, only 32 countries offer children full legal protection from corporal punishment. Despite no lack of local and global advocacy efforts, societies where corporal punishment is not applied to children remain the exception rather than the rule (Montague 1978).

From this perspective, the still prevalent use of corporal punishment (spanking, belting, slapping, whipping, etc.) in many milieus is significant. Rather than reduce it to a sign of immigrant maladjustment or attribute it to psychopathologies, it can also be interpreted as an enduring toleration and in some cases growing appreciation of physical pain as a legitimate disciplinary measure. In many present-day societies, the use of physical force by authority figures remains a battleground for competing truth claims about discipline and cultural identity. Despite consistent and growing evidence of spanking's negative short-, medium-, and long-term effects on children's mental health (McCord 1995; Afifi et al. 2012), parents, guardians, and community leaders continue to advocate it for two main reasons: first, it is irresistibly effective; children generally stop performing an undesirable action with alacrity after being struck. Secondly, it is condoned by certain authorities who lay claim to superiority on such matters at least in the domestic, academic, or religious sphere (Pearl and Pearl 1994). For instance, among those drawing inspiration from the Old Testament, some are reluctant to deny that "He who spares the rod, hates his child" (Proverbs 13:24). Cultural but not necessarily religious conservatives exhibit a similar attitude: the ban on corporal punishment in UK private schools was effected as recently as 1998 and by a narrow majority at that. And in the US, spanking is still the default prerogative of schools in a number of states. To these persistent forces countering the abolition of corporal punishment in homes and schools – and by implication in the public sphere – one must add an even wider faith in violence as a legitimate means to resolving disputes, the right to privacy, and religious and cultural autonomy (Straus and Donnelly 1994). As we edge into the twenty-first century, the high regard in which numerous societies continue to hold each of these principles suggests the durable attractiveness of corporal punishment. Modern penology may have encouraged a rethinking of the link between physical pain and punishment, but it has hardly been able to sever it (Garland 2011).

Overview

With more than two million adults serving time in American prisons and jails, another five million adults under forms of correctional supervision such as probation or parole that threaten imprisonment for violators, and an incarceration rate of more than 700 people per 100,000 population, the United States leads the world in incarceration (Glaze, 2011). Although imprisonment has come to dominate American corrections, the prison as a form of punishment is a relatively recent historical development, emerging as part of a transnational conversation in the United States and Europe in the late eighteenth and early nineteenth centuries, and later in various forms throughout the rest of the world. To be sure, while neither the use of confinement nor the loss of liberty as punishment was invented in the United States, American penal innovation greatly influenced corrections on a global scale.

The history of corrections in America is one of failed reform. In response to the economic, political, and social concerns of each historical moment, reformers, politicians, and the American public have embraced various models of corrections emphasizing deterrence, retribution, incapacitation, and/or rehabilitation. But the reforms implemented to reduce crime, solve prison overcrowding, or reduce recidivism, for example, often generated additional problems, which combined with other contemporary concerns yielded further reforms. What follows is an overview of these shifting practices and goals in American corrections, from the colonial period through the present and in a transnational and global context. The entries in this volume examine methods of corrections that have at different times in history been endorsed, sometimes instead of, but often as a supplement to, imprisonment.

Corrections in Colonial America

Punishment in English colonial America reflected the legal and cultural traditions of the mother country, with adaptations appropriate to local conditions and needs. Like their counterparts across the Atlantic, colonial courts meted out a variety of public, corporal, and humiliating punishments as a way of deterring crime. Depending in part on the type of offense, but more often on the status and history of the offender, punishments might include the stocks or pillory, the whipping post, flogging, ear cropping, the wearing of signs, branding, or standing in the gallows. Fines were commonly imposed for lesser crimes and first offenses and were sometimes accompanied by, or substituted with, a shaming or corporal punishment. The most serious crimes incurred sentences of banishment or even the gallows. The aim was not to reform the individual offender, but to produce such a grim spectacle to deter a fearful public from sinful acts of crime (Kealey 1986).

The types of corporal and shaming punishments employed throughout colonial America derived from the English criminal code. But although the harsh “bloody code,” as it later came to be known, was in force in the colonies, local conditions and British salutary neglect resulted in its less frequent and less intense application in America. The English criminal code enumerated 50 crimes that were punishable by death when it was introduced in 1688, and over the next century the number of capital crimes increased to more than two hundred. However, a practice of royal and clerical pardons resulted in only a fraction of those condemned in England being hanged, and in seventeenth-century colonial America, a shortage of labor discouraged the frequent use of maiming punishments or the gallows, resulting in an even lower rate of execution than in Britain (Morgan 1985; McLennan 2008; Rothman 1971).

As in England, criminals in the American colonies were not typically sentenced to indefinite or extended confinement in workhouses or jails, nor were such institutions equipped for long stays. Jails were used to ensure an individual’s whereabouts either until his trial or sentence was complete or until any monies owed might be recuperated, and workhouses were utilized most often for vagrants. For the most part, colonists saw little use for imprisonment as punishment, holding that it served neither as a public deterrent nor as a means of securing labor, but instead created a class of dependents that developing colonial economies were ill equipped to sustain.

Some colonists had come to view English punishment as sanguinary and unjust, advocating instead the use of confinement and hard labor. In Quaker Pennsylvania, William Penn's 1682 "Great Law" reduced capital offenses to murder and designated imprisonment in the workhouse for most criminal offenses. The law and the experiment with imprisonment were short-lived, however; it was repealed in 1718 and the English criminal code was once again reinstated.

Britain's system of pardons provided many condemned prisoners with reprieve in the form of banishment. These men joined the masses of convicted young larcenists on a journey across the Atlantic to the British colonies in America or the West Indies. With the passage of the Transportation Act of 1718, banishment became the leading punishment for property offenses, the most common form of crime in Britain. In some jurisdictions, banishment made up more than half of the sentences for all convicted criminals. Between 1718 and 1775, as war approached, more than 50,000 British convicts were transported to American colonial shores. Transported convicts made up roughly one quarter of all British immigrants to the American colonies during this period, and one half of all English immigrants. Convict transportation, some in England argued, not only solved the problem of crime at home, but also helped to solve the problem of labor in the colonies. On the other side of the Atlantic, especially in the Chesapeake where the majority of convicts debarked, many colonists resented serving as England's dumping ground for rogues, anxious about the crimes that these felons might – and did – commit. More enterprising colonists saw an opportunity for cheap labor. Shippers carried convicts and indentured servants in the same hold and auctioned their labor to the highest bidders in the colonies for profit and to defray the cost of transport. Like indentured servants, though commonly at a fraction of the price, convicts sold into penal servitude were contracted to labor roughly 7 years before being freed. But whereas indentured servants were more easily absorbed into colonial society upon expiration of their contract, penal servants faced persistent stigma. Colonists tended to identify penal servants more closely with their black slaves than with white servants, passing legislation that restricted penal servants' legal rights to testify in court, vote, and even receive freedom dues, a customary land grant provided upon expiration of the term of indenture. As war with the American colonies loomed, British convict transportation ceased in 1775, leaving both the British and the fledgling United States to seek new solutions to the problem of corrections (Ekirch 1985; Grubb 2000; Morgan 1985).

The Birth of the Prison

Historians have offered several explanations for the birth of the prison in Europe and America in the late eighteenth and early nineteenth centuries. Perhaps most famously, Michel Foucault situated the shift from corporal punishment focusing on the body to disciplinary punishment centered on the soul within the context of a growing population and increasing class tensions, an industrializing economy, and the emergence of human sciences. While the humanitarian concerns of reformers worked to gain public acceptance of the prison, Foucault argued, it was the demands of the modern industrial age for disciplined bodies that led imprisonment to become the dominant form of punishment in the west (Foucault 1977).

Foucault emphasized the increase in access to the internal life of the citizen implied by this shift. While early colonists and Europeans left determinations about the soul to God, their nineteenth-century successors believed they could impel internal change through control of the prisoner's body. With convict transport cut off during the American Revolution and increased social and economic dislocation as a result of industrialization, the promise of reforming delinquents into productive laboring classes through imprisonment was appealing to England's upper classes who grew anxious about rising crime and a growing population (Ignatieff 1978). Reformers, such as William Allen, Elizabeth Fry, John Howard, and Jeremy Bentham, supported the use of imprisonment on religious, humanitarian, and utilitarian grounds, as a means of correction and reformation. The Penitentiary Act of 1779, influenced heavily by Howard's 1777 report on *The State of the Prisons in England and Wales*, authorized construction of two new prisons, which would attempt to reform convicts through the use of solitary confinement, disciplined labor, and religious instruction. The Act went largely unenforced, however, especially as by 1787 convict transportation had resumed, this time to colonies in New South Whales (Australia) and Van Deiman's Island (Tasmania). Similarly, in France, legislation drafted in the wake of the French Revolution providing for the construction of prisons largely went unfulfilled. Just as in the United States, it would be another several decades before Europe embraced a penitentiary system.

The American Penitentiary

In the United States, the 50 years following independence marked both the rise and the institutionalization of the penitentiary. Although the forms and aims of corrections changed dramatically in only half a century, it is important to remember that the shift from public corporal punishment to a reliance on imprisonment was gradual and incomplete. Legally sanctioned public executions were carried out well into the twentieth century, and corporal punishment remained a mainstay of prison discipline throughout the nineteenth and twentieth centuries. Moreover, calls for the reform of American corrections had many different motivations, from religious and humanitarian concern to intellectual and cultural shifts, class anxiety, and social and economic changes. Imprisonment was one of many efforts to bring moral and practical order to society, including schools, almshouses, and asylums.

The first wave of reform came in the 1780s, as many states, led by Pennsylvania, revised their criminal codes to reduce the number of capital offenses. By the eighteenth century, first-degree murder remained the only crime punishable by death in most northern states. America's ruling intellectual and elite classes were guided by Enlightenment concepts of rationalism, humanity, and the social contract, and these ideas also influenced their notions about effective corrections. As in Britain there was anxiety among the elite over social instability and the unruly lower classes, but part and parcel of the work of forging a new nation was establishing a system of punishment that aligned with the new republican ideals. Many reformers who opposed capital punishment did so not only on humanitarian grounds, but argued that it was ineffective, unchristian and even dangerous for society. The alleged effectiveness of shaming punishments in the colonial era relied on a close-knit, face-to-face society where the scorn of neighbors and friends was humiliating to the offender and, crucially, onlookers could imagine themselves in the convict's place. But with the demographic changes and the increase in mobility and size of the population that took place after the American Revolution, shaming lost its effectiveness. Further, capital punishment, Thomas Jefferson wagered, did little to maintain loyalty between a citizenry and its government. Moreover, Benjamin Rush argued, such public displays of violent execution had a brutalizing effect on spectators, spurring further criminal activity. Early American juries often failed to convict defendants who faced punishments they deemed too harsh for the crime, even when they believed the defendant to be guilty. Thus, reformers opposed the widespread and public use of capital punishment, embracing instead the proportionality advocated by Italian philosopher Cesare Beccaria as most efficacious. Beccaria's *On Crimes and Punishments*, translated into English in 1767, was widely read by America's intellectual classes (Masur 1989; McLennan 2008).

But as states turned away from the use of public corporal punishment, it was still unclear how exactly convicted criminals should be punished. Pennsylvania embarked on a brief experiment in restriction of liberty, sentencing convicts to hard labor on public roads. These work gangs were meant to serve as a warning to onlookers of both the penalty for crime and a reminder of the power of the state to punish. In fact, the laboring gangs often drew mocking mobs and crowds of sympathetic spectators who sometimes provided convicts alms. Concerned about the corrupting influence of the convicts on the public and chagrined by the jeering crowds, local leaders scrambled for an alternative, revising the state's criminal code once again in 1789 to provide for sentences of imprisonment at hard labor in Philadelphia's Walnut Street Jail. Opposition to imprisonment as punishment was relatively minor but was made both on religious and republican grounds. Strict Calvinists believed that only biblical punishments could be justly imposed. Others argued that imprisonment threatened Americans' property rights because it would require raising taxes to maintain convicts in confinement – a breach of the social contract. Still, critics of the prison were relatively few (McLennan 2008; Meranze 1996; Masur 1989).

In 1790, the Pennsylvania legislature established Walnut Street as the state prison and ordered the construction of the penitentiary house on the grounds of the jail to include 16 solitary cells for the most hardened criminals. Most convicts and those still awaiting trial were held in the jail's large rooms at night and spent their days in the yard, shoemaking, nail making, weaving, or stone sawing to defray the cost of their imprisonment and to earn small amounts of money for use upon release. Conditions were stark; inmates frequently grew ill, and as the jail's population swelled, so too did tensions, idleness, and violence. New York City's Newgate Prison, built in 1796, faced similar troubles. Inmates at Walnut Street, Newgate, and other early American prisons protested their forced labor and squalid living conditions through disobedience, work slowdowns and stoppages, destruction of tools and machinery, and even open rebellion.

By the second decade of the nineteenth century, overcrowding, inmate violence and escapes, as well as administrative and financial disputes forced authorities to acknowledge the failure of these early institutions and spurred the second wave of reform. Evolving and competing penological philosophies, coupled with economic, social, and political concerns in Jacksonian America, led to the development of two distinct institutions and systems of imprisonment at Eastern State Penitentiary in Philadelphia and Auburn Prison in upstate New York. Both prisons became models of a new type of penitentiary, replicated across the country and around the world. Perhaps more important than the differences between the systems was the fact that they marked the institutionalization of incarceration as the American response to crime.

Classification and segregation of convicts at Walnut Street was legislated in 1790. However, the implementation of this practice was limited by the physical structure of the prison. With only 16 individual cells, the remaining convicts were housed together, in groups of 20 to 30 per cell. As Walnut's inmate population gradually swelled, the state legislature succumbed to public pressure and authorized the construction of two penitentiaries – Western State near Pittsburg in 1818 and Eastern State in Philadelphia in 1821 – that would be large enough to accommodate every inmate in solitude. Designed by the famous architect John Haviland, the impressive Eastern State Penitentiary opened its gates in 1829. It was built on the theory that removing the fallen individual from all potentially negative influences, functionally isolating him completely, would furnish him with the necessary conditions for reflection, repentance, and finally, redemption. To facilitate the reformation of the criminal in this introspective manner, Eastern housed inmates individually for the duration of their sentence, providing only a Bible, occasional handicraft work, and his conscience to occupy his time. As such, each of the initial 250 cells boasted plumbing, heating, and an adjacent private exercise yard surrounded by 10-foot high walls. The vaulted ceilings in each cell were meant to encourage spiritual reflection and the thick walls between cells served to prevent communication. Visitors and correspondence were strictly forbidden, the only exception being calls from the minister. (Teeters and Shearer 1957).

Using Bentham's panopticon as a model, Haviland designed the prison with a central rotunda from which one jailer could monitor activity on all of the seven radiating cellblocks. An imposing stone wall surrounded the prison, 12-ft thick at the base and 30 ft high to keep the public out and the convicts in. The thick-walled design of the prison's cells and the administration of the facility all served to enforce a strict rule of silence. Even so, inmates subverted authority by tapping messages to one another on pipes. Although such a focus on the redemption of the soul promised a more humanitarian form of punishment, to keep order, jailers again turned to the body, this time behind the prison's thick walls (Meranze 1996).

Construction began on New York's Auburn Prison in 1816. Like Newgate, it was initially patterned on Walnut Street Jail. Reformers and legislators believed that the problems at these early prisons stemmed from overcrowding and that more space would solve the matter. By 1819, however, the situation had not improved at Newgate and Auburn had developed its own problems. In response to a particularly heinous riot at Newgate in 1819 the legislature took action, authorizing corporal punishment in the prison and ordering the grading of prisoners by offense, housing the most hardened criminals in solitary confinement. That same year, construction began on what would become Auburn's distinctive cellblock: two rows of individual cells, measuring 7 ft long, 3 ½ feet wide, and 7 ft high, were placed back to back and stacked five-stories high inside of a larger building. Construction was completed in 1821. The first 80 men selected for the new punishment of solitary confinement were locked in their cells on Christmas Day of that same year. There they were meant to remain for the duration of their sentence. Over the first year, jailers were alarmed by high rates of illness, injury, death, and insanity among these men. In 1823, New York's Governor pardoned all survivors and New York abandoned the sentence of solitary confinement.

A new system of penology began to develop at Auburn during the 1820s. Prison administrators and reformers found value in silence and seclusion but regarded the complete and total isolation of inmates as unnatural and inhumane. Thus, the new Auburn boasted common dining and work facilities. Still isolated from the outside world and forbidden to have contact with their families, prisoners left their cells during the day to work and eat in silence among their fellow inmates. They marched in lockstep, a form of walking developed at Auburn to prevent communication among inmates during movement, with each man holding his arms just under those of the man in front of him, and turning his heads to one side, to face the guards while marching in unison. The Auburn system incorporated the advantages of convict labor – inmates learned skills and the value of hard labor, vital to their reform, while contributing to the cost of maintaining the prison – into a silent system. Indeed, an important part of Auburn's promise to the state was the reform of inmates at little or no cost to taxpayers. Because inmates worked and dined in communal spaces, cells were only used for sleeping so could therefore be made smaller, thus costing less to build and maintain. The construction cost in the 1820s and 1830s for a prison modeled on Auburn was $91 per cell, whereas in an institution patterned on the Pennsylvania system cost an astronomical $1,650 per cell (Conley 1980; Lewis 1965).

From the beginning, inmates worked to supply prison needs. In addition to providing physical labor for the construction of the prison itself, inmates worked on the institution's farm to supply food, in the kitchen to cook meals, and did basic general maintenance. Auburn's very small female population, first admitted in 1825, performed much of the sewing, ironing, and laundry. Before long, private industry had infiltrated the prison and convict labor was contracted to the highest bidder. Inmates worked in the production of barrels, hats, chairs, tools, locks, shoes and boots, clothing, carpets, buttons, combs, harnesses, brooms, clocks, buckets and pails, wagons, and even rifles. The introduction of mulberry trees in the late 1830s to begin silk production speaks to the diversity of industry in the prison and the extent to which prisoners were now considered part of the low-skilled pool of cheap labor that also included women, children, immigrants, and African-Americans (McLennan 2008).

Both the Pennsylvania and the Auburn systems were considered reformist and modern, and the merits and disadvantages of both were hotly debated by reformers and penologists. Thousands of visitors from across the country and around the world flocked to the two prisons; emissaries from Europe and Latin America toured the institutions, taking note of the system best suited for their nations. Notable travelers included Gustave de Beaumont and Alexis de Tocqueville in 1831 and Charles Dickens in 1842. Blueprints and notes on the American penitentiaries could be found as far flung as China, Japan and, Mexico, and Peru (Botsman 2005; Salvatore 1996).

Europe embraced the Pennsylvania system perhaps because it offered a clearer alternative to the workhouse model that Auburn more closely resembled; Holland and England had employed workhouses in corrections in the seventeenth and eighteenth centuries (Spierenburg 1987). The Pennsylvania system was also met with some popularity in Latin America, where, however, lack of funds and local racial and ethnic ideologies resulted in only its partial implementation. But it was the Auburn system that came to dominate American penology, in no small measure because it fell in line with the new ethic of production ushered in by industrialization. The Auburn system allowed for not only a self-supporting prison system but one that could turn a profit.

As the century wore on, the drive for profit and the strict imposition of silence at Auburn and other prisons built on the Auburn model resulted in the widespread use of physical punishment. Inmates were whipped; given “baths” (bound hand and foot, with necks braced, and placed in a barrel while a steady stream of ice water dropped from a great height onto their heads); forced to wear the 40-lb iron “yoke” across their necks; or were “bucked” (hung upside down in their cells until they passed out). Just as reformers in the early nineteenth century railed against the brutish sanguinary punishment of the colonial days, reformers in the late nineteenth and early twentieth centuries clamored for the abolition of these inhumane practices.

An Era of Reform

In the antebellum South, prisons and other state-supported institutions were less common than in the North. Where they did exist, state prisons were typically smaller models of the Auburn system that embraced contract labor, usually in agriculture rather than in workshops. Their inmate population was almost exclusively white. Masters commonly punished slaves in private and on the rare occasions when slave punishment was carried out by the state it was usually corporal and administered in public. Even after the Civil War and the abolition of slavery and despite the rewriting of legal codes such that the numbers of convicts in Southern states increased dramatically, the Southern penitentiary remained largely the domain of whites. Racist pseudoscience supported popular beliefs that blacks were inherently deviant, beyond reform, and thus not well served by a stint in prison. Instead, white southerners argued, lacking the institution of slavery for their management, blacks needed to be taught labor discipline. A combination of this type of paternalism, anxiety, and racism coupled with pressing economics drove the development and institutionalization of a system of convict leasing in the South. Moreover, the language of the Thirteenth Amendment that abolished slavery in the United States and its territories made a provision for involuntary servitude for parties duly convicted of a crime. A post-Reconstruction backlash against black economic and political gains resulted in the criminalization of large numbers of African-Americans, many of whom were then rented out to private firms or individuals for farming, mining, or other hard labor, with all revenue returned to the state. The lease system offered little economic motivation for the renter to protect the health or life of the prisoner, and convicts faced grueling work under brutal conditions. Death rates among leased convicts in the South were extremely high, leading reformers to argue that the lease system was worse than slavery. Yet convict leasing persisted in most Southern states well into the twentieth century. Eventually convict leasing gave way to the chain gang; rather than renting labor to private hands, the state retained it (Curtin, 2000). So horrific were conditions even into the second half of the twentieth century that some inmates engaged in self-mutilation, the most common form of which involved severing the Achilles tendon, or heel stringing, so as to avoid forced labor (Perkinson 2010).

In the North, the inhumanities of the prison system and convict labor in the late nineteenth and early twentieth centuries were more understated, tucked behind the thick stone prison walls and out of the public eye. State budgets for prison building and maintenance in the post-Civil War period were tight; new prisons were built with small, cheap cells and older institutions fell into disrepair. Plagued by overcrowding, prisons often slept two to three inmates per cell, far from the reform ideals of silence and isolation espoused in the early nineteenth century. Dense and decrepit living conditions had severe health and psychological consequences for inmates. Moreover, with little centralized oversight for most state prisons, wardens often relied on corporal punishment to keep order and drive labor. Reverend Enoch Cobb Wines and Theodore Dwight's 1867 *Report on Prisons and Reformatories of the United States and Canada*, commissioned by the Prison Association of New York, highlighted the deplorable conditions in American prisons and called for an overhaul of the system such that prisons might more genuinely work to reform the convicts sentenced within. The report served as the catalyst for an historic meeting of the First National Prison Congress in 1870 in Cincinnati. There, delegates from more than 24 states as well as from Canada and South America adopted a Declaration of Principles that viewed crime as a moral disease to be treated through revised sentencing that could provide rewards for good behavior, education and industrial training for prisoners, the abolition of contract labor, the scientific collection of criminological data, and the professionalization of prison staff. Influenced by innovations in penal reform in Australia and Europe, namely, William Crofton's "Irish System," the Declaration of Principles called for the provisions of early release, or parole, and indeterminate sentencing. The Principles made clear that it was in society's interest to rehabilitate the convict, and it was the goal of the prison to remake the delinquent as a productive, self-respecting citizen (Rotman, in Morris and Rothman, eds., 1995).

The Declaration of Principles stood as the cornerstone of the progressive prison reform movement in the late nineteenth and early twentieth centuries, guiding American sentencing and corrections policy over the century. It reflected the effort of Progressive Era reformers who, whether motivated by humanitarian concerns or social anxieties relating to mass immigration and the rapid industrialization and urbanization of the period, sought to improve society's moral fabric by making it more efficient and less corrupt. Embracing a scientific, positivist approach to criminology, these progressives sought to model the prison on secular society, focusing on positive learned behavior rather than religion as the vehicle for reform. Progressive "new penology," as it was called, left its mark on American corrections with innovations such as probation, parole and indeterminate sentencing, reformatories, and the juvenile court system (Rothman 1980; Sullivan 1990).

Penologist Zebulon Brockway, commonly credited with first implementing parole and indeterminate sentencing in the United States, is viewed as the father of the reformatory movement. Although "good time" laws that reduced time imprisoned for good behavior were in existence as early as 1817 in New York, such legislation was employed more as a method to control overcrowding rather than a tool to encourage rehabilitation of the offender. With the shift in Progressive Era penology toward reform based on learned behavior, parole took on new meaning and came into wider use in the late nineteenth century.

In 1876, Brockway was appointed warden at New York State's brand new Elmira Reformatory for youthful male offenders, aged 16–30. After successfully lobbying the state legislature in 1877 for a law permitting indeterminate sentencing with parole, Brockway was able to implement the Declaration of Principles' ideas for individualized, reward-based reform through a graded merit system at Elmira.

Inmates were classified according to their educational and work performances as well as general conduct and psychological makeup. Good behavior allowed promotion to a higher grade with greater privileges and eventually early paroled release. Poor behavior, on the other hand, would result in demotion to a lower grade, the loss of privileges, and longer periods of confinement. Young men in the lowest grade were subject to the older penal practices, such as wearing bright uniforms, being prohibited from receiving visitors or correspondence, and being required to walk in lockstep. Similar provisions for parole and indeterminate sentencing were soon widely adopted. In 1910, legislation enacted parole for federal prisoners; and by 1927, Florida, Mississippi, and Virginia were the only states without a parole system.

Through a program of (gendered and racialized) vocational training and an appropriate system of rewards, Brockway and other "new penologists" believed the criminal would be reformed and society would be well served. Progressive wardens across the country implemented programming that they hoped would inspire a sense of responsibility, self-worth, and citizenship in their inmates. Elmira's inmate-written newspaper, the first of its kind, began publication in 1883. This period saw the introduction of inmate sports teams, musical concerts, lecture series, and later, films to break the monotony of the prison routine. At Sing Sing Prison, just north of New York City, warden Thomas Mott Osborne famously instituted an inmate self-governing organization, "The Mutual Welfare League," which was responsible for organizing entertainment, managing the prison newspaper, and even maintaining discipline. For good work and behavior, inmates earned fake money with which to pay for the cost of living, including renting cells – the more desirable cells being more costly. By simulating free society in the interest of the prisoner, Osborne argued, the convict could be transformed into a responsible citizen (Rothman 1980).

In addition to these inmate-focused programs, Progressive prison reformers encouraged the professionalization of a prison staff and relied on the analysis of new penological experts. The late nineteenth and early twentieth centuries witnessed the professionalization of many fields, including medicine, law, and education. The burgeoning fields of sociology and psychology provided scientific and medical interpretations of criminality that reinforced reformers' notions about rehabilitation. Extending the medical analogy, "new penologists" viewed the convict as a sick patient who would be released once cured. The prison thus functioned as a hospital, and its staff made up the nurses and doctors. Classification of inmates was based on psychological and sociological categories and allowed for individualized treatment. Progressive trends toward specialization and scientific management were apparent in American corrections with the creation of separate facilities for mentally disabled offenders, for women, and for juveniles and in the classification of men's facilities as either maximum or minimum security.

Unsurprisingly then, progressive penology and the reformatory movement brought major changes to the administration of criminal justice for women. For most of the nineteenth century, female prisoners were so few in number that they garnered little attention from prison administrators. Moreover, because Victorian sensibilities regarded women as the moral sex, a female criminal was considered depraved and incapable of reform, much like black convicts in the South.

Viewed by prison administrators as nuisances, female convicts were usually housed together, tucked away in an attic or area adjacent to the men's institution. There the women performed cost-saving labor such as sewing, laundry, and ironing but were generally left to their own devices, receiving little exercise or fresh air for their trouble. Neglect and abuse were common.

In the late 1860s, middle-class women reformers in the Northeast and Midwest became concerned with improving conditions for the growing number of incarcerated women. To protect them from abuses, reformers argued, female offenders should be housed separately in reformatories and looked after by female matrons. The reformers did little to account for female felons, who would remain in custodial settings. Rather their interests lay with "fallen women" such as prostitutes and unwed mothers. Not previously subject to state punishment, women charged with such moral crimes were seen as ripe for betterment and given indeterminate sentences by the courts, the length of which would be figured by their progress at the reformatory. Thus, reformatories focused on a "redeemable" population of young, almost exclusively white women convicted mostly of misdemeanant public order crimes. Custodial prisons, on the other hand, tended to hold older, more hardened, and disproportionately African American female criminals, women convicted of felony, violent, and property crimes.

Reformers sought to feminize the female reformatory to suit what they saw as women's more passive nature, believing that fallen women could be rehabilitated given the proper conditions and training. Unlike male prisons, which held convicts behind metal bars and high walls, women's reformatories tended to house small groups of inmates in cottages in rural settings. Progressives believed that in a familial arrangement, with exposure to the outdoors and fresh air, and under the guidance of morally exemplary matrons, fallen women could be redeemed. Reformatories reinforced traditionally accepted gender roles through the threat of incarceration in state penitentiaries, parole revocation, and the transfer of intractables – women who refused to reform – to asylums for the feebleminded. These institutions were often run by well-educated, professional women, such as Katharine Davis at Bedford Hills in New York, who later went on to serve as the first female Commissioner of New York City's Department of Correction (Freedman 1981; Rafter 1990).

The Reformatory Movement, finally established by the early twentieth century, faded in the 1930s as support for Progressive reforms waned. During this period, national concern with prostitution diminished, feminist momentum slowed, and funding was sparse. As states closed women's units in state prisons, the female felon population was transferred to reformatories, displacing the petty offenders who had been the focus of the Movement. With felons filling reformatories, misdemeanants were once again sent to local jails, and the system turned to a custodial model with remnants of the Movement: separate female facilities and differential treatment that locked women into gender roles (Rafter 1990).

The progressive efforts at classification and individualization had long-lasting effects on the application of criminal justice for youth. Prison reformers had long been concerned with the corrupting influence that hardened criminals might have on youthful offenders. But until the late nineteenth century, only piecemeal efforts were made to accommodate young people in the criminal justice system. All of that changed with the establishment of the juvenile court in 1899 in Chicago. This court created a completely separate system for juveniles charged with offending the law, and it attempted to decriminalize youth by removing them from criminal court. The separate court promised a more individualized approach to dealing with juvenile delinquency and with it a rehabilitative ideal that utilized probation over incarceration. The Chicago model quickly spread throughout the United States. By 1912, 22 states had juvenile courts, and by 1928, only two states lacked them (Binder 2001).

The juvenile court system also helped facilitate the more rapid adoption of probation for youth and adults. In the mid-nineteenth century, the practice of probation was born through the actions of religious and wealthy Bostonian named John Augustus. Between 1841 and his death in 1859, Augustus provided bail for more than 1,000 people in the Boston courts, convincing the judge to release offenders into his charge temporarily, during which time they could persuade the courts that they had been reformed. Massachusetts adopted probation for juveniles in 1878, and, following the establishment of a juvenile court system, other states quickly followed suit. New York was the first state to adopt probation for adults in 1901. Probation, along with parole and indeterminate sentencing, furthered the Progressive Era aims of individualizing punishment.

Despite these gains, prison reform of the late nineteenth and early twentieth centuries fell far short of the Progressives' professed goals. Their efforts to model prison after society were moderately successful. They succeeded in abolishing the rule of silence and the use of striped uniforms as well as in allowing for greater communication with family and in bringing educational and vocational training and some entertainment into prisons. But behind prison walls, physical abuses continued. Even at Elmira, a state investigation revealed in 1899 that inmates were whipped (Pisciotta 1994). Overpopulation and lack of funds persisted and were compounded by resistance to changes from poorly paid prison staff. In a bid for efficiency, Progressives created large prisons managed by a centralized professional bureaucracy (Rotman, in Morris and Rothman, eds., 1995).

During this period, the federal prison system expanded rapidly. Prior to 1891, federal offenders were mostly held in state facilities. Ground was broken on the first federal prison in Leavenworth, KY, in 1891 (though construction lasted 30 years) and the first federal prison for women was established in 1902 in Alderson, WV, modeled on the cottage-style reformatory.

Post-WWII Corrections

By the 1950s, long years of tight budgets from the Depression into WWII had left prison facilities in poor condition. Overcrowding, lack of medical facilities, bad food, poor management, unprofessional staff, and endemic brutality led to a string of riots across the country in the 1950s. Experts charged that the problem stemmed partly from a lack of rehabilitative programming. Postwar optimism, economic prosperity, low crime rates, and a faith in psychological treatment encouraged the embrace of rehabilitation by both the public and correctional professionals. Prisons in the late 1950s and 1960s saw great changes in their physical environments. Common areas became more plentiful and more spacious; paint colors were selected to brighten the facility; gyms, libraries, and classrooms were added to prison grounds. The quality of food improved, educational and vocational programs were increased, and discipline was more relaxed, giving inmates an opportunity to form study groups and attend counseling and training sessions.

At the same time, demographic shifts, urban crisis, and new legislation and law enforcement practices changed the face of America's prison population. As the number of incarcerated Americans grew, so too did the disproportionately high numbers of black, Latino, and Native American men, women, and youth who spent time behind jail and prison bars.

But despite the apparent improvements, mistreatment of inmates and poor conditions persisted. Led by the Black Muslims, a prisoners' rights movement gained momentum in 1965 with the Supreme Court ruling in *Cooper v. Pate*. The ruling gave inmates standing in the courts and initiated federal involvement in state corrections to protect the rights of prisoners. Change in American prisons frequently depended on inmate initiative – through the courts or by other means. Inspired in part by tactics of protest employed in the civil rights movement, inmates across the country engaged in collective and individual acts of resistance including hunger strikes, work stoppages, and prison takeovers to call attention to their inhumane treatment. Inmate writing in the form of published memoirs, poetry, literature, and letters also helped to successfully garner the attention of the media, lawyers, and the general public. Facing public and governmental scrutiny, corrections staff felt under attack from inside and outside of the prison and clamored for greater protections and improved working conditions. Tensions mounted. Although for a variety of very different reasons, the general consensus was that American prisons were failing (Gottschalk 2006).

The crisis of corrections was manifest in the riots in the late 1960s and early 1970s, perhaps most famously at Attica in 1971. The political and public response was on the one hand concern over treatment of prisoners, but on the other, an urgent and loud call to stop coddling inmates and, fueled by fear of growing crime rates, to get tough on crime. The 1973 Rockefeller Drug Laws established mandatory minimum sentencing that eliminated judicial discretion and set a pattern followed in many other states (most famously in California in 1994 with the "Three Strikes Law") and on the federal level in the 1980s. The 1974 Martinson Report echoed this sentiment, arguing that rehabilitation did not work.

By the late 1970s, tougher laws, enhanced policing, and stricter sentencing had resulted in the rapid increase of the American prison population that showed no signs of slowing. Between 1970 and 1980 the prison population doubled, then more than doubled again over the next 15 years. This despite crime rates during the same period remaining stable or declining. Racialized fears of crime, shifting public sympathies to emergent victims' rights groups, and strengthened and politicized law enforcement and corrections union organizing worked together by the 1990s to guard against effective political challenges to the tough on crime politics that maintained high incarceration rates, especially among low-income and black and Latino Americans (Gottschalk 2006). With more and more Americans receiving longer and longer sentences, the prison population grew at a seemingly exponential rate. To accommodate the ballooning numbers of inmates, the country witnessed a rash of prison building in the mid-1990s. The politics around deindustrialization, urban crisis, government spending, the cold war, and the string of recessions beginning in the 1960s expanded and entrenched the use of incarceration as the dominant form of corrections, despite the general consensus based on extensive bodies of research that prisons do not work to reduce crime.

History of Criminal Investigation

Steven G. Brandl
Department of Criminal Justice, University of Wisconsin-Milwaukee, Milwaukee, WI, USA

Overview

During the course of history, police organizations have responded to a variety of external forces that have caused changes in how organizations perform the investigative function and the methods used to investigate criminal occurrences. This entry describes the evolution of the criminal investigation function in the United States. The predecessors of modern detectives (informers and parliamentary reward, thief-takers, thief-makers) are discussed, the tactics and technologies of early investigations in the USA are examined, the development and importance of private detectives and state and federal law enforcement agencies are discussed, and changes in the investigative function through the political, reform, and community problem-solving eras of policing are chronicled.

The purpose of this entry is to provide an overview of the history of the criminal investigation function in American law enforcement. An understanding of history, the history of criminal investigations in particular, is important for at least three reasons. First, history provides a context in which to place modern criminal investigation and thus allows for an appreciation of how much or how little things have changed over time. Second, as the adage goes, those who do not remember the past are condemned to repeat it. To move forward, we must understand from where we have come. Accordingly, an understanding of history may provide insight into previous attempts and new methods of solving persistent problems. Third, if history is cyclical, if it repeats itself, then we may be able to predict the future by knowing the past (see Brandl 2003). It is with these understandings that attention is turned to the history of criminal investigations.

The Evolution of the Investigative Task: English Developments

American policing and criminal investigation has its roots in English policing systems. As English society became more complex, and as traditional mechanisms (e.g., family, community) for controlling individuals' behaviors began to lose their effectiveness over time, there was a need for an increasingly sophisticated system of social control. Policing was first an individual responsibility, then a responsibility of the group. With the Frankpledge Model of 1100 AD, all males older than the age of 12 years were designated as responsible for the protection of the group. Then, the Parish Constable system of the 1200s required a constable to organize and supervise watchmen, who would protect members of the town or village. Variations of the watchmen arrangement lasted until formal police departments were created in the early 1800s. It was only then that the modern detective was born.

Informers and Parliamentary Reward

A system of parliamentary reward operated during the 1700s and early 1800s in England. With this system, a reward was offered by the government to anyone who brought criminals to justice or provided information that led to the apprehension of criminals; the more serious the crime, the larger the reward. Although this system may sound like a historical equivalent of a modern-day tip line, there were major differences, one of which was the legal context in which parliamentary reward operated. During the time of parliamentary reward, more than 200 offenses were punishable by death. These offenses included theft, vagrancy, forgery, and even cutting down a tree without permission. The methods of execution included hanging, burning, and drawing and quartering. Many referred to the laws of the time as the *bloody code*. Most people, however, did not support the legal system nor did they believe the legal code was just. As a result, victims were often unlikely to pursue charges, witnesses often refused to testify, and juries were often not willing to convict. There was public sympathy for petty criminals who faced the possibility of execution (Klockars 1985). The problem was that by benefiting from providing information that would lead to the apprehension of petty criminals, informers were viewed with the same contempt as the legal system. Informers were not the answer; they were part of the problem.

Thief-Takers

In the early 1800s, *thief-takers* came to be. A thief-taker was a private citizen who was hired by a victim to recover stolen property or to apprehend the thief. The fee that the thief-taker charged was most often based on the value of the property recovered, and thief-taker only received compensation when the property was returned. The most desirable crimes to investigate, therefore, were ones that involved considerable property and ones for which the property was easily recovered. As such, thief-takers were not likely to spend much time on crimes for which the property was not likely to be recovered or on thefts that involved small amounts of property (Klockars 1985). In essence, the thief-takers most often worked on behalf of the rich, not the poor. In addition to this "selective attention" problem, there was an even more serious problem with thief-takers: Thief-takers often worked in cooperation with thieves. Some thief-takers even employed thieves (Klockars 1985). No question, the thief-taker arrangement was extraordinarily corrupt. The thief would steal from the victim, the victim would hire a thief-taker, the thief would sell the property to the thief-taker, and the thief-taker would then "sell" the property back to the victim. Everyone prospered at the victim's expense.

Agent Provocateur and Thief-Makers

Along with thief-takers there were *thief-makers*. A thief-maker was an individual who tricked another person into committing a crime and then would turn that person in for the parliamentary reward. Thief-makers were often thief-takers who resorted to deception, seduction, trickery, and entrapment to apprehend criminals and receive the monetary rewards (Klockars 1985). These people essentially created criminals for their personal benefit. Not surprisingly, the methods used by these individuals were frequently viewed by citizens as outrageous and unacceptable.

London Metropolitan Police Department

With the 1800s came the Industrial Revolution and the dramatic and rapid increase of the population of cities, where people lived to be in close proximity to where they worked. Factory production was the basis of the new economy. With Industrial Revolution also came an increase in wealth among some people and poverty among others. "Urban" problems were born – sanitation and health issues, ethnic conflict, and crime. With all the changes came political pressure for the government to institute a more formal, more sophisticated, and more effective system of property protection. It was in this context that in 1829, the London Metropolitan Police Department was established.

Introduced early in the London Metropolitan Police Department was the concept of the "plain clothes police officer" – a detective to some, a police spy to others. In designing the job of detective, tremendous public resistance had to be overcome. The resistance was caused, in large part, because of the problems associated with earlier investigative arrangements – the problems associated with parliamentary reward, thief-takers, and thief-makers. To overcome these obstacles, and to allow detectives to be accepted by the public, certain features were incorporated into the design of the detective position (Klockars 1985).

First, to address the problems of parliamentary reward (when petty criminals faced unjust punishment because of the actions of informers), detectives were linked to the crime of murder. There was no public sympathy for murderers. The "architects" of the detective position capitalized on stories of murder and offered "detectives" as a way to combat this horrible crime. In addition, detectives were to play a dual role. Not only were they to help bring punishment to the worst of criminals, they were also supposed to save the innocent from the worst of punishments (Klockars 1985). One can see very clearly the direct association between detectives and murder in early detective fiction (e.g., Poe's *Murder in the Rue Morgue*, Doyle's *A Study in Scarlett*), and this likely helped sell the idea of the police detective to a skeptical public.

Second, to address the problems associated with the thief-taker arrangement, the most significant of which was that thief-takers only worked on behalf of the rich, detectives were to be given a salary (Klockars 1985). If detectives were given a salary, it was argued, they could work on behalf of the rich and the poor alike. Ideally, they could investigate crimes for which the property loss was small. In addition, given the profitability of working on crimes for a fee in a private arrangement, detectives were to be paid more than police officers.

Third, to address the problems associated with thief-makers, particularly the practice of thief-makers tricking people into committing crimes for the thief-maker's benefit, detectives were made "reactive" and were assigned "cases" (Klockars 1985). Only after crimes occurred were detectives given the responsibility for investigating them. As a result, there was limited opportunity for thief-maker trickery. Detectives were to be evaluated in terms of their success in solving crimes. As a result, detectives were given more control over how they were to spend their working time and more discretion in determining how to investigate the cases they were assigned. These features – being responsible for the most serious of crimes, receiving a salary, and being reactive – eventually neutralized public resentment toward detectives and paved the way for their incorporation into police operations.

The Evolution of the Investigative Task: American Developments

At the time of the ratification of the US Constitution, there were few federal laws and, accordingly, the policing function was almost exclusively a responsibility of local government. Policing was quite informal and consisted most often of volunteers assigned to the "watch" who would guard the village or town at night and later during the day. Local control of the police function was a desirable feature of American policing because, ideally, it allowed residents (and politicians) to influence more easily how policing was conducted in their community. The desire for local control also helped explain why the creators of the Constitution were resistant to the idea of an all-powerful national police force.

The First American Police Departments and Detectives

It was not until the mid-1800s that formal municipal police departments were created. These institutions were primarily located in the large and rapidly growing cities of the eastern United States (e.g., Boston, Philadelphia, New York). The Industrial Revolution created similar problems in America as in England. Of particular significance were the violent labor protests and the rioting that stemmed from clashes between immigrants and native-born Americans (Conti 1977). Municipal police detectives, those with primary responsibility for criminal identification, did not appear until later in the 1800s, and this development occurred largely in response to public concern about the increasing amount of crime. For example, in most years of the early to mid-1800s, there were no homicides recorded in Suffolk County (Boston), Massachusetts. Between 1860 and 1869, however, 70 homicides occurred. During the 1870s, 107 homicides were reported (Lane 1967). Detectives in America had much in common with those in England – they were responsible for the most serious of crimes (at least in image), they were to receive a salary, and they were primarily reactive.

The mid-1800s to the early 1900s has been characterized as the political era of policing (Kelling and Moore 1988). As the name suggests, policing at the time was all about politics; the police organization was an arm of the political machine. Politicians, particularly mayors and ward politicians, controlled virtually every aspect of policing including who got hired, what work officers performed, and who got fired. Besides political connections, there were few selection standards. There were tremendous opportunities for corruption. Police supervisors were few, and their influence over beat officers was minimal because there was no mechanism to provide for supervision. There was little ability for citizens to summon the police when needed because there was no means of communication. Officers patrolled on foot. The police made few arrests. According to Lane (1967), more than half of all arrests made at this time were for public drunkenness. This was an offense that beat cops could easily discover and no investigation was necessary. The police simply did not have the capability to respond to and investigate crimes. When an arrest was made, it was usually as a last resort. Making an arrest in the late 1800s usually involved a lot of work; officers would literally have to “run ‘em in” to the police station, or, when arresting a drunk, the officer would use a wheelbarrow and wheel him into the station (Haller 1976). “Curbside justice” with a hickory baton was often seen as an easier and more effective alternative by officers.

The political era of policing did not provide a large role for police detectives. Like the beat cops, detectives had limited capabilities in responding to investigating crimes. During the late 1800s, Boston’s politicians actually disbanded the police department’s detective bureau because their contributions were viewed as minimal (Lane 1967). Although important qualities for beat cops were size and fighting ability, the most important quality for detectives was a familiarity with criminals and their tactics. Many detectives were selected from the ranks of prison guards, and some were reformed criminals (Lane 1967). With this specialized knowledge, detectives received more pay than beat cops. Detectives also received extra compensation through “witness fees,” compensation for providing testimony in court. Detective work was often a clandestine activity. Detectives were sometimes considered to be members of a secret service (Kuykendall 1986). Detectives depended heavily on criminals for information to solve crimes. Detectives often worked in an “undercover” capacity to collect this information. Detectives never wore uniforms. Rather, they often wore disguises, even in court, to protect their identities. Sometimes detectives submitted their court testimony in writing so as not to reveal their identity (Kuykendall 1986).

It was at about this time that identification systems began to be developed and applied to criminal investigations. The first technology that was used for this was photography. By 1858, the New York City Police Department had on file photographs of known criminals. This collection of photographs was known as a rogues gallery (Dilworth 1977). Although photographs were commonly used in "wanted posters" and assisted in the apprehension of criminals, photographs were extremely limited in their usefulness because criminals could alter their appearance either deliberately or simply over time. Of course, to be useful, authorities first needed to have a photograph of the wanted person.

The most famous identification system of the time was the one developed by Alphonse Bertillon, a French criminologist who lived from 1853 to 1914. His system was known as Bertillonage, and it was considered a major improvement over the use of photographs. The premise of the system was that the bone structure of an adult did not change over the course of a lifetime. Bertillon identified 11 measurements (e.g., length and width of the head, length of the left foot, the length of the left middle and little fingers), and these measurements, it was suggested, could be used to identify people and to differentiate one person from another (Muller 1889). Bertillon estimated that the probability of two persons having the same 11 measurements was more than four million to one (Rhodes 1968). Instruments and instructions were developed by Bertillon to make the measurement process as precise as possible. In addition, an elaborate filing system was developed to organize the classification of individuals from whom measurements were taken. Because it was difficult for the police to take measurements of criminals on the street, Bertillon also developed a scaled-down version of his system. Although the technique enjoyed initial success in confirming the identity of suspected and known criminals and was used by police departments in many countries, by the early 1900s, the deficiencies of the system were obvious. It was simply too cumbersome, error prone, and limited in its applicability to be viable as an identification strategy.

Along with the use of these identification methods, detectives at the time also used various "investigative" tactics to deal with crime and criminals. One common strategy was the dragnet roundup of suspects. When informed of a crime, the police would find and arrest all suspicious persons and would keep these people in custody until it could be determined that they did not commit the crime. In essence, the police would often resort to "rounding up the usual suspects."

Another commonly used investigative tactic at the time was the "third degree," which was also known as shellacking, messaging, breaking the news, or giving him the word (Lavine 1930). The origin of the expression "the third degree" is not clear, although some have speculated that the first degree was the arrest, the second degree was being transported to the police station, and the third degree was the interrogation (Kuykendall 1986; Skolnick and Fyfe 1993). Common methods of administering the third degree included beatings with a rubber hose (Haller 1976), placing a suspect in a sweat box for hours or days under constant questioning (Kuykendall 1986), drilling teeth, burning with lit cigars or cigarettes, and beating with blackjacks or batons (Lavine 1930). Many accounts suggest that the use of the third degree to obtain confessions was commonplace into the 1930s and beyond (Kuykendall 1986). However, it is important to note that in 1936, the US Supreme Court ruled in Brown v. Mississippi that prolonged beatings used to extract confessions were no longer a legally acceptable police practice. After the physical abuse of suspects abated, psychological coercion persisted, and in many situations, this coercion has been approved by the courts.

Sheriff, State Police, US Marshal, and the Bureau of Investigation

While police departments were being developed in the major cities in the eastern portion of the country, other areas were most likely to be served by sheriffs and marshals. In the western portion of the country, US marshals were often the sole police power (Ball 1978). Marshals often employed deputies who also served as sheriffs, deputy sheriffs, or constables. With the appearance of automobile and in the face of corrupt and ineffective municipal police agencies and sheriffs' departments, state police agencies were created to assist. In 1905, Pennsylvania created the first state police agency. It was designed to provide a police presence throughout the state, to assist the local police, and to provide police services in less populated, rural areas of the state (Conti 1977).

Also of significance at this time was the development of the Bureau of Investigation, to be later known as the Federal Bureau of Investigation. President Theodore Roosevelt initially asked Congress to create a federal detective force in 1907. Congress opposed President Roosevelt's idea on the official grounds of the long-cited public disdain for an all-powerful federal law enforcement agency. However, unofficially, it was significant that in 1906 two members of Congress had been prosecuted for fraud, the investigation of which was conducted by the Justice Department using agents from the Department of the Treasury. As a result, many members of Congress were concerned about giving the executive branch of government more investigative power (power perhaps to initiate more investigations of congressmen). Along with denying President Roosevelt's request, Congress passed legislation that prohibited the Justice Department from using investigators from other agencies. Not to be stopped by Congress, in 1908 President Roosevelt created a Bureau of Investigation by executive order and directed Attorney General Charles Bonaparte to develop the agency within the Department of Justice. Twenty permanent and eighteen temporary investigators were hired (Murray 1955).

With the turmoil surrounding its creation, it is not surprising that during the first years of its operation (1910s), the Bureau of Investigation was entrenched in scandal. However, at the same time, it was slowly becoming accepted as a law enforcement agency and was assigned law enforcement responsibilities. For example, in 1910 Congress passed the Mann Act, which prohibited the transportation of women across state lines for immoral purposes. Responsibility for the enforcement of the law was given to the Bureau of Investigation. Other statutes followed, prohibiting the transportation of stolen goods, vehicles, and obscene materials (Murray 1955).

In 1916, with 300 agents, and in the face of war in Europe, the Bureau was given power to conduct counterintelligence and antiradical investigations. In 1919, the country experienced a series of bombings with targets ranging from police departments to banks (and the residence of Attorney General A. Mitchell Palmer). These actions were believed to be the responsibility of communists and others who were "un-American." The bombings and their aftermath became known as the Red Scare. In response to the bombings, Attorney General Palmer established the General Intelligence Division (GID) within the Justice Department to increase significantly the ability to store information on radicals and those suspected of being sympathetic to radicals. John Edgar Hoover was named the head of GID. In 1920, using information from the GID, Attorney General Palmer authorized a series of raids (to be known as the Palmer raids) in cities across the country that resulted in thousands of arrests of people believed to be un-American or communists. The problem was that most of the people arrested were not radicals at all. The courts ordered many of those arrested to be released (Murray 1955).

Private Detectives

In the mid-1800s and early 1900s, private detectives also played an important role in criminal investigations. In addition, many corporations (e.g., railroads, iron and coal mines) hired their own police forces for the primary purpose of dealing with their labor strikes (Conti 1977). With regard to private detective agencies, the most prominent was Pinkerton's agency. Allen Pinkerton was a barrel maker turned Chicago deputy sheriff, turned Chicago detective. In 1850, he quit his job in the Chicago Police Department and established his own private detective agency. At first, most of the work of the agency involved protecting several midwestern railroads and railroad bridges from sabotage of the confederates as well as striking laborers. Pinkerton and his associates' preferred method of operation was to mingle with known rebels and criminals in taverns, hotels, and brothels to learn of their plans. In 1861, Pinkerton learned of a plan to assassinate the president-elect Lincoln and was able to persuade Lincoln to alter his travel plans to disrupt the plot. Pinkerton was also hired to spy on the confederacy, to collect information on their strengths and weaknesses, and to apprehend enemy spies. Also at this time, the Justice Department, having no investigators of its own, used agents from the Pinkerton agency. Pinkerton had investigative and operational advantages over governmental agents; in particular, the agency operated without concern for cumbersome political jurisdictional lines. This capability made Pinkerton ideal for pursuing mobile criminal such as train robbers.

Pinkerton also had a well-developed system of internal communication, record keeping, and files on criminals. Police departments often relied on this information to learn what criminals were working in their area. By the turn of the century, the agency had a system in place to share information with the investigative services of foreign nations: Pinkerton operated on a global scale (Conti 1977).

The Reform Era

With the problems of the political era policing system well noted, there were efforts made to reform the police, namely, to get the police out from the control of politicians. To do so required a new way of thinking about policing. This effort took the form of police professionalism. Forward-thinking police leaders such as O.W. Wilson and August Vollmer advocated a new philosophy and system of policing. This new way of thinking about policing was in direct reaction to the ugly politics of before. According to Kelling and Moore (1988), the system of policing from the early 1900s to the 1960s was known as the reform era.

The reform era was all about police professionalism and anti-politics. The police presented themselves as experts who had the specialized knowledge and capabilities to control crime. It was argued that if the police were able to distance themselves from citizens and politicians (i.e., professional autonomy), they would be the most efficient and effective. Crime control and criminal apprehension were viewed as the primary functions of the police. The new technology of the time contributed to and supported the ideals of the new way of thinking about policing. Specifically, the police patrol car allowed the police to increase their mobility and to respond quickly to crime scenes, random motorized patrol was viewed as a means of deterring criminals, and the patrol car provided separation between police officers and citizens. The two-way radio allowed police supervisors to be in constant communication with, and to have supervision, over beat officers. The two-way radio also allowed patrol officers to be directed to places where they were needed. The telephone turned police departments into 24 hour-a-day agencies that were just a phone call away. With the telephone, citizens could easily summon the police when needed.

During the reform era, detectives became an important tool in police departments' efforts to enhance their professionalism and to deal with crime. Detectives were the ultimate professionals. They were well paid and highly trained. The media at the time portrayed detectives as efficient and effective crime solvers. Similar to the police style in general, detectives often went about their work in a professional, aloof manner. *Dragnet*, a popular television show during the 1960s, captured this style well. The show was about two Los Angeles Police Department detectives and the investigations they conducted. They cut through the emotion of their work and became famous for their line, "Just the facts ma'am."

As a continuing attempt to provide organizational control over officers and detectives, detective work became much more removed from interactions with criminals. With scientific advances, more emphasis was placed on getting information from science (and from victims and witnesses) as opposed to from criminals. The rise of science was led in large part by the FBI. Through the 1920s and 1930s, several initiatives were embarked on by the Bureau, each of which helped solidify its reputation as the top law enforcement agency in the country. First, the

Bureau took the lead in the development of fingerprints as a method of criminal identification. In 1924, the Bureau began a campaign to collect fingerprints from every American. Representatives of the Bureau even went door-to-door in an effort to collect prints (FBI 1990). Fingerprints were recognized to have numerous advantages over the earlier identification (e.g., photography, Berrillonage). It was understood that fingerprints did not change and could not be changed, from birth to death. In addition, fingerprints were unique. Furthermore, there was a uniform method of collection and classification, and this methodology was relatively simple. Fingerprint printing and storage systems were relatively inexpensive. Finally, fingerprints were useful not only for identification but also for evidence, as they could be left by a suspect at a crime scene. Fingerprints could provide a clue regarding the individual who committed the crime. Photography and Berrillonage provided no such advantages. The major problem with fingerprints as a method of criminal identification was that matching a print of an unknown suspect to a potentially vast number of prints on file was a daunting and unproductive task. It was not until the development of Automated Fingerprint Identification Systems (AFIS) in the 1980s that this limitation was addressed.

The second initiative of the Bureau was the development of a crime laboratory. In 1932, with a borrowed microscope and a few other pieces of equipment, the Bureau's laboratory opened. During its first year of operation, the laboratory conducted 963 examinations – nearly all of which involved examinations of handwriting in extortion cases (FBI 1990).

Finally, in 1935 the Bureau began operation of a National Police Academy (to be known later as the FBI National Academy) to train select local police officers in investigative methods. Selection for and graduation from the National Academy was, and continues to be, a prestigious law enforcement accomplishment.

With these initiatives of the FBI, the agency took the lead in reform and crime fighting. It became the role model for other law enforcement agencies. Calvin Coolidge was elected president in 1923 and, in the aftermath of the Palmer raids, one of his first tasks was to reform the Justice Department, the Bureau of Investigation in particular. In 1924, J. Edgar Hoover was appointed the director of the Bureau of Investigation. In 1924 the Bureau had 441 agents. One of Hoover's first tasks was to upgrade the personnel standards of the FBI agents. Hoover fired about one quarter of all agents and mandated additional training for others. Hiring standards were raised, and training in law or accounting was required. A training school was established for various skills and for learning the procedures of the Bureau. According to Hoover, promotion was to be based on performance, not seniority. Control and standardization were the themes that reflected his management style.

During the late 1920s through the 1930s, numerous high-profile crimes and criminals cook center stage with J. Edgar Hoover and his G-men. In particular, gangsters became larger than life, capturing the imagination of millions of Americans. With the assistance of Hollywood and detective fiction writers, he was able to portray his agents (and himself) at the same mythical levels as gangsters. Gangsters were portrayed as public enemies, the Bureau of Investigation's G-men were cop-heroes, and J. Edgar Hoover was the top cop.

In 1932, the nation was transfixed over the news of the kidnapping and murder of the infant son of Charles and Anne Lindbergh. Kidnapping laws were passed by Congress, and the Bureau of Investigation was made responsible for this and other high-profile investigations.

World War II brought new challenges. With the rise of totalitarian abroad, a concern with internal enemies developed. By request of President Franklin D. Roosevelt in 1936, the FBI resumed with increased enthusiasm their information collection activities of domestic communists and radicals. By1939, Hoover had reestablished the GID. The war years provided the FBI with a powerful rationale for monitoring political radicals. In addition, the passage of the Smith Act in 1940 provided a legal basis for FBI domestic security investigations. The Smith Act made it a crime to advocate or conspire to advocate the forceful overthrow of the government. During the early 1940s, the FBI underwent dramatic growth, with the number of agents doubling to nearly 6,000 (FBI 1990).

The 1950s saw a decreasing concern with domestic communism and an increasing concern with organized crime; new laws strengthened the Bureau's jurisdiction in organized crime cases. Aggressive use of wiretaps continued unabated (FBI 1990).

The Community Problem-Solving Era

The 1960s was a troubling time for many Americans and the police. In the 1960s, America was in the grip of the Vietnam War. There were war protests across the country. It was the time of the civil rights movement and the related demonstrations, marches, and riots. The police became viewed by many as an "occupying army" in the low-income, minority ghettos of urban cities. The police were called "pigs." In the1960s, President John F. Kennedy was assassinated, as was Senator and presidential candidate (and former Attorney General of the United States) Robert Kennedy and civil rights leader Martin Luther King, Jr. American society was in turmoil. Fear of crime was increasing dramatically. Actual crime was also increasing; the crime rate doubled from 1960 to 1970. Helter Skelter and Charles Manson were front-page news. The Beatles sang *Revolution*. The police were experiencing a crisis, yet they were supposed to have the knowledge and capabilities to control crime successfully. If the situation was not bad enough for the police, the US Supreme Court rendered several landmark decisions (e.g., Mapp v. Ohio, Miranda v. Arizona) that were seen as "handcuffing" the police. In addition, in the late 1960s and early 1970s, several major research studies were conducted to examine the effectiveness of police operations. The Kansas Preventive Patrol Experiment (Kelling et al. 1974) concluded that random motorized patrols did not deter crime. The RAND study on detectives (Greenwoord et al. 1977) concluded that detectives contributed little to solving crimes and that many detectives could be replaced with clerical personnel.

In the face of this multifaceted crisis, the police realized that the old ideas of professionalism no longer worked. The police needed to get closer to the community to enlist their support and assistance in fighting crime. With this new realization came the community problem-solving era of policing (Kelling and Moore 1988), for which community policing is of central importance. A cornerstone of community policing is that police and citizens must be "coproducers" of crime prevention. The reform era emphasized police-citizen separation, the community era emphasized police-citizen cooperation.

Skolnick and Bayley (1988) identified four definitional elements of community policing. First and most important for the investigative function, community policing involves the community in efforts of criminal investigation and crime prevention. Second, community policing consists of a reorientation of patrol activities. It is realized that the patrol car is not the only means by which police services can be delivered. Community policing initiatives allow for the placement of police personnel in mini-stations, provide for home visits, or provide for foot patrols (as well as patrol via bicycle, scooter, horse, roller blades, and so forth). Third, community policing requires increased accountability through citizen input into police practices and policy. Citizen satisfaction is a legitimate goal according to the community policing philosophy. Finally, with community policing, the police understand that different communities have different priorities and problems. Accordingly, community policing requires the decentralization of command and provision of services to individual neighborhoods.

All these features are supposed to result in several desired ends. First, such initiatives are supposed to reduce crime. Because community policing programs allow the police to have more interaction with the public, there are likely to be increased opportunities for the police to receive information that leads to crimes being solved (Skolnick and Bayley 1988). Crime may also be reduced through citizen education and involvement in crime prevention programs. Crime may be reduced by paying attention to the conditions, the disorder, which may lead to an environment in which crime can flourish (Wilson and Kelling 1982). Second, community policing programs are often expected to reduce fear of crime. This goal may also be attained through citizen education and involvement in crime prevention activities, as well as through the increased emphasis placed on reducing signs of disorder. Finally, because community policing programs enable citizens to have input into policing in their neighborhoods and make the police "easily accessible, frequently visible, and caring in their relationships with citizens" (Goldstein 1987, pp. 8–9), community policing programs are often expected to improve citizen attitudes toward the police.

Although the research that has examined the effects of community policing has shown that it often does not work as expected (see Rosenbaum 1994), the means and ends of community policing, in principle, seem to be quite congruent with the task of criminal investigation. The basic task of the police in a criminal investigation is to collect information that will lead to the identification, apprehension, and conviction of the subject who perpetuated the criminal act. Much of the research on the investigative function highlights the role of the public as suppliers of information to the police (Greenwood et al. 1977). Simply stated, the police are dependent on the public, and community policing makes this dependence explicit.

Strategies that provide an opportunity for community residents to share information with the police in solving crimes are particularly relevant in the era of community policing. For example, tip lines are quite common in criminal investigations today. The Crime Solvers, Crime Stoppers, and WeTip programs are supported by many communities across the country. In addition, police departments frequently establish designated tip lines for major investigations.

Along the same line, school liaison officers are located in a setting where they are available not only to assist students with questions or problems that they may have but also to obtain information about crimes from them. Similarly, police involvement with community watch groups provides a public service and also, arguably, makes it easier for residents to contact and provide information to the police that may assist in investigations. These strategies make police dependence on the public explicit and are congruent with the ideals of community policing.

Along with an explicit dependence on community residents for information, other developments in criminal investigation have occurred during the community problem-solving era of policing. Chief among these is DNA analysis as a method of identification. DNA analysis represents an extraordinary advance in science and in identification methods as applied to criminal investigations. The science of DNA, along with the introduction of computer technology to store, record, and match DNA prints across individuals, has the potential to revolutionize criminal investigative methods. In addition, other technology in the form of computer networks and databanks are also changing criminal investigations in dramatic ways. COMSTAT, an operational approach to policing which is based on "gathering accurate and timely intelligence, designing effective strategies and tactics, the rapid deployment of personnel and resources, and relentless follow-up and assessment" (Dabney 2010, p. 34), also has the potential to dramatically affect how criminal investigations are managed and performed. In addition, empirical research continues to be conducted on the criminal investigation process, the contribution of detectives in solving crimes, and the impact of forensic evidence on crime solving (e.g., Eck 1983; Brandl and Frank 1994; Baskin and Sommers 2010).

As before, the FBI is often considered at the forefront of technological changes in the criminal investigation process. Today, the FBI crime laboratory is the most scientifically advanced and well-funded in the world, although it has been subject to criticism for its "sloppy" work in several cases (Kelly and Wearne 1998). The FBI also operates the NCIC – a computerized network and storage system of crime information. The FBI continues to operate the National Academy and it provides many other types of operational assistance to federal, state, and local law enforcement agencies (see FBI 1999), including psychological profiling.

During the course of history, police institutions and organizations have responded to a variety of external forces that have caused changes in their structure and function. From these changes emerged the criminal investigation function and investigative methods. Most people would argue that much progress has been made in criminal investigations. Ultimately, that is for the future to decide.

Overview

For thousands of years, mankind has developed and applied vague or specific thoughts about what behavior should be labeled as criminal, who the criminals are, and what the causes of crime may be. Philosophers in the eighteenth and early nineteenth century put forward the rational criminal who is free to make choices and criticized the cruel and unjust criminal justice system. The scientific study of crime started in the beginning of nineteenth century with mathematicians searching for empirical regularities between countries and areas in administrative governmental data. Sociologists, psychologists, and physicians introduced societal and individual causes of crime in a comprehensive way. Later, new developments in other disciplines triggered new thoughts on the causes of crime, notably strain, control, and cultural theories. These have been dominant for about many decades, although critical theories emerged in the 1960s and 1970s of the twentieth century. Recent developments of theoretical criminology point at including disciplines that have not been very involved in the field of crime like neurosciences and econometrics so far.

The First Rudimentary Ideas

For thousands of years, mankind has developed and applied vague or specific thoughts about what behavior should be labeled as criminal, who the criminals are, and what the causes of crime may be. In the heydays of the Egyptian, Chinese, Greek, Inca, or Roman empires, criminal laws were introduced to criminalize certain behaviors and how to deal with criminals (Kerner 1998). These written (in stone, on papyrus, walls, or clay tablets) or oral laws (UK) were introduced to protect the social cohesion of the empire, the existence of primary groups, or the power of those who were in charge. Till that time conflicts were settled by private parties; the state was not involved.

In the Middle Ages, the search for the causes of crime in Europe was more than ever regulated by religious motives: those who committed crimes "must" offend God's will and "therefore" must be possessed by the devil. Draconic tortures were applied to release the man or the woman from that evil. Until that time scientific knowledge as we have nowadays did not exist. Monks copied unique written texts about religion or other affairs that were stored in monasteries. Spiritual explanations were at that time the dominant thought about the causes of crime. Desiderius Erasmus (1466 (?)–1536) was one of the first philosophers who wrote about the "natural" causes of crime. He related the occurrence of criminal behavior not to the "spirit" of the individual but to poverty in general (although without any empirical evidence). The physician G. Battista della Porta (1535–1615) was the first who systematically was searching for observable causes of crime. He opened the brains of hanged criminals in order to study irregularities in their shape, color, and structure. In the age of Enlightenment, new vague thoughts about crime were developed, of which the rudiments can still be found in criminological theory of today. During Enlightenment intellectuals promoted the idea of ratio and philosophy and in general the upcoming scientific work. They challenged widespread superstition and abuses of rights of residents by those in power and by the church. Combined with the upcoming Protestantism, the individual became more and more central in the new philosophies (as they called science those days). This was an important period in the study of crime, because many of our contemporary fundamental assumptions about the causes of crime originated in the seventeenth, eighteenth, or nineteenth century (although the words may be different and specifications may have been very well elaborated during the last 300 years).

The Upcoming Scientific Search for Causes of Crime

What happened? In the seventeenth and eighteenth centuries, science in general begins to expand and to make progress in explaining many (natural) phenomena. New instruments made it possible to explore in more detail the human body, several illnesses, and nature in general. The fast growth of mathematics laid the foundation of many new natural sciences like physics, chemistry, medicines, biology, anthropometry, and physiognomy. Social philosophers stood near the cradle of the political and social sciences and of early psychology. The cruel and unfair criminal justice system of their time inspired many philosophers to suggest improvements of criminal law. Cesare Beccaria (1738–1794) and Jeremy Bentham (1748–1832) focused on the issue of the criminal justice process and how to deter individuals from crime (Marsh 2004). They came up with the precursor of rational choice paradigm in which individuals are assumed to assess the benefits and costs of criminal behavior. If the benefits are higher than the costs, they will commit a crime. It was assumed that people have a free will to make decisions to commit crimes. That was revolutionary in a period when spiritual and religious thoughts dominated the thinking of people. It took about 200 years of silence until an economist and Nobel Prize winner Gary Becker again suggested rational choice decision making as an explanatory model of why individuals commit crimes (Becker 1968). Today, the rational choice perspective is popular in criminology, especially in geographic criminology. Routine activity theory and crime pattern theory that explain why crimes cluster at certain places are, for instance, based on the rational choice perspective as well as the basic principles of crime prevention (Clarke and Felson 1993; Cornish and Clarke 1986; Felson 2008).

Long before the name of criminology was introduced by Raffaele Garofalo in his 1885 published *Criminologia*, researchers empirically studied crime under the label of moral statistics or criminal science. The foundation of empirical criminology was laid in the beginning of that century when Belgian, French, and British mathematicians and statisticians like Guerry (1832), the astronomer and first PhD of mathematics of Ghent University in Belgium Quételet (1984 [1831]), Ducpétiaux (1827), and Rawson (1839) and Fletcher (1848) of the Royal Statistical Society of London tried to uncover regularities in the social and geographic distributions of crime and criminals between counties, areas, cities, and countries (Beirne 1987; Weisburd et al. 2009). The publication of the *Comptes Générales de l'Administration de la Justice Criminelle en France* in 1825/1826 inspired them to explore official data on crime in more detail (Weisburd et al. 2009, p. 6). These scholars were the first who studied crime as a social phenomenon that is unequally distributed over society (Guerry 1832, 1833, 1864). Quételet (1847) discovered the normal distribution in statistics in order to assess the "normality" of empirical regularities he demonstrated in research. These scholars were inspired by the reform movement in their countries of which fighting illiteracy and illness among the poor was the priority political issue. That is the reason why they studied the empirical relationships between illiteracy and wealth and personal and property crimes in France, England, and the low countries (now the Netherlands and Belgium). They did not systematize their thoughts into structured theorizing. Instead, they made up inventories of all kinds of correlates of possible causes of crime and criminals (good examples of that kind of inventories are Afschaffenberg (1906) and Parmelee (1918/1919)).

Later in the nineteenth century, Charles Darwin formulated his evolution paradigm on the origins of species (and like many original thinkers encountered conflicts with religious powers of his time). Darwin's revolutionary thoughts completely changed the human perspective on the roots of mankind. The physician Cesare Lombroso (1835–1909) was fully impressed by Darwin's theory. He elaborated Darwin's innovative way of thinking and applied it to the explanation of crime (Lombroso 2006 [1878]). As physician he studied sentenced criminals as if they suffered from a drawback in the evolutionary process, believing that "those" people can be recognized by outer stigmata. Scholars in his time had an optimistic and naive view on science (positivism) assuming that scientific knowledge could change the world in a better place to live in. Lombroso later studied in his career many other topics as well (mostly social aspects of crime), among others the spatial variations in the distribution of crime across areas, provinces, and countries (Lombroso 2006 [1878]).

A landmark in the study of crime causation was the work of the sociologist Emile Durkheim (1858–1917). He built on the analyses of social philosophers and the first sociologists who observed in the nineteenth century macro-social processes in the speedy developing societies in Europe (Bierstedt 1978). Saint-Simon (1760–1825) can be viewed as the first who envisaged the new industrial society, and together with the younger Auguste Comte (1798–1857), he analyzed the disruptive consequences of the many European political revolutions. The abrupt changes in political structure and society that they observed led to a bigger gap between the state and the families and individuals when intermediate institutions disappear. Also Georg Simmel (1858–1918) was very critical at the new technical, urbanized materialistic culture that emerged in Europe. Ferdinand Tönnies (1855–1936) focused more on the social changes in society. In his view, societies transformed from *Gemeinschaft* into *Gesellschaft*, leaving behind the small-scale agricultural villages with strong social cohesion and informal social control. In modern societies of a *Gesellschaft* type, trade and industry took the lead; laborers recruited from rural areas and ties between people were weakened. People in Europe became more individualized, and sociologists feared the negative consequences for society and for crime rates. Durkheim built on their thoughts and focused on the relationships between people and the impact of societal changes on them (Durkheim 1951 [1897], 1964 [1893]). He argued that relationships between people are based on cohesion, division of labor, religion, (scientific) knowledge, and morality, and when societies become more heterogeneous, their collective conscience is diminished. Anomic societies lose their power to regulate social relations between people, and increased levels of crime are a consequence. People with less ties feel free to break the moral rules more easily. Central is the idea that external forces from society (measured by structural features) explain why people commit crime. Durkheim demonstrated empirically that in societies with lower levels of social integration, people tend to commit more suicides and more crimes.

Further Developments in Early Twentieth Century

Durkheim had a profound influence on the emergence of two important theoretical perspectives in criminology: the *anomie* paradigm and *control* paradigm (Cullen and Messner 2007). Growing up in the relative deprived neighborhoods of South Philadelphia as a son of a Ukraine immigrant family, the sociologist Robert Merton (1910–2003) experienced personally at young age that the American society offered unequal opportunities to different social groups (Coser 1977; Cullen and Messner 2007). He published at the age of 27 his famous article on anomie and social structure in which he stated that the American society promoted central material ends (American dream) to pursuit (cultural) goals to all citizens, but certain social groups – especially the lower classes – encounter structural closures to reach these ends in a legally prescribed way (Merton 1938). The discrepancy between culturally defined goals and legal opportunities create tensions or strains in society that people try to reduce by applying adaptive behavior patterns. Merton's anomie theory aims to explain why aggregates (social groups) withdraw from society, conform, become rebellious, ritualists, or innovative. According to Merton, innovative people try to reach cultural accepted goals by committing crimes. Among others, Merton inspired many criminologists to study the role of subcultural values (Albert Cohen (1918–)) and poverty on the overrepresentation of the lower classes in the official crime statistics. Richard Cloward (1928–2001) and Lloyd Ohlin (1918–) focused on the differential opportunities of people having to use legal or illegal means to reach material goals and developed a typology of kinds of subcultures by merging differential association theory (see later) and anomie theory. Robert

Agnew (1953–) elaborated Merton's anomie theory in an individualistic way for his strain theory (Agnew 1992, 2006). In that theory he stated that three kinds of strain (negative relationships and stressful life events when other people prevent a person from achieving valued goals, take away something valued, or impose on the person that is unwanted) may lead to criminal behavior as a kind of response pattern. Steve Messner and Richard Rosenfeld elaborated the idea of American dream as cultural goal that leads to more competition between citizens (Messner and Rosenfeld 1997). And more competition between citizens in the context of a relatively dominant economic institution vis-à-vis family, education, and other social institutions leads to more crime in societies, an idea that has also been raised earlier at the beginning of twentieth century (Bonger 1969 [1905 and 1916]).

Durkheim on the other side inspired other influential criminologists to focus on the effects of social control on crime. Travis Hirschi (1935–) is the best known protagonist of this perspective. In line with Durkheim's reasoning, Hirschi stated in *Causes of Delinquency* that if an individual is not tied to society, he is free to deviate from the norms, e.g., free to commit crimes (Hirschi 2006 [1969]). That view was opposite to the mainstream and dominating cultural deviance theories of his time. Hirschi was especially critical of the differential association theory, arguing that individuals need a certain level of commitment to society and social ties with other people to refrain them from crime. The family (especially parents) plays a central role in establishing ties.

Hirschi was certainly not the first to introduce the concept of social control as a condition for crime. A number of predecessors can be mentioned. Edward Ross (1866–1951), one of the most influential sociologists of the United States, was the mastermind of the concept of social control. Around the turn of the twentieth century, he pointed at internal and external kinds of social control that regulate criminal behavior (Ross 1918 [1901]). Walter Reckless (1899–1988) focused later on social control as exercised by parents on their children: parental supervision (Reckless 1940, 1961). When parents do not succeed in supervising their spouses, the children will develop weak self-control and weak other internal controls. If they succeed, kids can resist the worst neighborhood influences that normally lead to more crime (containment). Albert Reiss Jr. (1922–2006) specified kinds of social control into personal and social control that both refrain youngsters from criminal behavior (Reiss 1951); Jackson Toby introduced the concept of "stakes in conformity" referring at how much a person has to lose when he breaks the law (Toby 1957), later followed by F. Ivan Nye who distinguished four dimensions of social control (direct social control, internalized social control, indirect social control, and access to legal means (Nye 1958)). All of their work was integrated by Hirschi and specified in testable propositions.

The idea of social control has been expanded in several new directions. Travis Hirschi, collaborating with Michael Gottfredson, proposed a general theory of crime in which was stated that human's low self-control was the key explanatory mechanism in the explanation of crime (Gottfredson and Hirschi 1990). Low self-control is developed by psychological deficits or by parents in unorganized families by "inconsistent" parenting styles on their offspring. Blumstein and his colleagues (1988) started more empirical research on criminal careers, putting aside static views on offenders. The idea of a small group of active offenders was revealed by Wolfgang and his colleagues in their Philadelphia study (Wolfgang et al. 1972). Later research found out that offenders are influenced by the number and nature of risk factors they encounter during their life course (Farrington 1988, 2002; Loeber and Wikström 1993). This life-course perspective has been developed by several scholars. Dan Nagin developed a method to analyze empirically various trajectories of offending (Nagin 2005). John Laub and Robert Sampson (Laub and Sampson 2003; Sampson and Laub 1993) initiated the developmental criminology and explored the idea of varying social controls during the life course that may be responsible for the variations in crime when people coming of age. They based their analysis on the data of two matched groups of 500 delinquents and 500 nondelinquents collected by Sheldon and Eleanor Glueck for their pioneering empirical study on juvenile crime in the 1950s (Glueck and Glueck 1950). Rolf Loeber in Pittsburgh (Loeber 1990), Marc LeBlanc in Montreal (Leblanc 1997), and Farrington with his longitudinal study of male laborers in London (Farrington 2002, 2003) have brought up new dynamic views on the causes of crime. Terry Moffitt's distinction between adolescent-limited and persistent criminals also inspired many present studies on criminal careers, recidivism, and redemption (Moffitt 1993). Although her distinction between two groups of offenders is probably too simple, she inspired may researchers to study criminal careers with a variety of explanations for distinct career trajectories (Cullen 2011). In the 90s of the last century, new promising horizons emerge from the idea that perhaps neurological defectives play a role as cause of crime (Rafter 2008; Raine 1993). In the future, when scientists know more about DNA and the human gnomes, new kinds of causal theories will be developed and tested.

The City of Chicago and Its Scholars

The city of Chicago played a special role in criminology. It is probably the most researched city in the world. From 1850 till 1930, the city grows from 4,470 to almost four million residents from all continents longing for a new and hopefully prosperous future. Various scholars in sociology, economy, psychology, and criminology carried out innovative theoretical and empirical studies on the structural changes of their city in the newly established University of Chicago. Inspired by former journalist Robert Park (1863–1944), pragmatic academics like Ernest Burgess (1886–1966), Clifford Shaw (1896–1957), and methodologist Henry McKay (1899–1980) started quantitative and qualitative geographic criminological studies on the impact of urbanization processes on human behavior and institutions (without being aware till 1933 that in Europe there already existed a long tradition of this kind of research) and on the spatial distribution of crime in cities. A very important contribution stems from William Thomas (1863–1947) who introduced the concept of social disorganization in criminology (based on his ideas on social change (Thomas 1966: p. 3)). Later Louis Wirth (1897–1952) elaborated that concept (Thomas 1966; Thomas and Znaniecki 1918/1920; Wirth 1938). George Mead (1863–1931) laid the foundation for his symbolic interactionism, inspiring social control theory and labeling theory (Mead 1974 [1934]). Thorsten Sellin (1896–1994) developed his culture conflict theory of crime (Sellin 1938), and Edwin Sutherland (1883–1947) elaborated in different versions his differential association theory (Cohen 1968; Sutherland 1924, 1934, 1939, 1947), while Burrhus Skinner (1904–1990) created his operant version of behaviorism (Ronald Akers based his social learning theory partly on his thoughts) (Skinner 1976). The concept of social disorganization is still in the center of many etiological and geographic studies in criminology (Kubrin and Weitzer 2003; Sampson 2010). Robert Bursik worked in the 1980s in the Chicago tradition and elaborated that concept to study the effects of *changing* neighborhoods on crime concentrations in that city (Bursik 1984, 1986, 1988). With colleague Harold Grasmick (1993), Bursik also highlighted how different types of community controls (private, parochial, public) were related to neighborhood crime, disorder, and citizen's fear of crime. Robert Sampson (1995) and his colleagues continued that line of investigations by putting forward the idea of collective efficacy as one of the explanatory characteristics of neighborhoods (Morenoff and Sampson 1997; Sampson 1987, 1995, 2010, Sampson and Groves 1989; Sampson et al. 1997). The Chicago school was and still is not a united framework of thought but an umbrella under which various brilliant scholars have been developing divergent theories, especially on the causes of crime. Various scholars of all over the world are studying the spatial clustering of crime in their cities. New specialized developments are to be observed in the field of crime pattern theory

(Brantingham and Brantingham 1991), of crime location decision models, or of the mobility of offenders, based on ideas that have been developed many decades earlier. One of the most popular theories on spatial crime distributions is the routine activity theory (L. Cohen and Felson 1979; Felson 2008) that has influenced spatial and environmental criminology for the last 30 years now. New methodologies and better administrative data and surveys to include measurement of social processes (Raudenbush and Sampson 1999) allow to study smaller units of analysis, elevating clusters of crime and victimization, even in neighborhoods where normally there is a low level of crime (Eck and Weisburd 1995; Oberwittler and Wikström 2009; Sherman and et al. 1989; Weisburd et al. 2009). A new criminology is emerging to address the issue of unequal crime places in cities, not large neighborhoods anymore.

Symbolic interactionism as developed by Mead was important not only for sociology but also for criminology in two respects. Edwin Sutherland (1883–1947) built his famous differential association theory in the 1930s and 1940s on the theoretical roots of symbolic interactionism (Sutherland 1947). Criminal behavior is learned in a social process within social groups by an excess of positive definitions to law violation above negative definitions towards law violation. He also combined the macro perspective of Chicago sociology on urbanization, social disorganization, and social groups with the micro theory of Mead on how people learn attitudes and behavior in intimate groups. Sutherland not only studied the crimes of young people in this respect but applied his theory also on homeless people as well as professional thieves and managers of powerful corporations (Sutherland 1937, 1983 [1949]). Sutherland had a great number of students who dedicated their academic life in exploring, defending, and extending the differential association theory (Cressey 1964, 1969; Glaser 1972). The differential association theory inspired many empirical studies on the impact of peers on the criminal behavior of adolescents.

After the Second World War: The Rise of New Criminological Theories

In the roaring 1960s of previous century, a young generation opposed the authority of states and the power of social and legal institutions on several ways, leading to various nontraditional criminological theories: labeling theories, critical criminology (of all different schools of thought), and feminist criminology (the same). Howard Becker (1928–) put forward the labeling perspective and focused on the role of moral entrepreneurs in society to criminalize people and behavior (Becker 1963). As proclaimed by symbolic interactionism, people can change their identity because of the reactions of other people on their behavior. Becker studied the culture of so-called deviant groups in society and how law enforcement pushes them to deviate more often and seriously from the norms of conventional society. Becker's legacy is also partly built on the studies of others. Frank Tannenbaum (1893–1969), sent to prison for a protest demonstration when he was a young man, focused attention on the negative consequences of the criminal justice system, especially the prison system on individuals (Tannenbaum 1938). Erving Goffman (1922–1982) became famous in psychiatry and in criminology for his study on total institutions, like prisons, (mental) hospitals, or army camps, that are in full control of those who were forced to live in it (Goffman 1961). Edward Lemert (1912–1996) distinguished between primary and secondary deviance (broader than crime) and demonstrated that official reactions force people to change their identity into a deviant one (Lemert 1951, 1967). Stigmatizing criminals or mentally ill people forces them to continue their deviant behavior or as Becker called it, the state (especially the police) amplifies deviancy in society. Inspired by the roaring 1960s and the 1970s, more critical criminologists focused the attention to all kinds of sources of conflict in society that promote crime. Richard Quinney (1970) argued that crime emerges in a politicized society when those who are in power control the lower class by criminal law; William Chambliss stressed the power of interest groups to influence the legal system and studied state crimes instead of crime of those without power (Chambliss 1969; Chambliss and Seidmann 1986), and Turk elaborated the conflict perspective by proposing a theory of criminalization that attempted to explain that societal conflicts between authorities and individuals will result in criminalizing the individual (having less power) (Turk 1969). Critical criminology became more influential when Walton, Taylor, and Young published their criticism on traditional theoretical thinking in criminology, including labeling and conflict traditions (Taylor et al. 1973), later followed by (Taylor et al. 1975). The emergence of feminist criminology was related with the second-wave emancipation and liberation of women in the western world in the 1960s and 1970s. Criminology was (and mostly still is) a male-dominated scientific discipline focusing on male problematic behavior. Klein was one of first critics of male criminological theories (Klein 1973), stating that traditional theories largely explained the criminal behavior of men and the few theories that explain criminal behavior of female offenders used simplistic and stereotypical assumptions about women. Smart also raised serious questions about the assumptions of many criminological theories on the nature of women in general and on the female offender in particular as law abiding by nature (Smart 1976). Feminists also emphasized gender differences in treatment by the criminal justice system as offenders and as victims. Often female offenders are punished more harshly than males and often psychiatrically by the justice system "because their criminal behavior is against their law-abiding nature," and women who are victimized are not "true" victims but rather seduce the "innocent" male offender. Freda Adler's *Sisters in Crime* argued that women, once liberated, will play a role in the male world and consequently (have to) act more aggressive and competitive like men (Adler 1975). Because of the progressing emancipation of women, they will have higher crime rates in the future. By 1980 feminist criminology could be classified into different schools of thought: Marxist, socialist, liberal, and radical schools (Jagger and Rothenberg Struhl 1978). However, these classifications were soon replaced with uniquely feminist approaches (e.g., doing gender; sexed bodies, intersectionality (Daly and Maher 1998; Simpson 1989)).

Integrated and Elaborated Theories

John Braithwaite (1951–) started from an anomaly between labeling theory and other theories like strain and control theories predicting that the criminal justice system is aiming at reducing crime and at the same time stimulates crime (Braithwaite 1989). Braithwaite introduced the idea that the outcome of justice processing depends on the kind of shame that is exploited by the system. Disintegrative shaming leads to more recidivism and integrating shaming reduces future criminal behavior; reintegrative shaming will reduce crime in the future because offenders will stay integrated in society. David Garland (1955–) extended the sociology of punishment by opening the discussion between punishment and control in an area of expanding culture of control in which the media, politics, and moral entrepreneurs play their part (Garland 2001; Garland and Sparks 1995). His inspiration comes from classic philosophers and sociologists as Durkheim. By creating fear and anger about their safety among the citizens, control can expand far beyond the limits of civil rights in the contemporary world we are living (Garland 2001).

The Current State of Theoretical Criminology

One of the conclusions of this brief overview is that during the last centuries, a great number of causal ideas have been developed in criminology to address the explanation of criminal behavior or crime rates. Many of these ideas are still presented and discussed in full length in the textbooks of our discipline to teach new generations of students in criminology. In most cases, after the presentation of the theories, criticism is presented as well, leaving the freshmen in doubt whether there might be one theory in criminology that meets the criteria of the discipline. From a distance the discipline looks like a battlefield of masses of rival and conflicting ideas about the causes of crime. Is it social class or mental deficits that cause crime? Is it the (inherited or socialized) propensity of crime or is the social and physical environment responsible for humans to commit crimes? Or are the laws of states the cause of crime?

Some may argue that this "wealth of ideas" is a blessing for the discipline; others would argue that its presence demonstrates the impotence of theoretical criminology. There is no superior theory (despite the claims of individual scholars) that can explain more and better than other theories, let alone can predict that a person will commit a crime in the future given the conditions of that theory. In the past, criminologists and others have also heavily and regularly criticized the state of causal theory. In the 1930s of last century, the mathematicians Michael and Adler (1933) critically evaluated criminology for the government and concluded that criminological theories are no more than empirical generalizations that do not meet any mathematical criteria of theory formation. Forty years later a German sociologist discussed the most important criminological theories of that time and judged them as vague, with unclear concepts and unspecified relations between them, without any formal structure and low explanatory power (Opp 1974). Wolfgang and his colleagues drew similar conclusions after evaluating criminology between the years 1945 and 1972 and observing empirical progress but hardly any theoretical improvements (Wolfgang et al. 1978). Bernard (1990) repeated earlier critics and questioned whether criminological theories have any explanatory power. He stated, "*Despite the enormous volume of quantitative research, there has been no substantial progress in falsifying the criminology theories that existed 20 years ago*" and that "*None of these theories has been falsified in the past 20 years*" (Bernard 1990, p. 147). Finally he concluded: "*Current controversies in criminology indicate that there is fundamental disagreement on even the most basic facts about crime*" and "*That being the case, the failure to accumulate verified knowledge in the context of specific theories should not be surprising. Even on simple correlations like those between age and crime, social class and crime there is no agreement*" (Bernard 1990, p. 329).

What might be going on with the discipline? Before condemning theoretical criminology, we must first try to disentangle the existing causal theories whether they are rivals or not to assess the state of a discipline (Lakatos 1970). However, that is a very difficult task to accomplish for criminology. *First*, we have to acknowledge that not all criminological theories can be compared because they are about different units of analysis. A majority of causal theories have individuals as subject of analysis, but an increasing number of others are about geographical areas, like street segments, neighborhoods, or countries, or social and ethnic groups, business corporations, states, organized groups, institutions like prisons or probation systems, police, or laws. In order to compare whether theories are rivals, they should at least have the same unit of analysis, or else one is comparing apples with pears. *Second*, in case of theories about individuals, the dependent variables (i.e., the behavior to be explained) differ too much prohibiting comparisons. Most theories are about criminal behavior in general, others are about a specific kind of crime like burglary or violence, some are about deviant behavior including mental disturbances or sexual or psychological abnormalities, some include all aggressive behaviors, and some even do not mention the kind of behavior that is aimed to be explained! *Third*, criminology is a product of intellectual influences of many other disciplines, notably sociology and psychology but also from medical sciences and law. As a consequence conceptual frameworks of these disciplines are introduced in criminology, without further reference to other, already existing theoretical concepts. The complex interdisciplinary discourse must be unraveled to assess whether we have distinct independent causal factors or not. *Fourth*, theories of which the propensity to crime is the object of explanation cannot be compared with theories in which criminal behavior is the outcome. For instance, in Hirschi's bonding theory, the outcome of the bonding process is that the individual is free to deviate, not the frequency or seriousness of the criminal offense. *Lastly*, most causal theories explain only little variance in the criminal behavior of humans as Weisburd and Piquero recently demonstrated (Weisburd and Piquero 2008). They pointed at the underdeveloped way of theory testing in criminology and the practice to use seldom primary data for that purpose. But that is only part of the story. Probably the fact that we have to do with only fragmented and limited explanations anyway is important as well.

Acknowledgement The author wants to thank professor Sally Simpson (Maryland) and professor Lieven Pauwels (Ghent) for their helpful comments on a previous draft.

History of Fines

Tomer Einat
Bar-Ilan University, Ramat-Gan, Israel

Overview

Criminal fines are monetary penalties paid to the state by offenders (Hillsman 1992). This sanction has several advantages over other types of penalties (Hillsman 1988; Zender 2004: 206). For one, it incorporates the penal functions of retribution, deterrence, and rehabilitation (Ashworth 2000). In addition, the amount of the fine can be tailored to the seriousness of the particular crime and to the specific individual's criminal history and resources (Uglow 1995). Furthermore, it allows the offender to remain in the community, maintain economic and social bonds (Radzinowicz and Hood 1996), and avoid secondary effects of incarceration, such as loss of employment and forcing dependents to rely on public assistance (Ruback and Bergstorm 2006). Moreover, the criminal fine is inexpensive to administer and can be enforced by existing criminal agencies (Klein 1998). Finally, criminal fines provide income for the state (Einat 2008).

Accordingly, it shouldn't be a surprise that the criminal fine has become practically one of the most important and frequently ordered sanction by many Western and non-Western criminal and civil courts. In some cases, it has even been accorded statutory priority over short imprisonment (Grebing 1982).

Curiously, despite the importance and frequent use of the criminal fine, little theoretical, empirical, and critical attention has been paid by modern criminology and sociolegal disciplines to its nature, underlying rationale, characteristics, and historical development (O'Malley 2009). Nonetheless, due to the relatively high number of historical, sociolegal, and criminological variables affecting the development, usage, enforcement, and impact of the criminal fine (Einat 2004 ; O'Malley 2009; Weisburd et al. 2008) as well as their complexity, the current review will incorporate only a few of them. A comprehensive review and analysis of such variables and aspects should, however, be the subject of a separate work.

Historical Development of the Criminal Fine

Monetary sanctions were known in a basic form to various ***ancient cultures*** that had passed through the stage of self-help and of private and blood vengeance while retaining the underlying principles of retaliation (lex talionis; talion). The purely material talion, namely, revenge through harm of equal severity, was restricted in favor of a discharge of the talion through the payment of money and through the performance of services having a monetary value. Such discharge corresponding with the developing notion of equivalence associated with barter and sale. Thus, monetary sanctions became the most common punishments in the early days of many states. Even if the compensatory character of these payments was to some extent still predominant, there were, however, cases of authentic fines.

For example, according to the criminal law of ***Hammurabi*** (2250 BC), stealing was punished by payment of five times the value of the stolen object. In the case of theft of domestic animals, the sanction amounted to the tenfold value, and in cases of theft of royal property or temple, the penalty extended to thirty times of the value.

This exponentiation principle frequently characterized other, less ancient, criminal law systems: The laws of ***Manu*** in India (1200–500 BC) prescribed numerous fines and also provided for confiscation. Offenders, unable to pay their fines, could have discharged their duties to pay through the performance of services, thus becoming "slaves of their punishment." In ***Egypt***, fines and confiscation were imposed for a variety of offenses, viewable as "breaches of public order," often, to the point of abuse. Under ***Mosaic*** law, monetary sanctions served the purpose of satisfying and compensating the victim. These penalties were either calculated in accordance with the exponentiation principle and in proportion to the harm caused or fixed by law. Following the exponentiation principle, the amount of monetary penalties was two to five times in cases of fraud, breach of trust, or theft. Additionally, offenses against the person could have been sanctioned by monetary sanctions, thus avoiding vengeance. Under ***Greek*** law, monetary sanctions appeared as original punishments and played a significant part in relief from severe punishment. In this manner, maliciousness, disregard of official duties, insult, and rape were punishable per se with monetary payments, either to the state or to the victim. Finally, monetary sanctions were of significant importance in ***Roman*** law: The monetary penalty went as *Multa* into the public pursue and as *Poena* to the injured party. Monetary sanctions imposed against offenses of property were a multiple or quadruple of the value of the harm caused. Capital punishment was accompanied by full or partial confiscation of property, which, being a source of revenue, later served the state well.

Germanic law exerted a special influence on the genesis of the criminal fine in Europe. It gradually restricted the dispute over the right of revenge in favor of compensation through performance of valuable services. Furthermore, an arrangement system was developed with different types of penalty. With the emergence of state administration of criminal justice, monetary sanctions finally lost their compensatory character and took the form of actual fines in most countries.

The Criminal Fine in the Modern Era

The criminal fine has not followed a stable and continual course in its development down to the present day, but has been subject to two major turning points.

The first crossroad came around the thirteenth century, with the development of severe form of physical punishment, which limited the imposition of fines to the domain of petty offenses and breaches of public order. Nonetheless, relief from such harsh sanctions was possible through the payment of fines.

The second decisive moment came around the beginning of the nineteenth century with a considerable growth in the importance of the fine, due to its appreciation by the authorities as a source of revenue, successive decline in the severity of physical punishment, and the fact that prisons were not generalized institutions for punishment (King 1996). Oddly, and in contrast to the legal discourse, these historical processes brought the fine into complete discredit in all Western European countries. The fine was generally regarded as a mediocre penalty, customarily imposed against misdemeanors, breaching of public order, greediness, and petty offenses (Briggs et al. 1996; Seagle 1948). For example, in seventeenth-century England, the criminal fine was frequent and typically light, usually from a few pence to a few shillings. The reason why fines were so small was that they were imposed on ordinary working people, people whose incomes and resources were minimal (Briggs et al. 1996). Between 1760 and 1820, close to 80 % of convictions in England resulted in the imposition of a fine, most frequently of only small amounts of up to a shilling (King 1996). Simultaneously, the proportion of offenders fined in England for assault drop from nearly 80 % to only 26 % (King 1996: 48–50). Corresponding with this, the proportion imprisoned (mainly for short terms) rose from less than 4 % to over 50 % (*Ibid.*). In short, between the thirteenth century and the nineteenth century, criminal fines were a default sanction for minor offenses, and short terms of imprisonment temporarily displaced them from their historically ancient dominancy.

Crucial international and national reconsideration of the criminal fine in most modern Western sanctioning systems occurred at the last third of the nineteenth century, mainly due to the strong criticism razed against the ineffectiveness of short-term imprisonment (Grebing 1982). The short prison term was seen to have neither reformative nor deterrent effects and was criticized for having extremely harmful, stigmatizing, and criminogenic effects, especially on first and occasional offenders. Garofalo (1885/1968), for example, argued that imprisonment for first and minor offenders was pointless because “if the occasion has been an exceptional one, if there is little likelihood of its future occurrence, there is no need of employing any means of elimination" (226). Furthermore, short-term imprisonment was perceived as costly to the family and administratively burdening. This criticism was fortitude by additional claim suggesting that short terms of imprisonment convert casual offenders into confirmed criminals (O'Malley 2009). Leading criminologists at that time – Garofalo, Rosenfeld, Walberg, Von Liszt, and Bonnevile De Marsangy – argued strongly for the abolition or, at the very least, general restriction of short-term imprisonment and for the fine's restitution. Their disapproval of short-term imprisonment and their view that the criminal fine could be used as substitutes for such sanction found ready acceptance in various European and Scandinavian countries. Movements and fights against short-term imprisonment were held in England, Italy, and Austria by leading academic criminal lawyers. In the Netherlands and Belgium, Prins Van Hamel propagated the program of the modern school of criminal law – pushing to the elimination of short-time imprisonment and the extensive use of fine and conditional sentencing. In addition, the problems arising from short imprisonment and the question of its replacement by fines (or other alternatives to imprisonment) appeared repeatedly on the agendas of international congresses. For example, the International Penitentiary Congress, held in London in 1872, in Rome in 1885, and in St. Petersburg in 1890, as well as the meeting of the IKV in Brussels in 1889 and in Oslo in 1891, dealt with the question of avoiding both short imprisonment and imprisonment in default of payment through the imposition of noncustodial forced labor, judicial reprimands, and suspended sentences.

Though the criticism against short terms of imprisonment and the significance of the criminal fine were well understood in principal by academicians, philosophers, lawyers, and several sanctioning systems, fines could not be installed to any degree in all European jurisdictions before the end of the nineteenth century, because of the extent of unemployment and poverty (Rusche and Kirchheimer 1939).

As of the end of the nineteenth century and into the twentieth century, due to increase in employment and real living standards that provided the conditions under which the fine could have become a more generally applied sanction (Rusche and Kirchheimer 1939), many European countries, legally and practically, began restricting the use of short-term imprisonment replacing it by criminal fines and suspended sentences (Grebing 1982). For example, in Germany, between 1882 and 1932, the percentage fined increased steadily from 11 to 47.5 %, having peaked at 50.5 % in 1930 (Rusche and Kirchheimer 1939: 167). Over the same period, the proportions sentenced to terms of over 3 months imprisonment remained stable, indicating that short periods of imprisonment were being substituted by fines (O'Malley 2009: 38). On the basis of rather thin evidence, Rusche and Kirchheimer (1939) concluded that "…In general therefore the application of fines in the first half of the nineteenth century was infrequent because the necessity of commuting the punishment into imprisonment would have unduly complicated criminal procedure…The decline in unemployment and the rising living standard in the second half of the nineteenth century, however, introduced a fundamental change…many of the difficulties lying in the way of a fine system lost their force" (168). Four decades later (1969 and 1975), the Federal Republic of Germany passed the first and second (respectively) criminal law reform acts declaring that short imprisonment under 6 months is to be the last solution and the fine was given statutory priority in this sanctioning area. Similarly, the Austrian and Brazilian legislatures followed this example and passed the rule that the fine must take precedence over a short prison term. Other countries such as Belgium, the Netherlands, Switzerland, Denmark, Norway, Finland, and Sweden pursued the objective of restricting short-term imprisonment – mainly through the imposition of fines and suspended sentences. Nonetheless, these countries have neither enacted a statutory minimum term of imprisonment nor introduced a priority in the selection of penalties in favor of the fine. Consequently, in spite of a noticeably large number of fines imposed, they exhibited (and still exhibit) a vast proportion of short-term imprisonment sentences especially in regard to medium-range crimes.

In contrast to the legislative and sanctioning policies mentioned above, the criminal fine was perceived negatively by several East European jurisdictions during the postrevolutionary years (Grebing 1982). It was regarded as inferior to reformative sanctions and, thus, almost completely neglected from many East European criminal codes. In this manner, the criminal fine was omitted from the leading principles of the 1919 Soviet Union criminal legislation, displaced by short periods of "correctional labor."

During the 1920s, the criminal fine tiptoed back only for a few trivial and financial-oriented offenses. This remained true until the late 1980s (O'Malley 2009) where fines seen as incompatible with some of the basic ideological premises of socialism. It was maintained that the fine was a criminal measure typical of the capitalist system in which everything, even the criminal justice system, was profit oriented. Consequently, fines made up only about 3–4 % of sanctions in the USSR, about 5 % in Czechoslovakia, about 10 % in Bulgaria, and 18 % in Poland (Frankowski and Zelinska 1983: 39).

While in most East European socialistic jurisdictions the fine "was held in considerably bad scent" (O'Malley 2009: 35), it could have been logically presumed that the United States, one of the most capitalist and wealthiest of nations that glorifies market processes, would be devoted to imposing fines for criminal offenses (*Ibid*.). In practice, this assumption appears to be and to have been solely true as regards to punishment against businesses and corporations. Individual offenders were hardly punished by criminal fines, and the few who had were usually fined due to petty financial-oriented crimes. For example, in the 1950s, over 90 % of antitrust violations and offenses against labor standards legislation, and almost the same proportion of offenses against food and drug legislation, were sanctioned by fines at the federal level. Nonetheless, when the focus shifted to assault, the proportion sanctioned by fines dropped dramatically to 10 %; in the case of theft dropped to only 4 %; and with juvenile delinquency dropped to a less than a 1/3 % (The University of Pennsylvania Law Review 1953). Furthermore, a broad repertoire of offenses attracting criminal fines more than half the time in Britain and more than three quarters of the time in Germany attracted sentences of fines in only 5 % of cases in USA at the federal level (Gillespie 1981). Even by the mid-2000s, at the federal US level, only 4 % of all offenders were ordered to pay a criminal fine (only 3.5 % received a sole fine), and this was true for only 1 % of those convicted of felonies. In addition, the proportion fined for misdemeanors was 29 %. In comparison, criminal fines were imposed in the same years against nearly 25 % of all criminal offenses in England and Wales (Home Office 2002) and against 70 % of offenders accused for misdemeanors. Lastly, at the state level, the criminal fine has hardly been used as the sole sentence in relation to felonies but was employed as an additional sanction in about 25 % of all cases – most frequently as an add-on to a sentence of imprisonment (Bureau of Justice Statistics 2004). Some states (e.g., Philadelphia) and federal guidelines explicitly limit the criminal fine to a supplemental role, something to be imposed in addition to the real sentence.

The practice of fines in America, both in federal and in state levels, thus suggests that the criminal fine has been losing ground over the past decade. In contrast to Europe where criminal fines increased in proportion and in money value precisely at the time they came to be regarded as a replacement for short periods of imprisonment, short terms of imprisonment did not decline in the United States in the same way (O'Malley 2009). Fines in the United States were not seen as comparable to short periods of incarceration and, consequently, did not attract significant penalties in dollar value. Hypothetically, this existing pattern stems either from the United States high commitment to the "Tough-on-Crime" punitive agenda and low commitment to reform – leading approximately 75 % of all sentenced offenders at the federal level to imprisonment (Bureau of Justice Statistics 2004) – or from doubts as to the correctional and/or rehabilitative value of the fine (American Bar Association 1971; The National Commission on Reform of Federal Criminal Laws 1971).

Overview

The nascent development of institutional forensic science as we know it today, in the late nineteenth century, was a crucial component in the larger process of the professionalization of policing. In the twentieth century, forensic science transitioned from a location outside of police agencies, primarily in universities, and an auxiliary role assisting police investigators toward greater integration with, and in some cases even location in, police agencies. The location of forensic science in police agencies brought many benefits in terms of coordination and control of the crime scene and potentially in the development of "intelligence-led policing" but also brought costs in terms of their perceived impartiality and its links to "mainstream" scientific institutions. The capabilities of forensic science have developed enormously over the course of the twentieth century, but research suggests that it continues to be underused by police.

Introduction

Forensic science may reasonably be viewed as having played an important role in the professionalization of policing that began in the late nineteenth century (Jones 1994; Laybourn and Taylor 2011). While there are histories of forensic science (generally written by practitioners) and histories of forensic medicine, expert witnesses, and the professionalization of policing (generally written by historians), the intersection of these developments remains underexplored.

Forensic science is, of course, quite old and predates the development of professional police and, indeed, police altogether. The origins of forensic science and medicine have been traced as far back as the ancient Egyptians, Greeks, Chinese, and Aztecs (Bell 2008). However, forensic science as an institution as we know it today, with dedicated laboratories, infrastructure, professional organizations, and so on, only began developing in the late nineteenth century. While this development began outside of police agencies, later some aspects of institutional forensic science were incubated within police agencies.

Institutional forensic science as it exists today generally traces its history to late nineteenth-century physicians who were interested in what was called at the time "legal medicine." The Medico-Legal Institute was founded in Paris in 1868 (Watson 2011) and "during the half-century following 1870, state- or municipally-sponsored institutes of forensic medicine were established in Paris, Berlin, Vienna, Budapest and many other principal cities of Europe" (Ambage and Clark 1994, p. 293). Late nineteenth-century pioneers included Alexandre Lacassagne in Lyon; Joseph Bell in Edinburgh (who has been identified as the Conan Doyle's model for the fictional detective Sherlock Holmes); John Glaister, Sr. in Glasgow; Bernard Spilsbury in England; Hans Gross in Austria, who published what has been called "the first textbook on criminalistics" (Jones 1994) in 1893; and R.A. Reiss in Lausanne. The primary site of this activity was at universities, specifically medical schools, in France and Britain, or law schools, in the German-speaking countries. As police agencies professionalized and became increasingly interested in solving crimes, these physicians were called upon to assist with investigations. Forensic science, however, was external to the police; there was no question of locating forensic science within the police agencies themselves.

Some have suggested that it was what we might call the "identification disciplines" – photography, anthropometry, and fingerprinting – that occasioned the crossover of forensic science from medicine and the university to police agencies (Valier 1998; Roux and Robertson 2009; Margot 2011; cross-reference: ▶ Identification and the Development of Forensic Science). These three techniques were all developed not for forensics, but for criminal record-keeping purposes: for linking offenders held in custody to their past criminal histories with greater accuracy without being thwarted by the use of aliases or the adoption of false identities. These technologies were adopted in divisions of police agencies known as "identification bureaus" and were manned by "identification clerks" generally drawn from the ranks of the police. One of these techniques, fingerprinting, happened to also lend itself to a forensic application: the linking of accidental prints (or "latent prints" or "marks") left at crime scenes to specific suspects. Although some early research on fingerprints was performed by physicians and scientists, it seemed natural to use the identification clerks, who classified fingerprint patterns for record-keeping purposes, as "experts" to analyze latent prints for forensic purposes. Thus, police identification clerks began to share the title "forensic scientist" with physicians and chemists (Cole 2001).

Fingerprinting became perhaps the earliest technique whose use was so routine that it could be delegated from physicians to "specially trained policemen as its use became widespread amongst police forces" (Crowther and White 1988).

The development of institutions fully devoted to forensic science, as opposed to treating forensic science as an aspect of, say, public health or pathology, took two general routes (Margot 2011). The first was the university. For example, in 1909, Reiss established the first stand-alone School of Forensic Science at Lausanne, associated with the faculties of both law and medicine (Margot 2011). In 1908, August Vollmer, the Police Chief of Berkeley, founded a Police School in association with the University of California which included forensic science among other topics intended to make policing more professional and generally "scientific" (Carte and Carte 1975). And, Calvin Goddard established the Scientific Detection Crime Laboratory at Northwestern University in 1930 (Tilstone et al. 2006).

The other route was outside the university, in institutions dedicated to criminal justice. Edmond Locard, a former student and assistant of Lacassagne, left the University of Lyon to found the Police Scientific Laboratory, the world's first police laboratory, in Lyon in 1912 (Watson 2011). Significantly, the laboratory was controlled by the court, not the police (Margot 2011). Other early "criminalistics" or "police science" laboratories were attached to government chemical or toxicological laboratories, as in Sweden (Ambage and Clark 1994). In England, many police agencies used the services of private laboratories (Laybourn and Taylor 2011). However, most crime laboratories outside universities soon fell into the control of police agencies. The Federal Bureau of Investigation crime laboratory opened in 1932 (Walker 1977). "By 1930, almost every European capital and many other principal cities has its own medico-legal institute, while France, Italy, Germany, Switzerland, Sweden and... Finland all had at least one 'police science' laboratory" (Ambage and Clark 1994, p. 293), as well as Egypt and Ceylon. The exception was England. The Metropolitan Police "rebuilt and reorganized" (Laybourn and Taylor 2011, p. 94) its old laboratory into a modern laboratory at Hendon in 1935, and the Home Office established the Forensic Science Service and opened its first laboratory in Nottingham in 1936 (Watson 2011). Neither of these was an institute of legal medicine, however – a proposal to house such an institute at the University of London failed, signaling the separation of forensic science from forensic medicine and the "apparently inexorable decline of English forensic medicine" (Ambage and Clark 1994, p. 307).

These two routes seemed to cause some tension between the development of forensic science outside and within police agencies (Margot 2011; cross-reference: ▶ Identification and the Development of Forensic Science). Many forensic scientists located at universities seeking to develop, expand, or maintain stand-alone institutes dedicated to forensic science were undermined somewhat by the steady assumption of routine forensic work by police agencies (Crowther and White 1988). Thus, forensic laboratories today tend to be located in law enforcement agencies, although there are also national laboratories and laboratories located in universities, prosecuting authorities, or judiciaries, especially in Europe (Tilstone et al. 2006). By the post-World War II period, even some university-based forensic laboratories, such as the pioneer laboratory at the University of Glasgow, came to be staffed in large part by the police (Crowther and White 1988), and the police won control of the Police Scientific Laboratory in Lyon (Margot 2011). Some have suggested that the university-police partnership that seemed to be emerging after 1920 never really came to fruition. Instead, nearly all technical developments in forensic science have come from mainstream academic or industrial science, not from either the police laboratories or the university forensic science programs (Tilstone et al. 2006). The US National Research Council (2009) also recently noted forensic science's "lack [of] strong ties to our research universities and national science assets."

Although forensic science began to be used early in the twentieth century in isolated places and cases, it was only in the 1930s "that detective and scientific work became more truly uniform and modernised and increasingly subject to government guidelines and direction (Laybourn and Taylor 2011). Innovation in forensic science and technology and its integration into police work provided clear benefits in terms of solving crimes, one, but by no means the only, function of the police. However, there have been recurrent complaints that forensic science was underused by police investigators. Many forensic techniques were useful in linking known suspects of crime scenes, but until the development of searchable databases, they were of little help in generating suspects when none existed. The development of computerized, searchable databases, therefore, was a crucial development, perhaps even more important than the remarkable innovations in forensic technologies themselves.

As Peterson et al. note (2010), "there is little published empirical data identifying the types of evidence routinely collected, and the extent to which this evidence is submitted to and examined in forensic laboratories." However, what research exists suggests that forensic science has been utilized far less than one might have imagined given its seemingly utility for investigating crimes. For example, Peterson et al. (1987) found relatively low uses of forensic science in a sample of criminal investigations in American cities. Ethnographers of detective work found police investigators far more focused on nonforensic activities like interviewing witnesses, informants, and suspects than on forensic science. Nonetheless, the utilization of forensic science appears to be increasing. Almost completely absent in Ericson's 1981 ethnographic report, it appears somewhat more in more recent detective ethnographies (Innes 2003; Jackall 2005). Nonetheless, researchers have continued to find forensic evidence, including DNA evidence, grossly underused and poorly understood by police (Raymond et al. 2004; Pratt et al. 2006; Strom and Hickman 2010). Strom and Hickman assert that in addition to the better-known backlog of forensic evidence at crime laboratories – where samples are not processed because of insufficient resources – there is a less well-known backlog of evidence that is collected by the police but never submitted to the laboratory for analysis. Consistent with Pratt et al.'s findings, Strom and Hickman's qualitative survey reported that the primary reason for underuse of DNA profiling is that it is conceived by police investigators as a tool for building evidence against a suspect identified by other means rather than as a means of generating a suspect by treating existing archives of genetic information as what have been called "DNA intelligence databases" (Walsh and Buckleton 2005). Peterson et al. (2010) likewise found forensic evidence to be submitted to laboratories at low rates. They concluded, "it is clear that criminal justice officials external to the laboratory screen much of the forensic evidence and have a major influence on evidence examination priorities and practices" (Peterson et al. 2010).

Whether police agencies' historic preference for non-forensic methods is desirable is an interesting question. As forensic capabilities, capacity, and efficiency increase and costs decrease, important questions will arise about whether greater reliance on forensic science in the investigation will be preferable from the perspectives of security, social control, social justice, civil and human rights, and economic rationality. Such questions have hardly been explored in criminology (but see, e.g., Duster 2004).

The tendency to locate forensic laboratories in police agencies undoubtedly facilitated close coordination between forensic science and police investigators and enabled coordinated control of crime scenes. However, this coordination apparently came at a cost. Recently, the location of the bulk of forensic science infrastructure in police departments has emerged as a major point of criticism of forensic science (e.g., Giannelli 1997). The criticism is generally twofold: First, philosophers and sociologists of science have generally cited independence from institutional, and especially state, control as crucial to allowing scientists to operate as if their sole allegiance is to scientific truth. This is generally thought to require the location of scientists in institutions where such freedom is permitted and encouraged. Universities, with their notion of "academic freedom," are the most common models, of course, but even industrial (especially the celebrated industrial research laboratories of the twentieth century, now largely an extinct species) and national laboratories have been conceived as bestowing varying degrees of such freedom and independence. If forensic science is to be considered a scientific endeavor (and this itself has been the subject of some debate), its overwhelming location within state institutions would seem to violate this requirement. Second, the *telos* of all forensic analysis is a report or testimony that a legal party (usually the state) can at least threaten to use (even if it rarely is actually used) in a criminal trial. Under an adversarial system of justice, the trial is seen as a contest between two sides; vigorous (though fair) pursuit of victory by each side is supposed to generate the best chance of reaching an outcome corresponding with justice. In such systems, the association, whether administrative, financial, or emotional, of forensic science institutions with one of those sides (the state) to the exclusion of the other (the suspect) seems irredeemably problematic. Even in inquisitorial systems of justice, the association of forensic science with the state seems at least as problematic, if not even more so.

For these reasons, the tendency for forensic science institutions to be located within state law enforcement agencies is generally cited as perhaps the leading deficiency of contemporary forensic science among those interested in the reform and improvement of forensic science today (e.g., National Research Council 2009). But the prospects for change seem daunting. The major points of resistance are probably political and resource driven; forensic science organizations are understandably skeptical that state governments would fund forensic science to even its current levels if its mission was construed as driven by science rather than public safety.

Removing forensic laboratories from police agencies would also entail some costs in terms of coordination, such as allowing forensic scientists to use the nature of the case to decide what items should be tested and how they should be tested. It is also argued that forensic evidence can only be understood in the context of the whole case (e.g., Margot 2011). Looking forward, it is argued that integration of forensic science into police agencies will facilitate the trend toward emerging "intelligence-led policing" (Ribaux et al. 2006; Margot 2011). Some scholars, however, argue that forensic science would improve with greater distance from police agencies. Forensic scientists would focus more on the "pure" results of their scientific analysis, and their interpretations of the evidence would be less tainted by contextual information about the case fed to them by investigators (Risinger et al. 2002; Dror and Charlton 2006; Krane et al. 2008). With these compelling principles at odds, the issue of whether the current arrangement of locating forensic science in police agencies is likely to be hotly debated in coming years. As this historical review shows, the current arrangement is not eternal: It is not as old as it may seem, and it is the product of specific contingent decisions and circumstances early in the history of interactions between newly professionalizing police forces and the nascent, hybrid field called "forensic science."

Overview

Criminologists have had a long enduring interest in the geography of crime and the explanation of spatial variations of crimes and offenders. In this entry, we describe the first century of empirical research starting in Europe in the late 20s and early 30s in Europe, especially in Belgium and France and in England (London). These studies contain the first analyses of registered figures on crime and prisoners. The results were also displayed on maps. There existed a vivid discussion between mathematicians, statisticians, and politicians during several meetings in London. The unit of analyses was in the beginning larger administrative areas and countries. The research agenda was inspired by new administrative data that became available in France in 1825 and by the political agenda of reformism, a political movement that after the Napoleon wars aimed at the improvement of education and health for the poor and illiterates. After 1860, the interest in geographic criminology in Europe diminished. Criminologists in Chicago took over the lead in geographic research in the beginning of the twentieth century.

The First Steps in France and Belgium

Geographical criminology begins with the publication of statistics on the French population by the French Home Office in the 1820s. The publication of the *Comptes Générales de l'Administration de la Justice Criminelle en France* in 1825 inspired many statisticians and other scholars to explore in more detail registered data on crime. Among the very first was Baron Charles Dupont who spoke for the first time about statistics on morality of people and the nation in a meeting of the *Conservatoire des Arts et Métiers* in November 1826 (Beirne 1987). As a cartographer, he published in 1816 tables on the "distribution of illiterates" across the regions of France. During this meeting, he promised to publish a map on crime and criminals soon. However, the Belgian Edouard Ducpétiaux was the first to publish a table with crime and suicide figures of regions in Spain, France, Italy, and England (Ducpétiaux 1827). He observed remarkable differences between regions and countries and concluded that the morality of nations differed (Ducpétiaux 1827, pp. 11–12). The Lower Lands (the Netherlands) were especially praised for their low crime rates and for a low number of homeless people (Ducpétiaux 1827, p. 29).

In 1829, the first geographical map of crime was published. Partly based on the *Comptes Généraless de l'Administration de la Justice Criminelle en France*, Michel-André Guerry and the Venetian cartographer Adriano Balbi published, on one large sheet, three maps on the distribution of crime in France in the years 1825–1827 (Balbi and Guerry 1829). It was a novelty in the new field of criminology that they made use of a cartographic method of presenting statistical material. They concluded from their work that (1) in certain regions in France (departments) with higher numbers of personal crimes (violent crimes), there was less property crime; (2) the area above the line of Orléans and Lyon showed the highest rate of property crimes in France; and (3) in urban areas, especially in the capital of Paris, the highest numbers of property and personal crimes could be observed. Later, when Guerry became head of the Crime Statistics Unit of the France ministry of Justice, he continued his work on mapping crime. In 1833, his influential *Essai sur la Statistique Morale de la France* was published (Guerry 1833). Inspired by the Reform Movement of the nineteenth century (in France and England, the Reform Movement focused its policy on public health and education for the poor), Guerry examined whether poverty and density of population might lead to higher crime rates. He observed however an empirical complexity. The rich north *departements* were confronted with higher property crime rates than the poor *departements* in the south of France. He concluded that the level of poverty was not the direct cause of crime. Similarly, his data suggested that population density was not a cause of crime.

The studies by Guerry soon became the subject of a heated debate between proponents and opponents of the Reform Movement, especially in England. A British Member of Parliament defended the work of Guerry, but the industrialist William Greg criticized Guerry's conclusion that education or poverty might not be a cause of crime (Greg 1835). In 1864, Guerry published again a comparison of crime rates between England and France (Guerry 1864). We can hardly imagine today the work he had to carry out collecting and analyzing the data, which included over 226,000 cases of personal crime in the two countries over 25 years and, for France only, over 85,000 suicide records (Friendly 2007). The results of this effort reinforced the findings he had published 30 years before.

His friend Alexandre Parent-Duchâtelet published in 1836 an empirical study containing maps on the distribution of prostitution from 1400 till 1830 in Paris (Parent-Duchâtelet 1837 [1836]). Because of the official control of brothels by the Paris authorities, systematic data were available on prostitutes, especially from the years 1817–1827. Even information regarding the *departements* they came from was collected. Not surprisingly, the center of the city had the highest number of prostitutes, especially *quartier 6*. He used neighborhoods, as defined by administrative boundaries as units of analyses.

The French scholar Michel-André Guerry is often bracketed together with the Belgium statistician and astronomer Adolphe Quételet who discovered the normal distribution in statistics with which deviations can be observed and calculated (Landau and Lazarsfeld 1968). In 1828, Quételet (1984 [1831]) examined the French *Comptes Gé nérales de l'Administration de la Justice Criminelle en France* in a lecture for the Academy of Science to show how crime rates vary with the seasons of the year. He demonstrated that June had the highest numbers of violent crimes of the year. He also examined crime data in each *arrondissement* and added: "It appeared to me that these numbers were able to give a sufficiently satisfactory idea of the state of knowledge in each department and especially for the inferior classes where most crimes are committed" (Quételet 1984 [1831], p. 30). He used provinces and countries as units of analyses. Groningen, South Brabant, Anvers, Limburg, and Drenthe had the highest crime rates of all provinces of the Lower Lands (including Flanders). He discussed these observations as was common in the period, in the context of social factors such as poverty, heterogeneity, composition of the population, and attractiveness of cities. He explained the higher rates of property crimes of the richer provinces, as we noted in our introduction, by the unequal distribution of wealth: A great number of people possess nothing compared to the relatively few rich citizens (Quételet 1984 [1831], p. 38).

The French and Belgian scholars were the first who scientifically analyzed crime geographically. These scholars focused on the administrative and political borders of their time in their spatial crime analyses. Nations, regions, counties, provinces, departments, and *quartiers* were the units of analyses, and they were used as a unit for systematic comparisons of crime figures. They were fully dependent on official crime data and other data that the government supplied arranged within these larger geographic units. While the early French and Belgian researchers concerned with crime and place also examined some variability of crime within cities, their overall focus was generally on larger administrative units. Importantly, these early criminologists in their focus on crime rates and official statistics also helped to encourage the more general development of a positivist empirical criminology.

The First Steps in England

France and Belgium were not the only countries where geographical studies on crime were carried out in the nineteenth century. Members of *the Statistical Society of London* also regularly published on crime topics in their statistical journal (first published in 1838). Two articles on crimes were included in the second volume. One was by a prison chaplain who wrote on *Criminal Statistics of Preston* and the other was a short article about the distribution and kinds of robberies in London and Liverpool (mentioned in Morris 1957, p. 53). In this and later papers of members of the Society, the influence of the work of Guerry can be observed.

In the year 1839, a lecture by William Greg on the spatial distribution of population density, fertility, education, and crime in the Netherlands (in those days, parts of Belgium and Luxembourg were also part of the Netherlands) for the *British Association for the Advancement of Science* of August 1835 was published by Ridgway and Sons (Greg 1835). He compared the crime figures on property crimes, violent crimes, and on serious crimes like rape, murder, and manslaughter in the Netherlands with those of England and France. The overall crime figures showed remarkable differences: For the year 1826, the data indicated that the Netherlands had less crime than the other two countries: 1:28.900 inhabitants, in England 1:23.400, and in France 1:17.570 (Greg 1835, p. 15). Greg also studied in more detail large areas of the Lower Lands. He counted the most crimes for the province of Overijssel, followed by South Brabant, Groningen, Drenthe, and West Flanders (like Quételet observed 25 years later). The lowest overall crime rates were found in the province of Friesland. For that period, the highest position of Overijssel in the crime ranking was striking because this province also showed the highest education level for all of Europe (Greg 1835, p. 24). Serious crime was more likely to be present in the provinces of South Brabant, Liege, Groningen, and East Flanders.

Rawson R. Rawson, then secretary of the Society, correlated variables such as age and sex with crime but also presented the number of crimes for the districts of England and Wales (Rawson 1839). He discussed the variability in crime across the districts and concluded that climate and ethnic differences in the population could not be causes of crime. He rejected the conclusions of Guerry on the relationship between education and crime. He assumed that the type of labor could be a cause of crime and divided regions in England into (1) rural areas with farms, (2) industrial areas, (3) mining areas, and (4) big cities. Rawson's research illustrates the critical role that the unit of analysis can play in the development of our understanding of crime at place. He is the first scholar to go beyond the usual administrative and political borders (Morris 1957, p. 55). Based on official data, he found that large cities had the highest crime rates and mining areas the lowest.

His successor at the Society, Joseph Fletcher, continued the work of Guerry and Rawson (Fletcher 1848, 1849). He studied for many years the relationship between education and crime by producing maps showing the levels of crime and illiteracy of England and Wales (later published in Fletcher 1850). According to Fletcher, there were four causes of the level of "immorality" of populations: (1) population density, (2) the distribution of property across societies, (3) the number of people earning their own income, and (4) the level of illiteracy of the population (indicated by the number of crosses instead of signatures in the registers of marriage). He indicated the level of immorality of the population by the number and nature of crimes committed, the number of marriages with a man younger than 21 (indicating forced marriage because of pregnancy), the number of illegitimate children, and the number of bank accounts in the population. He argued (1850) that not only were differences between regions important in the explanation of crime rates, but so was the speed with which these regions changed over time economically and demographically. With these ideas, Fletcher can be seen as a precursor of the French sociologist Emile Durkheim who introduced the concept of anomie to explain the impact of societal changes on people and society (Durkheim 1964 [1893]).

John Glyde (1856) was the first to question the validity of the research findings when large areas were chosen as units of analysis in geographic criminology. In his paper *Localities of Crime in Suffolk*, he showed very clearly that larger units of analysis hide underlying variations in crime. When smaller units than districts or *departements* were taken into account, significant differences in crime rates across smaller areas appeared. As Morris (Morris 1957, p. 58) notes: "Of the regional studies, a major criticism is that the county was the smallest territorial unit considered, but Glyde, by breaking Suffolk down into its seventeen Poor Law Unions was able to demonstrate that the 'County Aggregate' masked considerable differences between the smaller geographical units of which it was composed." Glyde also observed that middle-sized cities situated along main roads had higher crime rates than the mean of the large area they were part of. Jelinger Symons (2000 [1857], p. 281) also examined the relationship between urbanization and crime through ecological analyses of crime in Liverpool, Bristol, and Cardiff. In his view, it was the speed with which the population increases that explains higher crime figures.

In studies of crime and place in England in the nineteenth century, the work of Henry Mayhew cannot be neglected. He is well-known in criminology (and cited therefore) for his descriptive studies of the underworld of London in the middle Victorian Age (1851/1950). However, his detailed studies on the distribution of crime in England and London are also a rich source for those studying crime. He was an excellent observer of his time, describing in four voluminous books precisely and in detail the daily life of the Londoners, their habits, their cloths, their quarters, and streets in the Victorian era (Mayhew 1865, 1950 [1851/1862]). Mayhew also tried to uncover patterns in the distribution of crime in the city of London combining ethnographic methods as well as statistical data. Mayhew's was the precursor of Robert Park who advocated 70 years later a similar methodology. He interviewed prostitutes, criminals, and other citizens about alcoholism, poverty, housing conditions, and economic uncertainty. He was the first scholar who focused on small areas like squares, streets, and buildings as a unit of analysis in criminological research, predating modern interests in micro crime places (see later) by over a century. Mayhew also used police data of the seven Metropolitan Police Divisions and revealed that two of these divisions produced about 65 % of all the suspects in London.

The Decline of European Geographic Criminology

After 1870, the interest of French and English academics in geographic and statistical analyses diminished. At the same time, there are important exceptions. In one of them, Cesare Lombroso studied the geographical distribution of homicide, infanticide, parricide, and suicide across very large geographic areas in Italy (Lombroso 2006 [1878]). He explained the different violent crime rates between the north and the south of the country in reference to the "racial inferiority" of the southern population. The French criminologist Jean-Gabriel Tarde studied the relationship between urbanization and crime from a different perspective than earlier scholars (Tarde 1912 [1890], p. 338). By comparing the crime levels of larger areas, he argued that cities were exporting crime to the rural areas. He wrote: "... today we can see crime spreading from the great cities to the country, from the capitals to the provinces, and these capitals and great cities having an irresistible attraction for the outcasts and scoundrels of the country, or the provinces, who hasten to them to become civilized after their own manner, a new kind of ennobling" (Tarde 1912 [1890], p. 338).

According to Brantingham and Brantingham (1981, p. 12), the nineteenth-century geographic studies in the spatial distribution of crime have revealed important insights: (1) Crime rates vary substantially between geographical areas; (2) these variations are found at different levels of aggregation; (3) these variations persist over (long) periods of time; (4) high crime rates are highly correlated with the presence of other social problems like poverty, alcoholism, high population density, and illiteracy; and (5) lastly, that locations with high number of crimes correlate with the presence of attractive targets and potential victims.

Overview

After the turn of the century, the locus of geographic research on crime moved to the United States, and especially to the city of Chicago. A group of American sociologists, among them Robert Park, William Thomas, Louis Wirth, Ernest Burgess, Clifford Shaw, and Henry McKay, took a leadership role in the development of the criminology of place, in contrast to the statisticians, criminal lawyers, or psychiatrists who dominated criminology more generally in Europe (see entry on the ► History of Geographic Criminology Part I: Nineteenth Century). New theoretical concepts were introduced (notably social disorganization) and innovative methods and techniques to study empirically the distribution of crime in cities. In the 1950s, methodological critiques and developments in other areas of criminology diminished the research attention to geographic criminology. In the 1980s, young scholars reemerged the study of spatial issues studying the dynamics of neighborhoods, elaborating the concept of social disorganization. Recently, the focus is more laid on micro places like blocks, squares, and street segments, because empirical research revealed great variations in crime within neighborhoods.

Chicago and the Study of Dynamics in Cities: Variations in Crime and Offender Rates Between Neighborhoods

After the turn of the century, the locus of geographic research on crime moved to the United States, and especially to the city of Chicago. At the University of Chicago, a group of sociologists took the initiative to undertake new research on urban problems, which centered, in part, on crime (Beirne and Messerschmidt 1991; Bulmer 1984; Burgess and Bogue 1964b; Faris 1967; Harvey 1987). They also moved the action of crime and place research from broad comparisons across large geographic areas to more careful comparisons within cities. Interestingly, the Chicago School scholars were either not aware of or ignored till 1933 the work of nineteenth-century crime and place researchers in Europe (Elmer 1933; Levin and Lindesmith 1937).

American cities grew in the second part of the nineteenth century and first part of the twentieth century faster than ever before in history, with all the social problems associated with such growth. Chicago itself played an important role in the integration of large numbers of Italian, Irish, German, Chinese, Polish, Jewish, and Scandinavian immigrants. The city evolved from a very small settlement in 1840 (with 4,470 inhabitants) to a city with a half-million inhabitants in 1880. Ten years later, the population had increased to one million, and in 1930, to about 3.5 million. Crime was perceived as one of the most important urban problems:

“After World War I (1914–1918), Chicago sociologists turned their ecological attentions to a variety of social problems. Exacerbated by the severe hardships of the Great Depression, Prohibition, and by the well-publicized rise of gangland warfare and union racketeering, crime itself came to be seen as a major social problem in Chicago. Crime, therefore, was one of the chief topics studied by members of the Chicago-School.” (Beirne and Messerschmidt 1991, p. 362)

Now, a group of American sociologists, among them Robert Park, William Thomas, Louis Wirth, Ernest Burgess, Clifford Shaw, and Henry McKay, took a leadership role in the development of the criminology of place, in contrast to the statisticians, criminal lawyers, or psychiatrists who dominated criminology more generally in Europe (Vold et al. 2002).

William Thomas contributed to the criminology of place by introducing the important concept of *social disorganization*, referring to "a decrease of the influence of existing social rules of behavior upon individual members of the group" (Thomas 1966, p. 3). The concept naturally focused on neighborhoods or communities. Robert Park (1864–1944), who was recruited by Thomas, was the initiator of urban social research on crime places, shifting the unit of analyses from countries and large areas to cities and their neighborhoods (Park and Burgess 1967 [1925]). The city in his opinion was more than "…a congeries of individual men and of social conveniences – streets, buildings, electric lights, tramways, and telephones, etc; something more, also, than a mere constellation of institutions and administrative devices – courts, hospitals, schools, police and, civil functionaries of various sorts. The city is, rather, a state of mind, a body of costumes and traditions, and of the organized attitudes and sentiments that inhere in these costumes and are transmitted with this tradition. The city is not, in other words, merely a physical mechanism and an artificial construction. It is involved in the vital process of the people who compose it; it is a product of nature, and particularly of human nature" (Park and Burgess 1967 [1925], p. 1). Park argued that urban life must be studied in this context in terms of "its physical organization, its occupations, and its culture" *and* especially the changes therein (Park and Burgess 1967 [1925], p. 3). Neighborhoods in his view were the elementary form of cohesion in urban life.

His younger colleague, Ernest Burgess, drawing from an inventory of price changes in housing values and other real estate in Chicago by a real estate agent developed a concentric zone model of the distribution of social problems and crime for cities (especially for Chicago) (Burgess 1967 [1925]). Burgess suggested that Chicago included five concentric zones, each containing various neighborhoods, four of them situated around "The Loop" (the business center of the city): "the typical processes of the expansion of the city can best be illustrated, perhaps, by a series of concentric circles, which may be numbered to designate both the successive zones of urban extension and the types of areas differentiated in the process of expansion" (Burgess 1967 [1925], p. 50). Burgess' unit of analyses was a series of neighborhoods within cities that share similar characteristics. He assumed that depending on the distances to the center and the special features of these zones, the levels of crime would vary.

Clifford Shaw was one of the first Chicago sociologists to carry out extensive empirical research on the geographical distribution of crime on the basis of Burgess' zone model (Shaw et al. 1929). This study can be seen as a landmark in the history of geographic studies because of its detailed data collection, advanced methods, and innovative statistical tools. Based on the concentric zone model of Burgess, the authors studied the distribution of truancy of young people, juvenile delinquents, and adult offenders in Chicago. Assisted by young researchers like Henry McKay, Frederick Zorbaugh, and Leonard Cottrell, Shaw took natural areas as units of analyses (Abbott 1997) but in more detail than ever before in these kinds of studies. Shaw and his colleagues introduced new units of analyses. First, they introduced *spot maps* by plotting the home address of thousands of offenders on a map of Chicago. Second, he combined the offender address data with census data to created *delinquency rate maps* of square mile areas. And finally, he constructed *radial maps* and *zone maps*, which displayed delinquency rates at regular distances from the city center (Snodgrass 1976).

For further analyses on the distribution of crime across Chicago, Shaw et al. divided the city into 431 census tracts in 1910 and 499 in 1920 (Shaw et al. 1929). Each census tract included convenient age and sex groups of the population. Subsequently, these census tracts were combined into square mile areas with a minimum population of 500 residents. The technique was to allocate delinquents to their place of residence, and to divide the number of delinquents by the number of boys of juvenile court age, in order to compute rates for small areas. These rates were used by Shaw and his associates to make shaded maps or compute correlations.

In the same year, Shaw's research assistant Harvey Zorbaugh published his PhD in which he compared a slum neighborhood (the Lower North Side) with a wealthy area (Gold Coast) in Chicago, both situated in close proximity (Zorbaugh 1929). In this more qualitative study, Zorbaugh presented only a few maps, all of them less detailed in information than Shaw's study. However, his research demonstrated clearly that two areas in close physical proximity did not illustrate that physical and social distances coincide. As Park wrote in his foreword of Zorbaugh's study: "a situation in which people who live side by side are not, and – because of the divergence of their interests and their heritages – cannot, even with the best good will, become neighbors" (1929, p. ix), pointing to the invalid assumption of policy makers (and criminologists) of the time that people living in the same locality shared the same backgrounds and interests. This conclusion is very important for the choice of the unit of analysis in criminological research. This PhD study made explicit that administrative and political areas and social spaces are not identical. Depending on the size of the area, a variety of social communities with different identities can exist. Importantly, he concluded that the smaller the unit of analysis, the greater the chance of a homogeneous community.

In 1942, Clifford Shaw and Henry McKay published their magnum opus *Juvenile Delinquency and Urban Areas* in which they presented their geographical and etiological analyses of crime rates not only in the city of Chicago but also those of other cities: Philadelphia, Boston, Cincinnati, Cleveland, and Richmond. In principle, they used similar analytic tools as introduced in their study of 1929 (Shaw and McKay 1942). Again, they employed spot maps, rate maps, radial maps, and zone maps to illustrate concentrations of crime and offenders in the city of Chicago over a long period of time (up to 60 years). In all of the studied cities, they found similar patterns in the geographical distribution of crime. However, the units of analysis differed a good deal between the various cities. These differences were due to the lack of detailed official crime data in cities other than Chicago. The rapid changes in the city of Chicago over a long period of time enabled them also to study the effects of the dynamics of the city on crime and other phenomena. One of their findings was that: "The data on trends also demonstrate with equal sharpness the rapid rise in rates of delinquents in certain areas when a population with a different history and different institutions and values takes over areas in a very short period of time" (Shaw and McKay 1942, p. 382).

The Decline of Geographic Criminology

The Chicago studies inspired other criminologists to carry out empirical crime and place research in other cities (e.g., see Burgess and Bogue 1964a) like the relatively unknown policy report of Edwin Sutherland (1883–1950) on the geographical distribution of juvenile delinquency of the city of Bloomington, Indiana (Sutherland 1937). Also inspired by the work of Shaw and McKay and using the zone model of Burgess, Cyrill Burt (1883–1971) revealed there, like in Chicago, certain delinquent neighborhoods with high numbers of adult and juvenile offenders. Like Shaw and McKay, he used the location of the home addresses of delinquent boys and girls in the years 1922 and 1923 in London. Following the Chicago School findings, he noted that the highest concentrations in crime were found in three neighborhoods situated closely to the city center of London at the time: Holborn, Finsbury, and Shoreditch (Burt 1944 [1924]). According to Burt, these oldest but not poorest neighborhoods of London were for offenders of strategic importance, because they were situated closely to attractive crime targets in the inner city and – if necessary – they could function as a place to hide from the police.

On the other hand, as the decades passed, empirical and methodological critics of the Chicago approach began to emerge (Lander 1954). First, it was argued that Shaw (1929) and Shaw and McKay (1942/1969) could not distinguish between the dwelling place of the offender and the location where he or she committed a crime, neglecting the variability in the mobility of offenders. Secondly, by relying on official crime figures, their research was seen as biased because offenders of the lower class had (and still have) a greater chance to be processed in the criminal justice system (for instance, Beirne and Messerschmidt 1991; Chilton 1964; Chilton and Dussich 1974; Gordon 1967). Thirdly, delinquency rates after 1945 in Chicago did not conform to the distribution patterns of Shaw and McKay's early assumptions (Bursik 1984, 1986). European studies also showed contradicting results. Morris (1957) examined the offender rates of the county of Croydon (UK), but could not confirm the zone model of Burgess. Twenty years later, Morris' findings were replicated in the city of Sheffield (Baldwin 1975; Baldwin and Bottoms 1976). In Europe, the direct and indirect consequences of the operation of housing markets confounded the results of the geographical distribution of crime in American cities.

Another criticism that is key to our concern with units of analysis for crime place studies is that brought by Robinson (1950) who discussed the use of ecological correlations in geographical studies like that of Shaw and McKay (1942/1969). According to Robinson, the object of an ecological correlation is a group of persons, not a person: "…the individual correlation depends on the internal frequencies of the within-areas individual correlations, while the ecological correlation depends upon the marginal frequencies of the within-areas individual correlations" (Robinson 1950, p. 354). He concluded that ecological correlations cannot validly be used as substitutes for individual correlations. Such an ecological fallacy leads to meaningless conclusions. Looking back, these empirical and methodological critics diminished the attention of criminologists in studies of crime and place for almost 20 years.

Reemerging Interest in Communities and the Emergence of Study of Micro Crime Places

In the 1980s, Albert J. Reiss Jr. was to encourage a group of younger criminologists to return to the interests of the Chicago School where he had received his PhD in 1949. Reiss (1986) saw the criminological tradition as including two major theoretical positions, one that focused on individuals and a second that focused on crimes. Communities and crime was a main focus of the latter tradition and he sought to rekindle criminological interest in understanding variability of crime within and across communities. Editing an early volume in the *Crime and Justice* series, Reiss and Michael Tonry sought to bring *Communities and Crime* (1986) to the forefront of criminological interests (Reiss and Tonry 1986).

Reiss did not see the new interest as simply mimicking the insights of the Chicago School criminologists. Rather, he sought to raise a new set of questions about crime at place that had been ignored in earlier decades: "Recent work on communities and crime has turned to the observation that Shaw and McKay neglected: not only do communities change their structures over time but so often do their crime rates (…), a recognition that communities as well as individuals have crime careers" (Reiss 1986, p. 19). Many of the contributors to the Reiss and Tonry volume would become leaders of a new generation of criminologists, once again suggesting the important and enduring role of crime and place in advancing the criminological enterprise more generally. Among the contributors were Wes Skogan, Robert Sampson, Douglas Smith, Robert Bursik, Ralph Taylor, Stephen Gottfredson, and Lawrence Sherman.

This volume and other work developed in this period drew upon the identification of neighborhoods and communities to expand insights about the development of crime (Brantingham and Brantingham 1981, 1991; Bursik and Webb 1982; Clarke 1983; LeBeau 1987; Rengert 1980; Roncek and Bell 1981; Sampson 1985; Sampson and Groves 1989). Smith (1986), for example, identified neighborhood variation in the behavior of the police, suggesting the importance of place in understanding not only the etiology of crime but also the etiology of criminal justice. Skogan brought new insights not only to our understanding of the interaction of community characteristics and policing (Skogan 1987) but also more generally to the developmental processes that led to the emergence of crime and disorder in urban communities (Skogan 1990). More recently, scholars led by Robert Sampson have used a focus on the community to draw new insights into developmental crime patterns, arguing that social cohesion within communities and shared expectations of community members combine to affect both crime and social disorder (Raudenbush and Sampson 1999; Sampson 2010; Sampson et al. 1999; Sampson et al. 1997).

Consistent with Reiss' call for investigation of the criminal careers of communities, Bursik (1986; Bursik and Webb 1982) revisited crime in Chicago neighborhoods over time and challenged earlier views of the stability of crime within neighborhoods and communities, arguing that stability in crime patterns was a result of long-term stability in the social characteristics of places, and that instability in such patterns would also lead to instability in crime rates. Similarly, Schuerman and Kobrin (1986) identified stability and variability in criminal careers of places, focusing on the residences of juvenile delinquents as had Shaw and McKay (1942). Using the number of residential addresses of officially known delinquents by census tracts in Los Angeles as an indicator of aggregate crime, they found three general patterns that led to high crime rates in 1970. The first pattern they termed "emerging" and referred to those clusters that were relatively crime-free in 1950 but had moderate to high crime in 1960 and 1970, respectively. The second pattern, "transitional," refers to those clusters that had moderately high crime in 1950, a higher level in 1960, and an even higher level in 1970. The last pattern is referred to as "enduring" and refers to those clusters that had persistently high crime rates at all points in time. The vast majority of census tracts within the clusters were designated as having enduring crime rates over the time span, with fewer census tracts in the transitional and emerging categories.

Interestingly, though the approach of the Chicago School called for the identification of units of geography that would not be drawn from administrative data collection, but from the social units that defined neighborhoods or communities, this new generation of scholars concerned with communities and crime have generally used officially defined units for drawing their data and conclusions. In this case, the US Census definitions, most often census tracts or the smaller census block groups, have become the main source for defining the units of geography that are the focus of research in the USA, despite the fact that the goals of the census in creating physically contiguous geographic units are often inconsistent with the goals of community and crime researchers. Often, such studies will simply assume that census units such as census tracts reflect actual community boundaries (Hipp 2007), though some scholars in this area combine census units with the idea of creating boundaries of communities that are more consistent with the theoretical interests of researchers (e.g., see Sampson et al. 1997). Importantly, this new focus on communities and crime often led to study of much smaller geographic units of analysis than had drawn the interests of the early Chicago School scholars.

While a reemergence of interest in communities and crime had been one important source for renewed study of crime and place in recent decades, the 1980s produced a more radical reformulation of the unit of geography that should form the basis of crime place studies, continuing to push the unit of geographic analysis to a more micro level. Traditional criminological interest in place has focused on higher level geographic units such as regions, cities, communities, or neighborhoods. One reason for this focus on macro levels of geography is simply that data were often not available at geographic levels lower than the standard administrative or census divisions. But even when data were available, statistical and analytic tools were not readily available for linking crime easily with micro units of geography.

Certainly, the difficulty of mapping crimes to specific places and of analyzing geographic data were factors that prevented study of crime at micro units of geography, but another barrier was the lack of consistent theoretical interest in micro places as contrasted with research on individual criminality, or crime across macro geographic units (Weisburd et al. 2004; Weisburd and McEwen 1997). Such theoretical interest was not to emerge until the late 1970s and 1980s, about the time that computerized crime mapping and more sophisticated geographic statistical tools were to emerge (Weisburd and McEwen 1997). A new group of theorists challenged traditional criminological interests and began to focus more on the "processes operating at the moment of the crime's occurrence" (Birkbeck and LaFree 1993, p. 114). One influential critique that was to have strong influence on the development of interest in micro units of geography was brought by Lawrence Cohen and Marcus Felson (1979). They argued that the emphasis placed on individual motivation in criminological theory failed to recognize the importance of other elements of the crime equation. They argued that crime rates could be affected by changing the nature of targets or of guardianship, irrespective of the nature of criminal motivations. The "routine activities" perspective they presented established the spatial and temporal context of criminal events as an important focus of study.

Canadian criminologists Patricia Brantingham and Paul Brantingham (1993) made the connection between routine activities and place even more directly in their development of "crime pattern theory." Crime pattern theory focuses directly upon places by asking how targets come to the attention of offenders and how that influences the distribution of crime events over time and across places. Like Cohen and Felson, Brantingham and Brantingham routine human social and economic activities as a critical feature of the crime equation, but in this case, the place is made an explicit rather than implicit part of this equation, providing a "backcloth" for human behavior.

Drawing upon similar themes, British scholars led by Ronald Clarke began to explore the theoretical and practical possibilities of "situational crime prevention" in the 1980s (Clarke 1983, 1992; Cornish and Clarke 1986; Wikström et al. 1995). Their focus was on criminal contexts and the possibilities for reducing the opportunities for crime in very specific situations. Their approach turned traditional crime prevention theory on its head. At the center of their crime equation was opportunity. And they sought to change opportunity rather than reform offenders. In situational crime prevention, more often than not, "opportunity makes the thief" (Felson and Clarke 1998). This was in sharp contrast to the traditional view that the thief simply took advantage of a very large number of potential opportunities. Importantly, in a series of case studies, situational crime prevention advocates showed that reducing criminal opportunities in very specific contexts can lead to crime reduction and prevention (Clarke 1992; 1995).

One implication of these emerging perspectives is that micro crime places were an important focus of inquiry. Places in this "micro" context are specific locations within the larger social environments of communities and neighborhoods (Eck and Weisburd 1995). They are sometimes defined as buildings or addresses (e.g., see Green (Mazerolle) 1996; Sherman et al. 1989), sometimes as block faces, "hundred blocks," or street segments (e.g., see Taylor 1997; Weisburd et al. 2004), sometimes as clusters of addresses, block faces, or street segments (e.g., see Block et al. 1995; Sherman and Weisburd 1995; Weisburd and Green Mazerolle 1995). Research in this area began with attempts to identify the relationship between specific aspects of urban design (Jeffery 1971) or urban architecture and crime (Newman 1972) but broadened to take into account a much larger set of characteristics of physical space and criminal opportunity. In 1989, Sherman and colleagues coined the term the "criminology of place," to describe this new approach that drew its theoretical grounding from routine activities and situational crime prevention to emphasize the importance of micro crime places in the etiology of crime.

Recent studies point to the potential theoretical and practical benefits of focusing research on micro crime places. A number of studies, for example, suggest that there is a very significant clustering of crime at places, irrespective of the specific unit of analysis that is defined (Oberwittler and Wikström 2009; Roncek 1981; Weisburd et al. 2009). The extent of the concentration of crime at place is dramatic. In one of the pioneering studies in this area, Sherman, Gartin, and Buerger (1989) found that only three and a half percent of the addresses in Minneapolis produced 50 % of all calls to the police. Fifteen years later in a study in Seattle, Washington, Weisburd et al. (2004) reported that between 4% and 5% of street segments in the city accounted for 50 % of crime incidents for each year over 14 years.

Geographic criminology not only resurrected in the USA but also in Europe. In England, studies have been carried out in Glasgow, Liverpool, London, and Poplar to the spatial distribution of crime (Baldwin 1975). In Sheffield, Antony Bottoms established a research line on the geographic distribution of crime and victimization (Baldwin and Bottoms 1976), later with Paul Wiles (Bottoms 2007; Bottoms and Wiles 1992, 2002). At the University College London (former Jill Dando Institute) in London, spatial criminology is one of the main fields of research, and Ken Pease at the Loughborough University (Farrell et al. 2007). In the Netherlands, some studies have been undertaken in the past (for an overview, see Bruinsma 2007), and at the NSCR, geographic criminology is one of the main research themes. At Griffith University, Australia, a group of researchers study the spatial aspects of crime and guardianship. Leading centers in geography of crime are situated in Vancouver, Canada; George Mason University, Washington, USA; Temple University, Philadelphia, USA; University College of London (former Jill Dando), UK; the Netherlands Institute for the Study of Crime and Law Enforcement (NSCR), Amsterdam, the Netherlands; and at Griffith University in Brisbane, Australia. Many other universities and research institutes from all over the world are more or less active in the field of criminology that started almost 200 years ago in Belgium, France, and London.

Overview

This entry provides an overview of work in the developing field of "green criminology" (other terms and definitions will be described below). It discusses the breadth of topics covered in the literature, reviews some key contributions from writers in the field, and draws attention to some future directions for research.

Global extensions of environmental degradation are slowly but persistently breaking into every sphere of human life. Throughout the twentieth century and particularly following changes brought about by the First World War and accelerating after the Second, advanced societies have experienced complexity in their progress and development that has shaped changes in socioeconomic systems and in corresponding and linked criminal activities. Within this process, impacts on the environment have tended to be overlooked until relatively recently. Across the natural and social sciences, the preservation and sustainability of our environment is now recognized as a major issue for the survival of humanity and all species, and within criminology, it is now also being recognized that concerns about environmental harms, crimes, and damage should be given a more prominent place in the field. The consequences of environmental pollution, for example, are dramatic and drastic, including the extinction of plants and animals, poor health outcomes for some population groups, damage to food chains, depletion of natural resources, exacerbation of climate change, and natural disasters stimulated or worsened by human action. Environmental harms have become a topic of public discussion and frequent media reporting, as well as the subject of international conferences and scientific symposia, debates, and meetings of political leaders. In this context, a relevant branch of criminology has emerged and has been referred to as a "green criminology."

Fundamentals

"Green criminology" has grown internationally and is a good example of how the English-language research literature can fail to register and acknowledge pioneering work published in other languages. Opinions about the beginnings and formation of an environmentally sensitive criminology differ. Clifford (1998: 10) suggests environmental criminality is a relatively new field of research within criminology, beginning in the period around the 1970s, while Koser Wilson (1999: 155) states that criminologists showed an interest in environmental crime at a point when the momentum of environmental politics brought such crime within the orbit of criminal sanctions as a part of the criminal-legal system. Pioneering work from Slovenia by Pečar (1981) put forward early warnings about new ecologically damaging forms of criminality (Eman et al. 2009: 584) and offered an etiology of forms of environmental criminality in Slovenia, defining the role of criminology and sciences related to this and setting out tasks necessary for the control of offending institutions. However, despite his forecasts and prescriptions, there was little subsequent interest in such a green criminology in Slovenia, and with no English-language translation, this entry made no wider international impact. This is one of the "moments" when a green criminology was "born." Pečar's work reflected emerging global interest in the green agenda, and unsurprisingly other writers in other countries also began to contribute, quite independently of each other, to such "moments" in the birth of a green criminology.

Pečar (1981) argued that criminology has a double role to play in the case of deviance against the environment: criminology explains the phenomena that have already been criminalized and against which the society reacts, and criminology also responds to social phenomena and events that are becoming much more important than traditionally considered. Criminology can make valuable proposals to society about appropriate reactions. From the point of view of this critical perspective, it follows that traditional criminality is not the most dangerous social deviance, because, as Kanduč (1992) wrote, ecological, political, and enterprise criminality are far more dangerous. A green perspective fits with a radical turn in criminology that focuses more

History of Green Criminology, Table 1 Timeline of environmental harms and degradation and development of a green criminology

1760–1945	*Industrialization, urbanization, population expansion, and colonization* establish momentum of pollution of air, water, and soil, and loss of huge woodland areas; first extinction of animal and plant species due to human actions and signs of global temperature change; pro-environmental sentiments become movements and expand, affinities with liberal, left, and Marxist viewpoints
1900–	*Development of environmental protection law*
	The end of nineteenth and twentieth century in Europe
	Between the First and the Second World War in the United States of America
1970–	The *beginnings of sociological research* on threats to the environment and the early origins of an environmental criminology. At the end of 1960s, critical criminology warns about threat to a healthy natural environment, for example, via work on corporate environmental criminality
	The *beginnings of environmental justice via* the Warren County case in North Carolina
1990	*Forming of green criminology*
	Lynch (1990) first uses the term *green criminology*, which becomes the synonym for an environmental criminology concerned with the natural world. Later terms such as conservation criminology and eco-critical criminology emerge
1998	*Growth of scientific publications in green criminology and of international network of criminologists*
	Beirne and South (1998) is first collection of essays on such green issues (e.g., environmental justice, animal abuse, green criminology, crimes against the environment) in a special issue of Theoretical Criminology. Halsey and White (1998) write on both sociological and philosophical viewpoints concerning threats to the environment and the relationship between humans and nature. Henceforth, international cooperation and development of green criminology at the national and international level begins
2004	Wider interest in environmental issues in the social sciences, especially criminology, in Serbia and Former Yugoslav Republic of Macedonia
	Halsey (2004) initiates a debate *pro* and *against* "green" criminology, based on discussion of Lynch and Stretesky (2003) about "the meaning of green" from various criminological perspectives
2006	Introduction of conservation criminology by Herbig and Joubert (2006)
2008–2010	New development of criminological investigation of environmental criminality in Slovenia and first scientific publications in the field of environmental criminology
2008	Introduction of ecoglobal criminology by White (2008)
2009	A beginning of development of green criminology in Bosnia and Herzegovina
	Beirne (2009) develops animal rights and protection as a green criminology interest field
2010	Introduction of the conservation criminology framework by Gibbs et al. (2010)
2011–2012	Wider interest in transnational environmental crime (White 2011; Ellefson et al. 2012)

Summarized after Rock (1994), Eman and Meško (2009)

on sociological and economic conditions and less on individuals and their characteristics.

Lynch (1990: 4) first introduced the term "green criminology" to criminological discussions as a new subfield that nonetheless, empirically and theoretically, still reflects existing traditions while fostering emergent directions. Lynch (1990: 3) acknowledged that a green criminology does not represent "an entirely new perspective or orientation within criminology" for "a number of criminologists have examined various environmental hazards and crimes," and studies of white-collar and corporate crime have made significant contributions in this regard (South and Beirne 2006). Nonetheless, the power and utility of a green umbrella or perspective (South 1998a) lies in loosely covering or unifying the study of environmentally related harms and crimes. As examples of what might be studied, Lynch suggested a non-exhaustive list as follows:

> environmental and wildlife laws and regulations; . . . the social harms associated with chemical and pesticide manufacturing on a local or global scale;. . . international treaties devoted to environmental protection; . . . environmental politics and power . . .; . . . unsafe working conditions and hazards created by pesticides, both in the field and in the factory; global political and economic structures responsible for the exportation of

> environmental hazards from industrialised, core nations to the periphery etc.; and [the] political, economic and class relationships that structure these outcomes (*ibid*.).

In addition, and pioneered in particular by Beirne (1995), the green criminology approach has also encompassed the increasing study of animal abuse, speciesism, and crime or harms against or involving animals (e.g., wildlife trafficking, see South and Wyatt 2011; Sollund this volume). Included here are diverse human actions that may cause suffering or death to nonhuman species or damage or destroy their habitats. For some writers, a wide range of animal welfare matters is at stake, and abuse of nonhuman species could entail physical, psychological, and/or emotional actions and harms, or indeed inaction or passive neglect (Cazaux and Beirne 2006). Varieties of environmental degradation and threat damaging to human populations (e.g., air and water pollution, soil erosion, oil spills, climate change) are, of course, also likely to be equally or even more harmful to animals and their habitats.

All this gives a sense of the subject matter content of a green criminology, but what of the conceptual approach that characterizes green criminology? Eman et al. (2009) have written of the development of green criminology research in Slovenia and South-Eastern Europe, noting along the way the challenges of definition and theory that arise. Thus, they observe "Different irregularities, indecencies, violations and crimes against nature are addressed among . . . criminologists as green crimes" (2009: 581) but then note that it has been hard to identify or develop a single theoretical approach in this area.

> The theoretical frame of green criminology is hard to define. White (2008: 14) is clear and brief: "There is no green criminological theory as such." Closest to [a] theory is South (1998a: 212), although he talks only about the perspective or ecological viewpoints and not about theory. . . . Clear definitions are rarely presented making successful research into green crimes more difficult. Halsey (2004) criticises green criminology because of its lack of a (suitable) definition and challenges criminologists to reduce ambiguity with a clear definition of green criminology (Eman et al. 2009: 581, footnote 9).

In her Presidential speech to the American Society of Criminology in 1998, Zahn (1999) wrote of the far-reaching impacts of pollution and biodiversity loss and indicated that in the future she expected to see more criminological focus on environmental crime, this in turn would bring "a new definition of victims to include species other than humans and a definition of offenders to include those who pollute for convenience . . . [and] for profit." Importantly, Zahn observed that "Just as Sutherland's white-collar crime expanded our crime paradigm (1949), . . . environmental crime will change it in the future." (Zahn 1999). South's (1998b: 445–453) typology reflects both new directions as well as classic core concerns in criminology such as breaching laws, making laws, and reactions to lawbreaking and law bending. Thus South proposed three foundations for a green criminology:

1. Studies of breaches of regulations, disasters, and corporate and state violations

   The themes of the relevant literature here concern (a) the study of regulation, for example, the positive and negative features, and the consequences, of different regulatory models; (b) pollution, disasters, and liabilities as "single-event" case studies; and (c) corporate and state misconduct or crimes which have environmental consequences, with the focus bearing on the perpetrators, culpability, and the nature of serial offending.

2. Legal frameworks, criminalization, and "shaming"

   Is concerned with the legal issues raised by environmentally damaging acts and how these should be classified (violations? crimes?) and responded to (by regulation? criminalization? Inspectorates? police?). Such cases may be difficult to prosecute because of lack of evidence and proof, blurring of the lines between the "willful criminal violator" and the "legal risk-taking entrepreneur," and/or corruption in the system. The problem of how to respond to such offenses in an effective legal manner through criminalization has been subject to debate and has embraced arguments against criminalization as well as powerful arguments in favor. Even if a prosecution is brought and is successful, penalties are usually modest relative to the damage done: if the corporation is fined, it will absorb such costs and/or simply pass them onto consumers. Attempts to identify and sanction key, responsible individuals have had only rare success and alternatives such as Braithwaite's (1989) notion of "shaming," and approaches based on principles of restorative justice seem promising based on the proposition that corporate image is a more vulnerable target for censure and sanctions than corporate assets and that "making good" may be more beneficial than imposing immaterial fines or trying to identify a "culprit" to receive a prison sentence.

3. Social movements, "green politics," and policy futures

   Numerous political and pressure groups debate, champion, question, and dispute matters related to the environment. These include anti-environmentalist organizations supported by corporate and state interests and pro-environment groups which may be extreme (e.g., employing terrorism) or controversial (championing animal rights as more important than human rights), as well as those engaging in "new social movements" and alternative lifestyles, or those of the middle-range political left, center, and right who support campaigns to "protect and preserve" and resist construction development projects. The importance of the feminist critique of masculine violence against the environment and, in the USA, the emergence of networks of black activists working against environmental damage to their communities (Bullard 1990) are expressions of protest that should also be noted.

Most "green" criminologists would probably agree that it is now quite clear what kind of subject matter is relevant but might also debate whether it would be possible or even desirable to attempt to impose a single theoretical proposition or framework on this area of work. There is therefore some variety in the positions outlined in the literature. Lynch and Stretesky (2007) refer to an eco-critical criminology as a contrast with the more familiar critical criminological approach that excludes nonhuman nature from its analysis and also (Lynch and Stretesky 2003: 218) "take the view that green crimes, like other crimes, are social constructions influenced by social locations and power relations in society." White (2003: 484) takes this point further, arguing that:

> investigating environmental issues from a criminological perspective requires an appreciation of how harm is socially and historically constructed. In turn this necessitates understanding and interpreting the structure of a globalising world; the direction(s) in which this world is heading; and how diverse groups' experiences are shaped by wider social, political and economic processes. Thus this area of criminology is at once basic and exceedingly complex.

More recently, White (2010: 6) refers to ecoglobal criminology as a framework or paradigm within criminology "that is informed by ecological considerations and by a critical analysis that is worldwide in its scale and perspective." The research agenda of an ecoglobal multidisciplinary approach can be used for the study of environmental harm. Furthermore, ecoglobal criminology defines different forms of environmental harm as "criminal," though they may not be considered illegal in conventional terms.

Herbig and Joubert (2006) have proposed the idea of a conservation criminology. Conservation criminology is concerned with environmental protection, adopting interdisciplinary and multidisciplinary research approaches to understanding environmental criminality, environmental threats, and related risks. This approach therefore offers the integration of criminology with natural resource disciplines, other social science fields, and risk and decision sciences. It encourages the examination of political, cultural, economic, and social influences on the definition of environmental crime. The parameters of conservation crimes can be seen as falling within existing and commonly used crime categories such as white-collar crime, organized crime, invisible crime, and property (economic) crime. Gibbs and colleagues (2010: 125–126) concur with Herbig and Joubert (2006) that conservation criminology identifies core themes in the environmental field of study and suggest that the focus of conservation criminology begins with assessment and study of environmental risks at the nexus between humans and natural resources that involve issues of crime, compliance, and social control (Gibbs et al. 2010: 128). Conservation criminology encompasses the study of wildlife, pollution, human populations, and other areas often considered to be mutually exclusive.

State of the Art

A green perspective in criminology offers an open framework rather than ties to a closed theory and lends itself well to interdisciplinary insights and collaborations. Research covers subjects such as environmental crimes and criminality, harm and victimization, legislation and regulations, protection measures, and public responses to violations. Green criminology is much more than just a discussion about environmental issues and reflects a critical criminological position on the need to defend the environment and to uphold the rights and safety of both humans and nonhuman species. The research agenda for green criminology is based on the objective of studying known forms (and uncovering unknown forms) of deviant and criminal behavior committed against the natural environment and those living beings dependent upon it.

Environmental crime is a now widespread problem across modern societies and may be defined as crime in formal terms where temporary or permanent acts or activities damaging the environment and species are determined and defined as criminal by (inter)national legislation. However, there are numerous forms of harm which lie outside the formal labels of judicially defined offenses but which have immediate or long-term consequences of a nature harmful or prejudicial to well-being, health, safety, and life. For example, artificial changes, degeneration, or destruction affecting air, water, soil, mineral materials, plant species, bacteria, and viruses can harm the natural environment or interrupt its natural changes with consequent and interactive impacts on human and animal species. These latter events may not be defined technically as crimes but are serious in their harmful outcomes and for this reason are considered within the framework of a green criminology. In any of these cases, the violator could be any or every one of us (corporations, companies, groups, individuals, etc.). Environmental crimes have multiple victims because besides, or directly through, the affected environment (biotic and abiotic natural elements), human and other species are harmed as well. However, as with many other forms of deviance and damage, not all are legally defined as crime but are nonetheless viewed as significant harms deserving censure, control, and remedy.

Basic human conditions for existence are essential and include air, water, and fertile soil. For a green critical criminology, it is obvious that these are resources to which all must have access and that fall within the notion of universal rights. Denial of such access represents the point of conflict between environmental rights and property rights. In this critical view, both the wealthiest individuals (or members of the wealthiest social class) and the wealthiest nations are guilty of overconsumption of natural resources and hence are the most significant contributors to environmental degradation and ultimately the impoverishment of other people and the planet. A rights-based approach to addressing such inequalities is complex but at the least might promote a substantive right to a healthy and pollution-free environment (Brisman this volume).

Climate change is expected to be a significant criminogenic force in future decades creating shortages of food and water that may lead to illegal markets and conflicts. In times and locations of impoverishment, human populations are more ready to exploit the resources of the natural world without regard for consequences and conservation, and they may also be more likely to move to other places that are known or believed to be more abundantly resourced. Both voluntary or forced migration and displacement can provide solutions but also simply lead to the reproduction of the original circumstances as money, labor market opportunities, or other resources prove to be unavailable. New cycles of vulnerability, victimization, offending, and perhaps yet further migration can be set in motion (South 2010; White 2008).

As well as having a criminological foundation, work in this area arises from socio-legal studies and environmental law (see, e.g., Farrall et al. 2012). However, Stallworthy (2008: 4–5) has argued that "...there can be a sense that environmental law discourse is ultimately shackled by a dependent, satellite status, a repository of greener values, but for the most part swimming against a distinctively ungreen tide of prevailing legal priorities." Obviously, this is not the end of the matter, and there can be few other areas of law with such a claim to significance for the future of the planet and its inhabitants. There is considerable scope to broaden legal discourse to incorporate "long unasked questions as to the ecosystem and biodiversity protection, as well as appropriate conditions for access and use of natural resources" (ibid: 3). This "broadening of the discourse" is undoubtedly happening. Today, international environmental policy is at the forefront of many progressive developments prefiguring more general trends in public international law. For more than a century, nation-states have adopted international environmental instruments that aim to have the force of law. They are of various types: global, multilateral, regional, and bilateral treaties; court-made and customary law; and soft law; and vary in the extent to which they affect national sovereignty and establish jurisdiction (DiMento 2003: 56). International environmental protection law is constantly changing with the high number of accepted international legal instruments (about 300 at the end of 2010) clearly pointing to the seriousness of the problem of violations of environmental protection. Attempts at meetings (in Rio de Janeiro, The Hague, Nairobi, Stockholm, Montreal, Kyoto, Buenos Aires, Johannesburg, and Copenhagen) to construct an international law of the environment have witnessed an intense and active but often confusing drama. DiMento (2003) questions whether these sessions, involving very different voices from high state representatives to indigenous people to NGOs and observers, can actually produce commonly agreed and understood effective law.

Methodologically, both qualitative and quantitative social science methods are appropriate and employed. Croall (2011: 360) notes that "as for corporate crime, there is no centralized source of information about environmental crime, and a wide range of sources, most from outside criminology, have to be used. Offences rarely appear in victim surveys, not being considered as 'criminal', and often being invisible. Like corporate or state crime, research is further hampered by difficulties of access and obtaining information, much of it regarded as confidential, as it is not widely regarded as part of the criminological agenda, funding tends to be scarce." Nonetheless, research in some areas such as environmental justice and environmental victimology does lend itself to survey methods but also to sensitive interview methods and to investigative data gathering, analyzing news coverage, or scientific reports, for example. In this respect, some green criminology studies lie close to epidemiological public health research and support the development and use of science in the interests of those who are victimized but frequently excluded from recourse to redress or protest. The victimized are paradoxically often excluded from debates and decisions most affecting them because greater economic power can mobilize expert opinion and promote particular positions. A green criminology can play an advocacy role using science and data on behalf of the victimized to tell the stories otherwise ignored. It is also felt that the use of a comparative approach and methods should be particularly fruitful and informative within green criminology. The use of comparative methods in criminology and criminal justice studies is necessary to ascertain social, cultural, political, economic, and other impacts on any differences in patterns of offending and attitudes towards environmental crime, in environmental protection laws, and in law enforcement responses to the violation of laws. For this reason, comparative studies should be more frequently used in comparing forms of environmental crime and environmental justice responses between two or more countries. However, it will always remain true that the identification of the particularities and specifics of each country must not be ignored and may require separate treatment. Heckenberg and White have provided valuable overviews of research methodology appropriate to this field and argue that the different dimensions of environmental harm need to be broken down as these "pose particular challenges for researchers insofar as different types of knowledge are required for dealing with specific kinds of environmental harm. Moreover, analysis needs to take into account considerable diversity in terms of: Who the victim is (human or non-human); Where the harm is manifest (local through to global); Main site where the harm is apparent (built or natural environment)" (Heckenberg and White 2013). The authors also advocate the compilation of data from across a wide range of possible and available sources, international, interdisciplinary, and cross-culturally, as the basis for analysis of contemporary issues but also for purposes of extrapolation and horizon scanning to identify future challenges and crises.

Key Controversies and Open Questions

At present, it seems that late-modern societies remain set on a path of continuing behavior seriously detrimental to the environment and, according to some commentators, worthy of description as "ecocide" and requiring legally recognized instruments of protection and response (Higgins 2010; South 2010). Social and economic conflicts arising from resource scarcity or exploitation, as well as climate change phenomena, present major challenges for human rights, civil society, and species preservation in many parts of the world. Climate change will be both criminogenic and a stimulus to control and security measures. The global flow of people and goods is intimately bound up with impact on the environment, and there is scope for protest, both peaceful and violent, about, for example, unnecessary transport, production of waste, and inequalities in access to food. Future conflicts and crimes may increasingly center on environmental resources, with global warming and accumulating resource poverty raising the temperature of existing tensions and accelerating processes of exploitation, whether between social classes, different ethnic groups, or regions and states competing for or claiming ownership of resources. Conflict and crime are likely to follow if legally sanctioned, but politically unpopular – as well as illegal – migration is stimulated by climate change-induced impacts on living conditions and the sustainability of agriculture, water availability, or other vulnerable systems. In such circumstances, the balance of rights such as freedom of movement versus measures that impose restrictions on mobility will come under scrutiny, and nationalist politics and national security preoccupations could lead to the creation of labels of "criminal" and "unwelcome threat" applied to those who should be seen as "victims" and "refugees."

Future Directions

The extension of this work in countries which have similar or very different profiles emphasizes one of the fundamental requirements for a future global green criminology – a program of comparative work. A research program to help reduce environmentally damaging activities and hence consequences could form the basis for a prospectus for green–crime-prevention research as well as propositions for remedial actions and responsive policies. In all of this, it has to be recognized that variations in definitions of offenses and differences of approach between jurisdictions mean that not only is enforcement hampered but data gathering and comparison are difficult – a further reason why we need comparative work and some harmonization of understanding and approach in areas of law and enforcement. Environmental issues affect different countries in different ways. Creating and enforcing national and international laws can be a very difficult process (Michalowski 1998: 328), particularly when dealing with environmental destruction and degradation issues. Environmental crime has no regard for national borders, so such problems often cannot be solved within the scope of national powers or policies. In cases such as safeguarding of international waters, seas, and air, or international transport by planes (noise and emissions), or transportation of hazardous materials and waste, or destruction of forests (acid rain), then interstate or international law is necessary. Such transnational action should lead to the determination of (international) standards which support the objectives of achieving environmental protection, and relevant research will be required (Meško et al. 2011).

Increasing efforts to regulate and control could create new forms of criminal offense or at the least widen the embrace of those found guilty of breaches of expectations, rules, or local laws. Insofar as this is part of a process generally set in train to protect the common interest and defend victims of uncontrolled and irresponsible actions, the principles are not dissimilar to the traditional operation of criminal justice; however, as much that needs to be regulated or curtailed is currently acceptable and legal behavior, then new groups of offenders and victims may be created. This may occur in relation to, for example, controls to mitigate climate change or requirements to conserve energy or water. This set of circumstances will create a set of issues for future research.

As criminality changes through time, so does criminology. The discovery of patterns of environmental crime in any region and the sharing of findings about similar green issues will enable cooperation between countries and support their responses to environmental issues.

Conclusion

In the twenty-first century, a relevant criminology needs to be aware of the meaning of the environment for the survival of the planet and its inhabitants (South 1998a; Eman et al. 2009: 581), and therefore, its intellectual breadth must accommodate crimes and harms relating to the interdependencies between environments, humans, and animals. Human beings share the planet with other animals, plants, and living beings (such as microorganisms and microbes) in a natural cycle, without which it would be impossible to survive (Eman et al. 2009: 581). The development of a green (or ecoglobal or conservation) criminology as a perspective or approach has been a product of a period when environmental issues have become more prominent on public and political as well as scientific agendas. Such a new direction in criminology has emerged independently in different countries but with a broadly shared and similar main objective – to study and critique crimes and harms against the environment on a regional, national, or global level. As this green field grows, one of its main strengths is the increasing international joining together and networking of these various branches.

History of Juvenile Courts

Megan C. Kurlychek
School of Criminal Justice, University at Albany, State University of New York, Albany, NY, USA

Overview

The juvenile court of today, often referred to as a quasi-criminal court, is seen primarily as a slightly less severe version of the adult criminal court. It exists to hold youth accountable for offenses committed while still offering some semblance of rehabilitation or treatment. Like adults, we speak of these juveniles as being arrested and sentenced. However, their sentences are typically less onerous than those imposed on more mature and culpable adult offenders by the criminal court. In reality, however, there are many more differences between the two systems of justice than a mere mitigation of punishment, not the least of which are their underlying purposes and origins. Indeed the seeds of the juvenile court were sown in social welfare and not the criminal justice system. The catalyst of its creation was not to merely modify the adult court, but rather to provide an entirely separate system of justice for juveniles that was not based on punishment at all, but rather treatment and rehabilitation. Youth were viewed as being different than adults because they were but "potential" adults. It was to be the experiences of these formative years that would determine who they would only later become as adults. Thus, keeping adolescents, even those committing serious offenses, away from more hardened adult criminals and providing them with education and treatment services was seen as the moral obligation of society to produce the next generation of upstanding citizens. It was from this sense of civic responsibility and "moral" obligation that a juvenile court was to be born.

The following sections will present the historical facts leading up to the establishment of the nation's first juvenile court, trace the evolution of the court over time and space, and place the events of modern times in their historical context.

Before the Juvenile Court

In early America the colonies were settled by groups of people who shared similar ethnic origins and homogenous religious beliefs. In these small communities, it was easy to maintain order as everyone had a role to play and shared values that assisted the community in enforcing norms without the need for much outside formal intervention. However, as America and its cities began to grow, large influxes of immigrants changed the landscape of America. Known as the "melting pot," the historical image often presented is one of these groups coming together and melting into a harmonious society which benefited from the unique contributions of its various members. In reality, cities grew in pockets as settlers from different nations huddled together for security and protection from the unknown others (e.g., in New York City still today there exist areas such as Chinatown and Little Italy). In addition, with the diversity brought by the new immigrants, American cities also became a host for other social ills at the center of which was abject poverty.

As the immigrant families struggled to find the land of opportunity they were promised, their children also suffered. There was not a formal public educational system or compulsory attendance laws as there are today, so many adolescents simply gathered together in groups to form what might be known as the earliest youth gangs. Because of the difficulty finding jobs and the low wages paid to many of these workers when they did find jobs, it became more common for these youth to beg for money, play instruments, or perform on street corners for change and even pickpocket or steal. Violent crime, while less prominent, still existed as mistrust bred conflict between citizens from various ethnic and religious backgrounds.

When a youth was arrested for one of these behaviors, the most typical blanket charge was "disorderly conduct." Brought before an adult court judge, the choice was then for the court to simply do nothing with the youth or place him in an adult jail/lock-up facility. Both options proved problematic. To do nothing was to send a message to the youth that he/she could simply get away with it. This would then promote further deviant and criminal behavior because no consequences were experienced for negative behaviors. On the other hand, to take a youth and place him/her in adult jails with hardened criminals was to expose that youth to more criminogenic ideas and behaviors, also leading to further criminality.

This problem was first formally addressed by the Society for the Prevention of Pauperism. This Society, which was established in 1817 by two prominent Quakers, Thomas Eddy and John Girscom, indeed defined the problem not as juvenile crime, but rather as pauperism, that is, people who were poor because they never learned a good work ethic or were ridden with other social ills such as alcoholism that prevented them from becoming productive adults. Because such people were often confined in poor houses or prisons, the first report of this Society issued in 1818 focused on the conditions in New York City's penitentiaries. A second report released a year later drew attention to the fact that there were no separate facilities for juveniles in these penitentiaries. This was followed by a third report, written by Cadwallader Colden, mayor of New York City, who concluded that such confinement of youth with adult criminals was harmful because the penitentiary was “a fruitful source of pauperism, a nursery of new vices and crimes, a college for the perfection of adepts in guilt” (Pierce 1969).

The fourth report, issued in 1822, took one step further, recommending the establishment of an entirely separate penitentiary for juveniles. In addition, since this facility was envisioned by the society for the *prevention* of pauperism, it was designed so that its focus was not upon punishment, but rather the reform of these young offenders through the provision of a good education and a strong work ethic.

Early Institutions for Juvenile Offenders

In 1825, New York opened the first such institution called the House of Refuge. As noted, this was not to be a place of punishment, but rather of reform. Youths sent here were to find refuge from the negative influences in their homes or on the streets that were leading them down the wrong path, that of an adult pauper or criminal. Based on the concept that delinquency was related to poverty, these institutions thus adopted several practices from poor houses as well. First, these juveniles were not sentenced for a certain length of time proportionate to their offense, as in criminal courts. Rather, boys were committed until their 21st birthday and girls until their 18th birthday (this was later amended to be the same as the boys) (Bernard and Kurlychek 2010). Second, commitment to the institution did not require a criminal conviction. A city alderman could simply issue an order admitting the youth, or a parent could apply to the board of the House of Refuge. As such, it is not surprising that this institution received few, if any, youths who would have been sent to an adult penitentiary. For example, in its first year of operation, the New York House of Refuge received 73 children (Fox 1970). Of these, 63 had been sent for either vagrancy, running away from a poorhouse, or stealing. If the House of Refuge did not exist, these youth would most likely have had no intervention because of the adult court judges’ reluctance to lock up these children with adult offenders (Pierce 1969). Finally, also consistent with the practice in poorhouses was the heavy emphasis on work. Commentators on the children in the House of Refuge emphasized the connection between idleness and temptation.

The idea of the House of Refuge spread quickly. A second house was established in Boston in 1826 (1 year after the first one in New York) and a third in Philadelphia the following year. As these houses grew so did questions about their operation, particularly the practice of holding children who had committed no offense other than being poor. Once such challenge came before the Pennsylvania State Supreme Court concerning a young girl, Mary Ann Crouse. Like many others, she had not committed any criminal offense, but was a poor child who appeared to be in danger of growing up to become a pauper. On the complaint of her mother, she was brought into court and committed to the House of Refuge. Her father objected to this and filed a writ of *habeas corpus* (a legal demand for the state to explain why it is holding someone). This case raised a crucial legal issue: that there should be no punishment unless a crime has been committed. Thus, this case argued that the House of Refuge was a form of punishment, and therefore, it was not right to hold a child in its grasp who had committed no such offense.

In 1838 when the Court handed down its final decision in this case, it would, however, disagree. The Court rejected the father’s arguments and held that sending Mary Ann to the House of Refuge was perfectly legal because it was not punishment. The Court reasoned as follows:

> The object of the charity is reformation, by training its inmates to industry; by imbuing their minds with principles of morality and religion; by furnishing them with means to earn a living; and, above all, by separating them from the corrupting influence of improper associates. To this end, may not the natural parents, when unequal to the task of education, or unworthy of it, be superseded by the parens patriae, or common guardian of the community?... The infant has been snatched from a course which must have ended in confirmed depravity; and not only is the restraint of her person lawful, but it would be an act of extreme cruelty to release her from it. (Mennel 1973, 22–23)

This case is important for two primary reasons. First, it held that the purpose of the institution was in fact charity, thereby confirming its roots in social welfare rather than criminal justice. Second, it borrowed from an English doctrine used in chancery rather than criminal courts to validate the role of the state in holding such children. This doctrine, *parens patriae*, allowed the state to act as the parent or guardian when the natural parent was unable to do so. Originally intended for use only when children were orphaned, the Pennsylvania Supreme Court clearly extended the reach of such a doctrine to hold to children whose parents were still alive, but not raising their children in a manner seen as fit by the state.

This was not to be the last word on the matter, however. The House of Refuge movement continued to spread with over 40,000–50,000 youths having been confined in these houses by 1868. As the Houses became more crowded, other problems ensued as well. It was harder to control the behavior of inmates, which led to strict disciplinary practices. It also became more and more difficult to find jobs for these children upon release, leading them to simply be sent back to their homes. As such, the practices of the Houses, rather than merely their charitable roots, came into question, leading to a second challenge to their power. In this second case, the parents of Daniel O'Connell, similar to the father of Mary Ann Crouse, filed *a writ of habeas corpus* challenging the right of the state to hold their son, who had committed no criminal offense, in such an institution. This case, originating in Chicago, went before the Illinois Supreme Court. In a finding contrary to that of the earlier Crouse case, this Court found that commitment to the House of Refuge did constitute punishment as follows:

> Can the State, as parens patriae, exceed the power of the natural parent, except in punishing crime? These laws provide for the "safe keeping" of the child; they direct his "commitment" and only a "ticket of leave" or the uncontrolled discretion of a board of guardians, will permit the imprisoned boy to breathe the pure air of heaven outside his prison walls....The confinement may be from one to fifteen years, according to the age of the child. Executive clemency cannot open the prison doors for no offense has been committed. The writ of *habeas corpus*, a writ for the security of liberty, can afford no relief, for the sovereign power of the State as parens patriae has determined the imprisonment beyond recall. Such restraint upon natural liberty is tyranny and oppression. (Platt 1977, 103–104)

Thus, this case ended with the Illinois Supreme Court ordering Daniel released to his parents. According to the argument presented by Bernard and Kurlychek (2010), the different finding was not based on different practices or circumstances between the two cases, rather it was based upon the court's decision to focus on actual practice in the later case rather than "good intentions" as in the former case.

The First Juvenile Court

Despite this seemingly final decision by the state court, the sentiment behind the creation of the Society for the Prevention of Pauperism and these early institutions had not changed. This sentiment was that a growing portion of the nation's children, particularly those in urban centers, were in need of help.

While the first juvenile institutions reviewed above had been founded by men, the first juvenile court was to be largely the result of the work of women. Although women typically did not have political power at this time, the fact that these women were addressing the care of children, a typical female concern, allowed then entrance into an otherwise male realm of influence. Also, these women were the wives and daughters of prominent and powerful men who ran Chicago's political and business establishments – in other words, they "had connections." Like their husbands and fathers, these women were wealthy, white, Anglo-Saxon, and Protestant. According to Anthony Platt's classic work, "The Child Savers" (1977), these women had the sense that their culture and way of doing things was indeed superior to other cultures and races and wanted to instill their values into the next generation of youth.

Despite their desire to "help," these women had no clear path to do so. For the greater part of the previous century, youth were able to be removed from their homes without question and put in institutions designed to "help" them. Now, thanks to the O'Connell decision such a practice was illegal. While juveniles who committed serious crimes could still be brought before the adult court and put in institutions, for most juveniles who were committing minor acts of delinquency, the choice was again to do something that seemed too harsh (lock them up with adult criminals) or something too lenient (to let them off scot free).

For example, Julia Lathrop, who was later Chief of the Federal Children's Bureau, reported that in the 6 months prior to the establishment of the first juvenile court, 332 boys between the ages of 9 and 16 were sent to the city prison in Chicago (Lathrop 1912). Of that number, 320 were sent on a blanket charge of "disorderly conduct," which could represent a variety of offending behaviors from very trivial to fairly serious. About one-third of these were pardoned by the mayor, meaning the ultimate outcome was to again do nothing. So it was that the officials in Chicago were faced with the same dilemma that led to the creation of the House of Refuge only 75 years earlier. Not surprisingly then, much of the rhetoric of the time mirrored that put forth by the Society for the Prevention of Pauperism. For example, the previous report by Julia Lathrop went on to argue the following:

> There are at the present moment in the State of Illinois, especially in the city of Chicago, thousands of children in need of active intervention for their preservation from physical, mental and moral destruction. Such intervention is demanded, not only by sympathetic consideration for their well-being, but also in the name of the commonwealth for the preservation of the State. If the child is the material out of which men and women are made, the neglected child is the material out of which paupers and criminals are made. (Lathrop 1912, 4)

Such advocacy by the Child Savers ultimately resulted in the Illinois Conference of Charities voting to recommend the establishment of a separate court for juveniles. The idea, suggested by Frederick Wines, one of the most prominent penologists in the country, quickly gathered support, and on January 1, 1899, a juvenile court law was enacted unanimously by the Illinois Legislature. This new court, built on charity rather than principles of justice, was designed to serve the best interests of the child and society. For these reasons it did not look like a criminal court, but more closely resembled a chancery court. Because chancery court was intended to help children who lacked proper parental care, this model fit the goals of the child savers well. It allowed them to intervene again in the lives of "needy" children even if a crime was not committed and without the due process protections provided in adult court. Indeed, drawing on the early Crouse decision handed down from the Pennsylvania Supreme Court, the new juvenile court was to be based on the parens patriae doctrine and to serve "in the best interests" of the child.

To establish a juvenile court as a chancery court required two separate steps: Jurisdiction over juveniles had to be (1) removed from criminal court and (2) established in the new juvenile court. The process of the new court was then to be confidential, informal, and ultimately beneficial to the child. Because it was not a criminal court, not only did due process protections not apply, but neither did standard criminal justice terminology such as being tried, found guilty, and sentenced. Instead these juveniles were "taken into custody" by the state. A social history was to be prepared by a case worker, a role originally taken by social workers that would later evolve into juvenile probation. This social history was not to focus on a specific offense committed, although that was indeed part, but included interviews with family members, friends, educators, and the like. If it was determined that official court intervention was needed, a petition was filed asking the court to hear the case. At this stage, however, many youth were handled informally and services given without further need for official declaration of delinquency. In some cases, however, the youth would be adjudicated delinquent by the juvenile court judge.

Similar to being found guilty in adult court, adjudication indicates that there was evidence that the youth was involved in some act of delinquency or a status offense. However, being a civil court, the standard of proof was preponderance of the evidence (51 %) instead of proof beyond a reasonable doubt which is the criminal court alternative. Also, an adjudication of delinquency implied something else: that the youth was in need of care and treatment. This later part often outweighed consideration of evidence that any offense was committed. After all, if the ultimate goal of this new court was to help needy youth, it would be much better to provide services to a youth in need before things were to become worse. Upon adjudication, the juvenile court judge was then to determine a disposition crafted in the best interests of the child. Thus, it was not a punishment for the offense committed (if any) but a treatment plan. This disposition stage in juvenile court was to be very different from sentencing in adult court, where punishments were administered that were proportional to the offense committed.

To keep the process informal, no lawyers were present at proceedings, just the juvenile, the probation officer or case worker, the juvenile's parents, and the juvenile court judge. All records were confidential to protect the youth from being stigmatized or labeled as a delinquent in the community. Moreover, to avoid the youth internalizing any feelings of being a hardened criminal, youth were not fingerprinted, photographed, or otherwise processed in the formal ways of an adult offender (see ▶ Labeling and Deviance).

The juvenile court was seen as a success, and variations of this model were adopted in many jurisdictions across the nation, with all 50 states and the District of Columbia enacting official juvenile court systems by the mid 1900s.

Challenges to the Court

As the juvenile court evolved, considerable focus was placed on keeping these juveniles away from adult offenders in placements similar to the earlier House of Refuge movement. Many jurisdictions enacted cottage systems which were to provide small homelike environments for these youth. But as the court grew, so did its clientele, and again, overcrowding led to the development of large state-run institutions that more resembled prisons than a "home." As the "beneficial" nature of these institutions came into question, so eventually did the informal nature of the court and its seemingly unyielding power to confine youth for extended periods of time with little to no evidence of any wrongdoing by the child.

The time period of the 1960s was characterized by great social change. Many challenges were brought before the nation's courts addressing violations of citizens' rights and liberties. The new juvenile court was not to be immune. It was during this same time that the first formal challenges to this new system of justice were to be heard by the nation's highest court, the United States Supreme Court. The case of Morris Kent was the first in a series of five cases often lumped together under the terminology "the due process movement." In this case, Kent was accused of very serious charges including several counts of breaking and entering, burglary, and rape. Based on the serious nature of the charges and Kent's history with the juvenile system, the juvenile court judge had decided to waive the case to adult court without a formal hearing. It was the informality of the juvenile court judge's procedure that was brought into question before the Supreme Court. After reviewing the facts of the case and the juvenile court statute of the District of Columbia (the court of original jurisdiction), the Court determined that waiving a juvenile to adult court without a formal hearing and the right to an attorney was indeed a violation of the due process protections provided by the United States Constitution. While this decision was rather narrow, focusing on the juvenile court statute of the District of Columbia and addressing only one decision point – the waiver decision – its message was clear: The Supreme Court was now willing to address issues of due process in the nation's juvenile courts.

The next case to reach the Court, In re Gault, was to delve much deeper into the core of the juvenile court and its informal practices. In this case a young boy of 15, Gerald Gault, had been accused of making a prank phone call. Without notice of charges or notice to his parents, he was taken into custody. Gerald admitted to dialing the number but indicated that his friend had made the lewd comments on the phone. The victim, Mrs. Cook, did not appear in court or give testimony against Gerald. Yet, he was adjudicated delinquent and committed to the state's Industrial School until his 21st birthday. While he probably would not have been held nearly this entire time, it is still interesting to contrast this outcome to what would have been a possible penalty for a prank phone call if Gerald had been in adult court: imprisonment of not more than 2 months and a fine of $5–50. Similar to the cases reviewed before of Mary Ann Crouse and Daniel O'Connell, Gault's parents filed a writ of habeas corpus saying that their son's due process rights had been violated. The specific rights in question were the right to a timely notice of charges, the right against self incrimination, the right to cross-examine witnesses (remember Mrs. Cook did not appear), the right to an attorney, the right to a transcript of the proceedings, and the right to an appeal. All of these rights were not granted under the state's juvenile court law.

In its decision, the Supreme Court granted the first four of these rights stating that:

> Under our Constitution the condition of being a boy does not justify a kangaroo court. (In re Gault 1967)

Another change to the juvenile court was to be close on the heels of this decision. In the case of In re Winship a youth accused of shoplifting was challenging the standard of proof used in the juvenile court. In this case the youth was adjudicated delinquent, and his attorney specifically questioned the judge on whether there was proof beyond a reasonable doubt that he was guilty of the offense. The judge replied that there was not, but that there was a preponderance of evidence and that was the standard for juvenile court. Upon review of this case, the Supreme Court decided that the same standard of proof (beyond a reasonable doubt) should hold in juvenile as in adult court.

In 1971 the case of McKeiver v. the Commonwealth of Pennsylvania was to similarly make its way through the state courts and all the way to the United States Supreme Court. Here, the question at hand was whether to afford juveniles a right to a trial by a jury of their peers. Contrary to the previous two decisions which clearly extended due process rights to juveniles, this case was to mark what is known as "the end" of the due process movement. In this decision the Court held that while the decisions in Gault and Winship focused on insuring accurate fact finding (admission of guilt, cross-examination of witnesses, standard of proof), there was no evidence that a jury was more successful than a judge at determining the facts of a case (see ▶ Juries, Lay Judges, and Trials). Moreover, the plurality for the first time in this series of decisions noted the beneficial nature of the juvenile court and suggested that this particular right would most interfere with the underlying purpose of the court, which was to rehabilitate and not punish the youth. While this reasoning may sound contrary to the prior decisions, it is important to note that individual judges did not for the most part change their vote. That is, those who voted to extend rights to Gault and Winship voted to extend the right to a jury trial as well and vice versa. The difference seemed to be in the changing nature of the Court. Most specifically, Justice Fortas, who had written the majority opinion in both the Gault and the Winship decisions, was gone, replaced by President Nixon's conservative replacement, Justice Blackman. Justice Warren, who had served as the Chief Justice throughout most of the civil rights movement, was now replaced as well by a more conservative Chief Justice Burger.

This shift from liberal to conservative politics was to effect more than the makeup of the Supreme Court but criminal justice policies across the nation. While the Due Process movement was credited with providing protections to juveniles, it also did something more subtle – it redefined them from needy youth to defendants in court in need of rights. It is only a small step from envisioning these youth as defendants in court to envisioning them then as full-blown criminals. Thus it may come as no surprise that the next major reform to the juvenile justice system was to target its very core: its social welfare roots.

Now referred to as the "get tough movement," the period of the 1980s and 1990s introduced the most prolific changes to the juvenile court since its inception (see ▶ Juvenile Justice in the Get Tough Era). Rather than being based on national court cases however, this movement was spearheaded by a media campaign of fear promoting the view of juveniles not as needy and dependent youth but as vicious and hardened criminals in need of punishment (Zimring 1998) (see ▶ Juvenile Violence). As the changes took place at the state level, the flavor of juvenile justice still differs somewhat across states, with some being identified as more punitive (e.g., Texas and Florida), while others maintain the more traditional child-saving orientation (Massachusetts). Many states, however, now fall somewhere in the middle trying to balance the historical treatment focus of their juvenile system with a recognition that there are some juveniles from whom society needs to be protected. This new mission of juvenile justice was grown from a model of juvenile probation, the Balanced Approach, proposed by Dennis Maloney, Troy Armstrong, and Dennis Romig (1988). It has since been combined with principles of restorative justice and is promoted by the federal Office of Juvenile Justice and Delinquency Prevention as Balanced and Restorative Justice (BARJ) (see ▶ Restorative Justice and State Crime).

In addition to the purpose of juvenile justice, its practice was altered as well. According to a report by the National Center for Juvenile Justice (Torbet et al. 1996), the get tough movement also changed the confidentiality provisions of many states, allowing for the name of arrested juveniles to be released to the media and to their schools for certain types of offenses. In addition, many states now routinely fingerprint and photograph juveniles accused of felonies, thereby making the process more similar to adult court than a social welfare agency. Every state also readdressed practices for transferring certain juveniles to adult court for processing and created new and innovative ways to transfer more and more juveniles to adult court. For example, in addition to the discretionary waiver hearing set forth by the Kent decision discussed earlier, many states enacted tough new statutory exclusion provisions that exclude from juvenile court jurisdiction either certain offenses (violent offenses) or certain youth based on combinations of their age, prior record, and current offense. Other states awarded both juvenile and adult court concurrent jurisdiction over such classifications of youth and offenses and placed the decision of which court to file charges within in the hands of the prosecutor. This practice is often referred to as "direct file" or "prosecutorial waiver." Fifteen states have also enacted blended sentencing laws that allow juvenile court judges to impose adult court sentences and/or adult courts to impose juvenile sentences, thereby further blurring the boundaries between juvenile and adult courts.

Although the legacy of the due process movement led to the redefinition of juveniles as "criminal defendants" rather than needy and dependent children, unfortunately, many of its original provisions did not sell as well. According to a series of state-level reports conducted through the American Bar Association's Juvenile Justice Center, at the turn of the twenty-first century attorneys are still not present at many adjudication hearings. Furthermore, when attorneys do represent youth, they are most often overworked public defenders with little to no training in juvenile justice procedures (Brooks and Kamine 2003; Calvine 2003; Miller-Wilson 2003; Puritz and Sun 2001; Puritz and Brooks 2002). Moreover, Bernard and Kurlychek (2010) also propose that most cases never even reach the trial stage because juveniles are waiving their right to an attorney and confessing to acts before understanding the consequences of such a confession. Because historically the juvenile court was seen as there to help youth, parents often encourage children to confess to crimes, and without the advice of an attorney, such confessions are often offered. Once a youth has confessed, there is little need for an adjudication hearing, so the potential benefits of all other due process protections are negated.

The Juvenile Court Today: Purpose and Practice

The juvenile court of today retains some of the basic principles of its predecessor mixed with a blend of adult criminal court terminology, practices, and punishments. Some of these changes are indeed a direct response to what was seen as a more violent and dangerous type of juvenile crime originating in the inner-city drug markets of the 1980s. Others have been referred to as more "knee-jerk" reactions to an imagined new breed of juvenile offender that simply does not exist. In harsh reality, however, what has happened is that more of the punitive changes of the get tough movement have been embraced than the civil rights protections offered during the due process movement. That is, many juveniles now find themselves before a court focused on punishment without the benefit of full, if any, due process protections.

What does the juvenile court of today then look like? While again, the details will vary drastically state to state, in general, a youth will come into contact with the system via an arrest or a referral through a school (often for truancy) or a parent. Once referred, the juvenile will meet with an intake officer who will conduct a social history investigation and most likely attempt to have the juvenile confess to any charges. Upon confession, a diversion option might be offered (see ▶ Juvenile Diversion) such as an informal probation or community service upon the completion of which all charges will be dropped, still allowing the youth to proceed into adulthood with a clean slate. However, most youth will be processed formally in the juvenile court, where they will most often be adjudicated delinquent (usually without the representation of an attorney). A disposition hearing will then be held. The disposition hearing will most likely still result in a "sentence" of probation. However, about 23 % of adjudicated youth will find themselves placed out of home.

For most of those processed formally, their offense will follow them to adulthood and can count against them for educational, employment, and criminal justice purposes. For example, most college applications now ask if one has had a juvenile adjudication. Such questions are routine on employment and housing applications as well. Many youth also do not understand that the juvenile adjudication can count as a prior offense in adult court even though they were not convicted with all the due process protections offered in adult court. For example, in California a juvenile felony counts as a "first strike" in the state's three strike law.

In addition to concerns over lack of due process protections and lifelong consequences of system involvement, the system has also been greatly criticized for racial bias. For example, while African-Americans make up only about 16 % of the juvenile population of the nation, this group accounts for 27 % of all juvenile arrests. Furthermore, about 70 % of white arrestees as compared to 82 % of African American arrestees are referred to court for formal processing. These disparities continue throughout the system with African American youth being more likely than white counterparts to be detained, adjudicated delinquent, and placed out of home, and also waived to adult court (Snyder and Sickmund 2006). While some argue that due to social and other circumstances it may be that minority youth simply commit more crime, studies suggest that such factors do not account for the vast levels of disparity in the system. Moreover, the fact that the disparity continues throughout decision-making points in the system further points to an institutionalized bias against minority youth (Feld 1999; Bishop and Frazier 1988). Indeed the problem has gained national attention with amendments to the 1974 Juvenile Justice and Delinquency Prevention Act calling for states to directly address disproportionate minority contact with the juvenile justice system in order to be eligible for federal funding.

The Future of the Juvenile Court

With the more formal processes of juvenile court, the lifelong consequences, and the noted racial bias, some question whether there is even a need for a juvenile court at all. For example, noted juvenile justice scholar Barry Feld accuses the court of providing juvenile "injustice" and calls for the possible demise of the court altogether. According to Feld (1993) there are three possible solutions to the current problem. One is to restructure the juvenile courts to fit their original therapeutic purpose. The second is to admit that the new juvenile court is focused on punishment and not treatment and to provide juveniles within this system full due process protections including the right to a jury trial. The final, and in his view perhaps the most promising, is to abolish the juvenile court altogether and try young offenders in criminal court with certain modifications to both the procedure and punishment to account for youths' immaturity of judgment (see ▶ Hormones, the Brain, and Criminality).

Others, not yet willing to give up on the juvenile court, prefer the first option. Indeed, even after the get tough movement, public opinion surveys showed that when given the choice between spending tax dollars to imprison youth or to rehabilitate them, most still support the concept of a rehabilitative system (Nagin et al. 2006). Also, states that once embraced a get tough philosophy are beginning to relent on this position and reintroduce leniency for juveniles. For example, Connecticut recently raised its maximum age of juvenile court jurisdiction from 16 to 18, and a recent report put forth by Florida's Blue Print Commission (2008) indicates it is time to stop getting tough on juveniles and time to start getting smart.

This return to a rehabilitative philosophy fits well within an argument first made by Tom Bernard in 1992 and reaffirmed by Bernard and Kurlychek in 2010. According their book, *The Cycle of Juvenile Justice*, society fluctuates between thinking juvenile crime is "caused" by lenient programs for juveniles (e.g., rehabilitation) or by policies that are too harsh, thereby forcing officials to choose between doing nothing or imposing detrimental sanctions. Because these ideas clearly place the "cause" of juvenile crime within the system, efforts to reduce crime then also fluctuate between toughening up the system at times when it is thought to be lenient and introducing more lenient policies when it is thought to be too hard (e.g., the current status of the system after the get tough movement). Unfortunately, this misses the point that while the juvenile justice system can respond to delinquency, it does not, nor ever did, "cause" the problem. Juvenile delinquency developed as a consequence of complex modern society and its various social ills. Therefore, every new policy will eventually "fail" to solve the problem it did not create, thus pushing us on to the next turn in this cycle.

However, these authors do not leave us in a sense of perpetual hopelessness but acknowledge that although delinquency will exist as long as the societal conditions that created it exist, there still can be identified "best practices" in juvenile justice policy that help to alleviate the hardships faced by many youths. The federal Office of Juvenile Justice and Delinquency Prevention is a key leader in this endeavor, providing funding to state agencies, program providers, and research entities as they strive to find programs that truly rehabilitate youth into productive adult citizens.

Whatever the future holds, today the reality is that every state in our nation retains some form of a juvenile court that is neither entirely true to its child-saving roots nor fully implemented as a criminal court.

Overview

The creation of the juvenile justice system began with the efforts of benevolent individuals and institutions who responded to the evolving social, economic, and political issues in early America. The juvenile justice system reflected a change in society that addressed and recognized the distinct differences between adults and juveniles. The first juvenile court sought to avoid the adversarial system of the adult court and emphasized individual treatment and rehabilitation. The juvenile court addressed issues concerning those children who allegedly committed delinquent offenses as well as those neglected and abused children. The parens patriae doctrine gave the court authority over the child if the parent was deemed unable and/or unwilling to care for the child. The operation of the juvenile court remained relatively uncontested until the 1960s when the US Supreme Court intervened and questioned the practices of the juvenile court. Prior to US Supreme Court intervention, the juvenile court had complete discretion and authority over the treatment and placement of juveniles. The US Supreme court cases extended many due process protections offered adults to juveniles. Thus, began a shift towards punitive sanctions for juveniles. Although the juvenile justice system has tried to balance both rehabilitation and appropriate sanctions for delinquency, policy changes made in the late twentieth century tended to favor punitive sanctions and the criminalization of juveniles. However, it can be argued that the current juvenile justice system is again moving towards rehabilitation.

Introduction

Prior to the seventeenth century, there was no concept for childhood and thus juveniles who committed crimes were treated as adults. England's 1600 Chamberlain's Court, a court that handled disputes of English children who served as apprentices, is the forerunner to the current juvenile court of the United States. England attempted to address the problem of delinquency by developing ages of culpability, between the ages of 8 and 14, and by establishing havens to commit delinquent youth. In 1756, the English Marine Society, which also served to provide soldiers for war, was created for poor and delinquent boys and the House of Refuge for Orphan Girls was created in 1758 and in 1788, England established the first private juvenile prison.

The history of juvenile justice in the United States is based on English laws and began as early as the seventeenth century. According to Platt (1977), the plight to create a system in the United States that is unique to juveniles can be traced to the seventeenth century. The Stubborn Child laws were established in Massachusetts in the 1600s. This law was the first to distinguish the behavior of children from that of adults. The law granted the authority to punish children for behavior or actions deemed inappropriate. The Puritan ideals, which rested primarily in religion, emphasized the family, community, education, and the church to teach children how to be morally responsible law-abiding adults. The stubborn child law basically made disobeying a parent an act punishable by death. This law was the first of many that used the law to govern the behavior of children and to outline the expectations of parents. The enactment of the stubborn child law reflected political values of the Commonwealth as a means of maintaining social control by way of the law. The basic Puritan ideals of 1646 have, to a certain extent, withstood the test of time as politics and ideologies continue to guide the laws of today. The Puritans maintained that no individual was exempt from sin and it was the responsibility of the moral institutions (family, church, and community) to train and educate children in the proper manner. Social institutions were held responsible for molding children.

The term "delinquency" resulted from modernism and was coined in the 1700s. However, the issue of juvenile delinquency heightened during the nineteenth century. The rapid industrialization that took place during the 1800s in the United States brought about changes for which people and society may not have been prepared. Prior to urbanization, the parent and the community handled crimes by juveniles informally. Other methods used for controlling juvenile delinquency included indentured servantship, corporal and capital punishment, and transport to other countries, respectively. The means of social control for juveniles progressed to housing juveniles in adult prisons. Urbanization resulted in increased crime, as there was an influx of immigrants and a population boom.

Platt (1977) describes the rapid growth experienced by many towns, and how city populations grew at seven times the rate compared to the doubling of rural populations during the same time frame. Thus, cities grew at unexpected rates. As the population grew by drastic numbers, so did the competition for jobs and housing. The populations of cities, such as Chicago and New York, grew because of immigration and the migration of people from the southern part of the United States to the northern part of the United States.

Migrant families left the spacious surroundings of rural life, collective familial assistance, and cohesiveness for overcrowded urban life where the competition for jobs and housing was fierce. The design of the family unit was forever changed. The family lost fathers as authoritarian figures during industrialism because individualism became more important. People no longer felt a sense of community and the role of the father seemed to diminish. The move from communal life to individuality in the city brought light to the issue of juvenile delinquency. City life was viewed by reformers and the middle class as a breeding ground for a life of crime primarily for immigrant and migrant youth. Social reformers saw the need to redirect negative behavior and made attempts to transform the poor, immigrant youth into productive citizens.

The Reformers and Juvenile Institutions

The idea of helping children was a focal point of the progressive movement and the fight for children's rights taking place in the United States at the time (Hawes 1991). Social reformers viewed children as the innocent victims of the changing culture and industrial advances. The vulnerability of the children was a great concern to the child advocates of the time. Some of the better known reformers are known as the Chicago-based *child savers* (Platt 1977). Upper- and middle-class individuals stepped in to try and rescue poor, neglected, and mistreated urban children.

Before the reform attempts of the Chicago-based child savers, there existed other out-of-home placement options for children across the county. One of the first known homes for youth in the United States was the House of Refuge, which opened in 1825. As early as 1819, a report came out that mentioned a lack of separate penitentiaries for juveniles. The *Society for the Reformation of Juvenile Delinquents* established the New York House of Refuge for children who were in danger of growing up to be paupers and delinquents. The opening of the House of Refuge was the catalyst for the opening of at least 16 similar type homes in several other cities throughout the United States. The New York home opened with the intention of keeping youth apart from adults when confined. Youth confined to the House of Refuge could be committed with indeterminate sentences; youth did not have to engage in delinquent conduct to be committed and parents could ask for direct confinement.

Regardless of the attempts of reformers to rehabilitate juvenile offenders and poor youth, the House of Refuge settings did not alleviate juvenile delinquency. While the founders of the House of Refuge masked their good deeds for poor, immoral children by financially supporting the home, their true intentions were to keep members of the upper class in power. The wealthy supporters of the House of Refuge wanted to maintain control over the impoverished to protect their own status and maintain power over them using religion as a justification. The Houses of Refuge were known for enforcing corporal punishment, solitary confinement, and other physical punishments against children. Additionally, the children in these homes were used as cheap labor. A movement from privately run homes to state-run institutions was on the horizon. There was a disconnect between the promise of proper care and the abuse suffered by males and females at many of the Houses of Refuge; children suffered brutal beatings and physical abuse.

Although some may have the impression that the House of Refuge and reformatories are the same, they are discussed as distinct placements for juveniles. There was US transition from House of Refuge placements to reformatories. Reformatories replaced Houses of Refuge in the late nineteenth century because Houses of Refuge were deemed to be too harsh; yet, reformatories stressed training and subjected children to drills and constant supervision. Reformatories, unlike the Houses of Refuge were state-supported entities and strived to portray a parent–child setting for the juvenile. This did not prove the case because reformatories operated in a prison-like fashion with a coercive, rigid setting.

Reformatories began in the state of Massachusetts in 1848. Reformatories opened across the United States just as quickly as the Houses of Refuge. The best known of reformatories is perhaps the Elmira Reformatory established in 1876 in New York. In New York after the Civil War, there was an increase in crime which led to a lack of trust in the courts, police officers, and the overall justice system. The general public did not believe the justice system was doing enough to eliminate juvenile crime. As a result of the distrust, penal reformers favored a movement towards reformatories. Elmira was built to provide youthful offenders with structure and discipline to become obedient members of society. The core reasons for establishing reformatories were to segregate children from adults, remove children from the ills of society, minimize court intervention, indeterminate sentencing, enforce the cottage approach, make youth productive, and introduce compulsory education. Enoch C. Wines was the authority on reformatories prior to the twentieth century because he was an advocate of youth reformatories and an expert on crime and penology. Reformatory advocates assumed that hard work, discipline, and education could reverse poverty, poor parenting, and a dangerous environment and produce respectable members of society. Reformatories remained popular for about 40 years, and this foundation of rehabilitation can still be found in present-day juvenile correctional settings. Despite the names of these out-of-home placements, providing youth with educational, spiritual, and vocational enrichment appeared to be the goal. It was hoped that giving youth a solid foundation would prevent further delinquency. Children were held in reformatories without being convicted of a crime, and concern regarding this issue prompted the establishment of a juvenile court.

Child advocates were located throughout the United States; while reformers included men, the majority was women who had an interest in child care reform. The *child savers* were a group comprised of Chicago women, primarily of middle and upper class, who wanted to make an impact on shaping the lives of youth. The agenda of the child savers tied in to the progressive reforms taking place during the time. Many of the women who were fighting for reforms for children were also advocating for the rights of women and other social changes. The social reformers, club women, and politicians pushing for change were made up mostly of middle class, white Protestants hoping to change the lives of poor immigrants. While most reformers may have come from the middle class, a few of the women, like Louise de Koven Bowen, were quite wealthy. Ms. Bowen was independently wealthy even though she married a well-to-do banker. While the duties carried out by most of these women were done in their spare time, so as not to interfere with their family obligations, it seems that the tasks were more than hobbies. In addition to trying to reform city children, the women of the child savers movement also looked into the conditions of the jails where they found some children housed with adults. As a result of some of these findings, it seems the child savers preferred having youth, under 17 years of age, sent to reform schools instead of jails to save them from adult criminal labels.

Although many of the child savers were educated, they had limited choices for careers. Nonetheless, these women used their influence, money, and political connections to reform the way young people were handled in the justice system. Jane Addams, another woman born to privilege and wealth, founded Hull House in 1889. Jane Addams was a leader in many other Progressive Era groups that tackled organized labor and women's rights issues. As women like Bowen and Addams pushed for improving the way juveniles were handled in the criminal justice system and the foster care system, they utilized their maternal instincts, networking skills, and political influence. The women influenced the development of professional social workers. The serious issues highlighted by the child savers and their desire to have jurisdiction over children eventually led to the push for establishing the first juvenile court. Prior to the establishment of separate courts for juveniles, many youth were sent to poor houses, homes, reformatories, and industrial schools for indefinite periods of time or until the age of majority.

The men and women involved in the movement of children and youth reforms of the 1800s created, shaped, and impacted professions in the juvenile justice system. Just like the early reformers who founded the House of Refuge, the reformers of the latter nineteenth century wanted out-of-home placements that would have greater emphasis on education with the possibility of learning a trade or earning an apprenticeship. The juvenile court movement was a push to change punitive reformatories into humane schools where children could acquire skills in certain trades.

Preventing juvenile delinquency and reforming wayward children was based on the popular beliefs of the reformers. The people in charge of improving the social conditions of children did so by imparting their moral and spiritual values. Religion was used as the foundation. Members of Christian groups would enter city jails and teach Sunday school lessons to boys in hopes of imparting their own religious values and beliefs.

In addition to a strong religious foundation, the child savers believed strongly in the benefits of rural life. They believed rural living would decrease juvenile delinquency in urban areas; therefore, children were transported to western parts of the United States. Even before the Houses of Refuge was established, children were relocated to rural parts in the early 1800s; youth were sent to work on farms in other states. As the number of incarcerated youth in cities grew, supporters agreed to relocate many of the Houses of Refuge to rural areas. There was a belief that there was a purity in rural living which was a sharp contrast with the corruption of city life. A lack of confidence in Houses of Refuge led post-Civil War child savers to open more cottage-style homes for youth.

Cottage-like reformatories were different from traditional youth reformatories because fewer children were housed together; each cottage had its own dining, schooling, and recreational schedule. Additionally, each cottage was run by a married, Christian couple who served as the mother and father figure to the detained children. The cottage-plan reformatory was used to provide delinquent and neglected youth with a wholesome and loving home with the hope they would escape the temptation and corruption of the city. The new penology sought intensive supervision and to create an atmosphere of family life with the cottage plan. The cottage-plan reformatory would, theoretically, provide a natural, peaceful environment that was conducive to a healthy and productive life.

The Establishment of the Juvenile Court

The first juvenile court was established in Chicago, Illinois (Cook County), in 1899. However, before the bill to establish the court was signed into law, there was much debate and controversy. In addition to the women previously mentioned, there were other men and women who played key roles in getting the "*Juvenile Court Act*" passed (Anderson 1988). The Governor of Chicago at the time, John P. Altgeld, was an advocate for child reform. Governor Altgeld's advocacy days began when he was an attorney in the 1880s; he studied and wrote about the treatment of children processed through the criminal justice system. His writings mentioned that the handcuffing of children, housing them with adult offenders, and sending them to houses of correction prepared them for a life of crime.

As Governor, Altgeld appointed Julia Lathrop, a social reformer in her own right, to the Board of State Commissioners of Public Charities in 1892. Ms. Lathrop was a very close friend of Jane Addams. She visited all 102 counties in the state of Illinois. Julia Lathrop was also part of the Chicago Woman's Club, where she worked closely with Lucy Flower, the club president. Ms. Flower returned to Chicago in 1895 after spending time in Boston studying 25 years of the probation system. Upon returning to Chicago, Ms. Flower urged the women to propose legislation to have separate hearings for young offenders; however, the group's legal advisors did not feel comfortable moving forward with the proposal as it was. A year earlier in 1894, Mrs. Perry Smith, a volunteer with the Protective Agency for Women and Children also asked for a separate court for youth. And while some felony youth offender cases were heard on Saturday mornings, this involved only a small number of cases. A few years later, the push to establish the juvenile court continued with greater force.

The full title of the "*Juvenile Court Act*" that called for separate hearings for youth was "*An Act to Regulate the Treatment and Control of Dependent, Neglected, and Delinquent Children*." While the earlier attempts to push the legislation forward came primarily from the Chicago Woman's Club and perhaps even a handful of men, the women decided that the new legislation should be introduced by men, more specifically, male attorneys (Anderson 1988). The women would still play a vital role in getting the bill passed; however, the lawyers would lead the discussions and debates. One must keep in mind that many of these women were also involved in the ongoing fight for women's rights due to being treated as second-class citizens to men. Their status in the fight for children's rights was no different, but they were bright enough to place men in the forefront of the struggle. The bill was reviewed by Judge Harvey Hurd and it was determined that the passing of the bill, as it was written, would also go against the Illinois constitution because of a uniformity clause. Ongoing tensions between Chicago and other parts of Illinois meant that not everyone in the state would support a mandated, statewide initiative. As a result, Judge Hurd recommended the language in the bill be changed to be *permissive* rather than *obligatory*. Thus, cities could opt out of creating a separate juvenile court if they so chose.

The main opposition to the proposed bill came from those who supported the industrial schools for youth, perhaps, because of a potential loss of state funding. Oscar Dudley, a strong opponent to the bill, believed that there was still a place for industrial schools because not all children were equipped to live at home. The authors of the bill decided to bargain with the industrial school supporters and allowed them to retain the power to release youth or place them in foster care without the court's consent.

After much negotiation and some amendments, the bill would be signed into law and incarcerated youth under the age of 16 would be kept separate from adults, except in the cases of capital felony offenders. Some argue that the juvenile court was established to benefit law enforcement, judges, and prosecutors. Nevertheless, child care reformers seemed to gain a huge victory and the juvenile justice system in the United States was born. The creation of the juvenile court did not come without opposition. Although the creation of a separate court for children was a milestone, there were opponents who believed the juvenile judges had too much power over youth and their families.

While the United States was engaged in a war in Europe in the early part of the twentieth century, the struggle for reform continued at home. The United States Children's Bureau was created in 1912 with reformer Julia Lathrop named its first director by President Taft. A new concept of childhood developed as more and more children were encouraged to obtain an education. The creation of the Cook County Juvenile Court spurred the creation of other juvenile courts throughout the nation in the early part of the twentieth century. All but two states had some form of a juvenile court by 1927; and by 1932, there were over 600 juvenile courts in the United States. Shortly after the end of World War II, all states had a juvenile court.

In regards to juvenile justice, the interconnectedness of social influence and policies peaked in the 1960s. Although arguments and objections had been brought against the juvenile court since its inception, the first juvenile case did not reach the US Supreme Court until the 1960s. Five Supreme Court Decisions relating to juveniles will be discussed along with the social and political context of the time. Additionally, the policies surrounding treatment for offenders through the remainder of the twentieth century will be mentioned because treatment is also dependent on the social climate of the day.

The 1960s

During the 1960s and 1970s, states began to distinguish between treatment, punishment, and confinement of juvenile delinquents. Prior to the establishment of the first juvenile court, many of the offenses for which youth came to the attention of court were not criminal in nature. Youth viewed as poor, incorrigible, and disobedient could be incarcerated indefinitely or until the age of majority (18 or 21). Several decades after the establishment of the juvenile court, some youth were still being detained for committing status offenses. Often status offenders were punished more severely than other delinquents in the 1960s.

During the 1960s, the issues surrounding the labeling of youth came to light. Indeed, an entire theory on labeling was formulated by various individuals. Moreover, less imposing rehabilitative measures were promoted. Only the most serious of offenders were to be placed in institutions and detention centers. This stance towards rehabilitation followed the original premise of the juvenile court: the parens patriae doctrine. One of the best aspects of the original juvenile court was the care and treatment it could provide to children. Judge Ben B. Lindsey, the first juvenile court judge in Denver, believed the court was to be an extension of the community and society. Others refer to the juvenile court as being a provider of services to treat causes of misbehavior in order to restore the youth to be a responsible member in the family and the community at large. Despite the mindset of politicians and practitioners of the time, a number of juvenile court matters made their way to the US Supreme Court.

Supreme Court Decisions of the 1960s and 1970s

The social unrest of the 1960s and 1970s would bring with it challenges to the juvenile court process. Along with minority groups and women fighting for equal rights, certain juvenile rights, or lack thereof, were called into question. There are five landmark decisions that contributed to our current juvenile justice system.

The first juvenile landmark case to make it to the Supreme Court took place in 1966. *Kent v. United States* brought into question the transferring of juveniles to adult criminal courts. A District of Columbia 16-year-old was judicially waived to the adult court system without a hearing. The youth would subsequently be convicted and sentenced to 99 years in prison. Kent's attorney was not allowed to view his file and was denied psychiatric testing for his client. The outcome of the case called for hearings for juveniles being transferred to adult court. Additionally, District of Columbia youth were granted the right to counsel in a transfer hearing with the attorney also given the right to access a juvenile's social records. This court ruling would lay the foundation for the next Supreme Court case the following year.

Perhaps the most transforming of landmark cases relating to juvenile matters is *In re Gault* in 1967. A 15-year-old, Arizona resident Gerald F. Gault was accused by his female, adult neighbor of making an obscene telephone call. Gault's parents were not called about their child's detainment, and in two separate hearings, the complaining witness was not present. Moreover, the youth had no legal representation and was never advised of any rights. There was even a question as to whether the youth or his friend made the obscene remarks. Regardless, the youth was committed to the State Industrial School where he was to remain until he turned 21. The case went to the US Supreme Court. Upon hearing the case, the Supreme Court ruled in favor of Gerald Gault and granted all juveniles the following due process rights: (1) Right to timely notice of actual charges, (2) Right to an attorney in hearings, (3) Right to confront accuser, and (4) Protection against self-incrimination. In essence, juveniles were afforded many of the rights given to adults.

The mid-1970s brought a movement against detaining status offenders because they had not broken any actual criminal laws. President Ford's signing of the 1974 *Juvenile Justice and Delinquency Prevention Act* called for the decriminalization and deinstitutionalization of status offenders. Some status offenses are "redefined" so they can be considered delinquent offenses. Thus, in a matter of years, a shift towards a more punitive form of justice developed. There are three more important Supreme Court Decisions that took place in the 1970s.

The *Winship Case* of 1970 was also of great importance. In New York, 12-year-old Samuel Winship was charged with breaking into a woman's locker and stealing over $100 from her purse. Winship was found guilty because the state's burden of proof was based on civil proceedings "preponderance of the evidence" and not the "beyond a reasonable doubt" burden of proof used in adult criminal cases. A "preponderance of the evidence" means that more evidence exists that a person committed a crime than evidence that a person did not commit a crime. The standard of "preponderance of the evidence" was used in juvenile cases because they had always been seen as civil court matters, as opposed to criminal. The Supreme Court ruled that juveniles accused of crimes that may result in a possible loss of freedom through confinement should be afforded the same burden of proof of beyond a reasonable doubt.

A year later in 1971 came the case of *McKeiver v. the State of Pennsylvania*. Two teenagers charged with engaging in delinquent conduct, including 16-year-old Joseph McKeiver, were denied the right to a jury trial. The Supreme Court upheld the decision that while adults may have the right to a trial by jury, juveniles do not. States could choose to extend the right to a jury trial to juveniles, but it was not a federal mandate. The rationale behind the ruling was to preserve the foundational principles of the juvenile court system. Justice Blackmun and his colleagues were concerned that a jury trial would invite delays and possible publicity endured by adults. Nonetheless, some states do afford juveniles the right to a trial by jury.

In 1975, a fifth case came before the Supreme Court: *Breed v. Jones*. Seventeen-year-old Gary Jones was adjudicated for armed robbery and two other offenses involving a weapon. Jones committed the offense on February 8, 1970 and was adjudicated delinquent on March 1, 1970. The dispositional phase of the case was set 2 weeks later. At disposition, the court waived jurisdiction to the adult system. Jones' attorney appealed his case, arguing he had been subjected to double jeopardy. The Supreme Court upheld the ruling that Jones was subjected to double jeopardy and that transfer of jurisdiction hearings needed to take place prior to adjudication. Additionally, once any evidence is heard at a juvenile hearing, a youth cannot be subjected to adult criminal proceedings.

The five Supreme Court cases challenged and called for a change in how juvenile court matters are handled. While legal proceedings for youth remained civil in nature, the landmark decisions added an element of criminal court proceedings. The protests and outcries of the 1960s and 1970s would lay the groundwork for equal treatment across various sectors in society. As women and other minority groups pressed for reform measures, the treatment of juvenile delinquents was equally in the judicial spotlight. Although considerable strides were achieved, the decade to follow would bring a conservative political shift that would change treatment options from rehabilitative to punitive.

1980s to Present Day

The 1980s brought a different conservative, hardened perspective towards crime and offenders. Perhaps the media coverage during the 1980s and 1990s increased the public's concern regarding how criminals were being handled by the justice system. A punitive versus rehabilitation mode of dealing with offenders impacted the adult and juvenile justice systems. The penetration of "crack" cocaine and the increase in gun-related youth killings ignited the "war on drugs." The so-called war on drugs fueled by the conservative right during the 1980s brought forth stiffer punishments for drug offenders. As a result, there was an increase in drug offense–related arrests. This ushered in the conservative "tough on crime" agenda of the 1980s. Williams and McShane (2009) point out that by the time the Reagan administration was beginning the "war on drugs," drug use was actually on the decline. Regardless, an era of "deterrence and punishment" became the reality for juvenile offenders. It appears that the juvenile justice system abandoned its founding principle of rehabilitating juveniles.

The shifts in treatment echo Bernard's (1992) cyclical patterns in juvenile justice. The public is always viewing juvenile crime as being on the rise, either because we are too lenient or too harsh with our rehabilitation efforts. The latter part of the 1990s saw the emergence of a different perspective to the treatment of offenders. Some believe that even during the "tough on crime" era, practitioners were developing new strategies that focused on prevention, early intervention, and rehabilitation.

The "renewed" interest in rehabilitation was mainly due to the costs associated with an increase in the prison population. A tripling of drug offenders during the 1980s and 1990s meant an increase in incarceration rates. The cost of incarcerating a drug offender is significantly higher than the cost of treatment. Providing treatment for youthful offenders remains a popular response to delinquency in the early part of the twenty-first century. Modern-day child savers continue the fight to keep juvenile delinquents in the community and out-of-home placement as a response of last resort. Additionally, specialized courts like drug courts and mental health courts seem to provide delinquents with hearings that are reminiscent of the original juvenile court (Mendiola-Washington 2012).

The parens patriae doctrine seems to remain alive in the juvenile justice system. However, the question of how to apply the doctrine justly and adequately remains constant. Effective means of dealing with offenders will always remain a topic of debate. Ensuring youth receive the necessary services will depend on contemporary juvenile justice reformers. Indeed, the history of juvenile justice in the United States is fascinating, multifaceted, and forever evolving. The next 100 years will determine if rehabilitation, parens patriae, and the best interest of the child remain integral components of the juvenile justice system.

History of Organized Crime in Mexico

Elaine Carey
Department of History, St. John’s University,
Queens, NY, USA

Overview

Due to Mexico’s 1,969-mile-long shared border with the United States, transnational organized crime networks have long existed. Moreover, Mexican organized crime has long been tied to its modern political system. In fact, the Mexico’s modern political system emerged alongside the rise of organized crime. This entry examines the century-long organized crime from the period of the Mexican Revolution (1910–1921) to the present.

Guns and Drugs: The Mexican Revolution

Organized crime in Mexico is as diverse as in the United States because of Mexico’s proximity to the United States and due to the flows of people from other parts of the world to Mexico during the nineteenth and twentieth century. In Mexico, Chinese organized crime has played a role since the 1800s. With the passage of the US Chinese Exclusion Act of 1882, Chinese migrants sought to gain entry into Mexico in order to pass through its unpatrolled border. Chinese tongs operated in Mexico beginning in the 1800s. Even prior to 1882, the Mexican government approached the Chee Kung Tong in San Francisco to recruit and acculturate Chinese workers to work in the “hot lands” of northern Mexico. With the passage of the US Chinese Exclusion Act, tongs based in San Francisco operated a human smuggling network that moved people from China to the United States, Mexico, and Cuba due in part to a continued presence of Chinese in Mexico.

Mexico’s organized crime emerged before the Mexican Revolution and at times with the consent of the Mexican government. During the Revolution, military figures saw forms of crime as a means to accumulate wealth and materials to supply their armies but also as a means to create political power structures that endured after the fighting had ceased.

Even prior to the outbreak of the Mexican Revolution (1910–1921), antidrug crusaders recognized the logistical importance of Mexico to the international drug trade. Beginning in 1908, Canadian and US officials criticized Mexican port security that allowed an array of commodities to enter the country to be transshipped north to the United States. Significantly too, Mexican revolutionary figures had tapped into illicit flows of firearms that moved guns from north to south. Pancho Villa was one such smuggler who emerged as a northern cacique (boss). After his 1916 raid of Columbus New Mexico, Villa became a criminal in the United States, but in retrospect his criminal activities were far milder than some of his contemporaries. Villa was a and bandit, but he was also one of the most successive military generals of the Mexican Revolution.

Other revolutionary leaders, such as Colonel Esteban Cantú, sought profits through racketeering. Cantú extorted poppy growers and opium producers in the state of Baja California and subsequently went into the business himself. Another military leader, General Abelardo L. Rodríguez, displaced Cantú and took control of the border state just as Prohibition began in the United States. Rodríguez made a fortune in the vice boom that emerged to serve the thirsty and bored Americans who came south looking for drink and distraction. In the 1920s, the *jefe maximo* President Plutarco Elías Calls, from the state of Sonora, placated US demands regarding the control of narcotics, while his son-in-law was intimately involved in drug trafficking. Calles waged a battle against Catholicism as well as against Chinese. In both cases, these battles were for power. To Calles, from the state of Sonora, the church undermined modernization and national control. Sonoroan Chinese undermined Mexican-owned development.

The Anti-Chinese movement of the 1920s portrayed Chinese Mexicans as drug-addicted traffickers. While Calles officially left the government in 1928, he controlled it until 1935. Rodríguez led the state of Baja California until 1929 until he became a cabinet minister in the administration of Pascual Ortiz Rubio until he abruptly became president of Mexico in 1932.

In other Mexican states, the profitability of narcotics allowed for the consolidation of power into political dynasties, and the generals who emerged as political bosses and governors continued to be involved in organized crime such as prostitution as well as the narcotics industry. In Chihuahua, for example, General Rodrigo M. Quevedo created a political dynasty that held power for decades. Quevedo was part of a group of *cacique* governors who engaged in political power plays supported by illicit activities such as drugs, smuggling alcohol, prostitution, or extortion. President Manuel Ávila Camacho (1940–1946) worked closely with the United States in poppy crop eradication in states such as Sinaloa, Durango, Jalisco, and Baja California. During WWII, he arrested drug traffickers due to the pressure of the United States and jailed them without due process. All this took place while his brother Maximino was one of the *cacique* governors of the state of Puebla who also dabbled in the drug trade.

During prohibition, Mexicans in various positions of power recognized the opportunity to make money by supplying alcohol to the north. Mexicans on the US border resented Anglo laws that interfered with their of use of and profits from alcohol consumption and some went into the moonshine business in cities such as San Diego, Albuquerque, and Houston. Others smuggled alcohol along the US-Mexico border. In Texas, tequila smugglers gained a romantic foothold – they are remembered in song and popular culture on the border. The *tequileros* brought tequila from the agave producing areas of central Mexico, while *Tejanos* (Texans of Mexican heritage) served as guides in Texas. The *tequileros* sold to bootleggers who distributed the tequila to cities throughout the USA – the profits were enormous for the time.

For the political elites in Mexico, prohibition in the USA combined with the vice districts in Mexico created great profits. Bars, cantinas, and hotels as well as sex shows and prostitution became features of Mexican border towns. The governors of border states offered thirsty Americans a place to drink and indulge corporal pleasures. Profits lined the pockets of governors, narcotics agents, and police. Citizen groups routinely complained about the vice districts, but they were complaining to the very people who had the most interest in those industries.

The First War on Drugs

With the end of prohibition, it appeared that Mexican organized crime might suffer irreparable harm. But the routes created to supply bootleggers were converted to offer greater supplies of other commodities in demand: marijuana, morphine, and heroin. During the 1930s, struggles ensued between native Mexican drug traffickers and Chinese organized crime syndicates for control of the lucrative trade. Chinese Tongs also bribed the police to target other tong competitors for deportation. Chinese involvement in drug trafficking provided the Mexican government with a scapegoat for the country's role in the international narcotics trade. This led to raids of Chinese businesses and deportations. Nevertheless, the drug industry flourished and then grew exponentially into the 1940s.

In the 1930s, Jewish organized crime groups operated in Mexico – Mexico City had a Jewish immigrant community that dated from colonial times. Mexican Jewish groups transshipped Asian and European drugs through Mexico. Frequently, Jewish criminals repackaged foreign morphine and heroin supplies in Mexico. This counterfeit medicinal morphine or heroin was then smuggled across the US-Mexico border. The Mexican branches of Jewish organized crime supplied their distributors in cities throughout the USA. As in the USA, Mexican Jewish organized crime demonstrated cross-class and cross-ethnic alliances.

In striking contrast to the USA, women emerged as recognized bosses in cities such as Mexico City and Ciudad Juárez. María Dolores

Estevez Zuleta, known as "Lola la Chata," became a subject for American beat writer William Burroughs. And she had her husband Enrique Jaramillo, an ex-police officer, built a successful transnational trafficking organization that had labs and distribution sites in three Mexican states. Ignacia Jasso, la viuda de González, who some scholars argue created the first cartel, lived and worked in the border town of Ciudad Juárez but had fields of poppy and processing labs in multiple Mexican states. Her location on the border gave her direct access to the US market across the Río Grande.

The drug trade from Asia and Europe was disrupted by World War II, creating greater opportunity for Mexican traffickers whose heroin was found beyond its traditional domains of the US Southwest. Mexican narcotics in cities such as Chicago, Detroit, Toronto, and New York revealed alliances between Mexican and US organized crime.

Post-WWII

During the 1940s, the Federal Bureau of Narcotics (FBN, predecessor to the Drug Enforcement Administration (DEA), routinely requested names and information about narcotics traffickers and dealers operating in Mexico. Officials pressured the Mexican government to arrest traffickers and at times demanded their extradition. In 1947, the Mexican government established the *Direccion Federal de Seguridad* (Federal Security Directorate; DFS) in part as a response to growing US pressure. Organized similar to the FBI, the DFS was responsible for dealing with political insurgents as well as criminals. For much of its almost 40 years of existence, the agency developed a reputation for security failures and egregious human rights violations. Though the DFS was to fight organized crime, throughout the 1940s and 1950, Mexican organized crime families flourished. In Tijuana, for example, "Big Mike" Barragan and his wife Ismelda Galindo controlled heroin flows into San Digeo and supplied dealers as far away as Houston. They controlled bordellos, the dog racing track, and a taxi business. In 1955, Mexican traffickers such as Jasso and the Barragans became the subject of US senate hearings.

Emerging New Players

The 1960s and increased drug use led to greater wealth and new players entered the business. While many drug traffickers had enriched themselves, the 1960s and early 1970s marked a change in the levels of wealth, corruption, and transnational ties. Drugs continued to flow, and the ties between policing agents, government officials, and organized crime increased. Top commanders of the DFS were found to have become involved with the criminal drug organizations offering protection and information.

In the 1970s, it was apparent that the drug rings were becoming highly sophisticated. Cuban national Alberto Sicilia Falcón, a successful marijuana and cocaine trafficker, built a highly sophisticated organization that moved in elite circles and across borders. The US senate investigation into Silicia Falcón's organization revealed information regarding the US arms traffic to Mexico. He had become so wealthy that he had attempted to gain the rights to manufacture certain US firearms in Mexico in clear violation of the country's laws. The only reason that deal fell through was that Silicia Falcón was arrested. The senate hearings demonstrated that Falcón's wealth gave him access to business people on both sides of the border.

Investigations into the 1985 murder of DEA agent Enrique Camarena, who was stationed at the Guadalajara regional office, implicated a major trafficker, Miguel Angel Félix Gallardo and his lieutenant Rafael Caro Quintero. Evidence suggested that Caro Quintero had planned Camarena's murder. When he was arrested, Caro Quintero possessed a DFS identification card.

Transnational Organized Crime

In the 1980s and 1990s, Mexican organized crime diversified: In addition to heroin, cartels controlled marijuana, methamphetamines, and cocaine, and some branched into the human trafficking working with Salvadoran gangs such as Mara Salvatrucha or MS 13. In the 1990s, further evidence of ties between *narcotraficantes* and the political elite emerged. During his presidency, Carlos Salinas' family members were indicted on drug trafficking charges. In the mid-1990s, governors of the states of Morelos, Sonora, Chihuahua, and Tamaulipas were acknowledged to be involved in drug trafficking. Jesús Gutiérrez Rebollo, director of the National Institute to Combat Drugs, was arrested on corruption charges. He protected Amado Carrillo Fuentes, the "Lord of the Skies" and his Juárez cartel while pursuing their competitors, the Tijuana (Arellano Félix) cartel. Rebollo was sentenced to a prison sentence of 40 years.

Mexican drug trafficking organizations control most of the US drug market and have established varied transportation routes, advanced communications capabilities, and strong affiliations with gangs in the United States, overseeing drug distribution in US cities.

In 2007, President Felipe Calderón declared a war on drugs with the military playing a key role. He extradited Mexican drug kingpins to the United States and purged police departments of corrupt officers or disarmed them leaving little protection for citizens. The Mexican government's military response has resulted in fierce gun battles with cartel gunmen who have refused to surrender and have ambushed soldiers and police officers.

The Calderón and G.W. Bush administrations signed the Merida Initiative, a partnership between the two countries to fight organized crime by offering equipment and training to Mexican law enforcement. In 2008, Mexico received 400 million to combat the cartels. With Calderon's war on drugs and the Merida Initiative, the drug violence continued to escalate growing more brutal and violent with public displays of decapitated bodies, brazen recruitment efforts by cartels, and strategic killings of journalists, nongovernmental activists, and politicians. The 2012 election of Enrique Peña Nieto confounded US observers when the candidate routinely sidestepped direct questions regarding how he would handle Mexico's most vexing problems: drugs and organized crime.

History of Organized Crime in the United States

Howard Abadinsky
St. John's University, New York, USA

Overview

Organized crime in America has a history that stretches from 1920 into the twenty-first century. From its beginnings in urban America to the global connections that characterize the phenomenon today, organized crime has proven to be a dynamic enterprise. This entry provides a summary examination of the nearly 100 years that organized crime has existed in the United States beginning with the critical role of Prohibition.

The Role of Prohibition

Prior to the Prohibition era (1920–1933) vice – gambling and prostitution – insofar as it was organized, was dominated by big-city political machines aided by street gangs that proliferated among the urban poor. The gangs were local entities serving as the military wing of corrupt political organizations. They engaged voter fraud – voting early and often – and intimidation of political opponents. In short, they were violent errand boys at the bottom of an organizational pyramid that featured political bosses at the top. Then came Prohibition. The "Great Experiment" was a catalyst for organized crime, especially violent forms, to blossom into an important force in American society. Prohibition led to the mobilization of criminal elements in an unprecedented manner, and the ensuing competitive violence turned the power structure upside down. It also led to a new level of criminal organization.

Domestic production of alcoholic beverages is relatively large scale, requiring raw materials, production facilities, warehouses, and trucks, while liquor importation requires ships, warehouses, and trucks, and both need associated personnel. Above all was the need to protect the liquor businesses from predators who could hijack trucks and otherwise exploit a business that being illegal could not depend on law enforcement. Physical protection from the unparalleled surge of violence that accompanied Prohibition was essential for anyone seeking his fortune in the alcohol business.

The organizational pyramid that characterized pre-Prohibition crime was turned upside down – gang leaders pushed the politicians aside and became dominant players in many urban areas. Al Capone, for example, a Brooklyn-born thug became the single most important person in Chicago. In New York, a cabal of Italian and Jewish gangsters ruled a vast underworld and influenced city politics. In urban areas throughout the country, Prohibition changed the relationship between politicians, vice entrepreneurs, and gang leaders. Before 1920, the political boss acted as a patron for the vice entrepreneurs and the gangs: He protected them from law enforcement and they gave him financial and electoral support. The onset of Prohibition, however, unleashed an unsurpassed level of criminal violence, and violence is the specialty of the gangs. Physical protection from rival organizations and armed robbers was suddenly more important than was protection from law enforcement. Prohibition turned gangs into empires.

Prohibition encouraged cooperation between gang leaders from various regions – *syndication*. Domestic and imported liquor shipments were trucked intra- and interstate to warehouses at distribution points. At each juncture the shipment required political and physical protection. Only the criminal organization dominant in the local area could provide such protection. Syndication arose out of these needs, the result of meetings between important organized figures from throughout the United States.

Post-Prohibition Organized Crime

With the onset of the Great Depression (1929) and the subsequent repeal of Prohibition (1933), the financial base of organized crime narrowed considerably. Many players dropped out: Some went into legitimate enterprises or employment; others drifted into conventional criminality. Bootlegging required trucks, drivers, mechanics, garages, warehouses, bookkeepers, and lawyers – skills and assets that could be converted to noncriminal endeavors. For those who remained in the business, reorganization was necessary. When Prohibition ended, bootleggers were still young men – generally in their thirties – yet with wealth and nationwide contacts that had grown out of their liquor-related enterprises. In addition, they had substantial investments in restaurants, nightclubs, gambling, and other profitable businesses. In the 1930s and 1940s, they used their national contacts, diverse interests, and available capital to cooperate in a variety of entrepreneurial activities, legal and illegal.

One of these endeavors was labor racketeering. Leaders of organized crime engineered the domination of international labor unions by combining their control over union locals in their respective territories. Profits from Prohibition were jointly invested in the development of luxury casino hotels in Nevada and Cuba. When Prohibition was repealed in 1933, the United States (and the rest of the world) was experiencing the Great Depression. Ironically, a cash-starved society had a cash-rich criminal class. This led to the wholesale entry of gangsters into "banking": They became major loan sharks and, as a natural extension of this enterprise, assumed (often hidden) ownership of a variety of legitimate businesses.

Organized crime with roots in Prohibition remained a formidable entity into the 1960s, but the next decade was characterized by an irreversible decline. Although organized crime in the United States has a history that encompasses cities in every region of the country, outside of the Northeast and Chicago, there are few or no vestiges of the formidable criminal organizations that evolved out of Prohibition. The Irish, Jewish, and Italian communities from which these criminal organizations drew the bulk of their personnel failed to provide a continuous supply of replacements necessary for their survival. The Irish found success in politics and, although Jewish immigrants and their progeny played a vital role in the development of organized crime, by the third generation Jews had moved into business and the professions. Italian-American communities were sufficiently large enough to provide adequate replacement personnel in only a few cities, such as New York and Chicago. Even there, those aspiring membership in the American Mafia are a tiny fraction of the Italian-American community now solidly part of America's middle class and whose members are well represented in the ranks of professionals and public officials.

With the enactment of the Racketeer Influenced and Corrupt Organizations (RICO) statute, part of the Organized Crime Control Act of 1970, prosecutorial success reached unparalleled level of success. The long prison sentences of RICO encouraged disloyalty and American Mafia members routinely became government witnesses testifying against former colleagues, leading to a wholesale breakdown in discipline. In the meantime, new criminal organizations have emerged, eclipsing the remnants of the American Mafia. Some are domestic entities while many more are part of or have ties to criminal organizations outside the United States.

The New Players

In the 1960s, Colombians began immigrating to the United States in numbers sufficient to establish communities in Miami, Chicago, Los Angeles, and New York. Among them were criminals experienced in cocaine trafficking. Violence between rival Colombian "cocaine cowboys" brought terror to South Florida. When the gun smoke cleared units affiliated with the two major cartels in Colombia, Medellín and Cali, were dominant. Colombian cocaine traffickers eventually partnered with their Mexican counterparts who had long-established heroin networks in the United States. Both supplied Dominican organizations that wholesaled drugs to other groups further down the supply chain such as MS-13, a primarily Salvadoran organization with members organized into *clikas* active in different parts of the United States, particularly places with large numbers of Latino immigrants.

Since the collapse of the Soviet Union, Russian criminal groups have flourished in the United States in the absence of the corrupt political machines that provided a protective incubator for the Irish, Jewish, and Italian criminal organizations of an earlier era. They typically have military experience and many are college educated.

African American criminals dominated the numbers (illegal lottery) racket in cities such as New York, Philadelphia, and Chicago until they were overpowered by violent white gangsters such as Dutch Schultz (New York) and Sam Giancana (Chicago) who had superior police/political connections. Although blacks have traditionally been locked out of many activities associated with organized crime (e.g., labor and business racketeering) by prejudice, *dope is an equal opportunity employer*. African American criminal groups made important strides in the heroin business when the Vietnam War exposed many black soldiers to Far Eastern sources. Black criminal groups – African American, Jamaican, and Nigerian – use the drug trade as much as their Irish, Jewish, and Italian predecessors did bootlegging.

Added to the pantheon of organized crime are outlaw motorcycle clubs. The outlaw motorcycle club phenomenon dates to the years after World War II, when many combat veterans, particularly those residing in California, formed a motorcycle club that eventually became the Hell's Angels. From the fun-long, hell-raising clubs of the post-World War II era, the Hell's Angels and several other outlaw clubs, such as the Bandidos and the Outlaws, have parlayed their reputation for violence into self-perpetuating and disciplined organizations whose major source of income is from criminal activity, in particular, drug trafficking.

New players continue to emerge, prison-based gangs, Albanian organizations, and Chinese groups, as the history of organized crime in America continues to evolve.

History of Police Unions

Overview

Giving police officers a voice within police organizations raised vexing questions. In many nations, police officers were to "police by mutual consent" with the public but often did not experience mutual confidence between senior officers and the rank and file. They needed a satisfactory outlet for their grievances, an advocate to protect their interests, and input into their occupation. A union could hinder arbitrary power from above, but authorities worried that unions undermined the organization. However, officers without an authorized union worked at the mercy of superior authorities and were more prone to strike.

The earliest organizing efforts in nineteenth-century Europe, America, and Australia aimed not only at pay, pensions, and regular days off, but also at the "right to confer." They insisted that officers had the right to be consulted by police authorities on policy and conditions of service. Much of western Europe, Scandinavia, and Australia moved toward legalizing police unions during the early twentieth century. However, they remained prohibited in Britain and America. World War One put the police under immense economic and work stress, ending in strikes in Cape Town, London, Liverpool, and Boston. After 2 years with strikes, the British government responded by creating a police federation and with a comprehensive Police Act (1919). The United States went in the opposite direction, banning unions into the 1950s. American police had to rely on mutual aid and fraternal organizations to protect their interests. This adversarial attitude toward police unions persisted well after the unions began to be legalized after World War Two.

The Civil Rights era revived existing and new police unions in response to calls for reform and integration. Police union rights were linked to broader organizing rights. While still concerned with pay and conditions, unions began lobbying policy makers to improve internal conditions and address external issues. They used a variety of strategies, both old and modern. "Work to rule" and slowdowns continued. Media campaigns won over public and political support. This created concerns that unions were threatening police political neutrality, particularly after scandals where police unions and party leaders made secret deals promising support in return for specific policies. Recently, more positive directions for police unions included working for affirmative action across the African continent, and pioneering shared leadership programs in the United States. Challenges for police unions persisted. They earned a reputation for being reactionary and inflexible, though unions took steps toward cooperating in reforms and community issues in constructive ways. Research on police unions is sparse, and mostly focuses on recent decades. Scholars tend to have pessimistic assessments, but lately have explored linkages between workplace rights and civil rights. The picture, however, remains incomplete.

Fundamentals

Labor unions developed to protect basic worker rights such as fair pay, safe work conditions, and the right to confer, as well as address concerns unique to each occupation. While no universal model of police union existed, they typically focused on (1) pay, pensions, and allowances, (2) conditions of service, including discipline and promotion, (3) the right to confer, and (4) legal reforms and policies. Police officers first joined together not just for improved pay but also to end the tyranny of superior officers and authorities who refused to listen to them. The earliest unions already focused on the need to replace arbitrary power and corruption with fair standards and procedures for promotion and discipline. Always uncomfortable about the idea of the police "downing tools," they typically adopted "no strike" policies only abandoned under acute stress. World War One sparked police strikes in cities where police officers were overwhelmed by war-time inflation, and police unions were banned. In the twentieth century, police forces applied themselves to becoming a profession. Unions became more like white-collar associations that faced the similar challenge of trying to be professional but also address typical union concerns. Lobbying became more central after World War Two as police forces responded to Civil Rights movements and demands for police reform and integration. Forces slowly became more diverse with more women and minorities, yet minority groups continued to see a need for their own advocacy groups. Some unions became highly political, creating challenges for police organizations that insisted that they were politically impartial. These changes in police unions reflected changes in police officers themselves; nineteenth-century working-class policemen in strictly regimented departments gradually became in the twentieth century better educated and more diverse men and women in more complex, though still hierarchical, organizations.

Every police union had its own trajectory. They were diverse in size, goals, and power, over time and space. Police forces could have unions, but many had federations, associations, guilds, fraternal organizations, or societies that might carry out similar functions as a union and had greater or lesser authority depending on local conditions. Groups could be local, national, or international. Multiple groups coexisted. What kind of organization existed depended on laws and circumstances. For simplicity's sake, the terms "police union" and "union" will be used except when a specific group is mentioned. Australian, Dutch, French, and Scandinavian police unions were legal throughout the twentieth century but varied in size and style. When police officers were not allowed to unionize, they often set up societies and clubs. In 1918, Cape Town police had a committee that organized a successful strike, and in 1919, the Boston Social Club transformed itself into the Boston Police Union. After 1919, British police could not join unions, particularly not the National Union of Police and Prison Officers; its official replacement, the Police Federation, attained negotiation powers in the late 1940s. New Zealand followed a similar path, attempting to unionize and ending up instead with an official Police Association in 1935. In the United States, the Fraternal Order of Police was allowed while police unions and collective bargaining remained illegal until the 1960s. Today, US unions are highly local, Australia has state unions, and the Republic of South Africa has two national unions. Unions might be associated with a national federation or association, or remain unaffiliated. Only recently did police officers attempt to set up unions in authoritarian nations or nations transitioning from dictatorships to more open regimes, such as in Argentina and Swaziland where such unions were declared illegal. In recent decades, unions affiliated directly or indirectly with the International Council of Police Representative Associations (ICPRA), formed in 1996 to promote professional standards and police civil rights.

The key function of these unions was to give a voice to the rank and file who often felt they had no control within their occupation. Strains existed between upper and lower ranks over promotion and discipline, which could seem arbitrary and corrupt. Relations between unions and police authorities could be confrontational, friendly, or anywhere in between, affecting cooperation and communication. At the very least, unions provided a safety valve where officers could air grievances and blow off steam. Unions generally had a decent record on improving pay and protecting gains, though they were still at the mercy of economic downturns. They fought to create and protect fair procedures for promotion and discipline. They provided support during disciplinary cases, varying from advice to legal services. However, a simple idea such as improving conditions for senior patrol officers demonstrated how entangled issues could become. Suggesting rewards such as “master patrol officer” or favorable transfers created new problems balancing seniority, pay equity, and education. Unions sometimes got bewildered over how to improve education standards and attract quality recruits without undermining the pay and status of older officers. As unions got stronger in recent decades, police authorities and the public raised concerns that they had become too insular, defensive, and resistant to change. On the other hand, examples of dynamic, constructive unions existed. The question is whether this is the direction for the future or a few exceptions.

Most unions included the lowest two or three ranks so they represented the majority of, but not all, police officers. Higher ranks had their own organizations. Some unions included retired officers and a few included civilian staff. The New Zealand Police Association was unusual in including civilian staff and all ranks except the very highest. Where legal, joining the union was fairly automatic. Where official bodies existed, such as the Police Federation of England and Wales, joining the police meant joining the Federation. How active members were depended on how useful they considered their union to be. Alongside unions, societies existed to represent specific groups. Police authorities banned or tolerated them depending on their behavior and local attitudes. Initially, these tended to be linked to religion, such as Catholic or Protestant associations which could get themselves into trouble if they became too fractious. As forces diversified in the twentieth century, women’s and ethnic minority associations appeared, and more recently, groups for gay police officers. Religious groups persisted, but with greater variety. These organizations paralleled unions and often prodded them to address entrenched sexism, racism, and other forms of discrimination. Their relationships with both police forces and police unions could be acrimonious given often defensive police attitudes.

The legal status of unions depended on national and local laws. Many western nations authorized police unions early in the twentieth century. Police unions in the Netherlands, Scandinavia, and parts of Australia were permitted before World War One. French police unions began in 1905, to be legalized in 1926. Australian unions formed state by state until every region had one in 1945, the same year that the Police Federation of Australia and New Zealand was formed. German police unions formed during World War One and were active under the Weimar government, only to be shut down under the Nazis. Some nations barred unions but allowed “federations” or “guilds” that fulfilled similar or reduced roles. After police strikes in 1919, police unions were banned in Britain and America. The British set up the Police Federation of England and Wales while in America, the Fraternal Order of Police (FOP) provided a limited alternative. Despite deep antagonism from police chiefs who viewed unions as sources of corruption, tiny unions persisted, some affiliated with the FOP or the National Conference of Police Associations. Finally, American police unions were legalized in the 1960s though not all gained collective bargaining rights. They remained local and diverse, similar to their police forces, with most acting independently to protect local interests. Unlike the older unions in Europe and Australia, American unions tended to be more reactionary and antireform. To the north, provincial Canadian police had unions with collective bargaining rights, but as recently as 1999, the Canadian Supreme Court ruled that the Royal Canadian Mounted Police did not have the right to unionize. Instead, they had official staff relations representation which loosely resembled the British Federation but without its authority. Finally, unions appeared in emerging democracies such as the Republic of South Africa. The Police and Prisons Civil Rights Union (POPCRU) formed in 1989, and it continued to focus on civil rights issues both at home and across the continent. The South African Police Union was more moderate and took an apolitical approach. In 2003, two Argentine police groups asked the International Labour Organization (ILO) for support to address poor working conditions and tyrannical superior officers. However, the ILO limited the rights of police officers to unionize if such unions were banned by national law and did not back them (Marks and Fleming 2006). Attempts by Swaziland police to unionize met similar barriers. Police authorities continued to argue that unions undercut their authority, but forces with a long history of legal unions had better morale and less insubordination than forces without unions.

Early Unions and Police Strikes

The first police unions appeared in the later nineteenth century and their forms roughly reflected unionism generally. Early efforts focused on pay and conditions including training, uniforms, and work shifts, and internal questions such as discipline, tyrannical bosses, and basic fairness. They dealt with local and sometimes national governments since changes could require new laws. In areas without unions, mutual aid societies, such as the New York City Patrolmen's Benevolent Association (1892), and rank-and-file newspapers, such as Britain's *Police Review and Parade Gossip* (1893), provided police forums. With or without a union, police officers rarely supported the idea of striking, so other tactics had to be explored. Early actions included petitioning authorities, "work-to-rule" protests, and refusals to parade. An early protest in 1853 Manchester, where about half the force resigned over low pay, had shock value but had clear strategic flaws. More commonly, officers staged what amounted to "sit-down" strikes, refusing to leave the station until their grievances were heard. These could be effective though risky. London officers staged a protest demanding pensions in 1890. The 1890 Police Act did give police officers pensions, but protest leaders and 39 protesters were dismissed (Allen 1958). By the early 1900s, informal efforts became unions, police officers learning that unions were more likely to be taken seriously. If the unions were recognized, actions that might threaten dismissal were unlikely to be required. However, areas that resisted police unions left police officers with few useful options to get their voices heard.

The most prominent time of police strikes was during and immediately after World War One when war-time responsibilities and inflation put police officers under severe stress. The police officers resorted to strikes as a last resort after months of having their concerns ignored. Bad pay was a factor but abuse of power as well. None had recognized unions. The 1918 strikes in London and Cape Town, South Africa, had an advantage of taking place during the war, making governments eager to resolve the crises quickly. In January 1918, white policemen in Cape Town organized a strike over pay, understaffing, and overwork after months of being ignored by the Minister of Justice. Organized by a committee, a small group of younger, single officers struck, both protecting married men and keeping enough men on duty to cover beats. The strikers were imprisoned, provoking more men to strike. Eventually 100 out of 500 men struck, but order continued. The public sympathized with the strikers who acted with restraint, and at least in part after learning that patrolmen's pay had eroded so much that they had to live in "respectable" colored neighborhoods (Nasson 1992). The strike lasted 2 weeks when all the men returned to duty and their war bonuses were increased. In 1919, a commission was formed to improve their conditions of service. In August 1918, the London Metropolitan and City of London Police also went on strike. The strike began for similar reasons, with the addition of concerns over "victimization," and after being similarly ignored. The London police, however, had an unrecognized union, the National Union of Police and Prison Officers (NUPPO), and the firing of a union member sparked the strike. Effectively both forces went out, yet order did not break down. The government settled within a week, with police commissioners forced to admit ignorance of the dire circumstances of their own men and the public perceiving the police as having just grievances. Similar to Cape Town, no men were fired, pay and war bonuses increased, and a commission was called to examine police conditions. These two strikes ended successfully for the police officers. The war forced governments fearful of Bolshevism to respond quickly, and the quiet streets kept the public's support.

By 1919, with governments no longer constrained by war, strikes became less successful and more violent. Victory in the 1918 London strike spread NUPPO branches throughout Britain. Police officers elected union members to the Desborough Committee, the commission on police pay and conditions. However, union leadership made excessive demands, forgetting that with war over, the government had no reason to bend. While many British police were content with improved pay and willing to hear the Desborough Committee's recommendations, Liverpool police feared entrenched favoritism and internal corruption which persisted unabated. In August 1919, half the force went on strike, leading to 3 days of rioting. Nearly 1,000 strikers were dismissed. The NUPPO was suppressed and membership declared illegal. While the Liverpool strike failed, it did result in important additions to the 1919 Police Act regarding conditions of service, promotion, and training. At the same time, Boston policemen were arguing with their mayor over pay and conditions, and getting nowhere. Inspired by the English strikes, they formed a union recognized by the American Federation of Labor. Other American forces took similar actions. In September 1919, the Boston Police Commissioner banned their union, leading to a strike remarkably similar to Liverpool. After rioting and looting, over 1,000 strikers were dismissed. President Wilson condemned the strike as a "crime against civilization" (Russell 1975). Both the Liverpool and Boston strikes turned the public against police unions because of the violence. However, British and American authorities responded to the strikes quite differently. The Boston strike seemed to confirm US police chiefs' worst fears of Bolshevism infiltrating the police and left them wholly against police unions for decades. Other police forces that had been forming unions gave up the idea. Britain created the Police Federation, which for all its weaknesses recognized that officers needed representation and an outlet for grievances.

The 1918–1919 strikes highlighted a central question of police unions – police officers demanding the right to confer and police authorities fearing that unions undermined their authority. In the United States particularly, police chiefs adamantly opposed any kind of police unions. They argued that public servants could not be linked to outside authority, unions undermined discipline, and unions obstructed change. Yet ironically, police officers barred from organizing were more likely to strike while unionized officers were more willing to negotiate. The reality was that police officers were going to organize, so allowing them to organize openly and legally was a better choice. By banning police unions and portraying them as threats, US police forces may have created an acrimonious relationship that continued to echo after unions were legalized in the 1960s. Police authorities were correct to worry that unions threatened their personal discretion. Unions were more likely to be illegal in nations that stressed a strong, top-down management style of policing. Police officers organized out of a sense of powerlessness against arbitrary superior officers and worked to create due process. Later unions often became reactionary to protect these gains and remained fearful of arbitrary authority.

Unions and the Professional Police

During the twentieth century, police forces focused on earning recognition as a profession despite a lack of clear direction. Policing did not require a professional degree, forces often lacked mutual standards, and transferring between forces was difficult. The role of police unions in this shift remained ambiguous. Some maintained a union identity while others became more like professional associations. When tangible gains such as pay were more secure, the status of being professional could be appealing. Unions often shared the confusion over their identity, wanting to be perceived as professional organizations yet with the collective bargaining powers of unions. More important than semantics, the rank and file argued that they had positive contributions to make to policy and service conditions. In Europe and Australia, police unions were included in these deliberations while in the United States, typically they were not. When the Civil Rights era brought police forces under criticism, the union model revitalized and unions became more assertive. Nevertheless, professionalism remained important, stressing efficiency and high standards.

In the 1960s, police unionism surged, with existing unions becoming more active and new unions forming, particularly in the United States. But unions gained a reputation as reactionary and defensive, seeing calls for reform as attacks on their profession. They viewed change as an admission of failure, even as giving in to disorderly and rebellious protestors. The 1960s and 1970s were a low point for American and British unions, made up largely of white, conservative men who not only resisted reform but framed their refusals to diversify as defending their rights. The Fraternal Order of Police opposed affirmative action, requiring the Afro-American Patrolmen's League to protect black officers. In Atlanta, Georgia, in the 1970s, the two groups filed lawsuits and countersuits over promotion and job assignment issues. After 3 years of stalemate, all sides agreed on a policy of treating all officers on an equal basis (Lewis 1989). Bringing women into police forces presented unions not only with challenges to their masculine image, but more importantly, unions feared that women could be used as an excuse to erode pay gains. Most unions opposed women though some supported equal pay for women to protect the pay of men. The domination of police unions by white men explained the importance of minority organizations to protect the interests of minority officers and to prod the majority toward fairer policies.

Clearly, police unions deserved many of the complaints that they blocked innovations and calls for change. From the unions' perspective, they used collective bargaining and similar tools to protect hard-won gains. From outside and from above, they looked intransigent and outdated. In the 1970s, some US unions supported education incentive plans, but many opposed them for violating prized "equal pay for equal work" standards. Overall, US unions focused more on pay issues and less on the larger picture that a better education was better for policing (Juris and Feuille 1973). Union resorted to denying all problems in response to criticism for ineffectiveness, discrimination, or corruption. The standard approach was to launch public relations campaigns, present the "bad apple" idea, and even inhibit investigations. If problems were found, unions insisted that they be dealt with by the police. The London Metropolitan Police refused to acknowledge that they had problems with racism despite numerous commissions, investigations, and court judgments in the 1970s and 1980s. Only in 1999 when the Stephen Lawrence Inquiry Report accused them of "institutional racism" did the force admit that they needed to make changes. Support or opposition to change tended to rest on how successfully the rank and file was included in discussions. Both civilian reformers and superior officers could be patronizing and rude to police officers, viewing them as poorly educated and unable to make thoughtful decisions. When unions responded defensively, that confirmed the stereotype and perpetuated the problem.

Police unions became acutely worried whenever civilians got too close to policing's internal affairs. Replacing police officers with civilian staff could look like efficiency to reformers but like diluting the work force and a cost-cutting measure to police officers. The greatest threat was civilian review boards which sprang up in the 1970s in response to scandals as well as civilian activism. Unions loudly objected to civilian boards, seeing them as ignorant nuisances. The Police Association in Victoria, Australia, managed to shut down a Police Complaints Authority in the 1980s, and police unions in the United States fought hard against ombudsmen and civilian boards (Finnane 2008). Nevertheless, civilian review spread and unions had to adjust. Community policing programs, where civilians augmented the police, could also be problematic when local police forces were not adequately included. On one side, police unions resisted involving the community, equating such ideas with budget cuts and interference. On the other hand, civilians lacked creativity in including the police as partners in community policing (Sklansky and Marks 2008). Where police unions were included in setting up community policing programs, police fears of outside intrusions could be allayed. Chicago incorporated key terms regarding management and pay into its program. The program was a success and the local FOP endorsed it (Walker 2008). Broken Arrow, Oklahoma, set up a police shared leadership program in cooperation with the police union, a hint of what was possible when communications were open.

Police unions developed strategies to get their views across without disrupting order and without big strikes. These fell into four categories of on-duty action, off-duty action, media, and lobbying with two basic goals of affecting contract negotiations and government policy. Sometimes, a specific issue related to a particular incident provoked union action, such as when Pittsburgh police officers caught the "blue flu" to protest how the force handled transferring white and black officers in and out of inner-city neighborhoods in April 1970 (Juris and Feuille 1973). Work actions such as sick-outs and mass car servicing were planned not to endanger the public. Other options were "go-slows" and work-to-rule campaigns. Traffic ticket slowdowns reminded authorities that the police provided important revenue and were popular with the public. Detroit staged one in 1967 and Brisbane, Australia, in 1976, and both made their point quickly. Following a shift by trade unions generally, police officers began using brief 1- or 2-day strikes designed to force negotiations or policies. In May 1970, Rochester police staged an 8-h strike which resulted in negotiations resuming though a similar strike in Milwaukee in January 1971 failed in part due to public apathy (Juris and Feuille 1973; Fleming and Lafferty 2001). But more short strikes worked than failed, and they continued into the twenty-first century. Brazilian police in 2001, Dutch police in 2007, and Slovenian police in 2010, all staged short strikes over pay. The threat of major walkouts remained if police authorities misread their officers. In 1969, Montreal police and firefighters struck over pay but also over job hazards created by separatist terrorists resulting in looting, bank robberies, and violence. Unions preferred not to strike, but kept the option in reserve.

Off-duty union efforts ranged from public meetings and marches to letter-writing and media campaigns. When Dutch police were unhappy with pay negotiations in 2007, for example, thousands of off-duty officers staged noisy protests outside the Ministry of the Interior (Berry et al. 2008). Such efforts could work though could take patience to bring results. In the 1950s, the New York City Police Benevolent Association (PBA) evolved into a union role through a variety of media and legal actions. In 1958, when the mayor refused to negotiate a grievance procedure, the PBA published an "Open Letter to the Mayor of the City of New York" as a newspaper advertisement. They petitioned the city Department of Labor and finally appealed to the US Supreme Court. The PBA lost their appeal but proved to be tough advocates. In 1961, New York established a police grievance system. The political environment shaped what a union could expect. The 1950s New York Police operated in a city hostile to unions, where the mere threat that a union might be forming convinced the city to improve conditions (Levi 1977).

In theory, most police forces declared themselves to be politically neutral. Despite this, increasingly police unions took part in the political campaigns of candidates or parties with policies favorable to the police. Issues included improving police numbers, modernizing equipment, and reforming laws. This could be positive or negative on numerous levels with unions protecting their interests, working for reforms, and risking conflict of interest. An early example of a campaign came when the *Police Review* helped lobby Parliament to give the police 1 rest day in seven which resulted in the Police (Weekly Rest Day) Act in 1910. After World War Two, unions focused on getting sympathetic candidates elected at the local and national levels. They risked their apolitical reputations despite frequent protestations that their actions were impartial.

Dutch unions proved good at campaigning without losing respect, but Australian unions made some embarrassing miscalculations. In 1996, the Queensland Police Union was determined to unseat the local Labor government and campaigned against them successfully in a by-election. However, a "memorandum of understanding" between the union and opposition leaders came to light, promising policies favorable to the police. This provoked outrage and damaged the image of the union which was forced to reconsider both its strategies and its democratic values (Finnane 2008). Unions did not necessarily commit to one party. In the late 1970s, the British Police Federation conducted a law and order campaign that matched the policies of the Thatcher administration. However, by the 1990s, the Federation rebuked the Conservatives for saying that the police's primary aim was fighting crime, insisting that their first priority was protecting life and preventing crime (Berry et al. 2008). Unions continued to grapple with their declared political neutrality, yet with widespread involvement in political lobbying.

Openly political police unions existed, typically with multiple unions for police officers to choose from based on ideology. These could be motivated by one idea, such as POPCRU which spotlighted civil rights. The French police had competing unions aligned with local and national political parties. Since the 1970s, French governments consulted with unions over reform and policy, causing many police officers to wonder if their unions had become just another factor in corruption and favoritism problems. Then again, French police unions spoke out against police abuses of power, and supported creative reforms and modernized equipment (Horton 1995). They provide an alternate model to the apolitical one that could often be unrealistic. However, becoming too political had its own dangers. In India, ruling elites tended to use police as an arm of their governments, and allowed police abuses of power. In the 1980s, the police union in Gujarat turned the tables, becoming too powerful and blackmailing the local government. The union threatened not to police during confrontational annual holidays unless its demands were met. In 1988, the government refused to be coerced. The union called a strike, but its leaders were quickly dismissed and the union disbanded. Only in 2006 did Indian courts allow the union to reorganize. However, the problematic relationship between governments and police remained unresolved (Joshi 2000; Aggarwal 1988).

Police unions remained divided over the advantages of local organizations versus a more national focus. American unions often operated in isolation from each other while Scandinavian police unions supported nationalizing. Nevertheless, increasingly unions at least talked to each other, sharing information on pay and conditions to help with negotiations and working to improve professional standards. In 1996, acknowledging an increasingly global society, the International Council of Police Representative Associations (ICPRA) was founded with momentum from the Canadian Police Association. Its basic goals reflected a persistence of nineteenth-century concerns – open communication, consistent and fair procedures, proper training and equipment, political neutrality, and the right to freedom of association. Gaining full civil rights for police officers remained an issue; many police officers could not vote in the nineteenth century and many nations denied them suffrage in the twenty-first century. Their objectives included expanding collective bargaining and helping police forces establish their own associations. Overall, their agenda was practical, including improving qualifications of officers, standards of police methods, and professionalism. In 2012, ICRA was helping the Swaziland Police's fight to unionize and supporting Guardia Civil to gain rights being limited by the Spanish government. Membership was limited to national police associations, in part to encourage local unions to work together. Members in 2012 included Australia and New Zealand, Canada, the Fraternal Order of Police, Ireland, the United Kingdom, Portugal, Denmark, and the European Confederation of Police. The two Republic of South Africa unions were the only ones from Africa. No members came from Latin America, the Middle East, or Asia. However, IPRCA and other organizations were supporting efforts in those areas to unionize police forces.

Historiography and Future Directions

The historiography of police unions is unexpectedly thin. Official publications, such as the American *Police Unions and Other Police Organizations*, issued in 1919 and reissued in 1944, took a negative view of police unions as undermining policing's core values. With the exception of V.L. Allen's "The National Union of Police and Prison Officers" in 1958, the first substantial scholarship came out in the 1970s. Robert Reiner's sociological study, *The Blue-Coated Worker*, was based on interviews of British police officers, including their views on the Federation and police unions. In the United States, studies such as Hervey Juris and Peter Feuille's *Police Unionism* explored unions from the perspective of industrial relations and collective bargaining. Only in the 1990s and 2000s did historians begin focusing on police unions, notably Mark Finnane's *When Police Unionise* on Australia. Books on police strikes were more common but they did not focus on unions and they tended to be for a popular audience, such as Francis Russell's *A City in Terror* (1975) on the Boston strike which focused largely on Calvin Coolidge. Numerous articles came out, but they tended to focus on contemporary issues rather than history, with a few exceptions such as Nasson's 1992 article on the 1918 police strike in Cape Town. Articles on Swedish and Belgian police unions were not readily accessible to English readers. Unions were covered as part of larger works but typically only for a few pages. A large gap in the scholarship exists for history focused specifically on police unions.

Scholars of police unions can roughly be divided into pessimists, pragmatists, and optimists. Pessimists viewed unions as reactionary, conservative, and undermining authority. Most historians tended to take this stance, including many US police historians as well as sociologist Robert Reiner. Recently, pragmatists, notably Mark Finnane and Samuel Walker, reminded readers that the first priority of unions was to serve their members. The optimists were a new group, arguing that unions could move the police out of stale models and cooperate with the community in constructive ways. In 2006, many police scholars came together at an international, interdisciplinary conference on "Police Reform from the Bottom Up" at the University of California, Berkeley. It resulted in special issues of *Policing & Society* (March 2008) and *Police Practice and Research* (May 2008) which focused on ways that police unions could participate in reform, as well as be obstacles to such a role. The authors made an effort to move away from the dominant pessimistic view and explore more nuanced interpretations of police unions, as well as explore why the negative view of unions existed. Even here, though, the articles focused more on recent decades than on before the 1960s.

Union scholarship was often cast as a struggle for control between police authorities and the rank and file. One question explored was whether police unions weakened or strengthened police forces. They could hurt forces by undermining discipline or help them by breaking down a military mentality. More pessimistic historians argued that police unions became part of the military mentality, resisting civilian oversight and outside investigation. They pointed out the reactionary and insular behavior of unions against diversity and innovation. However, scholars remained uncertain on whether unions challenged top-down control or reinforced it (Marks and Sklansky 2008). In 1996, a study found that police officers were more satisfied with their jobs and had a better relationship with the public with less heavy-handed management, and that unionized officers reported better community relations. They concluded that shedding the "top-down" approach could be a good idea for both the police and the public (Magenau and Hunt 1996). For all their flaws, Samuel Walker pointed out the importance of unions in shared governance and the move away from authoritarian models of policing in America (Walker 2008). The tendency to view police unions negatively needed to be corrected and contextualized. Mark Finnane was also less epic in his expectations of police unions either for good or evil. Their primary task was to look out for their members' pay and pensions, and to be advocates in discipline and promotion cases.

In the 2000s, a democratic theory of police unions was advanced which remains controversial. Monique Marks and Jenny Fleming favored the argument that police unions needed to shift from the military model to a modern civilian, democratic model, and become agents of positive change. Fleming especially argued that police unions helped break down the militaristic attributes of police culture. Their idea was that unions helped police officers understand the importance of workplace democracy and so became willing to protect democracy more generally. Unions provided rights such as association, free speech, and voting, and supported work rights like collective bargaining, fair pay, and impartial discipline. Police officers who valued their own rights would protect the rights of others. The theory leaned on examples from the developing world, particularly POPCRU in the Republic of South Africa. Its applications tended to be more for recent and future developments. Dutch and Swedish police unions supported POPCRU in the 1990s, and in 2007, POPCRU began supporting Swaziland and Mauritian police officers working to unionize. Similarly, police unions from Australia and New Zealand worked with police associations in the Cook Island, Papua New Guinea, and Fiji (Marks and Fleming 2006). Whether unions helped police officers link workplace rights to broader human rights historically will require additional scholarship.

More research remains to be done on police union history to build a more complete picture of their role in police history. Clearly police officers will organize regardless of its legality. Why parts of Europe and Australia were comfortable giving the police rank and file a voice while Britain and the United States resisted is a comparison requiring further investigation. Australia suggests that having a long history of legal unions did not necessarily make a difference in community relations and openness to innovation and reform, but within Australia, this varied from state to state. American forces condemned unions for so long that they may have created the pent-up frustrations that burst out in the 1970s. However messy unions could be, having police unions decreased acrimony and improved morale. What is perhaps most startling is that the early concerns of police unions from the nineteenth century share so much with the 2004 goals of the International Council of Police Representative Associations. Unions continue to complain about poor relations with their superiors, just like unions in the nineteenth century. The central concern remains the right to confer.

History of Probation and Parole in the United States

James T. McCafferty[1] and
Lawrence F. Travis III[2]

[2]School of Criminal Justice, University of Cincinnati, Cincinnati, OH, USA

Overview

Probation and parole are two types of community supervision that form the "bookends" of corrections in America. Probation is a community supervision sanction imposed in lieu of incarceration, while parole involves supervision of individuals released from incarceration. Together, these two broad types of supervision take on the lion's share of criminal clients under the formal control of the criminal justice system. Designed to surround incarceration, these correctional settings offer offenders conditional release into the community. Offenders receive formal, written supervision conditions, and a supervision officer monitors their progress and behavior in the community. An offender who commits a new crime while on community supervision or violates the supervision conditions may be placed into an institutional setting. Within probation and parole, offenders may be managed differently. Offenders who commit more serious crimes and are also considered high risk may be placed on higher levels of supervision that have stricter conditions, as opposed to less serious offenders who may not be monitored as closely.

The current systems of probation and parole developed in America during the mid-nineteenth century; however, the historical purposes and use of these systems of community management have European origins. As an alternative to incarceration, justice officials have traditionally used probation and parole for offenders that do not need to be incarcerated. By monitoring these criminals outside of prison, the community supervision agencies can help alleviate prison crowding and keep criminal justice costs down. Supporters believe that parole can also have a positive benefit by influencing prison behavior by acting as an incentive for good behavior. Scholars, politicians, and the public have attacked community supervision for being ineffective or "soft" on crime. Research suggests that with proper identification of risk and appropriately matched correctional interventions, community supervision can be effective at keeping offenders from recidivating and reducing correctional costs.

Like any other area in criminal justice, probation and parole present issues of financing, management, and newer issues concerning the role of technology in supervision. In response to greater numbers of people under correctional control and strained budgets, community supervision is most likely at the beginning of the next phase of its evolution: increasing the effectiveness of supervision through proper identification of risk and needs of offenders, while matching clients to the appropriate level of supervision and keeping criminal justice costs to a minimum.

Introduction

Today, imprisonment is an accepted and frequently used criminal sanction; however, the criminal justice system supervises a majority of criminals in the community. Nearly 7.1 million people were under correctional authority at the end of 2005. Community supervision monitored nearly five million of those people (Glaze and Bonczar 2006). For as long as statistics on the correctional population have been tracked, about two-thirds of those under correctional control have been supervised on probation and parole.

Taken together, probation and parole are the "bookends" of incarceration in America because these systems "surround" incarceration. Probation is a community supervision sanction imposed in lieu of incarceration, while parole serves to supervise individuals released from incarceration. Offenders placed on formal supervision must abide by specific conditions and must report to an officer responsible for tracking their progress and behavior in the community. Should the offender violate these conditions, the court or paroling authority can revoke the community supervision status. If found to be in violation of supervision conditions, the resulting violation (or revocation) hearings often lead to stricter community supervision conditions or incarceration.

Many people consider incarceration, especially the prison, to be the cornerstone of correctional intervention in the United States. While America's prison population has drastically risen over time, probation and parole are still responsible for a majority of offenders under formal control. As prisons become increasingly crowded, it is important to address alternative sanctions to incarceration because community corrections will receive many criminals that otherwise might have been sent to prison. This entry will discuss the historical origins of community supervision and their function within the community. It will also address important contemporary issues confronting community corrections including effectiveness, appropriate identification of criminals' needs, financing, and the role of new technology in supervision. This entry will conclude with a discussion of the future of probation and parole.

The Development of Probation and Parole

Probation and parole developed in the United States during the nineteenth century; however, these systems are not uniquely American inventions. During the Middle Ages and early Modern Era, feudal law would often require a strict sentence of corporal or capital punishment for criminal behavior. Over time, due to changing societal values and the reemergence of unified nation states, English justice officials were in need of an alternative to corporal and capital punishment and early forms of incarceration. Justice officials began to explore community supervision for several reasons, including early forms of prison crowding and as an altruistic recognition that the behavior of some offenders did not warrant imprisonment or capital punishment.

The development of probation can be traced to formal statutes and church intervention in England. During the medieval period, clergy members accused of crimes could have their cases moved from a criminal court to a church court. As a form of asylum, the "benefit of clergy" would allow the accused to avoid hanging as a penalty for their crimes. By reading the 51st Psalm, the criminal could claim the status of being a member of the clergy. The 51st Psalm was recognition of the offenders' remorse and repentance but also a literacy test to identify true clergy members. By the early nineteenth century, English statutes would end this practice due to misuse by illiterate, common criminals that would commit the verse to memory and misrepresent themselves as clergy members (Travis 2012). In its place, the English established statutes to allow court officials to exercise a form of official judicial reprieve. This formalized practice allowed sentencing officials to delay sanction under the conditions of good behavior for a set amount of time. At the same time, the courts developed release on recognizance (ROR), a practice that released accused persons awaiting hearings before circuit magistrates. Court officials had the discretionary power to release accused offenders into the care of a sponsor or by the offender posting some form of collateral. This practice was also an early forerunner to the system of bail in the United States. Together, judicial reprieve and ROR influenced alternatives to incarceration that were more formal process functions that directly led to the creation of probation and parole.

Early use of ROR in America first occurred in Massachusetts in 1830. In *Commonwealth v. Chase*, a woman was freed after pleading guilty without sentence being passed. In her case, the court released her, allowing her "upon her recognizance for her appearance in this court whenever she should be called for, to go at large" (as cited in Cromwell et al. 1985). Today this type of release is common for criminals with minor charges.

John Augustus is considered the "father of probation" and the creator of the most widely used correctional sanction in criminal justice. Originally a shoe cobbler in Boston, Massachusetts, Augustus became a volunteer probation officer in an unofficial capacity, when in 1841 he persuaded local court officials to release nonviolent drunkards into his custody in lieu of incarceration. Augustus would conduct a rudimentary background investigation of these individuals (a forerunner to presentence investigations), and if he chose to sponsor an individual, he would post a small fee for their release and supervise the individual in the community where he expected certain conditional behaviors. Augustus expanded his work to sponsoring men accused of other crimes, women, and some children. Over nearly two decades, he managed almost 2,000 criminals in the community. The Commonwealth recognized his work by codifying "probation" as an official sanction and the law made John Augustus the first paid probation officer. Later, other states adopted the Massachusetts model.

Parole developed in a similar manner around the same time as probation. Like Augustus, who became dissatisfied with blanket incarceration, other justice officials began to recognize the shortcomings of imprisonment. Early proponents of parole-like actions did not believe that simple incarceration in prisons had the power to "reform" criminals. Instead of a determined period of incarceration served by an offender, they developed systems to allow prisoners the opportunity to earn early release from their sentence. For example, Sir Walter Crofton developed "tickets of leave" for inmates in Ireland. After an early period of solitary confinement, prisoners could improve their stage of treatment through hard work and good behavior. After passing through an intermediate stage of treatment in prison, inmates could secure their release with a "ticket of leave." Under this system, Crofton gave himself the discretion to release an inmate early from their sentence and report to local authorities that an offender would be returning home. Under Crofton's system, there was no formal supervision of the offender after his release.

Captain Alexander Maconochie is considered the "father of parole." As an administrator of a British penal colony, Maconochie developed a "mark system" that allowed inmates to improve their classification. When entering the prison, all prisoners were at the lowest level of classification – the "penal stage" which was defined by hard labor and intense supervision. After a period of time with good behavior, prisoners could earn enough "marks" to move to the "social" stage. At this level, prisoners would have better living conditions in a smaller group setting with less supervision. Prisoners reached the final stage ("individual") through even more "marks" and earned the privilege of living in a cottage while working towards their conditional release (Travis 2012). Maconochie's system also called for the loss of "marks" and status. If offenders were to have poor behavior or laziness, they could be penalized and demoted. This carrot-and-stick system gave the prisoners incentives for good behavior in the prison, which helped control bad behavior in the institution.

In 1870, at the meeting of the American Prison Association in Cincinnati, prison reformers pushed for the creation of parole and a system of reformatory discipline for United States prisons. A prison in Elmira, New York, was the first where prisoners could be sentenced to terms of indeterminate incarceration. Parole in America would develop two main components: (1) discretionary early release from prison for worthy prisoners and (2) a period of supervision in the community that follows release (Travis 2012). Parole could also be used to support discipline within prison.

Current concerns about community supervision focus on how offenders are supervised, the types of services they receive, and whether these types of community management can curb new crime. These concerns have spurred the creation of specialized courts, such as reentry courts. The purpose of these courts is to increase the courts' supervision of an offender and allow for better coordination of community-based services (e.g., treatment programs, job placement). Reentry courts may represent a new paradigm in community corrections, which have been largely unchanged in purpose or design for over a century. Much in the vein of drug courts and mental health courts, reentry courts serve a population of released offenders, with a goal of improving offenders' transition from an institutional setting to a community setting.

Legal Issues in Community Corrections

The Progressive Era of corrections in the early twentieth century survived legal challenges to the discretionary powers inherent in probation and parole. In fact, these legal challenges helped formalize the systems of how offenders secure an early release and how they are supervised in the community and violation procedures. For example, *Morrissey v. Brewer* (1972) required that parolees accused of violations be granted certain due process protections. Offenders had the right to (1) written notice of violation, (2) disclosure of evidence, (3) the right to a hearing and the right to present evidence at that hearing, (4) a limited right to confront witnesses, (5) a hearing before a neutral body, and (6) a written statement of the decision that addressed the evidence upon which it was based. *Gagnon v. Scarpelli* (1973) extended these rights to probation violators, stating that there was no substantial difference between probationers and parolees. In sum, the court combined these two different forms of supervision because they supported the interests of probation and parole clients in maintaining their conditional liberties and, by doing so, granted them certain due process rights during revocation hearings.

Note that probation and parole are restrictive forms of supervision for criminals. Even though criminals in the community enjoy greater freedoms than those incarcerated, they are still held to a higher standard of behavior than those not on supervision. Formal conditions restrict simple behaviors that most Americans take for granted. For example, unrestrained citizens can move across state lines without official permission from a court or paroling authority, but most of those under supervision must gain this permission before performing an otherwise legal behavior.

The Organization and Function of Community Supervision

While both are forms of community supervision, the level of organization of probation and parole can be very different. Generally, probation is organized at the county and municipal level, while parole is typically a state function. On the other hand, in some states, the same officer may be charged to act as both a probation and parole officer.

If an offender is placed on probation, that offender is under the jurisdiction of the court and has conditions imposed by the sentencing judge. The probation officer is an officer of the court, responsible for completing a presentence investigation for the court, holding the probationer to the set of standards specified by the judge, and acting as a fact finder for the court if there is a violation of these conditions. Parolees are under the jurisdiction of the paroling authority. The paroling authority will set the conditions of release into the community, while parole officers are responsible for holding the parolee to the set of standards specified by the authority. The parole officer operates much like a probation officer and has similar duties of monitoring clients and reporting any wrongdoing.

In its most basic form, probation and parole represent an agreement between the offender and the state. In order to gain his or her release into the community, the offender must agree to abide by a set of rules dictated by the sentencing judge or paroling authority. Violation of these conditions can be the basis for increased sanctions or the loss of liberty and subsequent incarceration. There are two broad types of violations. The first type covers new crimes committed by an offender while on supervision status. The second type covers technical violations that do not require any “criminal” behaviors. Due to the restrictions placed on probationers and parolees, these offenders must abide by a higher set of standards than those not under correctional control. Offenders can violate their conditions of supervision with such simple behaviors as unauthorized movement across state lines, using alcohol, or failing to report their new address to their supervising officer.

The status of probationer or parolee is sometimes known as being “on paper.” Probationers and parolees typically receive written rules or conditions of supervision. This listing of the conditions is the “paper.” Conditions serve many purposes. One purpose of written probation and parole conditions is to ensure that supervision can occur. That is, these rules are in place to define the behavioral expectations on the part of the offender and to define any further restrictions or treatments expected of them while in the community. These conditions also define how a probation or parole officer will interact with an individual. For example, if the offender is a known drug user, the conditions may require the officer to conduct drug tests with the client a defined number of times per month. Another purpose of written conditions is to place the offender on notice. Some conditions notify offenders that they may owe a certain amount of money in fines or may have to perform a certain amount of community service hours before he or she can be considered for outright release. Finally, this notice may be a simple time commitment, clearly defining that an offender must spend a specific period on supervision before discharge. Other conditions require the offender to seek or complete treatment. Finally, some conditions are designed to be punitive, such as requirements that offenders serve some jail time or write “punish lessons.”

Generally, probation and parole conditions are not universal across jurisdictions. There is a set of standard conditions that are expected of everyone in that specific jurisdiction (e.g., follow up with all subsequent court hearings and probation meetings, do not commit a new crime); however, while they are often similar, these standard conditions vary slightly in tone and expectation across jurisdictions. Probationers and parolees also receive special conditions. Instead of general expectations imposed on everyone on community supervision, these conditions are typically tailored to the individual (e.g., completion of treatment programs – substance or behavioral, restrictions on drug or alcohol use). General and specific conditions reflect the purpose of modern community corrections that offenders are formally controlled in the community while receiving necessary services to keep them from recidivating.

Issues in Community Supervision Effectiveness

Community supervision has come under attack from critics as being ineffective and “soft” on crime. Those that measure “effectiveness” as a total reduction in recidivism may never be satisfied with community supervision. The evidence reported in this section suggests that community supervision can be cost-effective and may have a positive impact on reducing criminal recidivism with certain types of offenders. The key to effective community supervision is embedded in proper identification of offenders that can behave successfully in the community with less state restriction. As the science of identification, rehabilitation, and controlling risk continues to improve, so will the effectiveness of community corrections. This section examines the effectiveness of the system according to research on the risk of offenders in the community, the cost-effectiveness of community supervision, and the successful types of community interventions.

Does Community Supervision "Work"?

The answer to this seemingly simple question may depend upon the yardstick used to define what "works" in terms of community corrections. Put differently, to define and measure what "works" may depend upon the point of view of the person asking the question. For example, politicians who campaign on crime policies may use a reduction in recidivism as evidence of a "working" system, while budget officials or economists may use a cost-benefit ratio to explore evidence of an effective system.

Community corrections should serve a basic purpose of community protection. Probationers should be appropriately identified as the type of people who do not need to be incarcerated and can operate pro-socially in the community. However, due to the increase in prison populations, community corrections are taking on more clients, some of whom may not be appropriate for this type of intervention. This is particularly a concern for probation since violent offenders are making up a larger portion of probationers (Auerhahn 2007), which can be attributed largely to a lack of bed space in prisons and poor identification of risk. Adding to this concern is the evidence that simple probation supervision may not be appropriate for certain types of offenders. Research indicates that probation has failed to prevent overall crime and is specifically ineffective with violent criminals and criminals guilty of fraud or forgery (MacKenzie et al. 1999). But probation can effectively prevent new crime for certain types of offenders such as drug dealers and people that engage in property crime. This illustrates an important point in moving forward: probation can "work" if clients are appropriately matched to the correct form of intervention and supervision. If evidence suggests that violent criminals are not appropriate for community control, policies should be reevaluated to make sure that these criminals do not receive a probation sentence. Alternatively, supervision practices might be changed to better monitor and control these types of offenders.

Other scholars have questioned the appropriateness of probation with certain types of offenders. Petersilia found that due to risks to public safety, felons in California were not appropriate for probation supervision. However, other scholars came to different conclusions when studying different states, citing that her results may be an artifact of California supervision. The concept of effectiveness was measured similarly across these studies, since each study was interested in *new* crimes committed by offenders, yet the researchers reached different results. The researchers could have defined and measured the concept of effectiveness differently and come to different conclusions altogether. For example, they could have examined whether the probation period was successfully completed by felons without any type of technical violations or time to recidivism.

Parole has also been harshly criticized by some scholars who have called for the abolition of parole in the United States. This argument hinges on ethical issues (e.g., supervision after incarceration adds extra punishment) and the lack of evidence supporting parole effectiveness. Indeed, measurement of parole effectiveness also suffers from the same measurement problems that plague probation research. Conflicting research defines effectiveness as curbing new crimes by parolees or keeping clients out of prison due to technical violations of their supervision conditions. The latter point is particularly important given that one-third of all inmates in state prisons were parole violators as of 2005 (Sabol et al. 2007). Some scholars have suggested that counting these types of offenders as failures of the system makes it impossible to adequately measure parole effectiveness (Flanagan 1985). In other words, it is important to identify how parole effectiveness should be determined: reduction in new crimes by the offenders, reduction in technical violations, or both. If parole keeps offenders from committing new crimes, then it may be successful. Research that measures technical violations in addition to new crimes may not be indicative of higher rates of crime.

The use of different outcome measures will lead to different conclusions about community supervision effectiveness. Generally probation and parole work to the degree that they (1) control risk of new crime, (2) reduce incarceration and correctional costs, and/or (3) match punishments with offenders. These three areas represent particular goals of the system and appear to suggest community supervision can be an effective form of intervention.

Controlling Risk

Attempts to identify and manage risk through probation and parole are difficult and imperfect but necessary for the system to operate within its means. A critical question for risk control of offenders in the community is a pure cost-benefit question: how safe is safe enough? Supervision of known criminals in the community will always present the risk of some offenders committing future crimes, but is there a threshold of new criminality below which officials would deem community supervision safe enough? If the widespread use of community supervision were to lead to an increase in overall crime, these types of interventions would be unacceptable. Minimizing new crime by these offenders would be optimal; however, if a level can be reached that maintains current crime rates, then the risk presented by community supervision would be no greater than that posed by incarceration.

The development of risk assessments and their appropriate use by probation and parole officers allow the risk of recidivism among correctional populations and specific types of offenders to be validly predicted (Holsinger et al. 2006). If an offender presents a higher risk of recidivism, justice officials may consider a higher level of supervision in the community or a period of incarceration. Risk can be eliminated entirely if the system had the means to incarcerate every criminal sentenced. However, even if the system had the means for blanket incarceration, an overwhelming majority of inmates would receive a simple discharge into the community.

Assessments of recidivism suggest that community supervision of offenders does not place the community at large under a greater threat of crime. Evaluations of parolee recidivism suggest that more offenders could be placed on parole with little to no change in the rate of parole failures (Wilson 2005). This assessment also noted that most of the failures could be attributed to technical violations, not new crimes by the offenders.

Cost-Effectiveness

Estimates suggest the cost of each new prison bed to be approximately $80,000, with an annual maintenance fee of $20,000 or more for each inmate's house. Even though the costs of incarceration are high, prisons continue to be built and the increased use of incarceration puts bed space at a premium. Yet, in reality the system does not have the means to incarcerate all offenders. Community supervision was born in part from a desire to reduce overcrowding and costs associated with corrections. Clear and Byrne (1992: 321) flatly say, "The frank bottom line for the intermediate sanction movement must be whether it is able to reduce overcrowding in corrections."

Though always dated, most cost evaluations suggest that community supervision of an offender will cost far less than incarceration. An early study measuring direct and indirect costs of different sanctions suggested a state could save nearly six million dollars in 1 year if 3,000 inmates were diverted from prison and placed on probation instead (as cited in Latessa and Allen 1997). More recent evaluations have attempted to examine this cost-benefit analysis with greater rigor, specifically, by accounting for recidivism rates of probationers versus parolees. These studies also support the conclusion that community supervision is more cost-effective than incarceration.

Matching Offenders with Effective Interventions

Properly identifying clients' needs and matching them to appropriate interventions may be key to determining greater effectiveness of community corrections. Since there is a wide variety of offender needs and crimes committed, the system must sustain a wide range of interventions. Matching offenders to the appropriate punishment begins with identifying a proper penalty for the seriousness of the crime committed. Thus, the first basic decision point is whether the offense merits prison or consideration for community supervision. Of course, under probation supervision, there exists a myriad of levels and types of supervision. Next, justice officials must identify the essential needs of the client and match him or her with the correct intervention. It would be pointless, for example, to require a forger with no history of substance abuse to attend Alcoholics Anonymous meetings.

Correctional rehabilitation has been continuously attacked for being "soft" and easy on crime. However, there is substantial evidence that when we correctly identify the needs of offenders and match them to a program with a strong treatment modality, the client will be less likely to recidivate. Gendreau found that 64 % of offender rehabilitation studies showed that appropriate correctional intervention can reduce recidivism, and if these programs are using the principles of effective intervention, their effectiveness can be strengthened (as cited in Latessa and Allen 1997). Assessment tools have been created that help correctional staff identify risk and needs. These assessment tools have changed the manner in which probation and parole officers conduct their jobs.

Other Issues in Community Supervision

This section examines broad current issues relevant to community supervision. As the science behind effective criminal control advances and government budgets become more strained, the issues of financing, management, and technology have become more relevant.

Financing

Several states have implemented incentive programs for counties that support the use of community supervision and community-based intervention programs. This type of legislation encourages counties to decrease the number of commitments to state prisons, while also helping to subsidize community corrections programs. In 1965, California was the first state to pass such legislation when it codified the Probation Subsidy Act. This law used a formula that estimated the number of offenders expected to be sentenced to prison by each county and then paid $4,000 to the county for each additional offender below that estimate who was not sentenced to state prison. Other states followed suit by passing subsides tied to the development and expansion of community intervention programs.

Some states and counties have also imposed supervision fees to help subsidize the cost of community supervision. Supervision fees can be found in the form of a one-time flat fee for supervision or a monthly fee paid by the offender for the privilege of maintaining community supervision. Criminal sentences increasingly include restitution as a sanction that orders the offender to pay money. Restitution can compensate the victim for any money lost during the criminal act or for subsequent medical bills. Some states also have general victim-compensation funds that each offender must pay into as part of their conditions.

Supervision fees and restitution can offset the costs of community supervision, but they also present new problems for the system. First, the collection of money puts probation officers in a situation where they become bill collectors, a role that these officers generally dislike. Secondly, while supervision fees are minimal (e.g., $10 per month), how should the system proceed if the client does not or cannot pay that fee? If the offender is employed, wages can be garnished through order of the court, but the time and money spent on securing this garnishment may offset the minimal fee collected. On the other hand, if the client is not employed or simply does not pay, this client could be violated for failure to pay these conditional fees. This will likely be counterproductive to managing finances since incarceration is more expensive than community supervision.

Management

Several models of organization of caseload work have been proposed and adopted, more recently focused on specialty supervision. The traditional casework model expects a single officer to provide needed services and supervision for a wide range of offender types. Sometimes referred to as "line officers," these supervision officers supervise the bulk of offenders in the community and have a wide, general range of responsibilities. New innovations in management have created specialty positions, such as team supervision and differential case management.

Team supervision is an approach that attempts to capture officers' strengths. This type of supervision would use an officer who might be particularly good at helping people find jobs as an employment officer. However, this type of group supervision can become confusing if the offender experiences a varied continuum of supervision. Another development in supervision involves tailored case management for specialty offender populations. For example, a few probation officers may be assigned specifically to supervise sex offenders.

The model case management system, developed by the National Institute of Corrections, has three components: (1) classification, (2) case planning, and (3) the assignment of workload units (Travis 2012). Classification is accomplished through risk and needs assessments that are completed by the probation officer and offender. Through these assessments, distinct categories of risk and program needs are created.

Technology

Innovations in technology have also influenced community supervision. As community supervision agencies adopt these innovations, they changed the role of the probation and parole officer. While some innovations have strengthened the ability of officers to execute their duties, some have added responsibilities that traditionally did not exist.

Mandated drug and alcohol testing are heavily used supervision conditions. Many scholars, policy makers, judges, and correctional staff believe that these types of testing will deter substance use and in turn reduce new crime. Testing can be in the form of blood tests sent to a lab to determine if an offender is using alcohol or drugs. More instant tests involve single or panel urine screens conducted on site by the probation or parole officer. If the offender is considered to be a habitual marijuana user, the supervising probation officer can use a single dipstick to test for THC present in the urine. If the supervising officer wishes to screen for a variety of drugs, a panel of tests contained on one stick can be conducted on urine. Drug tests have shaped the work of the modern day probation and parole officer. Officers now spend a good amount of time collecting and testing urine samples.

Electronic monitoring devices can be affixed to an offender's body to allow the supervising officer to monitor his or her whereabouts. Traditional electronic monitoring involves an ankle bracelet monitored by radio frequency through a transmitting device placed in the offender's home using a land phone line. The monitoring system will either randomly dial the offender's phone to ensure they were home or utilize a passive transmitter to notify the supervising officer when the offender is outside of the transmitting zone (e.g., a distance of 50 yards). If the client is not on house arrest, regular "windows of leave" may be entered into the system by supervising officers so that offenders could leave their home for work, school, treatment sessions, or basic necessities like grocery shopping or doctor visits. Newer advances in electronic monitoring involve the use of global position systems (GPS) to give supervising officers instant, geographically specific updates on the whereabouts of their clients.

Finally, in some jurisdictions, probation officers are required to collect DNA samples from clients. For example, Pennsylvania requires that certain offenders submit to a DNA test upon conviction. Originally collected through blood by a nurse, samples can now be collected through a cheek swipe conducted by probation officers. The DNA sample is processed by the probation officer and sent to the state repository, adding an additional responsibility to officers' role.

Discussion: Open Questions Concerning the Future of Probation and Parole

Having considered the historical ideologies, modern operation of probation and parole, and current issues facing these systems, this section addresses the future of community corrections. As discussed throughout this entry, the criminal justice system continues to increase the amount of offenders under correctional control – both in prison and in the community. Overcrowding in prison continues to be a concern for justice officials, but a less visible problem is bulging caseloads for community officers. This is highlighted by *Brown v. Plata* (2011), a recent United States Supreme Court ruling that orders California to release nearly a quarter of its prison population for reasons including inadequate physical and mental health care and prison overcrowding. The release of offenders into the community will have an immediate impact on the caseload sizes of community supervision officers in California. Yet this decision will also have longer-term effect on caseload size as judges may tailor future sentencing decisions to comply with overcrowding regulations set by the court. That is, judges may place even more offenders in the community that previously might have been incarcerated.

The larger issue for community corrections in the future is saturation: at what point will community corrections, like prisons today, become overburdened? Can similar logic used for defining overcrowding in prison be applied to community services? Prisons are designed to house a specific number of inmates, and should a prison reach and exceed its design capacity, it can be considered overcrowded. A review of the research on the relationship between caseload size and a positive probation outcome (e.g., lower recidivism rates) has not provided justice actors with any baseline number for an overburdened caseload. What research has suggested is that generally large caseloads are associated with an increase in property offenses and, in contrast, smaller caseloads are criticized for being too intense and have an unintended outcome of net-widening within the system. Other recent research has indicated that a reduced caseload size in addition to sound evidence-based treatment has the potential to reduce offender recidivism (Jalbert et al. 2010). Nevertheless, the balance between the two extremes is vague. More community-based offenders under correctional control will also place a larger burden on community-based mental health and drug treatment services. It may be unreasonable to assume that the inadequacy of social services in prison will be improved in the community when larger numbers of individuals are placed into the community under correctional control.

In response to overburdened caseloads and understaffed departments, some agencies have turned to new technology to help supervision. For example, in some states certain low-risk offenders are "supervised" by a kiosk. That is, the individual under supervision checks in periodically with a computer kiosk to pay fines or restitution and update any information with the court. The use of the computer kiosk (and its less engaging predecessor – the filing cabinet) raises ethical questions concerning the purpose of community-based punishment. As noted previously, probation and parole are less restrictive forms of supervision than incarceration. But these forms of supervision involve human interaction, checks on behavior and adherence to supervision conditions. If judges have identified a portion of offenders that do not need to be supervised because of their low-risk categorization or minor offense, why are these individuals on supervision? Furthermore, these offenders are not receiving any treatment or rehabilitation services from the court as part of their community supervision status. Therefore, the use of non-reporting supervision or kiosks does not appear to serve any clear purpose associated with community supervision.

The future of probation and parole will be dictated by the amount of resources given to these community agencies. If policy makers, court officials, and researchers continue to advocate for increased use in community corrections, more money must be funneled towards these official agencies and community agencies that lend social support. However, if probation and parole services reach a saturation point that result in the increased use of non-reporting supervision or inadequate services, these sentences become supervision and punishment in name only. Ultimately, for probation and parole to continue to increase their efficiency in case management and to optimize the effect on recidivism, these correctional systems should continue to utilize and expand evidence-based practices such as supervision and treatment strategies that adhere to the principles of effective intervention.

History of Randomized Controlled Experiments in Criminal Justice

Cynthia Lum[1] and Lorraine Mazerolle[2]
[1]Department of Criminology, Law and Society, George Mason University, Fairfax, VA, USA
[2]Institute for Social Science Research, The University of Queensland, St. Lucia, QLD, Australia

Overview

This entry examines the history of randomized controlled experiments in criminology and criminal justice. First, fundamental characteristics of randomized controlled experiments are briefly described, emphasizing the connection between this research method and evidence-based crime policy. Then, historical trends of experiments in criminal justice are reviewed, highlighting David Farrington's work in this area. The authors continue by connecting the history of experiments as well as their characteristics and the debates surrounding their use in the context of the evidence-based crime policy movement. Specifically, the authors suggest that the history of experiments in criminal justice and their relative rarity compared to other evaluation research cannot be divorced from the broader discussions and realities about the "what works" movement in criminal justice. Finally, this entry provides thoughts about the future of experiments in criminal justice and the research infrastructure being built to support them.

Fundamentals of Randomized Controlled Experiments

A randomized controlled experiment is a research method used to examine the effect that a treatment, program, intervention, or condition has on a particular outcome. In criminology, experimental methods are used to examine whether a crime policy or law, an offender treatment, a crime prevention program, or a new organizational process can reduce or prevent crime, lower recidivism, or temper fear of crime. Experiments can also be used to examine the impact that interventions have on legal processes and justice externalities, including differential treatment, legitimacy, employee job satisfaction, or corruption of justice agents. Although the terms *randomized controlled experiment* and *randomized controlled trial* are often used interchangeably, a trial implies the implementation of the experimental design.

Experiments are differentiated from other evaluation methods, such as "quasi-experiments" and before-after designs, because the treatment or condition is randomly allocated to some subjects (persons, places, situations, etc.) and not others. By randomly allocating an intervention to control and treatment groups, a researcher can ensure that no systematic bias contributes to group differences before or after an intervention is applied (Campbell and Stanley 1963). Specifically, random allocation allows for the assumption of equivalence between treatment and comparison groups, which allows the researcher to rule out confounding factors that might explain differences between groups after treatment (Weisburd 2003). By randomly allocating treatment, an appropriate counterfactual is developed in the control group, which shows what would happen if a program or treatment was not administered (Cook 2003).

Randomized controlled experiments have been called – not without debate – the "gold standard" of evaluation research, as it is seen as one of the best ways that evaluators can maximize a study's internal validity, thereby generating findings that are believable (Boruch et al. 2000a; Farrington 2003a; Weisburd 2000). Internal validity refers to an evaluator's ability to determine whether the intervention – as opposed to other effects – caused a change in the outcome measured (Shadish et al. 2002). This determination is also facilitated by good design and fidelity of implementation of the experiment. However, the label of "gold standard" relies on its strength in establishing internal, rather than external validity, a weakness of randomized controlled designs. Other criticisms are presented in more detail below.

Historical Trends in Experimental Criminology

Farrington (1983) and Farrington and Welsh (2006) have examined the history of the use of randomized controlled experiments (RCEs) in criminal justice and criminology in detail, and we summarize their efforts here. As they describe, the use of RCEs in criminology has focused on crime prevention and delinquency treatment programs, whose beginnings are marked by the Powers and Witmer (1951) Cambridge-Somerville Youth Study. This program was initiated by Richard Cabot in 1939 and involved over 500 delinquent boys, half of whom were randomly assigned to a treatment group and the other half to a control group. The Cambridge-Somerville Youth study is widely considered one of the earliest and most influential experiments in criminal justice research (Weisburd and Petrosino 2004). This experiment and McCord's (1978) follow-up research found that the treatment may have backfired, causing the boys who received the treatment to commit more crimes and have a lower quality of life.

After the Cambridge-Somerville Youth study, early experimentation in criminal justice did not necessarily show optimistic results, and many foundational experiments and reviews created a pessimistic environment for criminal justice interventions. Using a threshold of 100 or more subjects, Farrington (1983) identified 37 experiments in criminal justice in the first 25 years of this history (1957–1982), many of which did not show positive effects. The four policing experiments he reviewed focused on juvenile diversion schemes, two of which reported positive results of youth diversion programs and two reporting backfire effects of the programs. Six crime prevention experimental evaluations were also not optimistic (which included the Cambridge-Somerville Youth Study and its follow-ups). It appears the only experiment with significant positive findings in this crime prevention group was the one conducted by Maynard (1980), which examined the effects of a multi-site community-based intervention operated by the Manpower Demonstration Research Corporation. In that study, highly structured work experiences and job placement led to significantly lower arrest rates in the treatment than control group, but only in the short term.

Farrington (1983) also found 12 correctional experiments satisfying his criteria, focusing primarily on counseling offenders. Only three resulted in significant reductions in offending. Three court-related experiments were also discovered, with only one showing reductions of truancy by bringing children to court and using adjournments (delaying supervision by social workers) versus immediately assigning them to supervision. The authors concluded that the effect may have been caused by the type of worker handling adjournment versus supervision, the former more likely to be concerned with reduction of truancy than the latter. And finally, Farrington (1983) reports the results of 12 community-oriented interventions evaluated with experimental methods. Only one, he discovered, could be said to show significant reductions in offending.

An updated review conducted by Farrington and Welsh in 2006 proved more positive. They found 85 additional experiments between 1982 and 2004, many showing positive effects of the interventions studied. With regard to policing, the updated review reported 12 experiments, largely focusing on the area of domestic violence and repeat offenders, but some experimenting on police interventions at places. Of these 12 studies, six reported significant effects in the intervention reducing recidivism and crime. The place-based experiments were an innovation in the history of experimentation, which previously was focused on individuals. The Minneapolis Hot Spots Experiment (Sherman and Weisburd 1995) was significant in this regard, which was then followed by numerous place-based experiments in criminology. Overall, the policing research in Farrington and Welsh's new review had a more optimistic outlook, showing that police can indeed prevent crime among people and places.

Prevention experiments also grew from six in Farrington's first review to 14 in the updated review. Of the 14, six showed that interventions had significant positive effects, and some of the interventions have been highly influential in the discipline. In particular, the work of Olds and his colleagues (1998) on home visitation nurses showed that non-visited mothers tended to abuse and neglect their children more. His work, which subsequently contributed to his receipt of the Stockholm Prize, led to a movement for improvement in postnatal care using home visitation. Other developmental experiments involving sending kids to preschool, early child and parent skills training, multi-systemic therapy (as opposed to supervision and probation), and employment services showed positive effects. Unlike the vague counseling strategies covered in Farrington's earlier review, these promising interventions were more specific, targeted, and focused on developmental stages.

Farrington and Welsh also included 14 correctional experiments with interesting findings that challenged widely held beliefs. In particular, popular interventions like scared straight and juvenile boot camps showed backfire or nonsignificant effects on juvenile delinquency, while therapeutic communities, drug treatment, and cognitive behavior therapy proved promising (see also MacKenzie's review in 2002). Farrington and Welsh also located 22 court-based experiments, such as court-mandated treatment, restitution, intensive supervised probation, restorative conferences, and pretrial methods. Like corrections studies, many of these studies and their replications helped show that a number of traditional criminal justice programs were not as effective as initially believed (again, we point the reader to Farrington and Welsh 2006, for detailed discussions of these experiments).

Finally, Farrington and Welsh also found more community-based experiments (23 studies) than Farrington's initial review, which offered mixed results, especially in the area of intensive supervised probation. Petersilia and Turner (1993) found that, in some cases, community-based supervision led to increased offending, while in others, it led to decreased recidivism. This was highly connected to the reporting of probation violations and revocations, not necessarily to the frequency of crime commission, which is a much harder aspect to measure. MacKenzie's (2002) assessment of the corrections experiments was more nuanced, given these mixed findings. It appears that more tailored and structured community supervision programs that involve the right therapy, treatment, and employment opportunities can have an effect on recidivism, even if intensive supervised probation alone may not be able to do this. On the other hand, experiments in the corrections and community area have also shown that shock probation, scared straight, unstructured and vague rehabilitation programs, correctional boot camps, urine testing, community residential programs, and juvenile wilderness programs are not effective (MacKenzie 2002).

Randomized Experiments and the Evidence-Based Crime Policy Movement

The reviews by Farrington, Welsh, and MacKenzie show a general growth in experimental research since the 1950s and more optimistic findings about specific crime and justice relevant interventions. However, the history of experimental criminology is still a "meager feast" (Farrington 2003b) centered on American criminology (Farrington and Welsh 2006). Despite its gold standard label, the use of experiments has been relatively rare compared to other methods used in evaluating interventions (Weisburd 2003). Indeed, Farrington and Welsh (2006) still only discovered 122 experiments between 1957 and 2004, compared to the many more hundreds of evaluations conducted using other methods.

Others have also confirmed this finding of a dearth of experiments (see Boruch et al. 2000a; Palmer and Petrosino 2003; Petrosino et al. 2003; Sherman et al. 1997, 2002). Lum and Yang (2005), in a review of Sherman and colleagues' (2002) updated review of 657 evaluations of criminal justice programs, found that experiments accounted for 16 % ($n = 102$) of the evaluations reviewed. In contrast, the vast majority of studies in Sherman's updated review used before-after designs or compared non-comparable groups with and without treatment. Baird's (2011) review of the population of all 1,025 articles published in our field's leading journal, *Criminology*, from 1980 through August 2011, reveals only 14 articles (1.4 %) that used an experimental design. Moreover, Baird's (2011) review of the 14 experimental studies published in *Criminology* finds that even for those published in our leading journal,

> ...the descriptive validity of statistical power in many of the studies was low. Six of the studies did not report they were experimental in their title. Five studies did not report enough information to conduct power analysis. Errors such as failing to report directional hypotheses, sample sizes of groups, and alpha levels are critical omissions. For those studies that did provide enough information to calculate power, the power levels were generally high for large and moderate effects and were generally low for small effects. (2011, p. 15)

There have been numerous reasons given for the scarcity of experimental research in criminology and social science, and practical and ethical concerns are cited most often (see Boruch et al. 2000b; Clarke and Cornish 1972; Cook 2003; Farrington 1983; Lum and Yang 2005; Petersilia 1989; Shepherd 2003; Weisburd 2000). Some also believe that using experiments is challenging when studying the complexities of social relationships and issues (Burtless 1995; Clarke and Cornish 1972; Heckman and Smith 1995; Pawson and Tilley 1997), or that it is difficult for experiments to maintain high fidelity when implemented (Berk 2005). Lum and Yang (2005) also found, when surveying researchers about their choices to use or not use experimentation, that the lack of funding was often more a concern than ethical or even practical reasons. Indeed, Palmer and Petrosino (2003), when examining the history of the California Youth Authority (CYA), found that when funding switched from the experimentation-friendly National Institute of Mental Health to the Law Enforcement Assistance Administration, which rarely funded such studies, the focus of the CYA also moved away from experiments.

The practical, ethical, and funding challenges of randomized controlled experiments do not exist in a vacuum; they are also influenced by the context of the role and history of experimental evaluation in crime prevention more generally. In particular, the low proportion of experimentation may be a result (or symptom) of the messy quest for understanding and implementing "what works" in criminal justice, or the "evidence-based crime policy" movement. In general, this movement suggests that criminal justice practice should be guided by the best available research and analysis about interventions (Sherman 1998; Sherman et al. 2002), rather than by anecdote, feelings, habit, or opinions about best practices (Lum 2009). However, the goal to translate and use research in practice requires a keen sensitivity to practicality, ethicality, and costs. These core values of evidence-based crime policy can be, as previously mentioned, challenges to experimental criminology. Thus, while the demand for knowledge about effective interventions in the evidence-based crime policy movement certainly encourages more use of high quality evaluation designs, other core values can also work against that effort.

Two discussions may better illustrate the ironically difficult relationship between experiments and the evidence-based crime policy movement. The first involves the story of the Martinson Report (See Lipton et al. 1975; Martinson 1974) and the subsequent University of Maryland Report to Congress (Sherman et al. 1997, 2002). In 1975, Lipton, Martinson, and Wilks published a review of 231 evaluations of rehabilitative programs, to which Martinson publicly asserted that such programs had "no appreciable effect on recidivism" (Martinson 1974, p. 25). As described by Pratt et al. (2011), the report, which became known as the "Martinson Report," may have been one reason (in the context of rising crime rates and changing social cultures) for the decline of the rehabilitative ideal. At the same time, however, this shift from rehabilitation to punishment and the pessimistic assertions by Martinson arguably sparked the modern-day, evidence-based crime policy movement. Not only did evaluators wish to find what *did* work for rehabilitation and corrections, but they also wanted to increase the believability of such studies by using stronger evaluation methods (i.e., experiments). As Doris MacKenzie (2008) stated in a keynote address, an evidence-based approach to crime prevention "rejects the nothing works philosophy and instead examines what works to change criminal and delinquent activities. It is a belief that science can be used to inform public policy decisions about which programs or interventions should be used to change offenders."

Sherman and colleagues' (1997) University of Maryland Report to Congress, and the update to this report (Sherman et al. 2002) could arguably be viewed as an attempt to challenge the consequences of the Martinson Report. Not only did they take into account the many new evaluation studies generated between 1974 and 2002, but they also weighed and ranked the methods used in those evaluations to make judgments about how much we should believe specific study findings. Developing a Scientific Methods Scale (SMS), they rated studies in criminal justice according to the following scheme:

1. Correlation between a crime prevention program and a measure of crime or crime risk factors
2. Temporal sequence between the program and the crime or risk outcome clearly observed, or a comparison group present without demonstrated comparability to the treatment group
3. A comparison between two or more units of analysis, one with and one without the program
4. Comparison between multiple units with and without the program, controlling for other factors, or a nonequivalent comparison group has only minor differences evident
5. Random assignment and analysis of comparable units to program and comparison groups (Sherman et al. 1997)

Sherman and colleagues' methodological ratings were purposeful. The ratings implied that not all research could be considered equal. Conclusions of methodologically stronger studies were arguably more reliable than weaker ones in their assertions about "what works, what doesn't and what's promising" (the title of the report) in crime prevention interventions. The SMS scoring system solidified the importance of randomized controlled experiments in this endeavor, which were rated with the highest score of "5." Rating the believability (and usability) of evaluations in a document intended to influence criminal justice practices arguably helped to link experimental criminology with evidence-based crime policy more generally.

Given that the Maryland Report and the SMS ratings became part of the more general evidence-based crime policy movement, what has been its connection to the history of experiments in criminal justice? Analysis using the SMS ratings of studies may prove helpful in better understanding this complex relationship between experimental criminology and evidence-based crime policy. Weisburd et al. (2001) and Lum and Yang (2005) have studied the evaluations chosen by Sherman et al. (1997) and Sherman et al. (2002). Using their data, we present Tables 1 and 2. Table 1 shows that despite the increase of evaluations between 1997 and 2002, the proportion of evaluations using experiments remains consistently low. Of the 308 and 657 studies in Sherman et al. (1997) and Sherman et al. (2002), respectively, only 15–16 % of the studies employed a randomized controlled trial to evaluate the effects of interventions. Interestingly, there was an increase in the number of quasi-experimental studies in criminal justice between the 1997 report and the 2002 update (from 9 % to 25 %), and a decline in the proportion of lower quality studies (SMS = 1, 2 or 3). While this shows a general improvement in the state of criminal justice evaluation research, the proportion of experiments have remained the same.

History of Randomized Controlled Experiments in Criminal Justice, Table 1 Distribution of SMS scores across the Maryland Report (and update) studies

	Number of studies (with %)	
SMS score	Sherman et al. 1997	Sherman et al. 2002
1.00	10 (3.2 %)	15 (2.3 %)
2.00	94 (30.5 %)	151 (23.0 %)
3.00	130 (42.2 %)	224 (34.1 %)
4.00	28 (9.1 %)	165(25.1 %)
5.00	46 (14.9 %)	102 (15.5 %)
Total	308 (100 %)	657 (100 %)

Adapted from data from Weisburd et al. (2001) and Lum and Yang (2005)

Further, as Table 2 shows, the use of RCEs varies across different sectors of criminal justice research. Using the studies in Sherman et al.'s (2002) review, we find experimentation is more common in interventions related to family or employment arenas than in policing and corrections, two of the largest justice institutions.

Thus, while evaluation research has increased generally in criminal justice, and while the evidence-based crime policy movement arguably gained momentum between 1997 and 2002, the proportion of experiments generally, and within two large areas of criminal justice, remain consistently low. Further analysis of the initial Maryland Report by Weisburd et al. (2001) also revealed another relationship between experiments and evidence-based crime policy. They discovered an inverse relationship between study findings and research design. At least in

History of Randomized Controlled Experiments in Criminal Justice, Table 2 Scientific methods scores across different areas of criminal justice research in Sherman et al. (2002)

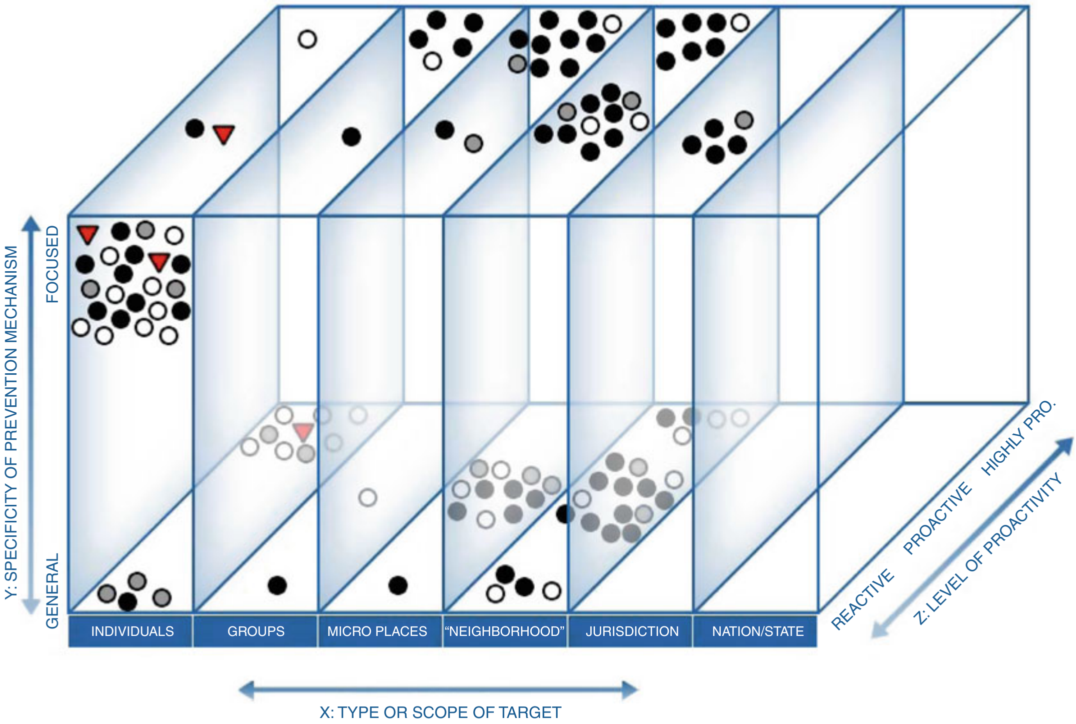
	Scientific methods score (1–5)					
	1.00	2.00	3.00	4.00	5.00	Total
Community	0 (0.0 %)	9 (31.0 %)	14 (48.3 %)	3 (10.3 %)	3 (10.3 %)	29 (100 %)
Corrections	0 (0.0 %)	56 (37.8 %)	53 (35.8 %)	19 (12.8 %)	20 (13.5 %)	148 (100 %)
Family	0 (0.0 %)	0 (0.0 %)	0 (0.0 %)	9 (26.5 %)	25 (73.5 %)	34 (100 %)
Labor	5 (9.6 %)	7 (13.5 %)	18 (34.6 %)	9 (17.3 %)	13 (25.0 %)	52 (100 %)
Place	4 (4.0 %)	37 (37.0 %)	51 (51.0 %)	5 (5.0 %)	3 (3.0 %)	100 (100 %)
Police	6 (5.4 %)	39 (34.8 %)	39 (34.8 %)	13 (11.6 %)	15 (13.4 %)	112 (100 %)
School	0 (0.0 %)	3 (1.6 %)	49 (26.9 %)	107 (58.8 %)	23 (12.6 %)	182 (100 %)
Total	15 (2.3 %)	151 (23.0 %)	224 (34.1 %)	165 (25.1 %)	102 (15.5 %)	657 (100 %)

Adapted from data from Weisburd et al. (2001) and Lum and Yang (2005)

the crime and justice evaluation arena, it appears that studies that employ more rigorous methodological designs (i.e., experiments) are more likely to find that interventions are not effective, or even may create "backfire" or harmful effects (McCord 2003). Their analysis emphasized the practical (and perhaps ethical) importance of using the best methods available when evaluating interventions to achieve the goals of evidence-based crime policy. Specifically, conclusions about "what works" based on less rigorous evaluations may lead to false optimism about the effectiveness of interventions in reducing crime and recidivism. This in turn might lead to bad decisions based on such research, clearly not a goal of the evidence-based crime policy movement. At the same time, this might also explain why experiments aren't used as often- findings are often less optimistic when researchers use this method.

The SMS ratings about research quality also raised important debates and questions about whether experiments should be rated so highly and have such a major influence on policy (see discussions by Hough 2010; Pawson and Tilley 1997). Although ranking experiments as the highest quality evaluation method available recognizes their scientific value, such rankings also make value judgments about the types of research that should be used to influence policy. The evidence-based crime policy movement not only emphasizes using good science (such as RCEs), but also the translation of that science into practice (Lum 2009; Lum et al. 2012; see also the "Evidence-Based Policing" entry in this encyclopedia). Some have argued these two goals may conflict with each other. In particular, Berk (2005) points out the difficulty in maintaining the fidelity of implementation in experimenting on justice interventions and the consequences for using results in practice (see also Petersilia 1989). Pawson and Tilley (1997) have discussed how experiments may not take into account the realities of interventions and their contexts and, therefore, may not always be the most optimal way of evaluating programs. Further questions have emerged in this debate: What should be the methodological threshold by which evaluation research could be used to inform policy? Are experiments the "best" way to guide policy and practice? The reviews of the research and the rating of studies have brought forth these questions and show that the pursuit of experiments within the evidence-based crime policy movement is complicated.

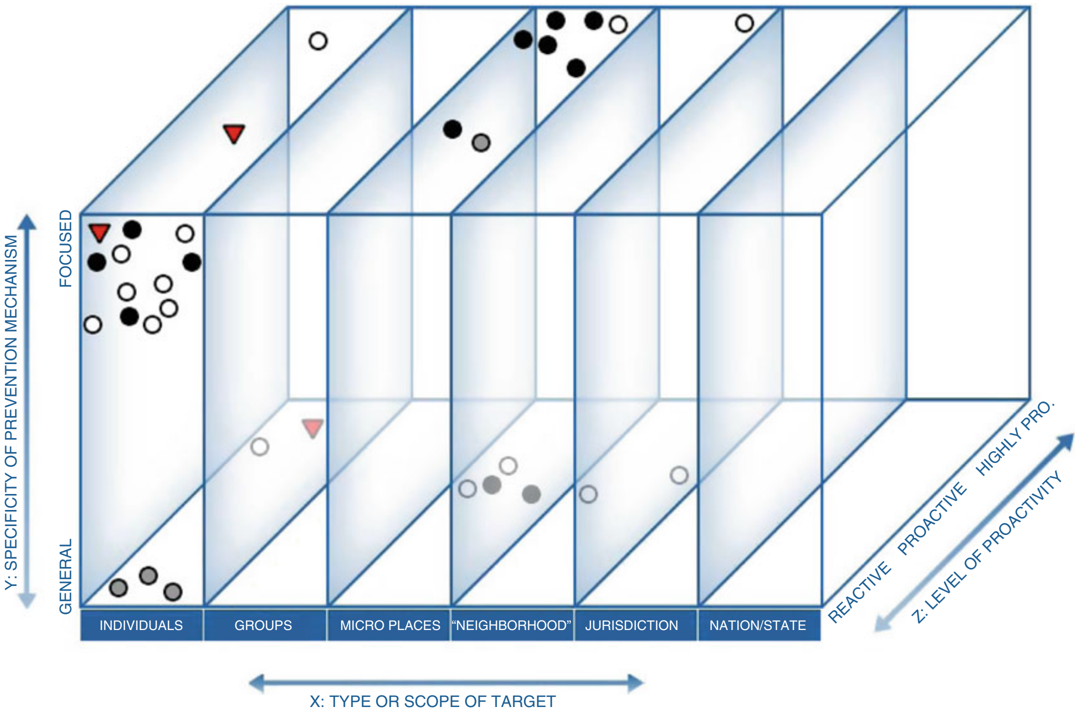
A second discussion that may further illustrate how the history of randomized controlled trials is entangled in the evidence-based crime policy movement involves policing evaluations within this broader movement. Starting with the early experiments in Kansas City (Kelling et al. 1974), Newark (Police Foundation 1981), and Minneapolis (Sherman and Berk 1984), evaluation research on police crime control interventions has accumulated over the last four decades. These evaluations – too numerous to list here – run the range of police crime control and prevention efforts, and use many different types of



History of Randomized Controlled Experiments in Criminal Justice, Fig. 1 The Evidence-Based Policing Matrix (Lum et al. 2009, 2011). ▼ Significant backfire (increased harm, recidivism, or crime), ○ Nonsignificant finding, ◍ Mixed finding (both significant and nonsignificant findings), ● Successful intervention (statistically significant finding)

research methods, from simple correlation studies to randomized controlled experiments. There have also been a variety of systematic reviews, many conducted for the Campbell Collaboration (see www.campbellcollaboration.org) in addition to the Maryland Report that have organized this research to glean generalizations on "what works." In 2004, the National Research Council also conducted a larger review of the gamut of police research (see National Research Council 2004).

Currently, the most comprehensive and consistently updated systematic review of evaluations of the range of police crime control interventions is the *Evidence-Based Policing Matrix* (Lum et al. 2011; see also www.policingmatrix.org). The Matrix (shown in Fig. 1) is a web-based tool that houses all police crime control intervention research of moderate to high quality. For studies to be included in the Matrix, evaluations must at least include a comparison unit of analysis that did not receive an intervention – similar to a Maryland Report SMS score of "3" or higher. The Matrix classifies all police intervention researches on three very common dimensions of crime prevention strategies: the nature and type of target, the degree to which the strategy is reactive or proactive, and the strategy's level of focus (i.e., the specificity of the prevention mechanism it used). The Matrix also color-codes studies by the outcome and significance of their findings. By "mapping" studies using these three dimensions, generalizations regarding the effectiveness of interventions with these characteristics can be visualized more easily. The visualization allows for multiple aspects of an evaluation to be seen simultaneously including the type of intervention



History of Randomized Controlled Experiments in Criminal Justice, Fig. 2 The Evidence-Based Policing Matrix – experiments only. ▼ Significant backfire (increased harm, recidivism, or crime), ○ Nonsignificant finding, ◍ Mixed finding (both significant and nonsignificant findings), ● Successful intervention (statistically significant finding)

studied, the finding of the intervention, and the methodological rigor of the study. The visualization also allows for practitioners to see groupings of research findings quickly, thereby allowing for generalizations from the totality of the research.

The explanation of the Matrix is covered in detail elsewhere (see Lum et al. 2011; also, see Lum and Koper's entry in this encyclopedia under "Evidence-Based Policing"). However, it is used here to illustrate the relationship between experiments and evidence-based crime policy. Because the Matrix provides for generalizations from the large body of police evaluation research through its visualization, it is primarily intended as a research translation tool for practitioners (Lum 2009). This speaks to a core value of evidence-based crime policy – that research should be meaningful and useful to decision makers, not just other researchers. Given this, the Matrix creators decided to include in the visualization studies that were not randomized controlled trials (studies that at least had a comparison group present were also included). Had only experiments been included, the Matrix would appear as it does in Fig. 2.

While Fig. 2 can show a few important ideas for police deployment, and while it also can show where we need more high quality research, some usefulness is also lost from its original form in Fig. 1. As in Fig. 1, we can see that highly proactive, micro-place, focused approaches seem to work well in reducing crime, and that reactive strategies geared toward individuals, even when focused, are not promising (and may cause more harm). However, the sparsely populated Matrix in Fig. 2 may be less practical to police departments trying to move toward an evidence-based approach to developing deployment options because of the scarcity of information caused by the filtering of studies of weaker designs. At the same time, including non-RCTs in the Matrix may lead to false optimism about, for example, the impact of neighborhood-based approaches on crime, of which there are many in Fig. 1. While studies evaluating neighborhood approaches are promising, we know from Weisburd et al. (2001) that there is an inverse relationship between methodological ratings and positive study findings. The authors' choice in including non-RCTs in this translation tool emphasizes their own compromise between pursuing evidence-based crime policy and upholding the importance of experiments in evaluating police interventions. Granted, this does not mean that evaluators should not strive toward using high quality research designs like experiments to evaluate interventions. But the comparison of Figs. 1 and 2 does show if we just focus on experiments, researchers may not have much to offer the policing community with regard to making deployment more evidence based (which could be discouraging for those advocating for evidence-based policing).

Both examples of the Maryland reviews and the Matrix indicate that the dearth of experimentation in criminal justice may not only result from difficulties in doing experiments. Experiments are part of the larger context of the evidence-based crime policy movement, whose proponents are still debating (and reconciling) the role of experiments in criminal justice policy.

The Infrastructure for Experimental Criminology

Amid this healthy debate about the role of experiments in evidence-based crime policy, there have also been efforts to create infrastructure to support experimental criminology that have become part of, and catalysts for, the history of the RCE. For example, the Campbell Collaboration (see http://www.campbellcollaboration.org) was formed – in part by efforts of those involved in the Maryland Report and by philanthropist Jerry Lee – to advocate for more rigorous evaluations of social interventions. Modeled after the Cochrane Collaboration for medical and public health interventions, the Campbell Collaboration sponsors systematic reviews and meta-analyses on specific areas (one major area being crime) to draw conclusions from the totality of evaluation research on a specific topic. The purpose of these reviews is to succinctly inform decisions makers about what the totality of the research says regarding a specific intervention. For example, if five studies examine the impact of pre-textual car stops to reduce gun violence and each has different findings, what can we conclude from all five studies? Like the Maryland Report, implied in this question is the need to rank studies on methodological rigor so that the most believable studies are relied upon more to draw such conclusions (Petrosino et al. 2003). The Campbell Collaboration, like the Maryland Report, again emphasizes the importance of ranking evaluations based on methods, thus emphasizing the importance of experimentation and its connectivity to evidence-based practice and policy. However, the Collaboration also is significant to the history of RCEs because it created organizational infrastructure and social networks around this idea, in not just criminal justice, but social interventions more generally.

Individuals involved in the Campbell Collaboration, especially Joan McCord, David Farrington, Lawrence Sherman, Jerry Lee, David Weisburd, Lorraine Green Mazerolle, Anthony Braga, Joan Petersilia, Frederick Lösel, Doris MacKenzie, Denise Gottfredson, David Olds, Jonathan Shepherd, Anthony Petrosino, Robert Boruch, Mark Lipsey, David Wilson, and others, also helped to build the infrastructure to support experimentation by forming the Academy of Experimental Criminology (AEC) in 1999. The AEC was established to recognize and encourage the efforts of scholars who had conducted experiments in the field through its Academy Fellows distinction. At the time of writing, there were 60 AEC fellows and 13 honorary fellows, all prominent members of the criminology community. In 2009, members of the AEC petitioned the American Society of Criminology membership to form the Division of Experimental Criminology (DEC). The DEC is now one of eight divisions within the American Society of Criminology and, in 2012, combined its efforts with the AEC through a joint web site and mutual activities (for more information on the DEC, see www.cebcp.org/dec). The further prominence and importance of experiments was reflected in the rising prestige of *The Journal of Experimental Criminology (JEC)*. Since its inception (2005) through the end of 2012, 86 of the 164 main articles have been experiments, while another 27 of the articles are meta-analyses or systematic reviews of research.

In addition to these organizations, a number of university centers related to evidence-based crime policy and experimental criminology, as well as more graduate training and presentations at conferences, helped build the infrastructure to support experimentation. Both authors' home centers, the Center for Evidence-Based Crime Policy (see www.cebcp.org) and the Australian Research Council funded Center for Excellence in Policing and Security (see www.ceps.edu.au), are examples of these efforts. Jerry Lee, the philanthropist mentioned above, also established Centers at the University of Pennsylvania and the University of Cambridge to carry out more experimental evaluations. Mr. Lee also helps fund the Stockholm Prize in Criminology, in which a number of experimentalists, including David Weisburd, Jonathon Shepherd, David Olds, and Friedrich Lösel, have been recipients.

The infrastructure supporting experimentation has also been facilitated by the federal funding arena, through in requirements in solicitations for funding by the U.S. Department of Justice Office of Justice Programs and the National Institute of Justice (NIJ). Numerous NIJ directors have supported more experimentation for evaluating crime prevention interventions following the efforts by James "Chips" Stewart who served from 1982 to 1990 and led more recently by Assistant Attorney General Laurie Robinson. In current funding solicitations by NIJ, for example, the following wording appears:

> Within applications proposing evaluation research, funding priority will be given to experimental research designs that use random selection and assignment of participants to experimental and control conditions. When randomized designs are not feasible, priority will be given to quasi-experimental designs that include contemporary procedures such as Propensity Score Matching or Regression Discontinuity Design to address selection bias in evaluating outcomes and impacts.
>
> *Research and Evaluation in Justice Systems* (NIJ solicitation number SL000981)

The Office of Justice Programs, under the leadership of Laurie Robinson, has also developed *CrimeSolutions.gov*, which, like the Maryland Report, judges studies of interventions by their methodological rigor and internal validity. Again, such rankings consistently highlight the importance of experimentation in evidence-based crime policy despite continuing debates.

The Future of Experiments

The history (and future) of randomized controlled experiments in criminal justice and criminology does not occur in a vacuum and cannot simply rely on the scientific merits of experimentation. Not only must RCEs answer to methodological challenges about their ability to establish causation, but perhaps an equally large obstacle to the future of experimentation is whether it can survive criticisms of evidence-based crime policy (and vice versa).

On a more fundamental level, the interaction and history of experimentation and evidence-based crime policy reflects a broader debate and discussion about the role of science in modern democracies. The ideology that science is important in governance and public health seems more accepted in the realm of medicine than social interventions. We hope that medical treatments have been tested in rigorous ways so that we can be assured that treatments will help us. The debates over the merits of experimentation in criminal justice interventions continue because science does not enjoy such acceptance in this realm.

History of Restorative Justice

Karen Heetderks Strong

Overview

In the final decades of the twentieth century, an approach to criminal justice, called restorative justice, emerged in response to concerns about offender recidivism, corrections costs, and crime victims' rights, along with encouraging outcomes in the use of victim-offender dialogue and restitution. Rather than defining criminal justice in terms of prosecution and punishment only, restorative justice focused on identifying and repairing the harms caused by criminal acts, holding offenders accountable for making things right with those harmed, and empowering victims and communities to participate in the response. In addition, restorative justice considered the proper roles and responsibilities of both government and communities for a just society.

Roots of Restorative Justice

Much modern legal structure and popular thinking about criminal justice views crime as if the government and its law are the injured parties. Violation of a government-imposed law calls forth a series of government-initiated responses: investigation and prosecution, followed by imposition of a sentence proportionate to the offense. The sentence frequently involves a fine (payable to the government) and some period of supervision or incarceration to express the legal and social condemnation of the proscribed behavior. By serving their sentence, criminal offenders are said to "pay their debt to society" but this usually only abstractly relates to the harm experienced by the actual victims of a crime. The idea that offenders have wronged individuals and violated communities, and thus must make reparation to those directly harmed, is at the heart of restorative justice. Its roots can be found in the legal codes of the ancient Near East, Rome, Europe, and Britain.

Examples of this direct connection between the harm to victims and the sentence may be found in the Code of Hammurabi (c. 1700 B.C.E.) and the Code of Lipit-Ishtar (1875 B.C.E.), which prescribed payment of restitution to the victims of property offenses. Other codes, such as the Sumerian Code of Ur-Nammu (c. 2050 B.C.E.) and the Code of Eshnunna (c. 1700 B.C.E.), provided for restitution even in the case of violent offenses. The Roman Law of the 12 Tables (449 B.C.E.) required thieves to pay double restitution unless the property was found in their houses, in which case they paid triple damages; for resisting the search of their houses, they paid quadruple restitution. The Lex Salica (c. 496 C.E.), the earliest existing collection of Germanic tribal laws, included restitution for crimes ranging from theft to homicide. The Laws of Ethelbert (c. 600 C.E.), promulgated by the ruler of Kent, contained detailed restitution schedules that distinguished the values, for example, of each finger and its nail. Each of these diverse legal codes represent a mandate that offenders and their families should make amends to victims and their families—not simply to ensure that injured persons received restitution but also to restore community equilibrium and avoid repeating cycles of revenge. Although actual practice may not have lived up to this intent, the presence of restitution as a legal obligation is significant.

In addition to these examples, there is evidence that practices in precolonial African societies showed a willingness to forgo punishment of criminal offenders in order to address the consequences to their victims and the community. Many sanctions were compensatory rather than punitive, intended to restore victims to their previous position. Contemporary Japanese culture exhibits a similar emphasis on compensation to the victim and restoration of community peace. The traditions of indigenous peoples, for example, the Maoris in New Zealand and First Nations in Canada, allowed for working out an appropriate response to crime in the context of the affected community. Offenders were involved in the process of determining guilt and harm and taking necessary steps toward restoration of those harmed. Practices associated with restorative justice such as group conferencing or circle processes have their roots in these indigenous ways.

Validated in part by these historical and indigenous roots, several twentieth-century social movements or critiques fed into the emergence of restorative justice theory. In addition to what may be generally called the informal justice movement, there were explorations and proponents of restitution, victims' rights, prison abolition, and alternative theories of social justice.

Informal Justice Movement

In the 1970s, amid a growing crisis of confidence in the legitimacy of formal, government structures, legal anthropologists noted that laws and legal processes are specific to their social and historical context and that, in virtually all societies, justice is pursued using both formal *and* informal proceedings. A series of proposals emerged for informal alternatives to government-controlled responses to crime, emphasizing greater participation of the parties, de-professionalization of the processes, and lessening both stigmatization and coercion for participants. Two leading proponents of informal justice were Jerold S. Auerbach and Nils Christie. Christie has been frequently cited in restorative justice literature because of seminal themes in his work. In his article, "Conflict as Property," Christie (1977) made the case that the criminal justice system reflects the government's theft of the dispute that is properly owned by the victim and offender. In his subsequent book on punishment, *Limits to Pain* (1981), Christie drew a connection between this "theft" and the use of punishment. In criminal law, values are clarified by graduated punishment. Rather than being established through conversation among the participants—the rightful "owners" of the conflict—values are communicated by the state through the infliction of degrees of pain. He proposed participatory justice as a better response to crime, a response characterized by direct communication between the owners of the conflict leading to compensation that satisfies the claims established between them.

Restitution Initiatives

Rediscovery of the historical notion that paying back the victim could be an appropriate modern criminal justice sanction led to *restitution initiatives* beginning in the 1960s. Several rationales were offered for the use of restitution: (1) the victim is the party harmed by criminal behavior, (2) restitution offers an alternative to restrictive or intrusive sanctions such as imprisonment in some cases, (3) there may be rehabilitative value in requiring the offender to pay the victim, (4) restitution is relatively easy to implement, and (5) this might lead to a reduction in more costly retributive sanctions when the public observes the offender actively repairing the harm done. Evaluations conducted in the 1970s and 1980s raised questions about whether restitution programs had adequately lived up to those expectations, but restitution has been increasingly ordered (and less frequently collected) in many countries nonetheless.

One proponent of restitution was Stephen Schafer (1970). He described the era of compensatory justice prior to the development of centralized governments in Europe as the "golden age of the victim" because it was a time in which the victim's interests and freedom of action were given greatest deference. He proposed that compensation could once again become a means of sanctioning offenders, either in conjunction with or as an alternative to imprisonment.

Abel and Marsh (1984) argued that restitution offers an approach to punishment that is ethically, conceptually, and practically superior to the status quo. In their model, most offenders would live outside prison under varying degrees of supervision as necessary, working and paying restitution to their victims. Imprisonment should be used only as a last resort for truly dangerous offenders and even they should be given the opportunity and obligation to earn wages and compensate their victims as well as paying the state to offset the cost of their incarceration. This recognition of the obligation of offenders for redress to their victims flowed into the formation of restorative justice theory.

Victimology and the Crime Victims' Movement

Beginning as early as the mid-1950s, some scholars took an interest in the needs and rights of crime victims and the deficiencies of an offender-oriented justice system. The notion that victims, not just offenders, ought to be considered in the study and response to crime began to gather momentum. In 1963, the first crime victim's compensation law passed in New Zealand. In the following years, similar initiatives were established in England and parts of the United States, Canada Australia, and Europe. In 1972, the United States federal government began the *National Crime Survey* (renamed the *National Criminal Victimization Survey* in 1990), signaling a desire to discover the extent of victimization beyond what was officially reported to law enforcement agencies.

The *First International Symposium on Victimology* was held in 1973, primarily dealing with research on societies' attitudes toward crime victims. Two years later, an *International Study Institute on Victimology* went further and introduced discussion of the treatment of victims and their standing in the criminal justice system. In 1975, Frank Carrington published *The Victims*, asserting that victims' "current sorry status in the criminal justice system need not be so and that something can and must be done to enhance the rights of the victim." Attention began to be focused on ways crime victims' interests should be specifically accommodated in criminal justice and community processes. The *crime victims' movement*, thus, rallied around victims' experiences and applied victimology research; it organized advocacy coalesced in three broad areas: (1) appropriate services to victims in the aftermath of the crime, (2) financial compensation for the harm done, and (3) victims' rights to information and intervention during the course of the criminal justice process.

Basic rights and protections for victims of crime began to be included in statutes in the late 1970s, and in 1982, the State of California became the first in the USA to pass a constitutional amendment guaranteeing crime victims' certain enforceable rights. Other jurisdictions followed suit. Specific provisions vary, but generally victims are granted the right to be treated fairly and with dignity, to attend the trial or other proceedings, to be awarded restitution, to be informed of certain events such as the offender's release and, further, to be heard at critical stages in the case such as sentencing or parole hearings.

All of these efforts and outcomes have served to make it explicit that crimes violate persons, not just laws; that victims have a legitimate and necessary role beyond simply giving evidence; and that the harms to victims ought to be acknowledged and addressed in a society's response to crime. These tenets have been incorporated into the idea of restorative justice.

Prison Abolition Movement and Alternatives to Incarceration

Questions about the use and validity of prisons were also gaining attention and during the late 1960s and into the 1970s, an informal reform initiative emerged in Europe and North America calling for the *abolition of prisons*. It garnered support from a number of political and philosophical perspectives around the common theme that prisons not only fail to rehabilitate, they are in fact places of acute and morally indefensible suffering for prisoners. Although the Society of Friends (Quakers) helped invent the "penitentiary" in the late 1700s, they joined the prison abolition movement in urging that the use of prisons be significantly curtailed or abolished and replaced by other responses to crime. In part, this was due to prison abuses—abuses that seemed to be inherent in the institution of prison itself and consequently not amenable to reform.

Some proponents of prison abolition called for prisons to be done away with completely. Others sought to decrease the use of prisons dramatically. Still others campaigned for a moratorium on construction of new prisons. In place of prisons, they suggested that restitution, compensation, community service, and reconciliation programs be established in local communities so that the response to crime could be decentralized and, to some extent at least, humanized.

This notion was appealing to jurisdictions facing budget crises due to economic recession in the 1980s. Community corrections programs providing alternatives to expensive incarceration under the auspices of probation and parole agencies included such things as day reporting centers, halfway houses, work release, and community service. These initiatives were organized with multiple goals including offender accountability, rehabilitation, surveillance, and fiscal efficiency. Proponents built public support for these alternatives by emphasizing that they impose a higher level of accountability on offenders. Rather than sitting out their time in a cell, community corrections required them to take an active role such as doing community service or working in order to make restitution to their victims.

Alongside these developments, programs emerged involving mediated conversations between victims and offenders with the aim of a mutually agreed and enforceable reparative outcome. Initially, such programs focused on juveniles and diverted them from the formal criminal justice system, with judges' cooperation in accepting and helping enforce reasonable agreements from the mediation. Rather than keeping victims and offenders away from each other, their interests represented principally by attorneys, these programs included them in informal processes that emphasized safety, dialogue, and agreement on appropriate redress and next steps. Outcome research found that the parties generally valued the opportunity to speak and be heard and had a higher level of satisfaction that justice had been served in the process, compared with those who simply went through the standard criminal justice approach. These experiments fed directly into the theoretical and practical development of restorative justice.

Social Justice Critiques

A conviction that justice could not be achieved in an unjust society found its voice in publications and advocacy alongside the prison abolitionists' practical concerns about prison abuses. One influential expression of this concern was *Struggle for Justice*, the report from a working group assembled by the American Friends Service Committee (1971). The report articulated concerns about sentencing practices that were disproportionately adverse for poor defendants and people of color and also the coercive nature of so-called rehabilitative programs in corrections. Similar concerns about disproportionate penalties and disparate sentencing practices contributed to the rise of the "just deserts" model for corrections. Andrew von Hirsch, in *Doing Justice* (1976), proposed that it is just for society to punish someone for a criminal offense but unjust to tailor the punishment based on considerations of future offending (such as deterrence or rehabilitation). Rather, penalties must be proportionate to the severity of an offense and uniformly administered so that all similar offenses carry the same sentence. This important development, however, did not address the concerns expressed in *Struggle for Justice* about harsh penalties, degradation of offenders, and the brutality of prisons.

Gerald Austin McHugh's *Christian Faith and Criminal Justice* (1978) argued that although Western penal models grew out of a medieval religious view of sin and retributive punishment, this was not the only relevant motif inherent in Judeo-Christian theology. Its profound themes of mercy, relationship, restoration, forgiveness, reconciliation, and hope ought also to be applied in response to crime. McHugh suggested that application of these values to criminal justice policy would result in very different structures and processes from those now in place. Daniel W. Van Ness' *Crime and Its Victims* (1986) and Howard Zehr's *Changing Lenses* (1990) also made the case that biblical justice is highly concerned with the needs and rights of victims, as well as with the worth of offenders, and that this has implications for the foundations and policies of a just society.

From a feminist perspective, scholar Harris (1987) called for a fundamental restructuring of criminal justice to reflect the equal value of all human beings, the social precedence of harmony and well-being over power and possession, and the assertion that the personal is the political. The criminal justice status quo, she asserted, is driven by the values of control and punishment. She suggested that a preoccupation with legitimate rights blinds parties to the need for a caring and interdependent response and that justice has a broader scope than individual rights. Citing Gloria Steinem's principle that the means you use are reflected in the ends you achieve, Harris called for a recognition and response to the need and opportunity for participation by all parties in order to justly address the needs of all.

Criminologists Pepinski and Quinney (1991) also explored the idea that crime has a personal dimension in which society has a stake. They examined the factors that positively contribute to peace and safety and cited these as the proper focus of criminology, as opposed to a negative focus ("what causes deviance and criminal behavior?," and "how do we win the war on crime and violence?"). Others echoed this positive, peacemaking focus for criminology, asserting that the goals of peace and safety require more than restraint of wrongdoing and its punishment. They need to be achieved through transformation of persons and social institutions, affirming individual responsibility for wrongdoing and also society's contribution to it and implementing effective, fair, humane, and peace-building community responses.

All of these movements influenced and contributed to the development of restorative justice and their themes are evident in its theory and practice. Johnstone and Van Ness (2007) have identified three main concepts that typically are incorporated (in some way) in definitions of restorative justice. The first is *encounter*. The parties involved (e.g., victim, offender, community members) are engaged together in discussing the offense, its effects, and what should be done about it. Rather than being done for them by professionals in a court of law, the parties themselves engage in a dialogue that is safe and fair for all concerned. The second concept is *reparation*, meaning that the response to an offense should involve redress by the offender to those harmed.

Preferably, the redress would be decided with the involvement of all parties. But if that is not possible, reparation in some form could and should still be made in order for the outcome to be considered at all restorative. The third concept is *transformation*; it is more expansive than the others. It recognizes social and structural issues that either are themselves unjust or create impediments to fair, harmonious, and healthy relationships among people and their social and physical environments. So beyond the restoration of individual instances of harm, restorative justice aims for a more just society and world.

The Meaning of the Term "Restorative Justice"

The first use of the term "restorative justice" was by Albert Eglash in several 1958 scholarly articles in which he suggested that there are three types of criminal justice: (1) retributive justice, based on punishment; (2) distributive justice, based on therapeutic treatment of offenders; and (3) restorative justice, based on restitution. Both the punishment and treatment models, he noted, focus on the actions of offenders, deny victim participation in the justice process, and require merely passive participation by the offender. Restorative justice, on the other hand, focuses on the harmful effects of offenders' actions and actively involves victims and offenders in the process of reparation and rehabilitation. Eglash's ideas and terminology were rediscovered decades later.

From its more popular emergence in the early 1990s up to the present day, the term has come to have a variety of meanings and nuances. Some definitions focus more on outcomes, others on processes. Howard Zehr (1990) described restorative justice in this way: "Crime is a violation of people and relationships. It creates obligations to make things right. Justice involves the victim, the offender, and the community in a search for solutions which promote repair, reconciliation, and reassurance." Martin Wright (1991) wrote that restorative justice would respond to crime in such as way as "not to add to the harm caused by imposing further harm on the offender, but to do as much as possible to restore the situation. The community offers aid to the victim; the offender is held accountable and required to make reparation. Attention would be given not only to the outcome, but also to evolving a process that respected the feelings and humanity of both the victim and the offender." Tony Marshall (1999) described it as "a process whereby all the parties with a stake in a particular offense come together to resolve collectively how to deal with the aftermath of the offense and its implications for the future." Van Ness and Strong (2010) define it as "a theory of justice that emphasizes repairing the harm caused or revealed by criminal behavior. It is best accomplished through cooperative processes that include all stakeholders."

The term, restorative justice, today is used throughout the world to describe processes and programs that offer alternatives to simply punitive approaches to handling offending and sanctions. Over time, the term has even gone beyond its original scope as a response to crime and its ideas are finding applications in handling neighborhood disputes, school discipline, and even workplace problems. All of these are built on foundations laid by some key developers of the theory of restorative justice.

Developments in Restorative Justice

Howard Zehr is sometimes called the "grandfather" of restorative justice. Zehr's early experience with victim-offender reconciliation programs led to articles, speeches, books, and teaching that have drawn others into theoretical and practical conversations about justice. In his 1990 book, *Changing Lenses*, Zehr consolidated and advanced his critique of criminal justice as failing to meet the needs of victims or offenders. He suggested that the current criminal justice "lens" views crime as lawbreaking and justice as allocating blame and punishment. He contrasted that with restorative justice, which views crime as a violation of people and relationships, which in turn leads to obligations to "make things right." Justice, then, is a process in which all parties search for reparative, reconciling, and reassuring solutions.

Another pioneer is Martin Wright, who contributed to the development of restorative justice thinking and practice, particularly in Europe. In his 1991 book, *Justice for Victims and Offenders*, Wright drew from his experiences as an advocate for victims and for prison reform. He argued that criminal justice should be restorative both in its process and its effect by expanding compensation, restitution, and mediation opportunities to permit greater participation by both victims and offenders. Wright suggested two governmental departments to facilitate this: one for crime prevention, emphasizing deterrence through enforcement rather than through punishment; the other to ensure a just response to crimes when they do occur, including victim support, mediation, and reparation, as well as courts that emphasize restitution.

In 1992, Virginia Mackey wrote an evocative discussion paper on restorative justice to facilitate conversation in the faith community on the problems of current approaches to crime and on biblically reflective alternatives. She proposed a restorative model built on six practical principles: (1) safety should be the primary consideration for the community, (2) offenders should be held responsible and accountable for their behavior and the resulting harm, (3) victims and communities harmed by crime need restoration, (4) the underlying conflicts that led to the harm should be resolved if possible, (5) there must be a continuum of service or treatment options available, and (6) there must be a coordinated and cooperative system in place that incorporates both public and private resources.

Whereas some discussions presumed that formal criminal justice processes are inherently counter to the foundational values of a restorative approach, Cragg (1992), a philosopher and a longtime volunteer with a prisoner advocacy and prison reform organization, thought otherwise. He found insupportable an emphasis on punishment, whose aim is to cause suffering. However, Cragg underscored the importance of formal processes that should provide within their frameworks the opportunity for informal resolution and offender acceptance of responsibility. Formal justice, in his view, need not be punishment-driven, but may incorporate restorative virtues such as forgiveness, compassion, mercy, and understanding.

Another theoretical framework related to restorative justice is "reintegrative shaming," a term used by Braithwaite (1989)—an influential critic of the just deserts movement and contributor to restorative thinking about justice. The term refers to positive ways for offenders to acknowledge the wrongness of acts for which they should rightly be ashamed. The point of the process is not shame but rather reintegration—concrete steps to take the offender from shame to being a fully accepted individual within the community. But it was not until a family group conferencing program was being organized in Wagga Wagga, a city in New South Wales, Australia, that reintegrative shaming and restorative justice were intentionally linked. In 1993, David Moore reflected on this approach to crime and reintegration from the perspective of moral psychology, moral philosophy, and political theory. He concluded that reintegrative shaming offered a framework for theoretical analysis and evaluation of the restorative potential of conferencing programs. It is important to note that the notion of "shaming" has been quite controversial among restorative justice advocates. Some believe shaming is inherently dehumanizing and thus is an illegitimate means even if it leads to good outcomes. Others distinguish between stigmatizing and reintegrative shaming, wherein the former makes shame an end in itself that is attached to the offender's identity and the latter is part of a humane process leading to removing the shame and restoring the individual.

Restorative justice includes victims as primary stakeholders who should play a direct role in the justice process. Some assert that there is a historical basis for questioning the criminal-civil separation in Western legal systems and allowing victims to have full standing to advocate on their own behalf for redress as a part of criminal proceedings. A scholarly debate on this point was published in 1993 in the *Criminal Law Forum*. Daniel Van Ness made the case for the idea that victims could be fully and procedurally included in criminal justice processes aimed at addressing the harms experienced by all stakeholders. Andrew Ashworth supported victims' interests in certain outcomes but warned that it is important to distinguish between the needs of victims for assistance and any legal rights that they might have in criminal courts. He also cautioned about attempting to accomplish larger criminal justice goals through sentencing policy. Together with von Hirsch, Ashworth has defended the objectives of just deserts as preferable to those of restorative justice for both just processes and outcomes.

An attempt to root restorative criminal justice ideas within a broader conceptual framework was offered in Burnside and Baker (1994), *Relational Justice*. Noting erosion in the quality of relationships in Western cultures, these authors considered whether "relationalism" might provide an antidote to problems including criminal justice. Although not specifically referring to restorative justice theory, contributors presented victim-offender mediation and family group conferences as examples of relational justice and suggested ways the activities of police, probation, and prison authorities might be evaluated by their capacity to strengthen relationships.

From the beginning, restorative justice's main focus was how to respond to crime. A number of writers have noted in passing that restorative justice principles may have relevance to crime prevention also. One of the more comprehensive proposals on that aspect of criminal justice policy was offered by Marlene A. Young, Executive Director of the US-based National Organization for Victim Assistance, in her paper *Restorative Community Justice*: *A Call to Action* (1995). She proposed a series of program elements that might constitute a model of restorative justice as a community responsibility with potential to develop more effective problem solving and foster healthier, less crime-prone communities. The elements of this model included community policing, community prosecution, community courts, and community corrections. The first, community policing, involves police officers actively building strong community bonds within the neighborhoods in which they function. Although none of these elements were new ideas, Young envisioned their integration into an overall structure that would shift from reactive to proactive engagement and increase the level of meaningful victim and community participation in prevention, adjudication, and corrections.

Victim advocates have often been concerned that restorative justice is actually offender-focused, suspecting that its programs are primarily designed to provide better conditions for offenders, with victims a secondary concern. Some claim that victims are being used as agents to achieve offender-focused goals. While this may not be accurate in theory, studies of actual practices of restorative justice show that there is validity in these concerns in at least some instances. For example, those who work with victims in some restorative justice programs are volunteers or professionals who lack sufficient expertise and understanding of the victims' needs and perspectives. The very methods designed to give victims a voice, such as mediation or circles, are sometimes compromised by pressuring victims to participate or giving them more of a sideline role. Efforts to inform and contact victims for participation are sometimes short-changed in the interest of moving to a quicker and less complicated process.

So-called restorative programs occur in the midst of social contexts and are affected by such variable factors as public mood, government acceptance, and available funding. Evaluations of practices and outcomes help monitor the extent to which the idea of restorative justice meets the reality of its implementation. Advocates naturally highlight a wide variety of studies that underscore the good outcomes achieved through restorative justice processes. Critics point out that the same attention must be paid to studies that reveal problems since the good intentions of restorative justice practitioners and proponents may not necessarily result in processes and outcomes that are, in fact, restorative.

Summary

Restorative justice is now a global idea. Not only has it been influenced by people and developments in many parts of the world, it has also been adopted in diverse cultures, economies, political systems, and legal structures. In fact, one of the remarkable features of restorative justice is that elements of it emerged almost simultaneously in different regions of the world. In some cases, the program or theory was developed prior to contact with the ideas of restorative justice being discussed elsewhere.

One way to sum up the history of restorative justice is to consider several stages of its growth and reach:

Stage One: *Restorative justice as a community-based alternative to the criminal justice system*. Early on, particularly in common law countries, restorative processes were viewed as an alternative, community-based response to crime that diverted some offenders out of the government-run process in favor of a more personalized and participatory one. That was certainly true of the first victim-offender reconciliation programs in Canada, the United States, and England. In countries in continental Europe, where the legality principle limits the discretion of police and prosecutors to divert cases out of the justice system, some legislative changes were needed, but the purpose of the changes was to allow pilot projects for demonstration and research.

Stage Two: *Restorative justice as a resource for public policy*. In the latter half of the 1980s, countries and organizations began exploring the policy implications of what was being learned from restorative processes. For example, Justice Fellowship, a nonprofit in the United States, embarked on a multiyear project to translate restorative vision into principles of public policy; Canada's Parliamentary Standing Committee (known as the Daubney Committee for its chairman) affirmed that sentencing law changes in that country should take into consideration what was being learned in restorative processes. New Zealand incorporated elements of Maori practices in revising its juvenile justice laws.

Stage Three: *Restorative justice as a viable part of the criminal justice system*. The final decade of the twentieth century saw remarkable innovation and expansion in restorative justice. New models, and variations on those models, were developed as conferencing and circles took their place with victim-offender mediation. Governments took steps to encourage the use of restorative processes through grants, research, legislative change, and, in some instances (such as the Thames Valley Police and the Royal Canadian Mounted Police), through offering restorative processes themselves. Organizations dedicated to promoting and expanding restorative processes emerged, offering practitioners and researchers the opportunity to network with others and to learn from their experiences. This information sharing has expanded dramatically through the Internet and the growing number of excellent sites dedicated to restorative justice.

Stage Four: *Restorative justice as an international reform dynamic*. The twenty-first century has seen multinational bodies such as the United Nations, the Council of Europe, and the European Union strongly endorse the potential of restorative justice and urge their member states to introduce and then expand their use of restorative processes. Restorative concepts have contributed to the development of Truth and Reconciliation Commissions to help address the deep social and personal consequences of violence and systemic injustice. Where early work with restorative processes was done by grassroots organizations, now they have been joined by multinational organizations in calling on governments to use these new approaches to criminal justice.

The future of restorative justice as an idea is intriguing. Although it has become an accepted and fairly common term, its specific meaning is far from uniform. In some ways it has become a catchall applied to a wide range of practices and policies that have one or another element typically associated with restorative justice. In addition to applications in the criminal justice area, restorative approaches are being considered and applied to conflict and discipline in schools, workplaces, and mass social conflicts. All these realities present a challenge to the idea of restorative justice. Some scholars have called for clear distinctions in terminology between theoretical, values-based foundations for restorative justice and their expressions in practice. Others have suggested a set of evaluative criteria or standards for what constitutes a restorative approach. Van Ness and Strong (2010) offer a framework for assessing a system to determine whether it is minimally, moderately, or fully restorative or if it is restorative at all regardless of its claims. In any case, the idea of restorative justice continues to develop, along with a proliferation of programmatic expressions that shows no sign of waning.

History of Staff Skills in Probation

Ioan Durnescu
Faculty of Sociology and Social Work,
University of Bucharest, Bucharest, Romania

Overview

In the last few years, the idea that "nothing works" has been systematically confronted, and more and more knowledge is accumulating to demonstrate that a lot could be done to reduce reoffending and improve public safety. An extensive body of literature now emphasizes what is known in terms of evidence-based practice and interventions based on different theoretical perspectives (risk/needs/responsivity, desistance, good lives model). Increasingly, research uncovers other aspects that influence the effectiveness of interventions, like treatment readiness and motivation for change, organizational structures, neighborhood characteristics, and so on. From time to time, a focus on the skills and characteristics of probation and parole staff appears in the literature and then disappears again. At the origins of probation, staff skills seemed to be quite crucial. Later they became important but not essential, and then they almost disappeared in the years of "nothing works." As a new body of evidence on "What Works" and desistance is accumulating, staff attributes make their way back into the mainstream of effective practice. Indeed, empirical research conducted mainly after the 1990s seems to support the idea that not only program content or offender attributes but also the characteristics and style of the personnel in charge of the implementation of probation interventions matter for effective practice. With this optimistic view a new line of research has developed in recent years on "who works" in probation service. However, some aspects remain unexplored, including the factors that explain differences between professionals in terms of skills and characteristics and how particular skills are associated with different supervision results.

In this chapter the concept of staff skill is understood as a behavior that could be learnt and is aimed at supporting the probation officer in doing his/her job. In contrast, others consider staff characteristics to be inner traits of the probation officer that are relevant to his/her job (e.g., morality, reliability). Obviously between these two categories, there is not a clear-cut but a fluid line that can be crossed sometimes, depending on the circumstances. One typical example is empathy. Some authors consider empathy as inherited or a moral quality, while others emphasize the idea that empathy could be taught and therefore could be considered as a professional skill (Trotter 2006).

Men of God

A number of scholars (Jarvis 1972; Vanstone 2004) suggest that the origin of probation was in the work of the Church of England Temperance

Society (in England and Wales) and the Washingtonian Total Abstinence Society (Boston, United States). The activity of early probation officers was almost exclusively missionary and was based on "Christian charity and humanitarian concern" (Jarvis 1972, p. 1). The main duty of the probation officer was to "save the souls" of the "drunkards" (Jarvis 1972, p. 2, citing the letter of Frederick Rainer from 1876). To achieve this goal, missionaries were expected to visit prisons and police courts; speak at temperance meetings; deal with "individual drunkards" (Jarvis 1972, p. 4); and provide practical help in terms of accommodation, employment, and emigration. Being mostly sustained by their religious beliefs, the missionaries had to have faith in every single individual and treat them all as holders of the "divine spark." For instance, to become a missionary at the London Police Court Mission, one was expected to be a "man of God, a man with vocation, a man of character, a man with experience and tact and full of the milk of human kindness" (Jarvis 1972, p. 8).

Thus, the early probation officer was expected to be "a man of God" and possess the right vocation and personality animated by the desire to make good. Going back to the distinction between skills and characteristics, note that a "suitable" probation officer was defined in the literature by his moral characteristics and not by his skills. What was primarily important was what the probation officer should be like and not what exactly he or she should do in offender interactions. In most of the historical literature, the probation officer was presented in a descriptive manner with no reference to effectiveness. The ideal probation officer's characteristics were taken for granted and described as if they emanated logically from the missionary of humanistic philosophy.

The Caring Officer

After the first Probation Acts were passed in United States and England and Wales (in 1878 and 1907 respectively), the courts were asked to consider the offender's age, offence, and character before making a sentencing decision. Punishment had to fit not only the offence but also the personality of the offender. In the process of determining "true responsibility" (Saleilles 1911), probation officers were asked to contribute in separating those offenders who deserved to be saved from those considered incorrigible. This new approach of punishment claimed indirectly a certain level of specialism. Not everybody could provide the court with a reliable and robust assessment. In this context some officials and scholars started to think about probation as a profession.

Trought (1927), for example, stated that probation as a profession "involves training and a technique based on scientific principles. It requires not only personality – the principal asset – but training on and off the job" (p. 193). However, probation officers continued even after the First World War to consider in their daily practice evangelical principles and the spirit of God as well as factors such as education, employment, social structures, and so on (Vanstone 2004). The tension between science and religion was mentioned several times in the literature (see for instance Le Mesurier 1935). Dr. Selbie (cited by Trought 1927) even went so far to define the probation officer as "the great teacher and the good shepherd" (p. 194). This tension is very well emphasized in the following: "knowledge without love is almost as useless as love without knowledge…" (p. 193). Therefore both dimensions – science and religion – were required to make a good probation officer. How these two factors worked together was an important source of ambiguity.

As defined in the Probation of Offender Act 1907, Section 4(d), the duty of the probation officer is "to advise, assist, and befriend [the client], and, when necessary, to endeavor to find him suitable employment." In order to implement these duties, a probation officer had to acquire or possess certain types of characteristics and knowledge:

> Apart from any question of personal qualities, such as tact, patience or common sense, it is evident that to deal effectively with all these different

> applications definite knowledge of two kinds is required: The officer must possess a sound knowledge of the law governing the grounds on which various summonses may be granted by the court . . . And it will be equally vital for him to have a practical working acquaintance with the charitable organizations . . . (Le Mesurier 1935, p. 58).

According to the same author, while Probation Committees were still interested in considering personality and vocational call in the hiring of probation officers, their training was key. This observation is even more obvious in the job requirements in England and Wales at the time:

(a) Education: Preferably graduation from college or its equivalent, or from a school of social work
(b) Experience: At least one year in casework under supervision
(c) Good personality and character: tact, resourcefulness, and sympathy

(Probation and Supervision, Juvenile Courts at Work, cited in Trought 1927)

In the process of professionalization, the link between probation and social work played an important role. Not only were significant parts of the probation responsibilities common with social work, but also the technicality borrowed by probation service from social work enhanced the professional status of probation. Even the casework approach comes from the social work tool kit, including the idea that the process should follow the so-called ASPIRE framework (assessment, planning, intervention, review, and evaluation). At the same time, religious values such as "love," "charity," and so on were still present in the probation discourse but apparently not on the front page of job descriptions.

The Caseworker

The link between probation and social work was further strengthened after the Second World War. For many years in England and Wales, most probation officers were educated in social work. In the context of significant progress in the social sciences, new methods of working with offenders were developed. One of these new methods was social casework, which was defined as "the creation and the utilization, for the benefit of an individual with personal problems, of a relationship between that person and a trained social worker" (Home Office 1962, p. 24). The same idea was emphasized by Perlman (1957) ". . .[the] casework process, like every other process intended to stimulate growth, must use relationship as its basic means" (p. 64).

Therefore, the principal medium of intervention was the relationship between the specialist and the client. The importance of this relationship was even greater in the context of working with "unwilling clients":

> If the relationship becomes one which [the client] values and which is of help to him, he is likely to be willing to use it. If it provides an experience which is unpleasant, he will be less willing to try to use it. (Monger 1964, p. 45)

Thus, in the mid-twentieth century it was believed that a significant part of the skills and characteristics that the probation officer should possess related to the imperative of creating a positive relationship. King (1958), for instance, stressed the capacity for "a warm and sincere concern" (p. 73). Describing the abilities of a caseworker, Heywood (1964) mentions that he or she needs to have the ability to be a "person of warmth and likeability" (p. 45) and a "quality of imaginative sympathy, allied to temperament" (p. 45). There are also multiple nuances that influence the relationship: the caseworker's "demeanour, attitude to life, optimism, pessimism, courtesy, thoughtfulness, warmth, coolness, perhaps the things revealed by his moral qualities" (pp. 45, 46). Furthermore, Heywood considers that the basis of casework consists of two elements: the application to supervision of casework principles of acceptance, self determination, client participation, and confidentiality, and "the ability and mastery of his subject which the worker brings and which give hope to the client so that he goes forward confidently with the worker to try to do something about his problem" (p. 46).

Increasingly during the postwar period, probation officers were required to develop certain skills in order to diagnose and treat offenders as well as develop positive relationships with them. As McWilliams states:

> The gradual movement from the religious, missionary ideal to the scientific, diagnostic ideal, depending, in part, on notions of professionalism, required that probation work should be something for which people were trained to enter rather than called to follow (quoted in May 1991, p. 12)

It appears that after the Second World War, probation officers were expected to acquire and develop technical skills specific to a scientific approach. At the same time their personal characteristics, although present, ceased to represent an important aspect of the recruitment and selection process. For instance, qualities like reasonableness, maturity, openness, warmth, and so on, although mentioned, were not high up in the requirements list. On the contrary, candidates were expected to attend different classes or to demonstrate some skills in order to be successful.

The aim of the probation officer was quite clear: to "heal" the offender through casework and other rehabilitative interventions. The offender was perceived as ill or not fully aware of their inner thoughts and therefore in need of treatment. It comes as no surprise that this phase of probation development is also known as the "medical stage." A large number of concepts and procedures employed by probation come from the medical world via the social work profession.

The Helper

In the early 1970s, at the request of the US Government, Martinson and colleagues evaluated a significant number of parole interventions and concluded that "with few and isolated exceptions, the rehabilitative efforts that have been reported so far have had no appreciable effect on recidivism" (1974, p. 25). The arguable conclusion was therefore that "nothing works," which meant, among other consequences, the abandonment of the rehabilitation ideal in public discourse. If rehabilitation does not work, what is left for the probation service to aim for?

As an answer to this question, Bottoms and McWilliams proposed the "non-treatment paradigm" (1979). This model prescribed a new role for the probation service, taking into account the structural characteristics of the service in England and Wales (e.g., proximity to prisons, a relatively large geographical coverage) and also the research on effectiveness. According to this paradigm, the probation service is left with four "primary aims": "(1) the provision of appropriate help for offenders, (2) the statutory supervision of offenders, (3) diverting appropriate offenders from custodial sentences and (4) the reduction of crime" (p. 168). Unlike the previous model of practice, the notion of "help" is defined by the client and not by the so-called expert, the caseworker:

> The caseworker does not begin with an assumption of client-malfunctioning; rather he offers his unconditional help with client-defined tasks, this offer having certain definite and defined boundaries (Bottoms and McWilliams 1979, p. 172).

Under this new paradigm the probation officer was expected to deliver help in client-defined terms. Based on a number of parolee studies, "help" was mainly understood as practical support aimed at assisting the parolees to overcome the obstacles of reintegration.

The "non-treatment paradigm" transformed the role, and therefore the profile, of the probation officer from treatment provider to a help provider, with the main role played not by an expert (as in the previous "medical model") but by the client himself. Furthermore, the probation officer was expected to select and supervise those offenders that could be diverted from custody. As Smith (2005) puts it, "The purposes of the service were thus re-written to stress its value as a vehicle for reducing, or at least controlling, the prison population" (p. 626).

The probation officer was expected to practice a new form of casework that maximized the areas of choice for the offender within the limits of the probation order. "Within-officer" skills such as collaborative assessment, task setting, and so on were still important, but the probation officer's personal characteristics were rarely mentioned. From the literature it seems that the shift towards a more “law enforcement”-oriented practice did not call for any special staff characteristics – at least, not the ones typical for social workers. The “nothing works” era was characterized not just by client-centered help but also a focus on crime control and surveillance. Although the control element existed previously to a limited extent embedded in the concept of supervision, during this era it became as important as the care dimension, if not more important.

The New Rehabilitator

At the beginning of the 1990s, Raynor (1988) and others in England and Wales and Ross et al. (1988) in Canada started to question Martinson’s conclusions. For example, Ross and his colleagues (1988) reviewed 40 years of experimental work with offenders and noticed that persistent offenders “suffer” from a range of thinking skills deficiencies (e.g., lack of awareness of consequences, lack of rigorous planning skills, insufficient negotiation skills). On this basis they designed the Reasoning and Rehabilitation program, which aimed to reduce crime by dealing with these deficits. Most of these initial studies mentioned different qualities that an effective probation officer should have, including the ability to motivate, model reasoning and problem solving, and identify cognitive distortions; creativity; and so on (Ross and Fabiano 1985). However, the role of staff skills in effective programming was unfairly overlooked at the policy level (Raynor et al. 2010).

Several meta-analyses (e.g., Andrews and Bonta 1998; Dowden and Andrews 1999) have suggested that interventions based on the principles of risk, need, and general responsivity (RNR) are associated with important reductions in reoffending. In short, the principle of risk suggests that the intensity of a program or intervention should match the level of offender risk. The need principle states that an effective intervention should target the offender’s criminogenic needs (e.g., substance misuse, peer associations, antisocial attitudes). The responsivity principle suggests that the style and mode of interventions should match the learning style of the participating offenders. Cognitive–behavioral and social learning strategies proved to be most effective in reducing reoffending. Other meta-analysis indicated that the integrated application of these three principles could reduce reoffending by 26–30 % (Dowden and Andrews 2004). However, most of these observations focus more on the program content and less on the way they are implemented by staff. At the beginning of the What Works movement, staff skills and characteristics were neglected to a certain extent. “[P]rogramme fetishism” (Smith 2005) replaced the focus on the attributes that a good probation officer should have.

Trotter (1996) was probably one of the first modern researchers to put staff skills back on the agenda. In his experimental study of probation services undertaken in Victoria, Australia, he concluded that prosocial modeling and reinforcement by probation officers were significantly correlated with a lower reoffending and imprisonment rate; the use of problem solving and role clarification was related to reduced reoffending; and empathy together with prosocial modeling was associated with reduced reoffending. In their meta-analysis, Dowden and Andrews (2004) completed the picture of the core correctional practices (CCP) essential in reducing reoffending. In their analysis they found that five particular skills and characteristics were associated with significant reduction of reoffending: effective use of authority, anticriminal modeling and reinforcement, problem solving, use of community resources, and quality of interpersonal relationship between staff and client.

Bonta and colleagues (2010) demonstrated that probation officers trained in using risk–need–responsivity principles are more effective than others. In that study, probation officers who were trained within the Strategic Training Initiative in Community Supervision (STICS) increased adherence to the need principle and also had a more clearly defined structure of the intervention (teaching focus), had better relationship skills, and employed more cognitive techniques than the probation officers that did not attend the training. These techniques were also correlated with reoffending rates after 2 years and the conclusion was very optimistic: the difference in reconviction rate between the control group and the treatment group was 15 % (25.3 % for the treatment group and 40.5 % for the control group).

Most of these conclusions were confirmed in the Jersey study by Raynor and colleagues (2010). This research was based on analyzing 95 videotapes involving 14 probation officers with a total of 384 offenders under supervision. The skills employed by the probation staff during supervision were evaluated using a checklist with nine dimensions: setup, nonverbal communication, verbal communication, use of authority, motivational interviewing, prosocial modeling, problem solving, cognitive restructuring, and the overall interview structure. Raynor and colleagues (2010) concluded that there are significant differences between individual probation officers in terms of "structuring" skills intended to bring about change (e.g., problem solving, prosocial modeling, cognitive restructuring), which might influence offenders' progress. They also suggest that offenders supervised by probation officers who scored above the average on the skills scale had significant improvements in their LSI-R scores. Another important preliminary finding is that "use of authority" and "problem solving" are also strongly associated with improvements in LSI-R score (Raynor, personal communication). As Raynor suggests, all these preliminary findings need to be investigated in larger studies.

Another group of researchers (see McNeill 2006 for a review of the literature) reformulated the question from what makes offenders reoffend (specific to the risk/needs/responsivity paradigm) into what makes ex-offenders desist from offending? This shift of interrogation generated a whole new body of research contributing to the desistance paradigm (McNeill 2006). From a desistance perspective, change is understood as a process that a probation officer needs to promote and support. Desistance is placed at the intersection between structure, agency, and reflexivity, emphasizing at the same time the importance of human and the social capital and also the motivation and the subjective identity of the offender.

One of the great merits of this new theoretical framework is that it stresses even more the importance of staff skills and characteristics in order to create a "legitimate and respectful relationship" (McNeill 2006, p. 55) and provide help to offenders in a more collaborative approach. This observation is in line with Farrall's (2002) conclusions based on the experience of a group of 199 probationers. After interviewing the probationers in three waves, Farrall (2002) concluded that desistance could be attributed to probation interventions in only a few cases where a probation officer helped with finding a job or reconciling an offender with his family. Apart from those isolated cases, desistance took place away from the probation service, in the probationer's personal and social context where different obstacles to desistance were addressed. The importance of overcoming obstacles to achieving desistance was stated again in (Farrall 2002), casting the role of the probation officer as supporting desistance by helping individuals to overcome barriers within their own personal and social context. Instead of "managing" the offender, an effective probation officer should practice a more collaborative approach in the "co-designing [of] interventions" (McNeill 2006, p. 57).

The importance of the mutual relationship between probation officer and offender was further explained in Rex's (1999) study of 21 probation officers and 60 probationers. The study was based on semi-structured interviews that were made in 1994. From the interviews, Rex (1999) concludes that probationers who attributed change to the probation experience benefited from an active and participatory supervisory experience. In terms of professional skills that probationers would like to see in the probation officer, Rex (1999) noted that the probation officer needs to be experienced, knowledgeable, reasonable, and also to display "expert qualities" (p. 371) that would encourage probationers to disclose sensitive information and feel confident that they are listened to and taken seriously. The same study stated that in order for probationers to feel committed and positively engaged in the supervisory relationship, the probation officer needs to demonstrate empathy and have the capacity to listen and show interest and understanding, enabling probationers to talk. Although it is not known whether or not these probationers were "desisters" and there is no demonstrated causal relationship between staff skills variables and desistance, the contribution of this study is significant for understanding the "user's perspective" of an effective supervision experience.

A new body of research focuses on the question of how to assist offenders to become constructive members of society (Ward and Maruna 2007). Together with others, Tony Ward developed a new theoretical paradigm of rehabilitation – The Good Lives Model (GLM) – that looks at the offender as a potentially useful member of the family, community, and society rather than a "risk carrier." Within this positive psychology framework, based on the human dignity principle, it is crucial to treat the offender with respect in their endeavor towards a better life.

The concept of "good lives" has a few interrelated features. The most important assumption is that humans are intrinsically seeking to live a fulfilling life. In order to do that, they look for basic goods that are worthwhile in themselves, such as knowledge, health, intimate relationships, and excellence in play and work. These are defined as primary goods and are considered objective and based on human nature. The secondary goods are instrumental to securing these goods (means). Most often crime is described as an illegitimate and inefficient way to secure the primary goods. Therefore, the treatment plan should incorporate the primary goods relevant to the person and provide conditions to legally secure them. It seems that using GLM enhances treatment engagement, promotes positive working alliances, and contributes to long-term desistance (Purvis et al. 2011).

Discussion

As demonstrated above, the role of staff skills and characteristics in probation services has had a sinuous career. Staff characteristics used to be very important in the early days of probation but faded away as professionalization and crime control paradigms advanced. As effectiveness studies became more prevalent, staff skills were initially neglected but have increased in importance over time. Within the new theoretical frameworks, the focus on staff attributes finds its way back to the forefront, especially as they relate to developing effective or positive relationships with offenders. Research is replete with evidence that some skills are better than others in reducing reoffending or desistance. The danger is now that the practice may take on board only those skills and attributes that are evidence-based (demonstrated by research that they are effective). By doing that, probation practice would suffer from being too restrictive and not allowing innovation and creativity. Probably a balance between evidence-based and practice-informed approaches would promote a more nuanced practice that would have as a core element the so-called human touch (see Partridge 2004). Although research has advanced a lot in studying probation skills and characteristics, more should be done in order to validate these findings in real life situations. Sometimes the "technology transfer" (Bourgon et al. 2010) into the real world is quite problematic and results do not always confirm what was discovered in experiments. Moreover, more research should be invested into producing explanatory models of how different characteristics and skills develop in probation officers. As most of the changes have an important subjective dimension, qualitative methodologies should be employed more and more. Probably, ethnographic methods would be more appropriate to capture the individuality and also the psychological features of the change process. Realistic designs described by Pawson and Tilley (1997) represent an approach that rejects the mechanical feature of the experiment and focuses the analysis on the person(s) in a given concrete situation. Thus, researchers can obtain a richer, a more sensitive, and complex picture of the social and psychological realities.

Evolution of substance abuse treatment

Overview

Efforts at combating the negative health and social consequences of substance abuse and dependence have always existed in the United States. Often swinging between the rival contexts of moralistic and positivistic discourses, these efforts have led to the articulation of the major therapeutic paradigms in the field of substance abuse treatment. The earliest interventions were grassroot interventions focusing on individuals with drinking problems whose goals shifted from moderation to abstinence over time. As the patterns of substance use and abuse quickly diversified along the processes of immigration and urbanization, a wider variety of substances and a more diverse assortment of users became targeted for an even richer array of therapeutic experiments. The gradual involvement of the state in the planning and administration of substance abuse treatment has resulted in the growing use of institutionalization and coercion to trigger and maintain the recovery process. The emerging consensus that substance addiction is a chronic and relapsing brain disease represents a redefinition of an old problem and will determine the direction of the science and art of substance abuse treatment in the years to come.

Introduction

Mind-altering substances have been a part of the human experience since the beginning of civilization (Katcher 1993; Saah 2005). Many of the psychotropic effects enjoyed by recreational drug users today were sought by ancient civilizations as a means of increasing their chances of survival (Saah 2005). Ancient civilizations also realized, however, that it was possible to enjoy and become addicted to certain substances. Five-thousand-year-old Egyptian records report that individuals suffering from alcohol addiction were often cared for in the private homes of people who provided treatment. Records from ancient Greek and Roman sources recommended that alcoholics receive treatment in “public or private asylums” (White 1998). This chapter will provide an overview of American substance abuse treatment from the 1700s to the present.

The Early Years of America: 1600 to 1900

Americans have consumed alcohol since colonial times, making alcohol the earliest use of an intoxicant by the settlers. Alcohol was an integral part of culture at the time, but public drunkenness was not tolerated (Levine 1978; Stolberg 2006). The production and consumption of alcohol increased steadily between colonization and the late eighteenth century. By 1810, the number of distilleries in the United States had increased exponentially to a staggering 14,191, with the average person drinking four and a half gallons of alcohol per year (White 1998). The level of alcohol consumption had reached its zenith by 1830, with the average American consuming approximately five to seven gallons of alcohol per year (Stolberg 2006). Alcohol had become easily accessible to, and affordable for, the general population, resulting in deleterious effects on society (especially the family) due to increased alcohol abuse (Katcher 1993; White 1998; Stolberg 2006). Treatment of addiction in the United States, therefore, began with alcohol addiction (Lemanski 2001).

Early Institutional Care for Addiction

In the late eighteenth and early nineteenth centuries, individuals suffering from an addiction to alcohol were grudgingly housed in a variety of locations. Individuals who were considered drunkards were frequently incarcerated in local jails (Rosenberg 1995; White 1998; Rothman 2001), which is especially interesting because alcohol was often served in early American jails (Rothman 2001). Hospitals were an option for medical care but were limited in number during the eighteenth and nineteenth centuries. Both almshouses (places for the poor, sick, or destitute to seek refuge) and asylums for the mentally ill also provided a place for alcoholics to stay but, like jails and hospitals, failed to provide treatment for addiction (Rosenberg 1995).

Benjamin Rush, a prominent physician and activist beginning in the latter half of the eighteenth century, proposed that "sober houses" be used to treat alcohol addiction through medical treatment as well as "religious and moral instruction" (Levine 1978; Baumohl 1990; White 1998). Rush, who initially advocated for moderation rather than abstinence, went on to describe the symptoms and potential social consequences of alcohol abuse in pamphlets that were distributed to the public in 1784 (Levine 1978; Katcher 1993; Lemanski 2001; Stolberg 2006). Early treatments of alcoholism used by Rush ranged from cold baths, vomiting, and aversion therapy to the practices of bleeding, blistering, and sweating the patient (White 1998).

Physicians in the early nineteenth century made significant contributions to the identification of key physical consequences of alcoholism, such as liver, stomach, muscle tissue, and nerve tissue damage. Delirium tremens (or the "D.T.s") were first described prior to 1819 as "alcohol-induced brain fever," and then later articulated by Dr. Walter Channing and Dr. John Ware between 1819 and 1831. The two physicians provided the first American documentation of a variety of symptoms of delirium tremens, such as hand tremors, hallucinations, vomiting, and loss of appetite. The term "alcoholism" was also coined in the mid-1800s by Dr. Magnus Huss, a Swedish physician who chronicled the development in global knowledge of alcohol addiction (White 1998).

The discovery of the physical side effects and consequences of chronic alcohol use, as well as the ineffective drive for abstinence during the temperance movement, played a role in the push for the institutional treatment of alcoholism (Baumohl 1990; White 1998). The American Association for the Cure of Inebriation (AACI) provided the first attempt at the professionalization of treatment services, arguing that addiction was a disease that should be treated rather than a vice or criminal offense that should be punished. In 1870, six managers of inebriate homes and inebriate asylums joined together to form the AACI. Inebriate homes were small facilities that provided some treatment for alcohol addiction but functioned primarily as a shelter for alcoholics. Inebriate asylums, on the other hand, were often large private or state-sponsored facilities that focused on the provision of medical treatment for alcohol addiction. Private sanitaria (often referred to as lodges or retreats) were also developed at the end of the nineteenth century to provide addiction treatment services to the wealthy (White 1998).

Types of services provided at the different types of addiction facilities included inpatient treatment, short- or long-term stays for detoxification, and the first attempts at outpatient services. The first attempts at a "continuum of care" were also made during the inebriate asylum movement. A local physician would first refer a patient suffering from alcohol addiction to an institution for the purposes of detoxification. After further evaluation, the patient would be transferred to a facility that provided long-term treatment for addiction. After the completion of long-term treatment, the patient would be returned to the care of their local physician, who would then provide any necessary aftercare (White 1998).

Specific treatment methods within individual institutions varied. The most important feature of early institutional treatment was isolating the inebriate from society so that the inebriate would no longer face the temptation of alcohol. Once isolated, many institutions began the process of detoxification. Detoxification could be done abruptly and without the aid medication (often referred to as “cold turkey”) or gradually with medications prescribed to alleviate the symptoms of withdrawal. Other types of psychotropic substances, such as cannabis, coca, chloral hydrate, and belladonna, were commonly prescribed for detoxification during the nineteenth century. Detoxification was often followed by an attempt to restore the patient to a healthy physical state, through the provision of medical treatment, healthy meals, fluids, vitamins, and exercise. It was also believed that massages, sunlight, and electrotherapy would aid in the recovery process. Music, counseling, aversion therapy, and religious instruction were other methods that were occasionally offered, but were not the norm (White 1998).

Construction of institutions for the treatment of alcohol addiction in the United States expanded to a total of one hundred facilities by 1902. This trend of expansion, however, was short-lived. The majority of the inebriate homes and asylums had either disappeared or been reallocated for correctional or psychiatric purposes by the 1920s. Contributing factors to the demise of the inebriate homes and asylums were lack of funding, technology, and professionalization as well as a waning of the optimistic belief that alcoholism could be cured. Although early attempts at the treatment of alcohol addiction were not successfully sustained, they conceptualized addiction as a disease rather than a personality disorder, revolutionized treatment of addiction, and provided the foundation for the continued development of future methods of substance abuse treatment (White 1998).

The Temperance Movement

The temperance movement played a pivotal role in the evolution of substance abuse treatment by sparking a new way of viewing addiction and recovery. The temperance movement began in 1808 as a response to the social problems resulting from the rapid increase in alcohol abuse among the American population (White 1998; Lemanski 2001). Alcohol abuse was initially thought to be a moral affliction rather than a disease. The original goal of the temperance movement, therefore, was to reduce alcohol consumption. Early attempts at reducing alcohol intake usually consisted of replacing spirits with beer or wine (Hall 2010; Stolberg 2006).

Beginning in 1831, a variety of temperance societies were created throughout the country in an effort to promote a communal recovery process rather than an isolated attempt at sobriety. The Washingtonian Society, founded in 1840, was one of the more well known of these temperance societies. The purpose of the Washingtonian Society was to provide a place for alcoholics to meet, hear temperance lectures, and share their experiences of alcoholism and recovery. Their method of recovery required members to publicly acknowledge their addiction and commit to recovery, share their experiences with other members, and engage in leisure activities without alcohol (White 1998). The Washingtonians also attempted to assist their fellow members in times of need, which is an aspect of the society that made it different from other temperance societies operating at the time. Efforts were made, through charitable donations, to offer legal assistance, shelter, food, and clothing to fellow Washingtonians as needed (Lemanski 2001).

The rapid growth of the Washingtonian Society, however, was met with an equally rapid demise. The Washingtonian Society had failed to establish a cohesive ideology, as well as an organized standard of practices for meetings, necessary to support continued expansion of the movement (Lemanski 2001). Perhaps more importantly, however, pledging abstinence was not a sufficient method of treatment for individuals suffering from alcoholism. By 1840, the goal of the temperance movement had shifted from moderation to abstinence (Katcher 1993). This shift in goals was largely a result of the growing recognition that alcoholism could not be cured through simple will power. Advocates in the temperance movement began to argue that the best way to fight alcoholism was to prevent future generations from drinking alcohol by prohibiting the consumption of alcohol (Lemanski 2001; Stolberg 2006).

The temperance movement continued to flourish until the Civil War began in 1861. Although the temperance movement stalled during the Civil War, the movement regained its momentum as a political endeavor after the war ended (Lemanski 2001; Stolberg 2006). Women's groups, such as the Women's Christian Temperance Union, began to push harder not only for temperance but also for prohibition. In 1869, the Prohibition Party was formed in an effort to make the distribution and transportation of alcohol illegal in the United States (Lemanski 2001). This policy initiative came to fruition with the adoption of the Eighteenth Amendment to the Constitution in 1920. As will be seen in the next section, prohibition had a powerful impact on substance use, abuse, and treatment among the American population in the early twentieth century (Katcher 1993; Lemanski 2001; Hall 2010).

Early Drug Treatment

While addiction treatment services focused predominantly on alcohol in the nineteenth century, there was a burgeoning interest in the treatment of other drugs (White 1998; Stolberg 2006). It is important to note that the use of psychotropic drugs was legal in the United States until the enactment of the Harrison Act in 1914. The availability of drugs (especially opiates and cocaine) greatly increased during this time period, resulting in the first drug epidemic. Physicians with experience in treating patients with drug addictions (usually to opiates) began discussing addiction in terms of disease rather than moral failure (White 1998).

More women than men used psychotropic drugs during this time period, most likely because opiates were the popular treatment for "female" maladies such as menstruation and hysteria. Opiate addicts in the nineteenth century were, more often than not, educated white women of a higher socioeconomic status. Due to the stigmatization of substance abusers, especially during the female-driven temperance movement, women often hid their substance use and abuse from their family and friends. When women did seek out treatment, the reported ailment was usually of a physical or psychological nature (White 1998).

Ironically, however, early treatments for physical, psychological, and substance abuse disorders often included the prescription of other drugs (Courtwright 2001). Opiates were often prescribed for physical and psychological maladies, while cocaine was often prescribed for alcohol and opiate addiction. Additionally, cocaine was frequently used as an anesthetic during surgical procedures. Unfortunately, the treatment of narcotics prior to the twentieth century predominantly focused on easing the suffering of withdrawal symptoms during the detoxification process through the prescription of other highly addictive psychoactive substances (e.g., codeine, hypnotics, bromides, and chloral hydrate). Early experimentation with maintenance programs began at this time, but the programs were largely ineffective because the narcotics used to maintain the patient continued to provide a high (unlike agonists that are used today, such as methadone). The cycle of addiction, therefore, was often sustained (White 1998).

The Miracle Cure

During the second half of the nineteenth century, several coinciding circumstances provided the perfect milieu for the sale of "miracle cures" for addiction. Miracle cures were usually in the form of a medication that could be taken for a short period of time for the successful treatment of alcohol (e.g., Mickey Finn Powders, White Star Secret Liquor Cure, and the Hay-Litchfield Antidote), hangovers (e.g., Alka-Nox, Wink, and Sober-Up), tobacco (e.g., Nicotol, Tobacco Redeemer, and Gustafson's Tobacco Remedy), or other psychotropic substances (e.g., Mrs. Baldwin's Home Cure for Cocaine, St. Anne's Morphine Cure, and Weatherby's Opium Antidote). A variety of tonics and syrups consisting of various mixtures of alcohol, opium, morphine, and cocaine promised to cure any addiction in the privacy of one's own home at a fraction of the cost of institutional treatment (White 1998).

Miracle cures could be purchased over the counter, through mail order services, and were also provided in treatment facilities (e.g., inebriate houses). Aggressive marketing strategies were used to advertise miracle cures to the public through the use of newspapers, magazines, billboards, and speaking events. Gimmicks, such as the use of the testimonial (e.g., 100,000 satisfied customers), the money-back guarantee, and discreet packaging, became very popular during this time period (White 1998). Some of these miracle cures, such as Leslie Keeley's Double Chloride of Gold Cure, actually became treatment franchises (Baumohl 1990; White 1998). Doctors and charlatans alike frequently attached their names to the production and promotion of a new, top-secret formula (e.g., Dr. Meeker's Antidote) that would purportedly revolutionize the treatment of addiction. The sale of miracle cures continued well into the mid-twentieth century (White 1998).

1900 to the 1950s

The goal of prohibition was to make the distribution and transportation of alcohol illegal so that the consumption of alcohol would become impossible. If the consumption of alcohol could be prevented, it was reasoned, then alcohol addiction would cease to be a social problem necessitating treatment (Hall 2010). Unfortunately, alcohol abuse rose while treatment options disappeared. The idea that alcohol was a physical disease necessitating medical treatment was once again replaced with the belief that alcohol was a lapse in moral character that could be cured by prohibiting inebriety. As a result, religious groups such as the Salvation Army continued to provide treatment services to alcoholics, but the institutional treatment of addiction completely disappeared until the late 1940s (White 1998; Lemanski 2001).

The Effect of Criminalization of Drugs on Addiction Treatment

Although it is widely believed that the "war on drugs" began with President Nixon in the 1970s, it could be argued that the "war" began with the passage of the Harrison Act in 1914. Prior to the Harrison Act, access to opiates, cocaine, and other drugs was unregulated. This lack of regulation, combined with the overprescription of both drugs, resulted in high rates of addiction. In 1912, the first morphine maintenance clinics opened in an attempt to treat the many men and women who had become addicted to opiates. Outpatient treatment was provided through the prescription of decreasing amounts of morphine for the purpose of weaning patients off of drugs at a pace that would allow them to avoid withdrawal symptoms (White 1998).

When the Harrison Act was passed, the possession of illicit substances was criminalized. It was at this point in history that the treatment of substance use and abuse shifted from a public health model to a criminal justice model. The passage of the Harrison Act limited the access to opiates and cocaine to physicians, who were then prohibited from prescribing the drugs to addicts for the purposes of detoxification or maintenance because the government believed that too many addicts were remaining on maintenance programs indefinitely rather than being weaned off of drugs (Levine 1978; White 1998; Courtwright 2001). By 1925, all of the morphine maintenance clinics had been closed (White 1998).

Thus, although the Harrison Act was intended to address opiate and cocaine addiction, it made it very difficult for addicts to receive any treatment whatsoever. Shortly after drugs were criminalized, the mandatory detention of substance users and abusers began. Many individuals suffering from addiction were sent to psychiatric hospitals or special "colonies" for mandatory treatment. Jails and federal penitentiaries were also flooded with addicts who had violated the Harrison Act. Between 1915 and 1929, the number of drug-related incarcerations increased from 63 to 1,889. Overcrowding of correctional facilities led to the creation of two federally funded and managed "narcotics farms," which served as separate facilities for drug offenders in need of long-term treatment (White 1998).

Drug abuse and dependence treatments during the first half of the twentieth century were often experimental in nature. For example, treatments for alcoholism were often applied to drug users. Other extremely invasive methods were also used, such as insulin-induced comas, electroconvulsive therapy (ETC), aversion therapy, psychosurgery (i.e., lobotomy), and serum therapy (where serum was withdrawn from blisters that were raised on the abdomen of a patient and then reinjected). Psychological approaches for the treatment of alcohol and drug addiction were also developed during the early nineteenth century, with psychoanalytic approaches being the predominate format. Although the prohibition of alcohol was eventually deemed a failed social experiment, the criminalization of other psychoactive substances remains to this day (White 1998; Lemanski 2001).

The Modern Alcoholism Movement

After the enactment of the Twenty-first Amendment to the US Constitution in 1933, prohibition ended and a new phase in the treatment of alcohol addiction began (White 1998; Lemanski 2001). A third paradigm shift in the treatment of addiction occurred between 1933 and 1955. This period is often referred to as the "Modern Alcoholism Movement" (p. 178). During this time, alcoholism was once again reconceptualized as a disease and public health issue rather than a moral weakness. Professionals and members of society alike began to believe that alcoholism could be treated. This new belief in the merits of treatment opened the door for the allocation of funds for new research on addiction to be conducted by professionals in the medical, psychological, and social work fields (White 1998).

The Modern Alcoholism Movement was not, however, a unified process. The activities of a variety of institutions and interest groups, often with very different agendas, worked separately to achieve social change. Three of the most prominent professional groups to exact change during this period were the Research Council on Problems of Alcohol, the Yale Center of Alcohol Studies, and the National Committee for Education on Alcoholism. These three groups collectively succeeded in redefining alcoholism; changing policies and treatment practices relating to addiction; convincing government and private sources to invest money in research, education, and intervention; and initiating alcohol treatment in the workplace. Another interest group, Alcoholics Anonymous, used a grassroots approach to become an especially integral part of the Modern Alcoholism Movement (White 1998; Lemanski 2001).

Alcoholics Anonymous

Treatment options for alcoholics had all but disappeared in the United States by 1930. In 1935, Bill Wilson and Dr. Robert Smith developed a self-help recovery group called Alcoholics Anonymous (A.A.) in an effort to fill this treatment void (Hubbard et al. 2009). A.A. evolved out of a nondenominational group, known as the Oxford Group, who sought to encourage positive societal change through individual spirituality. Although alcoholism was not the primary concern of the Oxford Group, many group members believed that religion could provide a strong foundation for individuals seeking sobriety. A small subgroup of alcoholic members, led by Wilson and Smith, formed within the Oxford Group to provide support to one another during their struggle for sobriety. The nonalcoholic members of the Oxford Group disagreed with this focus on sobriety, which led to the separation of this subgroup in 1937 (White 1998; Lemanski 2001; Alcoholics Anonymous 2012). The group was christened Alcoholics Anonymous in 1939 (White 1998; Alcoholics Anonymous 2012).

While the early years of A.A. consisted of relatively unstructured group meetings, Wilson and Smith soon began to focus on building a financially independent group with a guiding ideological framework. In 1938, Wilson began writing a book (called *Alcoholics Anonymous*) that outlined how he wanted the program to function and recorded the stories of the recovery of many of the group members. What began as six guiding principles eventually turned into the twelve-step program that A.A. is known for today. The twelve-step program provides an outline for the course of recovery that an alcoholic will follow as a member of A.A. (e.g., the member must admit that they have a problem and that they need help, put their faith in God, make amends, acknowledge that sobriety is a lifelong commitment). In this way, the focus was not on how or why the individual became an alcoholic. The focus has always been on how the individual will achieve sobriety, and the identity reconstruction that must occur for the individual to remain sober (Alcoholics Anonymous 2012).

After the publication of their book in 1939, A.A. gained a great deal of press coverage, which resulted in enormous popularity. Membership quickly grew to 100 members within that first year and then skyrocketed to 8,000 members by the end 1941 (White 1998; Lemanski 2001; Alcoholics Anonymous 2012). A.A. then began to play a pivotal role in the medical treatment of alcoholism. Hospitals had always grudgingly treated (or refused to treat) alcoholics because it was believed that alcoholism was the result of a moral weakness rather than a disease. Alcoholics also tended to be very difficult and frustrating patients, in already overcrowded facilities, who did not pay their bills. Members of A.A. made it their mission to change the perception of alcoholism from an untreatable moral weakness to a disease with the potential for successful treatment, and they succeeded (White 1998).

Through tireless advocacy, A.A. (1) convinced local hospitals that alcoholism could be treated, (2) showed hospitals how to treat alcoholism, (3) suggested that separate wards be established for the sole treatment of alcoholism, (4) suggested that these wards be managed by A.A. members to take the stress off of hospital employees, and (5) promised to pay the bills of any patient that A.A. had sponsored for alcohol treatment. A.A. then began to extend their treatment model to private, psychiatric hospitals, and prisons, thus playing a major role in the return to the disease model of addiction treatment (White 1998).

In 2011, it was estimated that there are 2,057,672 members worldwide (Alcoholics Anonymous 2012). A.A. has evolved into “the most fully developed culture of recovery that has ever existed- a culture with its own history, mythology, values, language, rituals, symbols, and literature” (White 1998, p. 162). The founders of A.A. chose to use the personal experiences of group members who have experienced alcoholism to provide support and guidance in the recovery process rather than utilize the services of professionals in addiction treatment. Nevertheless, Alcoholics Anonymous revolutionized addiction treatment in the first half of the twentieth century and has continued to influence social policy well into the twenty-first century (White 1998).

1950s to the Present

The Minnesota Model

The Minnesota Model of addiction treatment began with the establishment of a new method of alcoholism treatment in three Minnesota centers in the late 1940s: Willmar State Hospital, Pioneer House, and Hazelden. Willmar State Hospital functioned as an inebriate hospital beginning in 1912 but was converted into a psychiatric facility as a result of prohibition. Pioneer House opened its doors in 1948 in an effort to offer a different type of treatment option. Using A.A. as a program model, Pioneer House provided residential treatment for men with alcohol addiction for two to four weeks (White 1998). Hazelden Farm, a former retreat for alcoholic men, was then established a year later to offer A.A.-based residential treatment program (Hazelden 2012).

What is known today as the “Minnesota Model” evolved throughout the 1950s. One of the primary tenets of the Minnesota Model that emerged during this period was respect. The Willmar team argued that patients would greatly benefit from a recovery process built on mutual respect rather than degradation, which was a radical idea during this period. The staff at Willmar then defined alcoholism “not as a symptom of underlying emotional problems, but as a primary, progressive disease” (White 1998, p. 203) that should be treated using a multidisciplinary and holistic approach. They also believed that professionalization of addiction treatment was an integral part of this approach. Medical treatment was to be provided by doctors and nurses, counseling was to be provided by psychologists and social workers, and spiritual guidance was to be provided by the clergy. Perhaps more importantly, however, recovered alcoholics were also professionalized through training and the provision of credentials.

The Willmar team believed that recovered alcoholics were often the best counselors, but their position as a part of the addiction treatment team needed to be legitimized. The radical idea of professionalizing recovered alcoholics was met with a great deal of resistance but has become routine in current treatment models (White 1998).

The Minnesota Model continued to flourish and solidify during the 1960s at both Willmar and Hazelden, with several core elements emerging during this period (White 1998; Hazelden 2012). A 28-day stay became the standard treatment period, and patients were first prescribed medication to aid in the detoxification process (Lemanski 2001). A counselor, who often times was a recovering alcoholic, was assigned to each patient. Patients and counselors were usually matched according to age and gender in an effort to establish a supportive environment in which the patient would feel comfortable engaging in self-disclosure (White 1998). Individual counseling was supplemented by group counseling (which combined support and confrontation), lectures, and working through the twelve steps of A. A. Patients also received aftercare upon their return to the community (Quinn et al. 2004).

The Minnesota Model was immensely popular and had been adopted by 114 state agencies that provided addiction services by 1971. Presentation of the Minnesota Model at medical conferences took the treatment approach nationwide. Individuals suffering from alcohol addiction, as well as practitioners who wanted to be taught the treatment method, began pouring in from around the country. This innovative approach of treating chemical dependency is still followed today for both alcohol and drug addiction (White 1998; Lemanski 2001; Quinn et al. 2004).

The Resurgence of Drug Treatment

Treatment models for alcohol addiction and drug addiction evolved in vastly different ways due to the early criminalization of drug use. While treatment options for alcoholics continued to evolve, drug addicts began seeking treatment in psychiatric hospitals after the morphine maintenance clinics closed in the 1920s because there was literally nowhere else to go. Rapid withdrawal, and perhaps some psychiatric treatment, was the only help that drug addicts received in these facilities. A slight resurgence in drug treatment then began to occur in New York City in the 1950s, however, partly as a response to surging rates of adolescent heroin addiction. A few twenty-eight-day residential treatment programs were established inside of hospitals. Upon admission, patients were detoxified and then participated in individual and group therapy. After discharge, outpatient aftercare services were provided. Hospitals were still resistant to treating individuals suffering from drug addiction, so many individuals were committed for twenty-eight-day cold turkey detoxification on Riker's Island Penitentiary. Correctional detoxification continued until the practice was banned in the early 1960s. Treatments options were bleak, but both drug legislation and methods of treatment were about to be revolutionized in the 1960s (White 1998).

Narcotics Anonymous

In an effort to fill the treatment void, attempts to use the philosophies of Alcoholics Anonymous began in various locations in the late 1940s and early 1950s. The leaders of A.A. did not want to extend membership to drug addicts, so recovering addicts created their own version of A.A. The first of these meetings, which were called "Addicts Anonymous," took place in 1947 inside the federal narcotics farm located in Lexington, Kentucky. Addicts Anonymous meetings soon spread to other treatment facilities and hospitals, but when the organization established community-based meetings, the name was changed to "Narcotics Anonymous (N.A.)" to avoid confusion with Alcoholics Anonymous. The two programs are almost identical, with only slight differences in wording. Although N.A. got off to a very shaky start, almost disappearing in the late 1950s, it is now a thriving international organization (White 1998).

Community-Based Treatment

The first attempts at community-based support services for recovering addicts returning home after institutional care began in the late 1950s (De Leon 2000). Cities across the country attempted to provide outpatient treatment via social workers to individuals who had recently completed inpatient detoxification. These early attempts were largely unsuccessful, however, because follow-up appointments were often missed by patients. Continuing care for drug-addicted patients predominantly fell on private physicians, who often treated patients who had overdosed or contracted a sexually transmitted disease. Religious organizations continued to provide outreach services for drug addiction that often included medical and psychological treatment. N.A. also attempted to fill the void in community treatment, but it was not until Synanon, therapeutic communities, and new legislation permitting the use of agonist and antagonist treatment in community facilities that community-based treatment really took off (White 1998).

Therapeutic Communities

In mid-1958, a member of Alcoholics Anonymous named Charles Dederich began holding meetings at his home in California during which he experimented with different methods of group recovery for individuals addicted to both alcohol and drugs. These methods of group recovery were often confrontational, bordering on verbally abusive, and were intended to break down the defense mechanisms and excuses of addicts. His experimentation led to the idea for a therapeutic commune where drug addicts could live together during the recovery process. Dederich left A.A. to pursue his new treatment modality (which was essentially a residential treatment program), which he called Synanon (National Institute on Drug Abuse 2008; Janzen 2011). This first phase of development, known as Synanon I, became immensely popular with both the public and practitioners. By 1969, however, Dederich decided to take Synanon I in a new direction. While the goal of Synanon I was to rehabilitate addicts, the goal of Synanon II was to form an alternative lifestyle and to promote societal change. Synanon II evolved into Synanon III in 1974, at which time Synanon was declared a religion (Janzen 2011).

Synanon may have come to a decidedly bizarre end, but it did initiate a movement towards other therapeutic communities. Five hundred therapeutic communities using the early philosophies of Synanon were operating in the United States by 1975 (De Leon 2000). These new therapeutic communities focused on the rehabilitation and sustained recovery by adjusting the lifestyle, relationships, and even the personality of individuals suffering from drug addiction. Aggressive, confrontational, and even humiliating methods of group recovery were often used within a hierarchical system used to motivate patients to work for higher-status positions within the community (De Leon 2000; Inciardi and McElrath 2008; National Institute on Drug Abuse 2008). Most early therapeutic communities progressed their patients through three phases over a period of 18 months to 3 years. Patients first received isolated treatment within the therapeutic community, were then employed outside of the therapeutic community, and finally engaged in activities at the therapeutic community while living and working on their own (White 1998).

Therapeutic communities continued to evolve into the model that is used today. Residential stays are similar but tend to be shorter, with treatment methods that are not humiliating or as confrontational and aggressive. Today, therapeutic communities are also often linked to the criminal justice system and outpatient centers. Many jails and penitentiaries have therapeutic communities operating within their walls (De Leon 2000; National Institute on Drug Abuse 2008). The continued acceptance of therapeutic communities and other evolving treatment options, however, were contingent upon the wealth of new legislation that was occurring simultaneously throughout the 1960s.

Civil Commitments and Other Legislations

By the late 1950s, individuals who were suffering from drug addiction were viewed as people who were immersed in a destructive lifestyle that they were not willing, or able, to change. It was believed that addiction was a social disease that could be transmitted to other people; therefore, the family and friends of drug-addicted individuals were considered to be in harms way. Civil commitment, the court-ordered institutionalization of a mentally ill individual, provided a solution to these problems at the state level (Inciardi et al. 1996).

Involuntary and voluntary civil commitment to psychiatric institutions was extended to drug addicts in the early 1960s as a way of ensuring that substance abusers were treated rather than incarcerated. It was thought that addicts would be forced into the treatment that they may not be ready to seek for themselves while also preventing the spread of addiction to the community (Maddux 1988; White 1998). Patients were typically committed for 1 to 3 years, during which time they were detoxified and then provided with medical treatment and counseling. After discharge, the patient was returned to their community and received outpatient treatment (White 1998).

Civil commitment was not particularly successful at initiating sustained abstinence. With psychiatric facilities overburdened and patients continuing to relapse, the government became motivated to find different methods of treating patients in noninstitutional settings. The Joint Committee of the American Bar Association and the American Medical Association on Narcotic Drugs released a report in 1961 that recommended treating patients in community clinics. The more radical recommendation of this report, however, was the suggestion that investigations into maintenance programs be resumed. This step towards a disease model of addiction was further supported by several Supreme Court decisions in the early 1960s that prohibited laws that made addiction a crime, framed addiction as a disease deserving treatment rather than punitive action, and cautioned that civil commitment should be used sparingly. This paradigm shift made it possible for researchers claiming that immediate and sustained abstinence is not a realistic outcome for all drug addicts to be taken seriously (White 1998).

Pharmacotherapy

Using narcotics to medically maintain individuals suffering from opiate addiction was prohibited in the United States by the Harrison Act of 1914, but research concerning the practice continued to evolve. German researchers began developing a synthetic narcotic (White 1998; Joseph et al. 2000; Inciardi and McElrath 2008), called Dolophine, in the late 1930s. The use of Dolophine was discovered by the United States in the 1940s and was then marketed under several names by Eli Lilly, Inc. beginning in 1947 (White 1998). What is now known in the United States as methadone is an agonist that mimics the effects of other opiates but without the associated high. Methadone, therefore, can be prescribed in decreasing doses to individuals suffering from opiate addiction as way of weaning them off of the opiate without suffering withdrawal symptoms (Inciardi and McElrath 2008; U.S. National Library of Medicine 2009).

Methadone was used successfully for detoxification in a few US Public Health Hospitals in the late 1940s, but the use of narcotics for maintenance was prohibited until the addiction legislation of the 1960s called for research of new treatment methods (Courtwright 2001; Hubbard et al. 2009). In 1963, Dr. Marie Nyswander and Dr. Vincent Dole argued that methadone could be used not only to detoxify but also to maintain heroin addicts while they acclimate to the metabolic changes that occur during the recovery process. They argued that stabilizing the patient while their body underwent drastic physical change could prevent relapse (White 1998; Joseph et al. 2000; Courtwright 2001; Dole and Nyswander 2008).

Early experimentation occurred in intense inpatient settings. Patients received methadone along with counseling, while dosage levels were explored. Experimentation with dosage levels finally paid off in 1964 when Nysander and Dole discovered that one high dosage of methadone prevented intoxication, craving, euphoria, dysphoria, and withdrawal for 24 hours or more (White 1998; Joseph et al. 2000). Patients were able to function normally with very few side effects. Methadone became the wonder drug, and outpatient clinics were constructed all over the country. During the 1970s, federally funded methadone programs were established at record rates as a response to the return of heroin-addicted Vietnam veterans and a surge in urban crime. Today, methadone is provided in outpatient clinics, usually in conjunction with other addiction services (White 1998; Joseph et al. 2000; Courtwright 2001).

Experimentation with other drugs with the potential for maintaining opiate-addicted patients during recovery also occurred during the 1960s. An agonist called LAAM was another viable option discovered for maintaining patients with opiate addiction programs, but methadone remained the more popular of the two options. The effects of another group of medications, known as antagonists, were also explored. Antagonists, (e.g., nalorphine, naltrexone, and naloxone), block rather than mimic the effects of opiates (White 1998; Nutt 2010). These drugs work just as well as agonists (like methadone), but have no street value because they are not effective pain medications, which is a significant advantage. Antagonists are not popular among patients, however, because they do not suppress cravings and they induce withdrawal if taken when a patient has opiates in their system. Researchers have also been experimenting with partial agonists (like buprenorphine) and the combination of agonists with antagonists (like Suboxone®) as a way getting the best of both worlds (Nutt 2010).

Criminal Justice-Mandated Treatment

Prisons have always been major substance abuse treatment facilities, and criminal justice referrals have historically been the largest source of the publicly funded drug treatment admissions in local communities, accounting for 40–50 % of referrals to community-based treatment programs (Farabee et al. 2004). These community referrals and those admissions to prison- or jail-based treatment programs are generally known as coerced treatment. Coercive treatment approaches for drug addiction have been applied consistently throughout the twentieth century, beginning with the morphine maintenance clinics in some communities during the 1920s. The 1930s marked the establishment of the federal narcotics treatment facilities in Fort Worth, Texas, and Lexington, Kentucky. During the 1960s broad-based civil commitment, procedures were implemented in the federal system, as well as in New York and California. The present system, beginning in the 1970s, relies less on formal civil commitment procedures and emphasizes community-based treatment as an alternative to incarceration or as a condition of probation or parole. The inception of the drug court model in 1989 and of the prosecutor-led drug treatment alternative to prison (DTAP) model effectively propel the use of the threat of incarceration as the leverage and the application of graduated sanctions as the calibrator in the recovery process (Sung and Belenko 2006).

Some earlier researchers (Hartjen et al. 1982; Platt et al. 1988) have argued that little benefit can be derived when a drug user is forced into treatment by the criminal justice system because treatment can be effective only if the client is truly motivated and ready to change. The allocation of limited treatment slots to drug abusers who do not really want to be treated is perceived as ethically unjust and clinically unwise. Other researchers, on the other hand, posit that few chronic drug users will enroll and stay in treatment without some external pressure and that legal coercion is as justifiable as any other motivation for treatment entry (Anglin and Maugh 1992; Salmon and Salmon 1983). As a matter of fact, most clients begin their treatment under some type of pressure from their families or employers.

Legal coercion represents a range of options of varying degrees of severity across the various stages of criminal justice processing. It can be used to refer to such actions as a probation officer's recommendation to enter treatment, a prosecutor's offer of a choice between treatment and jail, a judge's requirement that the offender enter treatment as a condition of probation, or a correctional policy of sending inmates involuntarily to a prison treatment program in order to fill the beds. In all these instances, it is hoped that the external motivation (i.e., legal pressure or fear of punishment) may transform into internal motivation (i.e., desire to change and stop using drugs) and therapeutic engagement during the treatment process (Sung et al. 2001).

Decades of evaluative efforts have concluded that coercion in substance abuse treatment is both a therapeutic factor that can be planned and manipulated for recovery purposes (Young 2002; Young and Belenko 2002) and that it is particularly useful when administered as structured, incremental responses to treatment noncompliance (Taxman et al. 1999). Studies after studies have attested the effectiveness of criminal justice-based treatment (National Institute on Drug Abuse [NIDA], 2012). However, and most importantly, the fundamental lesson learned from evaluation research remains this: Coercion can create incentives to enroll and remain in treatment, but coercive tactics by themselves contribute very little to a drug-free lifestyle if they are not supported by evidence-based therapeutic and service components.

Conclusion

Substance abuse treatment in the United States has followed a spectacular trajectory over the past 300 years that was largely influenced by public perception of addiction, as well as social and political movements. The popularity and acceptance of medical models of addiction treatment have ebbed and waned according to strict moral climates, culminating in the interdisciplinary system of treatment that we have today. With the growing consensus that addiction to psychoactive substances is "a chronic, relapsing brain disease that is characterized by compulsive drug seeking and use, despite harmful consequences" (NIDA 2010, p. 5), treatment programs currently attempt to use a holistic approach that addresses the many facets of this public health challenge. Research continues to explore the biological, psychological, and sociological causes of addiction in an effort to provide new interventions that can treat addiction more successfully.

History of Technology in Policing

Mathieu Deflem and Stephen Chicoine
Department of Sociology, University of South Carolina, Columbia, SC, USA

Overview

Technology has fundamentally changed the face of society, and the effects that technological advances have had on the form and function of policing is no exception. In response to the changing conditions of society brought about by new developments in technology, law enforcement agencies have in turn adopted new technological advances in order to fulfill their function in the areas of crime control and order maintenance. This has in turn led to the historical development of the bureaucratization of law enforcement, which has transformed the police from a political enforcement apparatus to an autonomous professional institution. Technology has not only facilitated this transformation of police within their respective nations, but has also facilitated international police cooperation. The institutional autonomy and the technological advances in communications and transportation enabled international cooperation between police organizations which addressed, ironically, the new forms of crime that were enabled by those very same technological advances. Harnessing new forms of technology would become a constant theme in the efforts of international police cooperation, with new initiatives and meetings calling for the advancement of the means for law enforcement agencies of different nations to exchange information on criminals, suspects, and new means of policing.

Technological changes have occurred for the better part of a century, tracing back to, at least, the early nineteenth century, when police were highly connected with the political sphere and walked their beats with whistles and batons, up until the beginning of the modern era shortly after World War 2. By this time, the police had become recognizably modern, despite all the advancements that still had yet to occur in more recent decades. The changes in the institution of policing have not been limited to the means by which police pursue their goals, but have also altered the organization and goals of policing from political concerns to criminal objectives.

Fundamental Policing Technologies: Weapons and Communications

Early forms of policing bear only partial likeness to modern-day law enforcement. In terms of technology, police agents were traditionally outfitted only with a truncheon or baton and a rattle for raising the alarm (Johnson 1981; Manwaring-White 1983). These early police were largely on their own upon leaving the police station since the technologies of the time did not allow for communication between officers patrolling their beats and their command structure. As a result, officers in the police station were rarely aware of criminal situations on the streets unless a citizen lived close enough to walk to the station or until an officer returned from patrol (Johnson 1981). Due to the lack of communication technology at the time, there was also little ability to coordinate officers on patrol or to keep account of the officers' actions while on the streets. While the means of physical repression of the police have remained largely unchanged since the institution's early inception, the means of communication and transportation have transformed the form and function of policing in rather considerable ways.

Historically police agents were armed only with a nightstick in the United States or a baton or truncheon in Europe. The adoption of firearms by police was once a contentious issue in terms of the power of the state to arm against its people, and first occurred in the United States, arguably as a result of the embedded nature of firearms in American culture (Johnson 1981). The initial standing orders given to officers prohibited the carrying of firearms while on patrol, and the public was largely opposed to arming the police (Johnson 1981). At this time during the formation of the United States, many within the United States carried firearms, and conflicts among citizens sometimes escalated to the point that shots were regularly exchanged. The police of the time were charged with resolving such conflicts, but officers would often be shot while on duty. After several shootings of police officers had taken place, it became an informal practice among the police to carry a firearm despite the orders against this, and this informal practice eventually came to be institutionalized (Johnson 1981). In the United States, the first agency to adopt the multi-shot pistol officially was the Texas Rangers in the 1850s, and other agencies across the nation adopted firearms shortly after (NCJ 1998). In England the firearm was adopted considerably later on, and the police there were not visibly armed until a shoot-out took place involving two anarchists in 1911 (Manwaring-White 1983).

Major advances in the history of policing and technology have taken place with respect to communications technology. Police in the 1830s relied on the rattle, whistle, or loud shout in order to alert other officers in the area to come their assistance (Stewart 1994; Johnson 1981). These police were essentially isolated while on patrol, and the police station was unable to communicate with them while they were on patrol. As a result, the station could not coordinate nor direct its officers on the streets, the officers could not report on situations on the streets until they returned, nor ask for assistance. Citizens were likewise limited in their access to police assistance unless they lived within walking distance to the station or until they could find an officer along his route. Several technological advancements were pursued and instituted in the efforts to facilitate communications between the police, the citizenry, and the station.

From the late nineteenth century onwards, important advances in communications technology began to be adopted by the police. The first police telephones were installed in Albany, New York, in 1877 and were used to connect the five districts with the mayor's office. Similarly, in the United Kingdom telephones were first used to connect police in 1880, and by 1886 the emergency phone system had connected all of the police and fire stations in Glasgow in the United Kingdom. While these earlier advances enhanced the ability of police to communicate with other stations, the mayor, and other emergency services, the police call box allowed for communications between police on patrol, citizens, and police stations.

While today the police call box has been subsumed by the widespread use of the radio and telephone, and is perhaps more recognizable as the transportation of the time-traveling Doctor in the BBC series *Dr. Who*, it was once a major advancement in police communication (Stewart 1994). In 1884, the first police call boxes were installed in Chicago and Boston, and in 1891 the call boxes were also adopted by the Glasgow police (Stewart 1994). Other police agencies began using the call boxes extensively during the 1890s (Johnson 1981). The call boxes served as a line of communication between beat patrols and headquarters, as well as a rallying point where citizens could call the police. Police call boxes were placed at the intersections of several police officers' patrol routes with a light at the top. This light would be turned on to alert the officers if the station needed to contact them, or they could be activated by citizens in need of police assistance. Officers could therefore be signaled from a distance, via the signal, that their attention was needed at the call box. Inside the box was a telephone for communication with the station, creating some degree of communication between the officers, the station, and the citizenry (Reiss 1992; Stewart 1994; Johnson 1981). The police call boxes increased the response rate and efficiency of officers responding to emergencies and added to the efficiency of the police by reducing the number of patrolling officers needed and operational costs (Stewart 1994). Despite these advantages, the police call box would eventually become replaced by the radio, just as the police foot patrol would eventually give way to the use of the automobile (Reiss 1992).

As early as 1920 it was becoming apparent that the foot patrol method of policing was handicapped in light of the growing prevalence of the automobile (Walton 1958). The increasing size of residential areas in large cities were also beginning to strain police stations by making the costs of foot patrols prohibitive (Walton 1958). The foot patrols of the previous century were therefore ill-suited to the new social conditions, requiring a new approach to policing. Under these conditions, police forces developed rapid-response methods with the aid of the telephone, two-way radio, and automobile. In the United States, these practices began to develop during the 1930s, with the first radio patrol car used in Detroit as early as 1929 (NCJ 1998; Reiss 1992; Battles 2010; Johnson 1981). This system of officers patrolling in automobiles, coordinated through the use of two-way radios responding to calls made by citizens, created a more efficient, effective, and responsive police force (Johnson 1981). This development was strongly connected to the specific conditions of 1930s America. The radio police car was not used until much later in other national settings such as the United Kingdom which did not widely adopt automobiles in policing until the 1960s (Manwaring-White 1983).

The developments in the history of police and technology have been largely influenced by the changing conditions that the new technologies created, as well as the bureaucratic drive of the police towards adopting standards of efficiency in policing. The advances in technology facilitated the development of the institutional autonomy of police institutions from politics, since the development of communications technology led to greater reporting to headquarters and thereby created superior professional officers instead of politically loyal servants (Johnson 1981). Variable social conditions influenced the adoption of technologies among police across countries. Firearms were adopted earlier by police in the United States, for instance, because they were also more prevalent among the population. The radio patrol car was also adopted earlier there than in the United Kingdom, which did not face the same issues in terms of geographic expansion. Finally, offenders themselves facilitated technological changes of policing by possessing firearms or driving automobiles. The response of the police has often been to adopt these technologies in the form of a criminal-law enforcement arms race.

This arms race has not been confined to the character of local or national policing, but has also influenced the development of criminal identification technologies and their adoption.

Advances in Criminal Identification

In premodern times there was no issue in criminal identification since the size of the communities virtually ensured that everyone knew everyone else (Cole 2001). As societies expanded and geographic mobility increased due to advances in transportation technology, such as the train, it became easier for criminals to hide from their previous history by moving to a different area or even by merely adopting a different name. Problems with linking criminals to their previous convictions became particularly problematic when, during the 1850s, a movement towards harsher punishments for recidivists began (Cole 2001). Two central problems faced the courts and law enforcement officials attempting to link a suspect with a criminal past: the ability to access the information stored, and the ability to positively identify a recidivist or other suspect.

In the beginning of the nineteenth century, efforts in criminal identification were limited to descriptions entered in prison registers which did not contain a uniform language and were not necessarily specific enough to distinguish an inmate. Further, such records did not differentiate between individuals with the same name and had no ability to prevent the use of aliases (Cole 2001). One of the first improvements upon this system was the introduction of record-keeping technologies developed by Arnould Bonneville de Marsangy in 1844. Bonneville suggested the use of an alphabetical system to facilitate the search for inmate record and the use of index cards which could be added to and expanded without disrupting the order of the information (Cole 2001). This advance did not alleviate the problems with identifying recidivists, since criminals needed only to fabricate a false name in order to fool the system.

Other technological advances that facilitated criminal identification included photography, anthropometry, and fingerprinting. The earliest reports of photography come from British and French police in the 1840s (Cole 2001). The first picture of a convict was taken in Brussels in 1843. Police departments began to collect these photos and the Parisian police were the first to set up a picture collection of criminals in 1874 (Deflem 2002a). By the end of the nineteenth century, all major police forces had photographic identification services. The photographs themselves provided pictures to the names that convicts gave the police, but in making positive identifications it was the photograph's use in the anthropometric system that had the largest impact.

Two technologies developed around the late nineteenth century which would bring about drastic advances in the area of criminal identification. The first to be implemented was the Bertillonage, or anthropometry, a system which categorized criminals by the measurements of their bodies (Cole 2001; Deflem 2002b; Johnson 1981). The anthropometric system was developed by Alphonse Bertillon in 1870 and was adopted by the French government in the 1880s. The anthropometric system involved specific and precise measurements of the criminal body, a written description, and two photographs, one profile and one full face, which served as the predecessor to today's mug shots. Bertillon emphasized the consistency and accuracy of these measurements and descriptions, laying out a precise process by which to take measurements and developing a specific terminology by which to describe the criminal (Cole 2001). Bertillon also developed a filing system which grouped criminals by 11 key measurements grouped into three general categories: body, head, and appendages (Johnson 1981). Bertillon's final advancement was the "*portrait parlé*" or spoken portrait, which reduced the criminal's description to a language which could be easily transmitted via telegraph or telephone (Cole 2001). As a result of the anthropometric system, a criminal's identity could be confirmed, regardless of the name they presented, by matching their bodily measurements with those on file. However, this process required a trained Bertillon operator and took several man hours to make an identification since measurements often had to be taken twice in order to make a positive identification (Cole 2001). Furthermore, as the anthropometric system spread from France and was adopted by other countries, modifications to the process and instruments led to a loss in the efficacy of the system and problems in transmitting data of the *portrait parlé* to the police of other nations (Cole 2001). The anthropometric system would become dominant in most nations as it was initially regarded as more scientific than fingerprinting (Cole 2001).

Fingerprint technologies were explicitly developed to develop a classification system useful for law enforcement. In 1877, Sir William J. Herschel proposed using fingerprinting for criminal identification in India and Dr. Henry Faulds came to a similar conclusion independently in 1880 (Cole 2001; Johnson 1981). Most importantly, in 1892 Sir Francis Galton published his findings that fingerprints did not change over the course of a lifetime and that each individual's fingerprints were unique (Johnson 1981; Cole 2001). This led to the incorporation of fingerprints in addition to the anthropometric system in 1894 by Scotland Yard (Johnson 1981). At the same time, Juan Vucetich in Argentina also adopted fingerprints for criminal identification (Deflem 2002a). The United States was slower to adopt fingerprints, with St. Louis being the first to use them after a Scotland Yard official introduced the technique but it was not instituted widely nationally until the 1930s when J. Edgar Hoover made the FBI available for identifying fingerprints and training local officers (Johnson 1981). Similar to the *portrait parlé*, fingerprints were described numerically on the basis of certain specified characteristics in order to facilitate their transmission via telegraph (Deflem 2002b).

In 1899, the colonial legislature passed the Indian Evidence Act, which was the first endorsement of fingerprints as legal evidence, not only identifying criminals and recidivists, but also for finding and convicting them (Cole 2001). Originally, fingerprints were not conceived of as a forensic tool, but merely as a record-keeping system. The earliest forensic identification occurred in Europe in 1902, when Alphonse Bertillon, developer of the anthropometric system, matched a bloody fingerprint at a crime scene with a fingerprint available in a criminal file (Cole 2001). Scotland Yard began using fingerprints for forensic identification in the beginning years of the twentieth century. At the time, fingerprints in the courts were faced with the same hesitancy as DNA testing later would be. The accuracy and precision of the method had to be demonstrated to the courts in oftentimes theatrical displays until the method eventually had become more solidified (Cole 2001). By the beginning of World War II, fingerprint examiners had transformed fingerprints from a novel technique into the most credible and unassailable form of criminal identification evidence.

The anthropometric system developed by Bertillon remained dominant for several years, but eventually fingerprinting would gradually overtake this system as the primary means for identifying criminals. Fingerprinting had several advantages to the anthropometric system in that they were quicker and did not require skilled labor or specialized instruments (Cole 2001). Fingerprints were advantageous since they offered industrial-style speed, efficiency, productivity, and economy over the anthropometric system (Cole 2001). The appeal of the anthropometric system was one of quality and scientific rigor, but these arguments faded in part due to the human error involved in the measurement and description process as well as the growing confidence in fingerprints (Cole 2001). Furthermore, fingerprinting had the additional advantage that it could be used not only for criminal identification, but for forensic identification as well. Fingerprints could not only help identify a recidivist, but help convict a criminal suspect as well.

The methods of fingerprinting and anthropometry both included an organizational classification by which they could be categorized and retrieved, addressing the early problem of accessing the information that was stored. The anthropometric system was particularly time consuming in accessing its records since two measurements had to be taken in order to effectively find a single file (Cole 2001). As the police bureaucracies grew, so did their records, and efficiently finding matching records became a steadily more daunting task. By the 1930s, the FBI had amassed the largest volume of fingerprints. However, to successfully access them and compare them required other identification information, and it still required a great deal of time to go through the records (Cole 2001). As early as the 1920s, identification bureaus began turning to automated data processing technologies such as IBM punch card sorters to handle searching the large volume of records. In the 1930s, the FBI and New York State Division of Criminal Identification began using such IBM card sorters (Cole 2001). However, these methods remained technically awkward and still required human examination of the selected cards, though they did represent an advancement in the technologies of data management which would develop drastically during the digital age.

Technologies of criminal identification initially developed as a means to identify recidivists. However, in the course of their development, one of the most well-known forms of forensic identification, fingerprinting, also came to be developed. These technologies had to be revised and expanded in view of the adaptive behavior of offenders. Attempting to avoid identification because of prior convictions, offenders would give false names to avoid the harsher penalties that were given to recidivists. This development in itself was a function of the increasing size and mobility of society, moving away from the small community wherein everyone was easily recognizable. This societal mobility, as well as the newly developed forms of criminal identification, were key elements to the growing internationalization of policing which developed to confront the growing class of criminals without borders.

Technologies of International Policing

Many characteristics of society were fundamentally changed by advances in technology, and as a result, the practice and organization of policing changed as well. In order to address the changing times, the police had to adopt new technologies in order to confront the realities of crime control. Police gained a greater level of technical superiority in the course of pursuing their organizational goals as the means of crime control developed in technical respects. This increasing technical superiority was a key factor in the development of professional police bureaucracies (Deflem 2002a). As the institution of law enforcement developed as a bureaucracy, importantly, police institutions gained autonomy from the political institutions of the state. And this autonomy facilitated the international cooperation between law enforcement organizations. Autonomy from the political sphere was a necessary prerequisite for international police cooperation since otherwise political agendas would disrupt the goal of purely criminal-law enforcement. These changes in the structure of law enforcement institutions were necessary to enable international cooperation, which developed directly to address the growing connectedness across societies as a result of advances in communications and transportation technologies.

Technology was central to the development of international policing (Deflem 2002b). First, it enabled the development of autonomous and professional law enforcement agencies by contributing to the bureaucratization of law enforcement through the necessary advances in technical superiority that accompanied the adoption of new technologies. Second, advances in technology created new forms of crime and enabled the internationalization of crime since advances in transportation and communications enabled criminals to coordinate internationally as well as providing a new level of mobility between nations. The internationalization of crime provided the motivation for law enforcement agencies to collaborate with foreign counterparts, and the same technologies that enabled international criminal behavior also enabled the police to communicate and cooperate on a scale that was never before possible.

The initial efforts for international police cooperation were motivated by a period of revolutionary activity during the 1840s throughout Europe. It was widely believed by police that the internationalization of protest was aided by the technological developments since the mid-1800s (Deflem 2002b). The press and printed writings could orient public opinion and could be distributed beyond national borders. As a result, the means to publish and publications of "subversive" groups were targeted by the police of the time. Furthermore, railway lines across Europe grew exponentially from the mid to late nineteenth century, thereby drastically increasing the ability of individuals to move from one nation to the next. This development was seen by police as presenting greater opportunities for political dissidents to cooperate across national boundaries in order to overthrow the state and, later, for offenders to flee from the jurisdictions in which they had committed a crime (Deflem 2002b). These threats, made possible through the printed word and railways, motivated law enforcement agencies to pursue international cooperation.

The earliest technologies to influence international policing were those that enabled the exchange of information (Deflem 2002a, b). During the 1840s, Europe experienced a revolutionary period which led to the adoption of a political objective by the police who had not yet developed an institutional autonomy from the political sphere. This led to the creation of the Police Union of German States in April 1851 with the express purpose of sharing information to track down political radicals. The Police Union focused particularly on developing faster means of exchanging information. Union members held regular meetings and exchanged printed magazines with information on political opponents. Police bureaus of Vienna and Berlin, both members of the Union, would also print bulletins containing information on wanted suspects and extradited foreigners. In the late nineteenth century, these bulletins began to be sent across Europe. The Police Union of German States would eventually disband due to political conflicts between its member states, but later efforts to develop international police cooperation would become more successful, particularly in facilitating the spread of police technologies and the use of communication technology to exchange information.

The initial forms of information exchange among the law enforcement agencies of different nations relied on printed media that contained information and pictures of criminals and wanted suspects. This method of exchange was particularly developed among the political police in Europe, but it was also used for criminal purposes, and the distribution of published materials on criminals remained a favored means of information exchange throughout the twentieth century (Deflem 2002b). In the 1880s, the New York City Police Department would develop a collection of photographs of international criminals which it shared with European authorities. The anthropometric, or Bertillon, system and fingerprints were the most important technological innovations to the internationalization of law enforcement.

Internationally, the same technologies of communications and transportation that facilitated international crime made not only the exchange of information among police possible, but also the diffusion of new means of criminal identification. In December 1898, Italian authorities coordinated an international police meeting, the International Conference of Rome for the Social Defense against the Anarchists, in order to develop a system to combat anarchism (Deflem 2002a). Although the meeting failed to develop a system to address anarchism, it did result in enhanced cooperation among police on certain practical matters of police technology. In particular, with the exception of the authorities from France and Britain, all of the countries agreed to introduce the *portrait parlé* system that was developed for the anthropometric system for the identification of criminals. The system enabled the transmission of information on criminals among nations since the system reduced the information to a series of numbers easily transmittable by telegraph or telephone (Deflem 2002b). A synthesis of technologies therefore began to be used, the method of criminal identification, its system for communication, and the technologies of communication, in order to facilitate the exchange of information among the police departments of different nations. This focus on developing better means of exchanging information among the police of various nations has remained a constant theme in the history of international policing until this day.

Criminal identification and the means of information exchange among police agencies would also be the central theme at the First International Police Congress in Monaco in 1914 (Deflem 2002a). The meeting was ineffective in developing an organization for international police cooperation, but it did include discussions and resolutions relevant to the adoption of technology by police agencies across national boundaries. The Congress discussed ways to enhance the exchange of information among police agencies of different nations, and a resolution was passed calling for the nations in attendance to grant free use of postal, telegraphic, and telephonic means of communication in regards to international criminals (Deflem 2002b). At the meeting, also, a universal system of identification including fingerprints and photos was proposed as well as an international publication containing search warrants.

Technologies of criminal identification were particularly important for the further development of international information exchange among police. The anthropometric system developed by Bertillon had spread to several other nations, but the system was not employed universally by all agencies. Police agencies in several nations augmented the system, which produced a problem in the exchange of information since the measurements and descriptions could not be relied upon to be internationally uniform (Cole 2001). Fingerprints presented the same problem with respect to the means by which the characteristics of the print were described and which fingerprints were taken. To address this problem, a so-called Distant Identification system was introduced at the Monaco Congress as a means of harmonizing the codes of different countries (Cole 2001). In 1923, at the International Police Congress in Vienna, the system was eventually adopted.

The 1923 International Police Congress in Vienna led to the development of the International Criminal Police Commission (ICPC), the organization known today as Interpol. There is no better example of the role of technology in the development of international law enforcement than the ICPC (Deflem 2002a). The facilities and institutionalized means of information exchange had expanded since the organization's inception, and by 1934 the ICPC headquarters located in Vienna included specialized divisions on fingerprints and photographs, the falsification of currencies and other documents, and various other forms of information on suspects and convicts. The ICPC also established systems of technologically advanced means for international communication, including a telegraphic code, a system of radio communications, and printed publications in addition to meetings. In addition to a strong focus on the most efficient use of new technologies, the ICPC was primarily preoccupied with a new growing class of offenders that committed crimes that were intrinsically made possible by technological advances, such as train robberies and hotel theft. Other international police initiatives would similarly focus on the use of new technologies to carry out the function of crime control, including international conferences as well as international exchanges of information between law enforcement agencies regarding methods of policing.

Conclusion

Technology remains a central focus in the organization and practices of policing. In large part, the increasing reliance on technology by police is the product of the way society at large has changed as a result of technological advancements. Modern society has expanded and become more interconnected, producing a new context within which law enforcement must operate. In part, these changes in addition to old challenges have motivated the adoption of new technology by police. These advancements have also facilitated international cooperation among law enforcement, with technologies enhancing the institutional autonomy needed for police agencies to cooperate across national borders. These technologies include not only advances in communication and transportation methods, but also pertain to the means of criminal identification which evolved into various forms that can be communicated among police of different jurisdictions. Technological advancements have not only provided police the tools by which to engage in collaboration, they have also provided an impetus for police collaboration by influencing the internationalization of crime.

The means of communication among police regionally and internationally, the means of criminal identification, and the means of transportation have been central to the transformation of policing. These advancements began as steps towards addressing the everyday issues in policing. What was once the lone patrolman armed with a whistle and baton, walking his beat without oversight or coordination and often strongly connected with political power, has become a professional police institution that endeavors to achieve its goal of crime control efficiently. Thus developed a police that organizes patrol with automobiles and two-way radios, and that relies on identification methods using photographs and fingerprints and can share information across jurisdictions with the use of telegraphs, telephones, and mail. Changes in the means of policing have also directly addressed technologically enabled changes in society, specifically the growing societal mobility which made individuals harder to identify, the larger geographic space which made beat patrols cost prohibitive and ineffective, and the inability of the early police to coordinate their actions. Since that time, even more advancements in technology have further changed the institution of law enforcement. Undoubtedly, policing will continue to adapt to the changing circumstances that are brought about by technological advancements.

History of capital punishment

Overview

From the beginning of time, the death penalty has been enacted. However, throughout history, it has decreased more and more until today the world has the least number of people put to death for crime. This entry describes the historical development of capital punishment through the centuries and provides an account of the forms and methods used to execute convicted offenders. The entry further discusses the behaviors and crimes that led to the ultimate punishment, while presenting the controversies and legal aspects of capital punishment. Violent crimes and murder rates are also discussed in lieu of the ultimate punishment, and its potential effect on current crime rates.

Lethal injection, electric chair, firing squad, hanging, poison, drowning, drawn and quartering, immersed in boiling oil¸ stoning, crucifixion, sawing asunder, pressing, tearing apart by wild beasts, beheading – all of these and whatever more the mind could conceive have been used to impose the death penalty. As far back as the Ancient Laws of China, the death penalty was established as a punishment for crimes. In eighteenth Century BC, the Code of King Hammurabi of Babylon codified the death penalty for 25 different crimes, although murder was not one of them. The first death sentence historically recorded occurred in the sixteenth century BC Egypt where the wrongdoer, a member of nobility, was accused of magic, and ordered to take his own life. During this period, non-nobility was usually killed with an axe.

In the fourteenth century BC, the Hittite Code also prescribed the death penalty. The seventh century BC Draconian Code of Athens made death the penalty for every crime committed. In the fifth century BC, the Roman Law of the 12 Tablets codified the death penalty. Again, the death penalty was different for nobility, freemen, and slaves. Punishment was for crimes such as the publication of libels and insulting songs, the cutting or grazing of crops planted by a farmer, the burning of a house or a stack of corn near a house, cheating by a patron of his client, perjury, making disturbances at night in the city, willful murder of a freeman or a parent, or theft by a slave. Death was often cruel and included crucifixion, drowning at sea, burial alive, beating to death, and impalement (often used by Nero). The Romans had a curious punishment for parricides (murder of a parent): The condemned was submersed in water in a sack, which also contained a dog, a rooster, a viper, and an ape (Laurence 1960, pp. 1–3). The most notorious death execution in BC was – about – 399 BC when the Greek philosopher Socrates was required to drink poison for heresy and corruption of youth (Kronenwetter 1993, p. 71).

Mosaic Law codified many capital crimes. In fact, there is evidence that Jews used many different techniques including stoning, hanging, beheading, crucifixion (copied from the Romans), throwing the criminal from a rock, and sawing asunder. The most infamous execution in history occurred approximately 29 AD with the crucifixion of Jesus Christ outside Jerusalem by the Romans. About 300 years later, the Emperor Constantine, after converting to Christianity, abolished crucifixion and other cruel death penalties in the Roman Empire. In 438, the Code of Theodosius made more than 80 crimes punishable by death (Kronenwetter 1993, p. 72).

Britain influenced the colonies more than any other country and has a long history of punishment by death. About 450 BC, the death penalty was often enforced by throwing the condemned into a quagmire. By the tenth Century, hanging from gallows was the most frequent execution method. William, the Conqueror, opposed taking life except in war, and ordered no person to be hanged or executed for any offense. However, he allowed criminals to be mutilated for their crimes. During the middle ages, capital punishment was accompanied by torture. Most barons had a drowning pit as well as gallows, and they were used for major as well as minor crimes. For example, in 1279, 289 Jews were hanged for clipping coin (cutting coins into pieces for their worth). Under Edward I, two gatekeepers were killed because the city gate had not been closed in time to prevent the escape of an accused murderer. Burning was the punishment for women's high treason and men were hanged, drawn, and quartered. Beheading was generally accepted for the upper classes. One could be burned for marrying a Jew. Pressing became the penalty for those who would not confess to their crimes. The executioner placed heavy weights on the victim's chest. On the 1st day he gave the victim a small quantity of bread, on the second day a small drink of bad water, and so on until he confessed or died. Under the reign of Henry VIII, the number of those put to death is estimated as high as 72,000. Boiling to death was another penalty approved in 1531, and there are records to show some people boiled for up to 2 h before death took them. When a woman was burned, the executioner tied a rope around her neck when she was tied to the stake. When the flames reached her she could be strangled from outside the ring of fire. However, this often failed and many were literally burnt alive (Kronenwetter 1993, p. 72; Laurence 1960, pp. 4–9).

In Britain, the number of capital offenses continually increased until the 1700s when 222 crimes were punishable by death. These included stealing from a house in the amount of 40 shillings, stealing from a shop the value of five shillings, robbing a rabbit warren, cutting down a tree, disturbing the peace, and counterfeiting tax stamps. However, juries tended not to convict when the penalty was great and the crime was not. Reforms began to take place. In 1823, five laws passed, exempting about a 100 crimes from the death [penalty]. Between 1832 and 1837, many capital offenses were swept away. In 1840, there was a failed attempt to abolish all capital punishment. Through the nineteenth and twentieth centuries, more and more capital punishments were abolished, not only in Britain, but also all across Europe, until today only a few European countries retain the death penalty (Laurence 1960, pp. 9–14). Worldwide, this trend to abolish the death penalty also holds true. While in the past, the number of capital punishments was in the 1,000 each year, between 2007 and 2010, only 5,541 executions took place (excluding China where information is sparse, but it is estimated that 1,000 are still executed, in fact more than all other countries combined). The major exception today is with some Greater Middle Eastern countries. For example, during the time this entry was written, these countries had numerous executions: Iran – 1663, Saudi Arabia – 423, Iraq – 256, Pakistan – 171, Yemen – 152, Libya – 39, Afghanistan – 34, Syria – 33, Bangladesh – 28, Egypt – 12. A few other countries notable for their high execution rate during this time are: China with 1,000, United States – 220, North Korea – 105, Madagascar – 39, and Vietnam – 58 (Death Sentences & Executions 2007–2010, October 2012). It is documented that capital punishment was carried out in 23 countries in 2010 and only 20 countries in 2011. It is estimated that executions increased from 527 in 2010 to at least 676 executions in 2011. This increase was mainly due to significant increases in judicial killings in the three large Middle Eastern countries of Iran, Iraq, and Saudi Arabia (Death Sentences and Executions 2011, October 2012). The trend is clear. In 1977, only 16 countries had abolished the death penalty. By 2012, 141 countries had abolished by practice or by law (Death Penalty Trends, March 2012).

The first recorded execution in the English American colonies was in 1608 when officials executed George Kendall of Virginia for supposedly plotting to betray the British to the Spanish. In 1612, Virginia's governor, Sir Thomas Dale, implemented the Divine, Moral, and Martial Laws that made death the penalty for even minor offenses such as stealing grapes, killing chickens, killing dogs or horses without permission, or trading with Indians. Seven years later, these laws were softened because Virginia feared that no one would settle there (Kronenwetter 1993, pp. 72–73).

In 1622, the first legal execution of a criminal, Daniel Frank, occurred in Virginia for the crime of theft (Bedau 1982, p. 5). Some colonies were very strict in their use of the death penalty, while others were less so. In Massachusetts Bay Colony, the first execution was in 1630, but the earliest capital statutes do not occur until later. Under the Capital Laws of New-England that went into effect between 1636 and 1647, the death penalty was meted out for premeditated murder, sodomy, witchcraft, adultery, idolatry, blasphemy, assault in anger, rape, statutory rape, manstealing, perjury in a capital trial, rebellion, manslaughter, poisoning, and bestiality. Early laws were accompanied by a scripture from the Old Testament. By 1780, the

Commonwealth of Massachusetts only recognized seven capital crimes: murder, sodomy, burglary, buggery, arson, rape, and treason (Bedau 1982, p. 7).

The New York colony instituted the so-called Duke's Laws of 1665. This directed the death penalty for denial of the true God, premeditated murder, killing someone who had no weapon of defense, killing by lying in wait or by poisoning, sodomy, buggery, kidnapping, perjury in a capital trial, traitorous denial of the king's rights or raising arms to resist his authority, conspiracy to invade towns or forts in the colony, and striking one's mother or father (upon complaint of both). The two colonies that were more lenient concerning capital punishment were South Jersey and Pennsylvania. South Jersey had no death penalty except for murder and treason, both punishable by death (Mackey 1976 pp. xi–xii).

Under the direction of the Crown, all the colonies included the death penalty for major crimes, especially treason and premeditated murder, but William Penn's Great Act (1682) changed this in Pennsylvania and made the penalty imprisonment. By 1776, most of the colonies had roughly comparable death statutes which covered arson, piracy, treason, murder, sodomy, burglary, robbery, rape, horse-stealing, slave rebellion, and often counterfeiting. Hanging was the usual sentence. Rhode Island was probably the only colony which decreased the number of capital crimes in the late 1700s.

Some states were more severe. For example, by 1837, North Carolina required death for the crimes of murder, rape, statutory rape, slave-stealing, stealing bank notes, highway robbery, burglary, arson, castration, buggery, sodomy, bestiality, dueling where death occurs, hiding a slave with intent to free him, taking a free Negro out of state to sell him, bigamy, inciting slaves to rebel, circulating seditious literature among slaves, accessory to murder, robbery, burglary, arson, or mayhem and others. However, North Carolina did not have a state penitentiary and, many said, no suitable alternative to capital punishment (Bedau 1982, p. 7).

The first reforms of the death penalty occurred between 1776 and 1800. Thomas Jefferson and four others, authorized to undertake a complete revision of Virginia's laws, proposed a law that recommended the death penalty for only treason and murder. After a stormy debate, the legislature defeated the bill by one vote. The writing of European theorists such as Montesquieu, Voltaire, and Bentham had a great effect on American intellectuals, as did English Quaker prison reformers John Bellers and John Howard (Mackey 1976, pp. 7–8).

On Crimes and Punishment, published in English in 1767 by the Italian jurist Cesare Beccaria, whose exposition on abolishing capital punishment was the most influential of the time, had an especially strong impact. He theorized that there was no justification for the taking of life by the state. He said that the death penalty was "a war of a whole nation against a citizen, whose destruction they consider as necessary, or useful to the general good." He asked the question what if it can be shown not to be necessary or useful? His essay conceded that the only time a death was necessary was when only one's death could insure the security of a nation – which would be rare and only in cases of absolute anarchy or when a nation was on the verge of losing its liberty. He said that the history of using punishment by death (e.g., the Romans, 20 years of Czaress Elizabeth) had not prevented determined men from injuring society and that death was only a "momentary spectacle, and therefore a less efficacious method of deterring others, than the continued example of a man deprived of his liberty...." (Beccaria 1963).

Organizations were formed in different colonies for the abolition of the death penalty and to relieve poor prison conditions. Dr. Benjamin Rush, a renowned Philadelphia citizen, proposed the complete abolition of capital punishment. William Bradford, Attorney General of Pennsylvania, was ordered to investigate capital punishment. In 1793, he published *An Enquiry How Far the Punishment of Death is Necessary in Pennsylvania*. He strongly insisted that the death penalty be retained, but admitted it was useless in preventing certain crimes. In fact, he said the death penalty made convictions harder to obtain, because in Pennsylvania, and indeed in all states, the death penalty was mandatory and juries would often not return a guilty verdict because of this fact. In response, in 1794, the Pennsylvania legislature abolished capital punishment for all crimes except murder "in the first degree," the first time murder had been broken down into "degrees." In New York, in 1796, the legislature authorized construction of the state's first penitentiary, abolished whipping, and reduced the number of capital offenses from 13 to 2. Virginia and Kentucky passed similar reform bills. Four more states reduced its capital crimes: Vermont in 1797, to three; Maryland in 1810, to four; New Hampshire in 1812, to two; and Ohio in 1815, to two. Each of these states built state penitentiaries. A few states went in the opposite direction. Rhode Island restored the death penalty for rape and arson; Massachusetts, New Jersey, and Connecticut raised death crimes from six to ten, including sodomy, maiming, robbery, and forgery. Many southern states made more crimes capital, especially for slaves (Mackey 1976, pp. xvi–xvii).

The years 1833–1853 saw the next great reform era. Public executions were attacked as cruel. Sometimes tens of thousands of eager viewers would show up to view hangings; local merchants would sell souvenirs and alcohol. Fighting and pushing would often break out as people jockeyed for the best view of the hanging or the corpse! Onlookers often cursed the widow or the victim and would try to tear down the scaffold or the rope for keepsakes. Violence and drunkenness often ruled towns far into the night after "justice had been served." Many states enacted laws providing private hangings. Rhode Island (1833), Pennsylvania (1834), New York (1835), Massachusetts (1835), and New Jersey (1835), all abolished public hangings. By 1849, 15 states were holding private hangings. This move was opposed by many death penalty abolitionists who thought public executions would eventually cause people to cry out against execution itself. For example, in 1835, Maine enacted what was in effect a moratorium on capital punishment after over 10,000 people who watched a hanging had to be restrained by police after they became unruly and began fighting. All felons sentenced to death would have to remain in prison at hard labor and could not be executed until 1 year had elapsed and then only on the governor's order. No governor ordered an execution under the "Maine Law" for 27 years. Though many states argued the merits of the death penalty, no state went as far as Maine. The most influential reformers were the clergy. Ironically, the small but powerful group which opposed the abolitionists were also clergy. They were, almost to a person, members of the Calvinist clergy, especially the Congregationalists and Presbyterians who could be called the religious establishment of the time. They were led by George Cheever (Mackey 1976, pp. xix–xxv).

Finally, in 1846, Michigan became the first state to abolish the death penalty (except for treason against the state), mostly because it had no long tradition of capital punishment (there had been no hanging since 1830, before statehood) and because frontier Michigan had few established religious groups to oppose it as was the case in the east. In 1852, Rhode Island abolished the death penalty led by Unitarians, Universalists, and especially Quakers. In the same year, Massachusetts limited its death penalty to first-degree murder. In 1853, Wisconsin abolished the death penalty after a gruesome execution in which the victim struggled for 5 min at the end of the rope, and a full 18 min passed before his heart finally quit (Mackey 1976, pp. xvii–xviii).

During the last half of the century, the death penalty abolition movement was cut in half with many of its followers moving into the slavery abolition movement. At the same time, states began to pass laws against mandatory death sentences. Legislators in 18 states shifted from mandatory to discretionary capital punishment by 1895, not to save lives, but to try to increase convictions and executions of murderers. Still, abolitionists gained a few victories. Maine abolished the death penalty, restored it, and then abolished it again between 1876 and 1887. Iowa abolished the death penalty for 6 years. Kansas passed the "Maine Law" in 1872 which operated as de facto abolition (Mackey 1976, pp. xxx–xxxi).

Electrocution as a method of execution came onto the scene in an unlikely manner. Edison Company with its DC (Direct Current) electrical systems began attacking Westinghouse Company and its AC (Alternating Current) electrical systems as they were pressing for nationwide electrification with alternating current. To show how dangerous AC could be, Edison Company began public demonstrations by electrocuting animals. People reasoned that if electricity could kill animals, it could kill people. In 1888, New York approved the dismantling of its gallows and the building of the nation's first electric chair. It held its first victim, William Kemmler, in 1890, and even though the first electrocution was clumsy at best, other states soon followed the lead (Mackey 1976, p. 15).

The Second Great Reform era was 1895–1917. In 1897, US Congress passed a bill reducing the number of federal death crimes. In 1907, Kansas took the "Maine Law" a step further and abolished all death penalties. Between 1911 and 1917, eight more states abolished capital punishment (Minnesota, North Dakota, South Dakota, Oregon, Arizona, Missouri, and Tennessee – the latter in all cases but rape). Votes in other states came close to ending the death penalty.

However, between 1917 and 1955, the death penalty abolition movement again slowed. Washington, Arizona, and Oregon in 1919–1920 reinstated the death penalty. In 1924, the first execution by cyanide gas took place in Nevada, when Tong war gang murderer Gee Jon became its first victim. The state wanted to secretly pump cyanide gas into Jon's cell at night while he was asleep as a more humanitarian way of carrying out the penalty, but, technical difficulties prohibited this and a special "gas chamber" was hastily built. Other concerns developed when less "civilized" methods of execution failed. In 1930, Mrs. Eva Dugan became the first female to be executed by Arizona. The execution was botched when the hangman misjudged the drop and Mrs. Dugan's head was ripped from her body. More states converted to electric chairs and gas chambers. During this period of time, abolitionist organizations sprang up all across the country, but they had little effect. There were a number of stormy protests against the execution of certain convicted felons (e.g., Julius and Ethel Rosenberg), but little opposition against the death penalty itself. In fact, during the anti-Communist period with all its fears and hysteria, Texas Governor Allan Shivers seriously suggested that capital punishment be the penalty for membership in the Communist Party (Mackey 1976, pp. xxxii–xxxiv, xli). The movement against capital punishment revived again between 1955 and 1972.

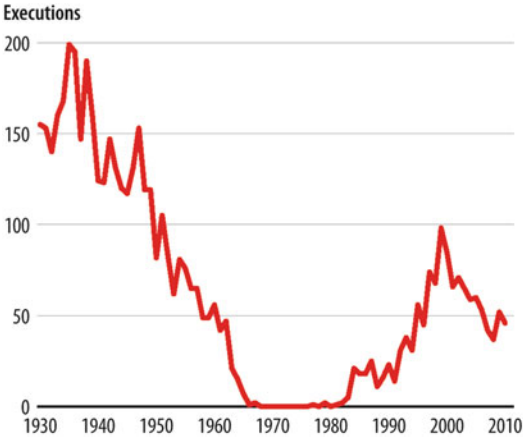
England and Canada completed exhaustive studies which were largely critical of the death penalty and these were widely circulated in the United States. Death row criminals gave their own moving accounts of capital punishment in books and film. Convicted kidnapper Caryl Chessman published *Cell 2455 Death Row* and *Trial by Ordeal*. Barbara Graham's story was utilized in book and film with *I Want to Live!* after her execution. Tim Robbins' produced and directed the movie *Dead Man Walking* based on Sister Helen Prejean's book about Matthew Poncelet, a prisoner in Louisiana State Prison. This Catholic nun became one of the leading proponents for the abolition of the capital punishment. Not only movies, but television shows were broadcast on the death penalty.

Hawaii and Alaska ended capital punishment in 1957, and Delaware did so the next year. Controversy over the death penalty gripped the nation, forcing politicians to take sides. Delaware restored the death penalty in 1961. Michigan abolished capital punishment for treason in 1963. Voters in 1964 abolished the death penalty in Oregon. In 1965 Iowa, New York, West Virginia, and Vermont ended the death penalty. New Mexico abolished the death penalty in 1969 (Mackey 1976, pp. xlvii–xlix). Some states reestablished capital punishment and some states

History of the Death Penalty, Fig. 1 Death row

abolished it. Some reestablished it and then abolished it again. Today, 33 states have the death penalty and 17 do not (2 of these, Connecticut & New Mexico, have outlawed the death penalty, but only for new convictions and still have people on death row). In the last 5 years, five states have outlawed capital punishment Fig. 1.

Trying to end capital punishment state-by-state was difficult at best, so death penalty abolitionists turned much of their efforts to the courts. They finally succeeded on June 29, 1972, in the case *Furman v. Georgia*. In nine separate opinions, but with a majority of 5–4, the US Supreme Court ruled that the way capital punishment laws were written, including discriminatory sentencing guidelines, capital punishment was cruel and unusual and violated the Eighth and Fourteenth Amendments. This effectively ended capital punishment in the United States. Advocates of capital punishment began proposing new capital statutes which they believed would end discrimination in capital sentencing, therefore satisfying a majority of the Court. By early 1975, 30 states had again passed death penalty laws and nearly 200 prisoners were on death row. In *Gregg v. Georgia* (1976), the Supreme Court upheld Georgia's newly passed death penalty and said that the death penalty was not always cruel and unusual punishment. Death row executions could again begin. Another form of execution was soon found. Oklahoma passed the first death by lethal injection law, based on economics as much as humanitarian reasons. The old electric chair that had not been used in 11 years would require expensive repairs. Estimates of over $200,000 were given to build a gas chamber, while lethal injection would cost no more than 10–15 dollars "per event" (Bedau, 1982, p. 17). Since 1976, there have been 1,131 lethal injections (35 states plus the US government use lethal injection), 157 electrocutions [last in 2010], 11 in gas chambers [last in 1999], 3 by hanging [last in 1996], and 3 by firing squad [last in 2010]) (Facts about the Death Penalty, September 2012) Fig. 2.



History of the Death Penalty, Fig. 2 Number of persons executed in the United States during 1930–2010. (Source: BJS, National Prisoner Statistics Program)

In 2011, all state executions were carried out by lethal injection. Today, the United States government lists 41 offenses punishable by death. They include espionage, treason, and death resulting from aircraft hijacking. However, they mostly comprise various forms of murder such as murders: related to the smuggling of aliens, committed during a drug-related drive-by shooting, during a civil rights offense, of a Congressperson or Supreme Court Justice, during a hostage taking, by use of a weapon of mass destruction, retaliating against an immediate family member of a law enforcement official, etc. (41 Federal Capital Offenses, October 2012).

According to Bureau of Justice Statistics, "Homicide Trends" (issued in 2011) murder rates recently declined to levels last found in the 1960s. In the late 1960–2000, the rate trended upward. It doubled from the 1960s to the late 1970s. In 1980, it peaked at 10.2 and fell to 7.9 in 1985. It rose again in the late 1980s and early 1990s to another peak of 9.8 in 1991 (FBI Uniform Crime Report 1992, October 2012). In late 1990s, it began to trend down. By 2000, it was 5.5 and by 2010 it was 4.8 (Homicide Trends in the U.S., November 2011, October 2012).

The controversy over the death penalty continues today. During the 1990s, there was a strong movement against lawlessness propelled by citizens' fears for their security. Politicians at the national and state levels were taking the floor of legislatures and calling for more frequent death penalties, death penalties for more crimes, and longer prison sentences. But, correlating with the drop of homicides, the annual death sentences in the United States have dropped dramatically since the year 2000. In the last 4 years, the number of death sentences has been lower than any time since reinstatement of the death penalty in 1976. Executions have declined as well, from a high of 98 in 1999 to just 37 in 2008; there were 46 executions in 2010, and 43 executions in 2011.

The battle lines are still drawn and the combat will probably always be fought. The arguments range from morality, to deterrence, to economics, to socioeconomic level to attorney ability. More than half of Americans today look toward alternative consequences for homicide rather than use the death penalty. However, this could change, especially if the homicide rate goes up. The death penalty seems positively correlated to this rate.

A number of important capital punishment decisions have been made by the Supreme Court. The following is a list of the more important ones along with their legal citations:

Wilkerson v. Utah 99 U.S. 130 (1878) – Court upheld execution by firing squad, but said that other types of torture such as "drawing and quartering, emboweling alive, beheading, public dissection, and burring alive and all other in the same line of. . .cruelty, are forbidden."

Weems v. U.S. 217 U.S. 349 (1910) – Court held that what constitutes cruel and unusual punishment had not been decided, but that it should not be confined to the "forms of evil" that framers of the Bill of Rights had experienced. Therefore, "cruel and unusual" definitions are subject to changing interpretations.

Louisiana ex rel. Francis v. Resweber 329 U.S. 459 (1947) – On May 3, 1946, convicted 17-year-old felon Willie Francis was placed in the electric chair and the switch was thrown. Due to faulty equipment, he survived (even though he was severely shocked). He was removed from the chair and returned to his cell. A new death warrant was issued 6 days later. The Court ruled 5–4 that it was not "cruel and unusual" to finish carrying out the sentence since the state acted in good faith in the first attempt. "The cruelty against which the Constitution protects a convicted man is cruelty inherent in the method of punishment," said the Court, "not the necessary suffering involved in any method employed to extinguish life humanely." He was then executed.

Tropp v. Dulles 356 U.S. 86 (1958) – The Court Ruled that punishment would be considered "cruel and unusual" if it was one of "tormenting severity," cruel in its excessiveness or unusual in punishment "must draw its meaning from the evolving standards of decency that mark the progress of a maturing society."

Furman v. Georgia 408 U.S. 238 (1972) – The Court looking at three cases struck down the death penalty in many states and set up the standard that punishment would be considered "cruel and unusual" if any of the following were present: (1) it was too severe for the crime; (2) it was arbitrary (some get the punishment and others do not, without guidelines); (3) it offends society's sense of justice; (4) it was not more effective than a less severe penalty.

Gregg v. Georgia 428 U.S. 153 (1976) – [The] Court upheld Georgia's newly passed death penalty and said that the death penalty was not always cruel and unusual punishment.

Tison v. Arizona 481 U.S. 137 (1987) – [The] Court upheld Arizona's death penalty for major participation in a felony with "reckless indifference to human life."

Thompson v. Oklahoma 108 S. Ct. 2687 (1987) – The Court considered the question of execution of minors under the age of 16 at the time of the murder. The victim was Thompson's brother-in-law, whom he accused of beating his sister. Thompson and three others beat the victim; shot him twice; cut his throat, chest, and abdomen; chained him to a concrete block; and threw the body into a river where it remained for 4 weeks. Each of the four participants was tried separately and all were sentenced to death. In a 5–3 decision, four Justices ruled that Thompson's death sentence violated the Eighth Amendment's prohibition of cruel and unusual punishment. The fifth, O'Connor, concurred but noted that a state must set a minimum age and held out the possibility that if a state lowers, by statute, the minimum death penalty age below 16, she might support it. She stated, "Although, I believe that a national consensus forbidding the execution of any person for a crime committed before the age of 16 very likely does exist, I am reluctant to adopt this conclusion as a matter of constitutional law without better evidence that [sic] we now possess." States with no minimum age have rushed to specify a statute age.

Penry v. Lynaugh 492 U.S. 302 (1989) – The Court held that persons considered retarded, but legally sane, could receive the death penalty. It was not cruel and unusual punishment under the Eighth Amendment if jurors were given the opportunity to consider mitigating circumstances. In this case, the defendant had the mental age of approximately a 6-year-old child.

Atkins v. Virginia 536 U.S. 304 (2002) The Court held in that it is a violation of the 8th Amendment's prohibition of cruel and unusual punishment to execute defendants with mental retardation.

Roper v. Simmons 543 U.S. 551 (2005) The Court struck down executions of juveniles on the basis of 14th Amendment due process and 8th Amendment cruel & unusual punishment, overturning previous decisions allowing death penalty for minors.

Overview

The series of Crime Victim Surveys started in the early 1970s in the Netherlands. Changing policy needs, stakeholders, and available interview modes have repeatedly led to important adjustments in the methodology, compromising comparisons of results over the years. Nevertheless, interesting trends spanning four decades can be constructed for some crime types. In this entry, an overview is given of the eight subsequent versions of the Dutch Victim Survey and their main characteristics. Next, longtime trends are presented for victimizations by burglary, bicycle theft, violent crime, and total crime. Trends in feelings of unsafety are shown from the early 1990s onwards.

Introduction

Already in the early 1970s, the need for a survey to measure crime by asking the general population about their experiences instead of relying on police records only was felt in the Netherlands. In 1973, the Ministry of Justice funded a pilot study by Jan Fiselier who experimented with different interview modes and different wordings of key questions (Fiselier 1978). In 1974, the Ministry commissioned the first round of what would develop into an annual victimization survey (van Dijk and Steinmetz 1980). The results were initially published in the statistical paragraph of the annual report of the Dutch Prosecution Service as a complement to statistics of recorded crime. The Dutch victimization survey has, as most other similar surveys, undergone many changes in its organizational setup and methodology (questionnaire, sampling, sample size, interview modes). Even the name of the survey has changed no less than seven times over the years, the current name being the “Veiligheidsmonitor” (Security Survey). During several years, two or more different surveys were conducted parallel to each other. The Netherlands has also participated in all rounds of the International Crime Victim Surveys (ICVS).

The many transformations which the Dutch survey has undergone can be explained by three main factors. The most important reason for changing the existing survey was that leading government agencies continued to formulate new information needs related to their topical policy agendas. For instance, in the Netherlands, the interest shifted from just measuring the trends in real crime to monitoring perceptions of the public regarding safety issues and the performance of the police. From the early years of the surveys, questionnaires included sets of questions on varying themes such as the use of crime prevention measures and victim needs. An important driver of adjustments in the survey’s methodology in the 1990s was the emerging need to monitor crime trends, safety perceptions, and police performances in all 25 police districts in the country. This new policy objective required much larger sampling sizes, sometimes of up to 200,000 households, with obvious costs implications having an impact on the choice of interview techniques.

The second factor driving the changes was the involvement in the survey or surveys of three different national government agencies: the Ministry of Justice, the Ministry of the Interior and Statistics Netherlands (CBS), and a changing coalition of the larger cities. All these agencies acted at times as co-funders of the survey with a stake in its contents and costs.

The third reason for the changes in the Dutch survey is common to all survey research, namely, the ever-changing nature of possibilities, costs, and benefits of various modes of data collection. As known, state-of-the-art modes of drawing samples and modes of interviewing have limited time spans. A telling example is the rise and decline of computer-assisted telephone interviewing. This technique offered a window of opportunity when fixed telephone penetration surpassed 70 % around 1985 in many Western countries, including the Netherlands, but has run into severe problems 20 years later due to the rise of mobile phones. The Dutch survey has since 1973 moved from postal questionnaires, piloted by Fiselier, to face-to-face interviewing, computer-assisted telephone interviewing, and finally mixed-mode interviewing, comprising web-based interviewing, postal questionnaires, and telephone interviewing.

Obviously, these changes in content and methodology, unavoidable as they may have been for either policy or technical reasons, have compromised the comparability of the results over time. It is well established that even minor changes in any aspect of the methodology can have a serious impact on the results (Van Dijk et al. 2010). In recognition of the known sensitivity of the survey to even minor changes, efforts have consistently been made to monitor such effects and to correct results for them. To support such analyses, existing surveys have sometimes solely for this purpose been repeated with smaller samples simultaneously with a newly designed survey.

Next to the victimization surveys among citizens, several business surveys have been conducted over the years, starting in 1977 with a limited retail business survey on shoplifting by Statistics Netherlands. In 2004, a standardized business survey was launched with has been repeated regularly since (MCB: Monitor of Crime in the Business Sector, *Monitor Criminaliteit Bedrijfsleven*). In this survey, information is collected on the victimization of businesses by burglary, theft, bribe taking, destruction of property, and violent crimes.

Characteristics and Methodology of the Surveys

Table 1 presents an overview of all Dutch surveys and the ICVS with their main characteristics, such as period covered, key organizing agency, mode of data collection, and sample size. Except for the two business surveys just mentioned, all surveys relate to victimization of individuals or households. To explain the characteristic of the surveys in more detail, a short description of each of the Dutch surveys is given in a commentary to the table.

Table 1 shows that there has been a distinct shift away from expensive personal, face-to-face interviewing towards the cheaper mode of telephone interviewing. In recent years, a shift has been made to the even cheaper mode of collecting data via self-completed Internet questionnaires. Another development is the incremental growth of the sample size, resulting from the policy need to monitor the performance of regional or local police units. Not reflected in the table is the changing content of the questionnaires with increasing numbers of items on police performance and perceptions of safety.

WODC Victim Survey (1973–1980)

The WODC Victim Survey (*WODC Slachtofferenquête*) was the first regular victim survey in the Netherlands. It was a direct answer to the political need to measure the real extent and trends of crime independent from police administrations of recorded crime in a period of rising concerns about crime.

The WODC surveys were carried out by a commercial polling company, NIPO, associated with Gallup/USA. Samples were drawn from a list of addresses maintained by the agency responsible for collecting radio and television license fees. There was some oversampling for the four largest cities in the Netherlands which allowed for the publication of city rates. A personal interview with a paper questionnaire was held with one person per household in the sample, older than 16 (or for the surveys before 1978, 18 years or older). The net sample varied somewhat but increased to 6,000 in 1980, with a response rate of 42 %. Victimization in the last calendar year was asked for (the interviews were all held in the first months of the following year).

Different crime types were asked for, mainly property crimes like burglary, bicycle or moped theft, and theft from cars. Starting in 1975,

History of the Dutch Crime Victimization Survey(s), Table 1 The Dutch crime victimization surveys

Survey name	Period (reporting years)	Responsible organization(s)[a]	Modes	Net sample size
Persons/household surveys				
WODC Victim Survey	1973–1980; yearly	MoJ[b]	Personal interview	6,000
ESM	1980–1984; yearly 1986–1992; every second year	CBS	Personal interview	5,000–10,000
ERV	1992–1996; yearly	CBS	Personal interview	5,000
PMB	1992–1998; every second year 2000–2004; yearly	MoJ, MoIA	Telephone interview	25,000–75,000
POLS	1997–2004; yearly	CBS	Personal interview	5,000–10,000
VMR	2004–2010; yearly	MoJ, MoIA, CBS	Mainly telephone interview; some personal interviews	5,000 (2004) 20,000 (2005–2007) 6,000 (2008–2010)
IVM	2008–2011; yearly	MoJ, MoIA, CBS, local police, city councils	Both Internet questionnaire and telephone interview; some personal interviews	About 40,000–220,000
VM	2012 onwards; yearly	MSJ, CBS, local police, city councils	Mainly Internet questionnaire	At least 90,000
Business surveys				
Shoplifting statistics (retail business)	1977–1983	CBS	Paper and pencil questionnaire	300–400 (1977–1981) 3,000 (1982–1983)
MCB	2004 onwards; yearly	MoJ, MoIA	Telephone interview	30,000–38,000
International surveys				
ICVS	1988–2005, irregular	MOJ	Telephone interview	2,000

[a] *MoJ* Ministry of Justice, *MoIA* Ministry of Interior Affairs, *CBS* Statistics Netherland, *MSJ* Ministry of Safety and Justice

[b] The research department of the Ministry of Justice WODC was responsible for this survey

questions on some violent crimes and vandalism were added as well. Also follow-up questions to identified victims concerning reporting behavior were always part of the questionnaire (including reasons for not reporting) and some other information on the crime such as damages, injuries, and weapon use. Questions on the use of prevention measures and some background characteristics of the respondent were also included. Feelings of safety were not covered by this survey.

ESM (1980–1992)

In 1980, it was decided that a regular victim survey should become a part of the program of Statistics Netherlands, responsible for providing statistics. This was the start of the ESM (Crime Victim Survey, *Enquête Slachtoffers Misdrijven*) which was conducted yearly in the period 1981–1985 and thereafter every second year.

The sampling method changed somewhat over the years. In the first years, it was primarily a person-based sample (persons older than 15), but for some cities, an address-based sample was taken. After 1982, the sample was completely taken from an address register. Data were collected with personal interviews using a paper questionnaire. The net sample was about 10,000 (1980–1986); this was reduced to about 5,000 in the last three surveys for reasons of costs (1988, 1990, 1992). As with the WODC Victim Survey, victimization in the last calendar year was asked for (the interviews were held in the first months of the following year).

The questionnaire was very similar to the WODC Victim Survey, covering the same types of crime and other subjects. Also, questions on neighborhood characteristics, prevention behavior, going out, and safety feelings were asked in the ESM. Nevertheless, when comparing the results of the WODC Victim Survey and the ESM, clear differences surfaced compromising any straightforward analysis of the longer time trends.

ERV (1992–1996)

In 1992, Statistics Netherlands decided to cut costs by integrating the victim survey in their ongoing program of population surveys. This, together with some technical improvements, led to considerable changes in the survey's design, resulting into a really new survey, the ERV (Justice and Security Survey, *Enquête Rechtsbescherming en Veiligheid*) which was held yearly in the period 1992–1996.

As with the ESM, the sample was based on an address register. If possible, two persons (15 years or older) living at the same address were interviewed, again through a personal interview. The results were directly introduced in a computer. The net sample was about 5,000 persons from about 3,500 households. The survey was held continuously over the year, and victimization in the preceding 12 months was asked for.

Although many crime types asked for in the survey were the same as in the ESM (burglary, bicycle theft, theft from a car, etc.), particularly the questions on violent crimes were changed. Some new questions on feelings of (un)safety were introduced.

PMB (1992–2004)

In 1992, another survey was started parallel to the ESM/ERV surveys of Statistics Netherlands: the PMB (Police Monitor Public, *Politiemonitor Bevolking*). At that time, a reorganization took place within the Dutch police, abolishing both the existing national state police and the many municipal police forces. Instead, the Netherlands was divided into 25 police regions with their own forces. Both the Ministry of Justice and the Ministry of Interior Affairs felt that information on victimization, safety feelings, and public opinion on the police was needed at the level of police regions. This was not possible with the limited sample sizes of the surveys from Statistics Netherlands. In addition, the questionnaire was judged to be insufficiently tailored to the policy and planning needs of both ministries, jointly responsible for policing. For this reason, a new survey was started. The PMB was held in the period 1992–2004, first every second year and after 2000 each year.

Samples were taken from a fixed-line telephone directory. Net response was at least 1,000 respondents for each of the 25 police regions. Individual police regions had the opportunity to buy in with additional samples in order to obtain information on an even lower level than the region (city or even district or neighborhood level). This resulted in a net sample varying from 25,000 (in 2002) to 90,000 (in 2003). Apart from 2002, the net sample was always at least 50,000. Interviewing was done by telephone. Fieldwork was done in the first months of the year, and victimization in the previous calendar year was asked for.

The questionnaire was not too different from the Statistics Netherlands questionnaire regarding victimization. More or less the same types of crime were covered. However, more emphasis was laid on vehicle-related crimes for all household members. Apart from victimization, a large part of the questionnaire was devoted to safety feelings, preventive measures, and opinions on police performance. The results were not easily comparable with the other surveys. One of the main reasons was that victimization rates of vehicle-related crime were not relative to the population but – for example, in the case of bicycle theft – relative to the bicycle owners. Another reason was the different interview mode (telephone vs. face-to-face interviews).

POLS (1997–2004)

In 1997, the ERV survey from Statistics Netherlands was fully incorporated in a more general survey, the POLS (permanent survey on living conditions, *Permanent Onderzoek Leef Situatie*). The POLS survey was a large modular survey with modules on different aspects of social living conditions. Victimization and feelings of safety were asked in one or more modules within this survey.

For the whole survey, a sample was taken from the general Dutch persons register (GBA, *Gemeentelijke Basisadministratie*) consisting of all persons living in the Netherlands (so not necessarily restricted to the Dutch nationality). The net response for the whole survey was 50,000 but only 10,000 for the modules including victimization and 5,000 for the module including more detailed questions on safety feelings. As with the ERV, the survey was held continuously, through personal interviews. Respondents were asked about victimization in the preceding 12 months.

The questionnaire was identical to the ERV questionnaire, with some minor changes introduced in 1999. Because only the sampling method was different, the results were more or less comparable to those of the ERV.

VMR (2004–2010)

Due to budget cuts, Statistics Netherlands – although realizing that informing the general public on safety issues was one of their responsibilities – could no longer maintain an expensive large survey based on personal interviewing. At the same time, both the Ministry of Justice and the Ministry of the Interior relied more and more on the results of these surveys (POLS and PMB) for the purpose of planning and evaluation. Another relevant factor was that many cities, most notably Rotterdam, had started to launch their own “safety monitors”, monitoring safety issues and living conditions at a local level. Driven by economical needs, both ministries and Statistics Netherlands decided to launch a joint national and police regional survey (the VeiligheidsMonitor Rijk), with the option to expand into a survey catering to local information needs as well.

As with the POLS survey, sampling was based on a person’s register (GBA). For the majority of persons thus selected, a phone number (fixed or mobile) could be found, and interviewing was done by telephone. The persons with no known telephone number were interviewed personally at home. The net response in 2004 was 5,000 (basically this was a pilot survey for comparison with both the PMB and POLS), about 20,000 in 2005–2007, and about 6,000 in later years (again mainly to compare the VMR with the subsequent survey). Like the PMB (but different from POLS), fieldwork was done in the first months of the year, and victimization in the previous calendar year was asked for.

The questionnaire was redesigned, but crime types asked for and other information were not too different from POLS and PMB. However, the changes in the questionnaire and in particular the other methodological changes caused a considerable break in the series.

IVM (2008–2011)

As was already foreseen at the start of the VMR, steps were made to fully integrate the VMR with the running local safety monitors. Both for financial reasons and to have uniform national and local safety indicators, the methodology of all surveys was standardized. The resulting IVM (Integrated Safety Monitor, *Integrale Veiligheidsmonitor*) started in 2008 as a joint venture between the Ministry of Justice, the Ministry of Interior Affairs, Statistics Netherlands, local police organizations, and city councils. The IVM was held every year until 2011.

The organization and the methodology of the IVM survey are rather complicated. The basic idea is that there is a nationwide sample resulting in a net response of at least 18,750 (i.e., at least 750 respondents in each of the 25 police regions) each year. The fieldwork for this sample is carried out by Statistics Netherlands. Besides, all local parties can add their local samples employing local polling companies. In practice, this resulted in total net samples of between 40,000 (2010) and 220,000 (2011). Sampling itself is done centrally, by Statistics Netherlands, in the same way as with the VMR (through the GBA). The persons in the sample are approached with a letter and are invited to fill in the questionnaire either through the Internet or on paper. Remaining nonrespondents are approached again and if possible interviewed by telephone (as in the VMR for most persons in the sample, a telephone number is known). If a telephone number is not found, respondents can, as a final resort, be interviewed personally at home, but this has rarely happened. The fieldwork takes place in the period September–December; victimization in the previous 12 months is asked about. To ensure uniformity in the methodology – in particular, the fieldwork – the IVM is coordinated by a central agency.

The questionnaire had to be adjusted considerably to serve the needs of all parties involved. To improve comparability of national and local data, the IVM questionnaire had a standardized modular design with some obligatory modules (such as the victimization module) and some optional modules (as on police contacts and attitudes towards the police). To improve comparability, the order in which the modules were placed was fixed; in particular, all obligatory modules were positioned at the beginning of the questionnaire. In the national and police regional samples, all modules were asked; local participants were free to add one or more optional modules (in the prescribed order) or not or to add some additional "free questions" at the end of the questionnaire. In the 3 years, 2008–2010 the VMR was held parallel to the IVM in order to analyze the differences between both surveys and repair the breaks in the series.

VM (2012 Onwards)

In the 4 years, during which the IVM was conducted, two problems became apparent. Firstly, the IVM is a relatively expensive survey because of the large number of interviews by telephone. And secondly, the large variation in the sample sizes caused methodological problems because the proportion of different interview modes differed over the years. Weighting of the results could not fully compensate for these differences as became evident from comparisons with the results of the VMR. Therefore, the decision was taken to redesign the survey in order to correct and stabilize its results: the VM (Safety Monitor, Veiligheids Monitor).

To prepare for the new design, a large-scale experiment was conducted with random assignment of respondents to four different modes (web, telephone, face-to-face, and paper). The experiment aimed to disentangle mode-specific selection and measurement bias in the crime survey (Buelens et al. 2012). The results will be used to improve a future mixed-mode approach. Although details are still under discussion, the central idea of the VM is that there will be a large net sample size (about 90,000), almost exclusively using web-based self-completion. Fieldwork is partly done by Statistics Netherlands and partly by one selected commercial company. To reduce costs further, the questionnaire is made somewhat shorter, although more or less the same crimes are asked for in the victimization module as before. This VM will be implemented in the fall of 2012.

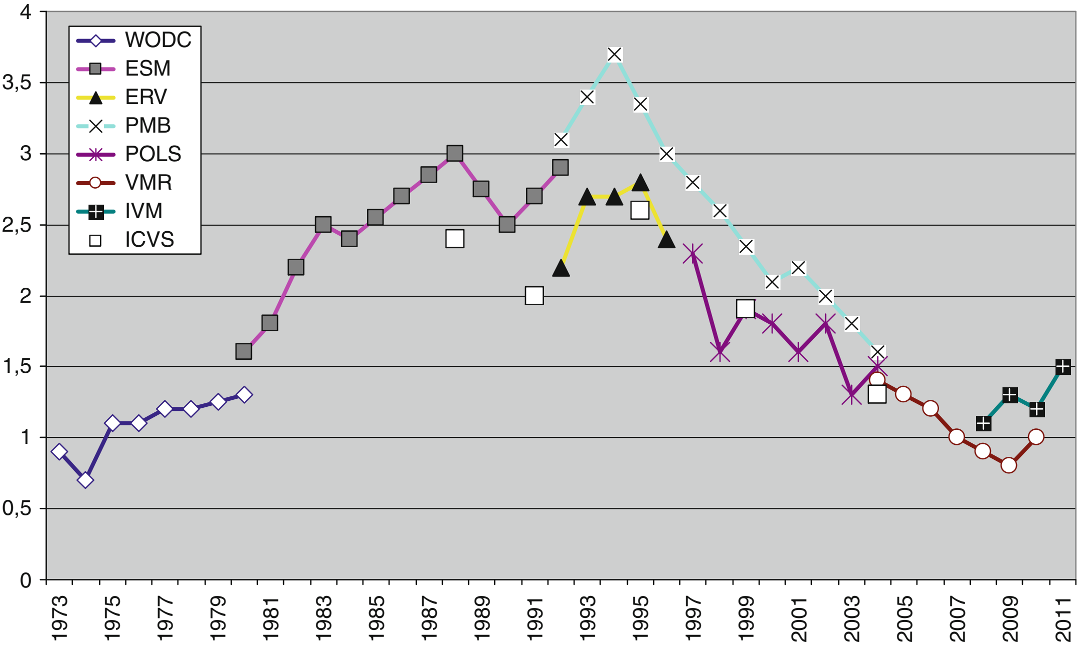
MCB (2004 Onwards)

In addition to the surveys where victimization and other safety issues were asked from citizens and after a limited survey on shoplifting in 1977–1983, starting in 2004 a business survey was carried out. This survey is organized by the ministry of Justice and the ministry of Interior Affairs. The net sample size of this survey was 30,000 in 2010. The survey has been carried out in the following five sectors of the business community: construction, retail, hotel and restaurant, transport, and commercial services. Interviewing is done by telephone.

Victimization by burglary, theft, bribe seeking, vandalism, and violence is included. Also total losses and damage by crime, the use preventive measures, reporting behavior, and experience with the police are covered.

Some Results, 1973–2011

Due to the different methodologies used, it is hazardous to directly compare victimization levels (and other results) from the different surveys. Straightforward comparisons do indeed often reveal striking differences between the results. Having said that, interesting findings regarding trends in victimization can be obtained for a selection of crimes and for some other



History of the Dutch Crime Victimization Survey(s), Fig. 1 Victimization rates for burglary, 1973–2011. Percentage of persons having been victim of burglary once or more in the preceding year

indicators. Trends in victimization rates – defined as the percentage of respondents that has been victim at least once – regarding two specific crime types will be presented here, i.e., burglary and bicycle theft. Both types of crime were included in the questionnaires of all surveys using more or less the same definitions. Next some trends in rates of victimization by violent crime and total victimization rates will be presented as well. Methodological problems will be more visible here because questions about these types of victimization were not formulated in the same way in the different surveys. Also we will look at trends in feelings of unsafety, starting in 1992.

Burglary

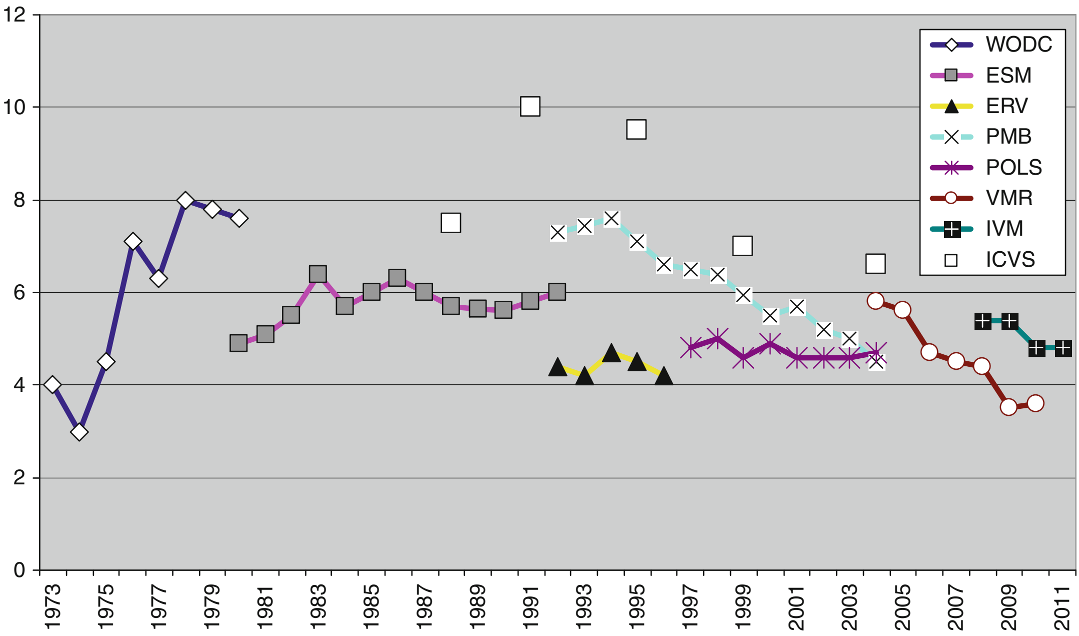
Data on burglary victimization are available for the period 1973 up to 2011. In several years, more than one survey has been conducted simultaneously. The data collected by the various surveys on victimization by burglary is surprisingly consistent across the eight different surveys (see Fig. 1). Level differences can be observed, but they are not too large, certainly not when realizing that the *statistical* 90 % confidence interval for the samples used and percentages found for burglary will typically be in the order of 0.5 %. Most of the level differences seen here are smaller than this confidence interval.

There is a clear upward trend from 1973 until about 1993–1995. Thereafter an almost continuous downward trend can be seen until 2008–2009. After that, it remains to be seen if the victimization rate is stabilizing or starting a new upward trend.

Bicycle Theft

As can be seen in Fig. 2, the level differences for bicycle theft are larger than those for burglary. Apparently the wording of the question, sampling method, and interviewing mode have had more influence on the measurement of this crime than was the case with burglary. For example, in some surveys such as the ICVS, respondents are asked whether any of the bicycles of the household have been stolen, whereas other surveys ask about the theft of one’s own bicycle only.

Although it is less clear than with burglary, the trends over the last 40 years are not too different.



History of the Dutch Crime Victimization Survey(s), Fig. 2 Victimization rates for bicycle theft, 1973–2011. Percentage of persons having been victim of bicycle theft once or more in the preceding year

An increase can be seen until about 1983; however, it is not obvious what the trend was in the next 10 years until about 1993. After 1993, almost every survey shows a downward trend, just like with burglary.

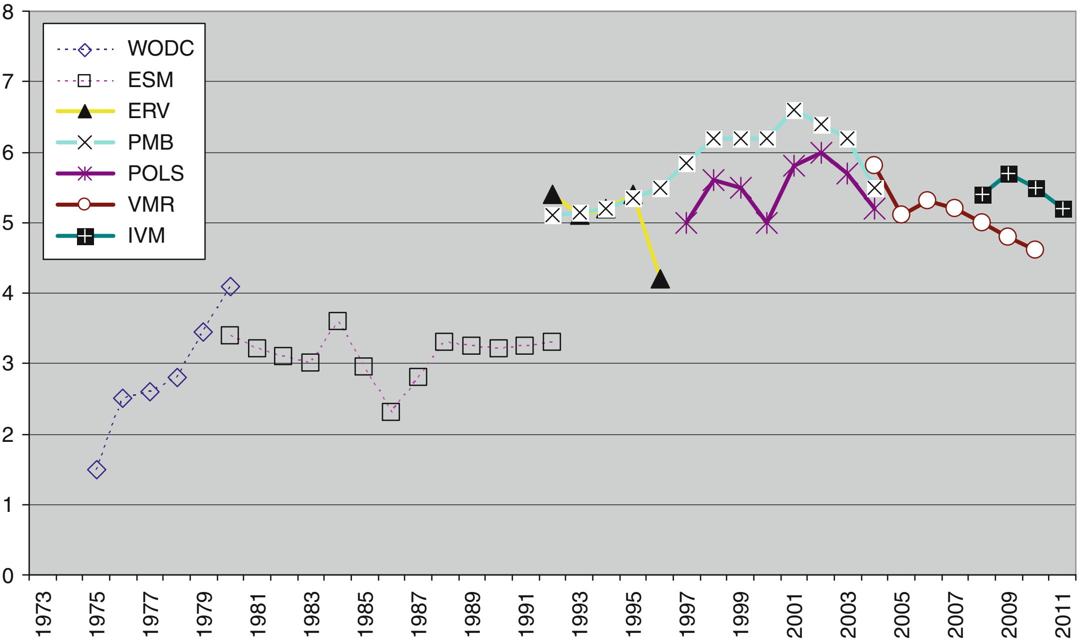
Violent Crime

It is very problematic to look at trends in victimization of violent crime for the whole period 1973–2011 due to the varying definitions employed. In the first WODC survey and the subsequent ESM, the question on assaults/threats was limited to incidents in the public domain. In the later surveys, these questions also included incidents in the private sphere. In Fig. 3, the results from the WODC and ESM surveys are represented by a dotted line describing trends in assaults/threats on the street or in other public places. Therefore, the level differences between these two first surveys and the later surveys are largely caused by the use of a broader definition in the latter. For the other surveys, level differences seem to be reasonably small.

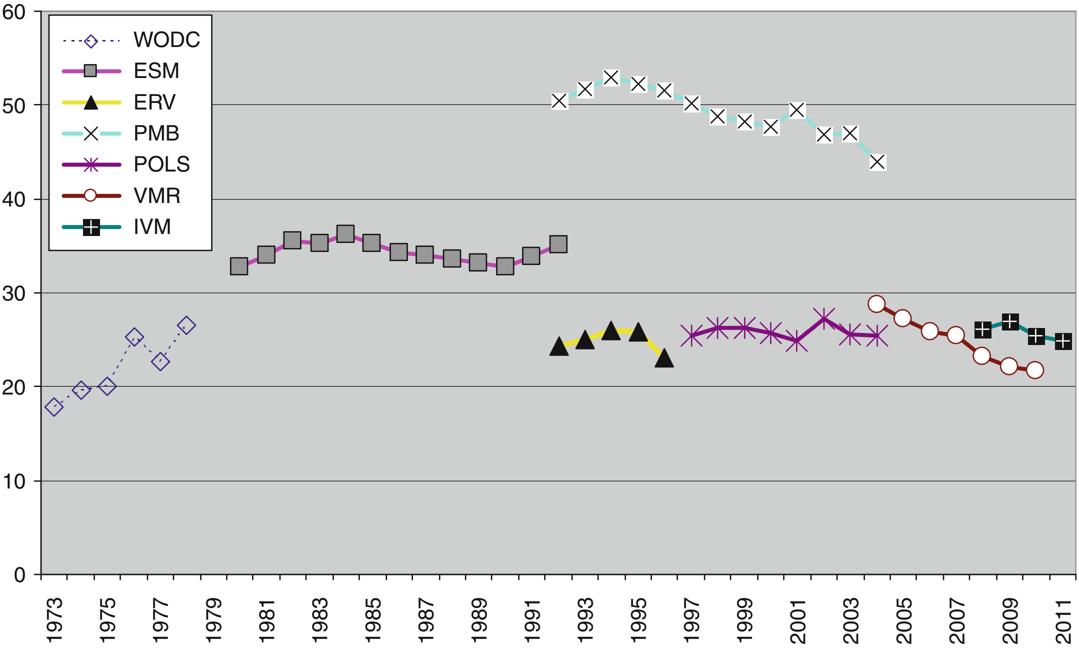
After an initial increase in the 1970s, as shown by the WODC survey, victimization for violent crimes seems to have remained stable until about 1993. Hereafter an increase can be seen which continued until about 2002 (with the ERV figure for 1996 as a notable exception). From 2002 onwards, all surveys show an almost continuous decrease.

Total Crime

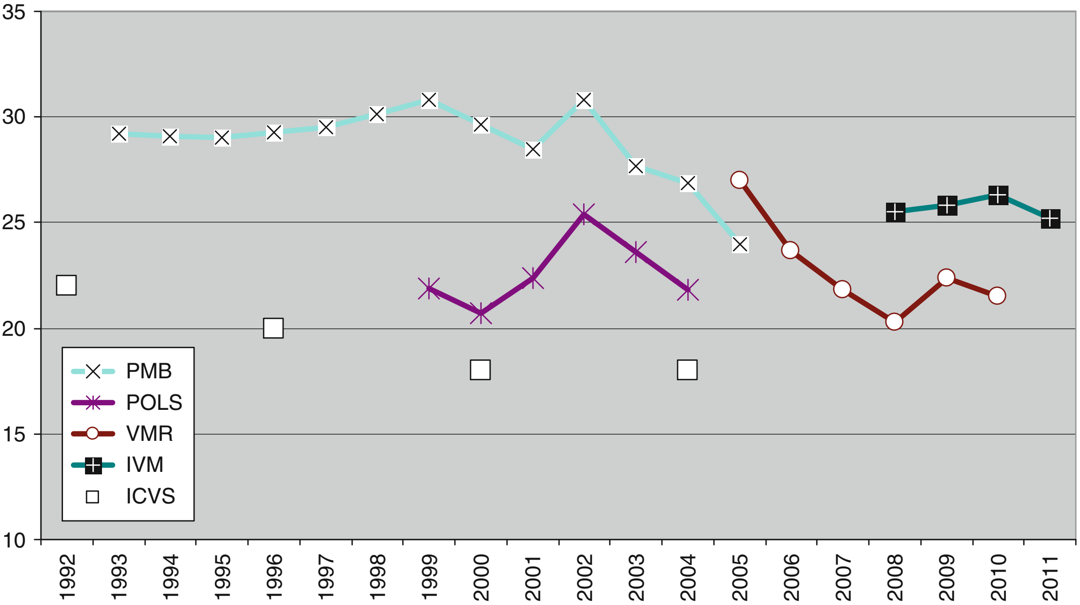
Victimization by total crime is defined in the Dutch surveys, as in the ICVS, as the rate of persons victimized by any of the types of crime included in the questionnaire. The WODC survey did initially cover a smaller range of types of crime than the later surveys. As a proxy of the total crime rate, the sum of the limited number of crimes in the WODC survey (at least until 1978) is taken. The level of victimization by total crime is clearly dependent on the list of crimes covered. For example, the inclusion or noninclusion of items on various types of vandalism (destruction of property) can make a big difference in the total rate. Considerable level differences can indeed be seen, in particular with the PMB which used the most comprehensive list of crimes (Fig. 4).



History of the Dutch Crime Victimization Survey(s), Fig. 3 Victimization rates for violent crime, 1975–2011. Percentage of persons having been victim of an assault/threat (for WODC and ESM only victim of incidents in public places) once or more in the preceding year



History of the Dutch Crime Victimization Survey(s), Fig. 4 Trends in victimization by any crime, 1973–2011. Percentage of persons having been victim of any crime (for WODC victim of a few crimes only) once or more in the year reported on



History of the Dutch Crime Victimization Survey(s), Fig. 5 Feelings of unsafety, 1992–2011. Percentage of persons feeling unsafe sometimes (for ICVS feeling unsafe after dark on the street)

The results of the first two surveys suggest an upward trend in total crime between 1973 and 1985. From 1994, a downward trend can be seen, particularly in the PMB, VMR, and IVM surveys.

Feelings of Safety

Starting in 1993 (or in the ICVS in 1992), respondents were asked how often they feel unsafe. In Fig. 5, the percentage of respondents “feeling unsafe sometimes” are given. Again, some clear-cut level differences can be observed which point at effects of the methodologies used. The lower rates found in the ICVS can be explained by the use of a different question: in the ICVS, unsafety feelings were restricted to experiences on the street and after dark.

However, trends appear to be fairly similar across surveys (e.g., looking at results of PMB and POLS).

By and large, feelings of unsafety have declined since 1992 with the exception of a brief spike around the turn of the century. This could well have been caused by the 11/9/01 attacks and the murder in May 2002 of a high-profile Dutch politician.

Conclusion

The Dutch national crime victimization surveys belong to the longest running and largest exercises in the field of crime surveying. The considerable investments made in the Netherlands in this line of research must be understood against the background of a continuous political debate about the problems of crime since the early 1970s and a strong infrastructure for policy-oriented criminological research. Over the years, the WODC (the Research and Documentation Centre of the Ministry of Justice and since 2010 the Ministry of Security and Justice) has been in a position to secure the survey’s continuation as its guardian angel. The popularity of the survey has been much enhanced by the growing political interest in its potential to provide performance indicators for local police forces and municipal security programs since the 1990s. The survey’s successes, though, seem to have come at a cost. The involvement of different stakeholders and executing agencies has impacted on organizational setups and methodologies. For this reason, the methodology of the Dutch survey seems to have been even more in flux than similar national surveys such as the NVCS and the BCS. The choice for web-based interviewing in future rounds of the survey seems propelled by cost considerations imposed by the use of relatively large samples required for the calculation of local rates. Although the mixed-mode approach is based on experimental studies, its rapid introduction may give rise to renewed debates about the survey's methodology in the coming years.

The available datasets of the Dutch surveys allow for attempts at longtime trend analyses. Results presented here provide unique survey-based evidence of a rise in different types of crime in at least one European country in the 1970s. Over the years, the datasets have been used for numerous secondary analyses by researchers (Wittebrood and Junger 2002; Van Wilsem 2003; Goudriaan et al. 2006; Vollaard and Van Ours 2011). The surveys have been one of the drivers of the current boom in Dutch criminology.

History of the Police Profession

Herbert Reinke[1] and Margo De Koster[2]

Brussels, Belgium

Overview

Policing as a professional métier emerged in many European countries and in Northern America throughout the nineteenth century, although in many countries gradually only. The move toward professional policing came from two sides: The authorities governing the police (the state, municipalities) strived for a more efficient and above all for a more accountable law-and-order maintenance, while members of the (uniformed) police perceived and used the enhancement of professionalism within the police a strategy for promoting career prospects, pay, and status. Police schools and police unions were part of this development. The strive for professionalism remained limited throughout most of the nineteenth century, because most of the uniformed policemen were rather a sort of general factotum than professional agents for law-and-order maintenance. The late nineteenth century saw in many countries the advent of specialized police branches, specializing on crime investigation, detection, and control (crime detections units, when rising fears of crime and disorder in the cities enhanced the demands for professional crime control). The social defense modus of crime control during the decades before and after the turn of the nineteenth to the twentieth century, focusing on perpetrators threatening "property," served a very specific notion of crime. In addition with the high level of public prominence allotted to crime investigation work, the (societal) status and prestige of the work of uniformed policemen decreased, whereby crime investigation acquired the status of "real" police work, although, seen from a quantitative perspective, crime detection is a minor part of overall police activity.

Key Issues and Concepts

The police understand themselves as a profession and the members of the police see themselves as professionals. Since the emergence of the concept "profession" in the social sciences, the literature has come forward with a number of theoretical approaches, proposing characteristics for describing "profession" and "professionals." There is a narrower conceptualization, which sees university trained occupations as professionals, but a wider concept is nowadays used quite often as well, which also includes institutions such as the police among the professions and includes the police personnel among the professionals. The characteristics describing professions and professionals allow for variation, but a number of core elements have come to stand out, depending on the respective theoretical approach, which allows summarizing definitions of the concept (Reiner 1978). There is a functionalist approach, which sees professions as generally characterized by the exercise of very particular skills, acquired through very specific training processes. This training and these skills generally involve the acquisition of corresponding specialized knowledge, which only the members of the respective profession have at their disposal. Within the functionalist context of this approach, professions and professionals are serving basic societal needs and values, appreciated by society. Another characteristic of "profession", which the literature refers to, concerns the existence of specific interest politics, which professions are pursuing. These interest politics are often indicated by the establishment of organizational structures, serving the promotion of the respective profession (income, status, etc.). In this context, unions are not only seen as representations of workers but of professions as well. Promotion means as well, that these organizational structures quite often enhance a sort of exclusiveness of the profession (skills, knowledge), which is strived at to clearly set it apart from other professions. The literature labels this understanding of "profession" and "professionals" as the control approach, seeing professionalism as a strategy for controlling the labor market. The control approach avoids the ideological layer to be found in the functionalist understanding of "professions" and "professionals," which has been criticized for not giving answers to questions about those within society, which are able to define and to enforce social need and values.

Critics have argued that applying the concept of "profession" to the police implies a basic contradiction. Due to the police's strict hierarchical structures and due to (at least throughout the nineteenth century) its military features, it is or has been rather a "bureaucracy" than a "profession" (Reiner 1978, 2000; Johansen 2005). But applying elements of the functionalist understanding of professionalization, which include the emergence of professions as a follow-up to societal, economic, and political changes and demand, allows for asking questions about the professionalization of the police during the nineteenth and the early twentieth centuries: Controlling rioting crowds and controlling disorder and crime turned out to be the challenges the police was to meet during this period.

The explosive growth many European cities experienced, and its problematic consequences, as well as upsurges of social and political unrest during the decades of the nineteenth century, led to heightened anxieties about crime and disorder.

The conditions under which people lived in the cities were seen as prerequisites per se for political unrest, immorality, and flourishing crime. These fears led to demands for police efficiency, followed by intense political and public debates about the organization and functioning of the police, and accomponied by considerable attempts all across Europe to professionalize the police.

Toward Professional Policing: Uniformed Polices in Europe During the Nineteenth Century

It was not before the last decade of the nineteenth century that professionalization became a significant concern among police forces in Europe. It not only became a concern for the state and for the municipal authorities directing police forces, it became a concern for the policemen themselves as well. Being a policeman in uniform meant in most European countries throughout the nineteenth century a combination of long-working shifts, a low pay, no training for the job, and low prestige. Most men in the uniformed police had a military background, even in those police forces which were supposed to be a civil police such as the English police (Emsley 1991). Being trained for the job was not part of the uniformed patrolman's work experience. Members of the Gendarmerie forces with their military background did have a military training, but lacked specific training for their policing duties as well. For the patrolmen in uniform, who emerged in European cities throughout the first half of the nineteenth century, wearing a uniform in a proper way, and walking the beat accordingly were in some way already the essentials to be taught to them. Until the First World War, walking the beat or being on patrol in the countryside remained for the patrolmen their core police activity.

European countries, although different in terms of political systems, political structures, and cultures during the nineteenth century, showed *grosso modo* similar lines concerning approaches for improvements of the recruitment and above all the training of its police personnel. During the latter years of the nineteenth century, these attempts accelerated, not only by establishing schools for improving the training of the uniformed police, but also by attempts and initiatives of the police officers themselves to improve their situation and their status. France, Belgium, England, Prussia, and the Netherlands (Meershoek 2007; van der Wal 2007) provide examples of these developments.

In France, it was the Third Republic which began paying attention to the recruitment and training of the police by taking first steps toward a professionalization of the police service. There were a number of reasons, why the new republican regime gradually began enhancing a professionalization of the police. Firstly, within the political system and the political culture of the Third Republic, an electorate based on universal suffrage could hardly be expected to remain indifferent to the standards and achievements of the police service; secondly, a republican government could not simply take over the police bequeathed to it by the authoritarian regimes which preceded it, which it had always denounced as dictatorial prior to its own accession to power; and thirdly, the French police, at least the one in Paris and in other major cities of France became confronted with the consequences of urbanization and industrialization, which complicated the policeman's lot significantly, raising the issue of how the police could adapt to these changes (Berlière and Lévy 2011).

This move towards a professionalization met difficulties due to the complex and conflict-loaded structures of the French police. The French police since the first decades of the nineteenth century consisted of a number of different polices. One of these polices, the *sûreté générale*, was rather an institutional roof, expressing the state's aspiration to cover police-related matters as "state." In reality, the French government ran its own police, besides the Gendarmerie, throughout the nineteenth century in Paris and in two other major cities only (Lyon, Marseille). Quantitatively, much more significant were the municipal and local polices. Within these structures, the criminal or judiciary police, responsible for crime investigation, was dependent on four police authorities. This institutional layout was in itself already complex, but it became even more complex, as the Third Republic never succeeded in putting forward a clear view as to who was responsible for the powers of the municipal police – torn as it was between a tradition that these police powers should be seen as emanating from the local authority and by centralizing tendencies. As a result, the municipal police found themselves dependent on the Ministry of the Interior in some matters, and on the local authority in others. The Ministry of Interior was, for example, responsible for the appointment of the *Commissaire de Police* (obligatory post in towns of over 5,000 inhabitants), and for fixing the size of the police force and that of the municipal police budget in county towns of 40,000 or more inhabitants. Towns of over 5,000 inhabitants thus had their own police (in towns of less, the *gendarmerie* took on the functions of the police), who theoretically came under the authority of a commissaire appointed by the Ministry of the Interior, but who were paid by the municipality. Apart from the post of commissaire, all the other municipal police appointments were made by the mayor, who also decided on their salary levels. They were recruited, paid, disciplined, and punished by the local authority. This system had several unfortunate consequences, among them conflicts between mayors and commissaires as the commissaire was placed in an impossible position. It required a great deal of balancing to keep the police between state and municipal authorities going, while his situation became totally untenable, if the municipality was hostile to the central government of which the commissaire was the representative (Berlière 1996).

The state of the municipal police was very insufficient: In towns with less than 40,000 inhabitants, the mayor and municipal council alone decided on how large a police force was needed, and in order to save money, kept these as small as possible. In certain towns, the Commissaire de Police – perhaps with one or two assistants – might be the only one acting as policeman. The standard of men and means in many municipal police forces was ridiculously low, and only Lyon and Marseille with its state polices had a more developed police system. The rules that existed under previous regimes were hardly altered during the period of the Third Republic. Instead, it was the military laws of 1872, 1889, and 1905 which had overriding effect on the recruitment of police: In order to encourage a further 5-year service after the period of conscription, a civilian post was ensured to men after they had completed their military service. Thus, for a long time, the great majority of French policemen were former soldiers. Only a fifth of the police employed at the turn of the nineteenth to the twentieth century were civil candidates. The way in which candidates were assigned within the police service to different types of posts was completely random, as candidates were assigned to places and functions according to vacancies and not according to their capabilities (Berlière and Lévy 2011).

The Third Republic thus started its police regime with a police that lacked professional training completely, but the last two decades of the nineteenth century and the years until the beginning of the First World War were marked by efforts to improve training patterns. Recruitment patterns and conditions of employment changed partially as well during these decades, leading to higher wage levels; to a system of allowances for clothing, housing, retirement, and children; to a month's holiday per annum; and for a retirement pension. Since it rather quickly proved to be impossible to fundamentally change and improve patterns of recruitment, attention from the 1880s onward focused on police training. A school for the municipal police was established in Paris in 1883. The courses there included dictation, instruction on how to deal with practical day to day police tasks, how to telephone and send telegrams, memorization of the streets of one's beat, the rudiments of first aid, and how to disperse a crowd, and instructions on how the police were to treat the public, and on how they were themselves to behave. The setting up of this school demonstrated a real desire to improve the level, training, and professional qualification of the police, but it remained for a decade and half the only institutionalized full time training facility within the French police. During the years before the First World War, particularly the Paris police started to upgrade its technical capacities and to enhance the professional specialization of the force by establishing a training school for all police in May 1914, where training was much longer, including new courses with a obligatory diploma course in descriptive studies for all higher ranks, by linking promotion with higher professional qualifications, and by creating a number of special services, in order to adapt the police to the transformations brought about by accelerating urbanization and industrialization (Berlière and Lévy 2011).

In neighboring Belgium, similar debates were going on and comparable initiatives were developed in the late nineteenth century. Critics of the police were widespread; they also came from within the police itself: Senior police officers openly admitted that both in terms of manpower and quality of their personnel, all municipal police forces had extremely low standards. Improvements turned out to be difficult to realize, however, as each municipality in Belgium had its own police force, financed and managed by the local authorities. As a result, municipal police forces were very different from one another, not just in terms of manpower strength but also in many other respects, such as the recruitment and training of police officers, their wages, equipment and weapons, accommodation and material resources, and the way in which they carried out police duties. The standard of men and means in many municipal police forces was very low, one of the consequences being that, even though so-called municipal autonomy in politics was frequently and fiercely adulated, many local authorities had to call out the army at the slightest excuse to maintain law and order. Only Brussels and Antwerp, the two largest Belgian cities, had more developed municipal police forces. The efficiency of the Belgian municipal police was not only undermined by their limited numbers, but also by the poor qualifications of their personnel, which were the result of inadequate recruitment and a complete lack of any professional training. There was a total lack of professional selection criteria for candidates applying for a post as constable; in general, only physical qualities (meeting the age and height requirements, being physically fit, and looking tough), behavior, and morality were taken into account. The candidate might be subjected to a low level type of examination chiefly concerned with writing and arithmetic, but the results were of little significance for eventual admission to the force. Nominations in the higher ranks, on the other hand, often depended on whether the candidate had personal relations with senior police officers and enjoyed local political support. Unsurprisingly, this recruitment pattern negatively affected the quality of the municipal police. The inability of the police authorities to recruit sufficient suitable or well-qualified personnel is further illustrated by the fact that all the forces were confronted with rapid turnover. This only aggravated problems of manpower strength, because another result was that a large number of police posts were permanently vacant. To make things worse, newly recruited constables were not given any serious training before letting them loose on the city streets. The training of policemen was carried out "on the job" and was oriented along the practical requirements of the police's everyday activities: The police constable had to get acquainted with his precinct and with the things he had to look after when on the beat. A number of "formalities" were briefly taught, such as some basic ideas about the Belgian penal code and the police ordinances that had been issued for the respective city or municipality, etc. In short, "real" professional training did not take place. Finally, professional specialization of the police through the creation of special services was still far off (Keunings 2009).

These problems and shortcomings of the Belgian municipal police did not escape the notice of contemporary observers, police reformers, and responsible politicians, and the whole of the period of 1890–1914 was marked by efforts to expand police forces and professionalize police work. In the major urban centers (Brussels, Antwerp, Ghent, and Liège), the municipal police grew considerably in per capita strength: The overall figures for the police personnel doubled. This increase occurred primarily in the lower ranks: manned with the plain constables; in Antwerp, for example, their size almost tripled between 1883 and 1914. By 1914, the proportion of police to population in the largest Belgian cities was not too far from that in other major European centers. Thanks to a subsidy of the central government, Brussels had even become the "best-policed" European city in terms of manpower strength (Keunings 2009; De Koster 2008).

The growth in per capita strength of Belgium's municipal police forces did result in an improvement in the conditions of service, more particularly in shorter working hours and a greater number of days of leave. In Antwerp, this evolution started off in 1898, when the City mayor announced that the city inhabitants had approved a municipal tax raise for the enlargement of the police force in a referendum, which permitted the recruitment of a hundred extra constables, a reorganization of the force, including new schedules, and the introduction of a "nicer" uniform. At that time, the average constable still had very long and irregular hours on the street, with two shifts a day of about 5 h and 20 min, except after a night shift (day of 4 h and a half). Moreover, police assignments and schedules reveal that policemen were often reassigned from one post to another and always rotated from one shift to another. At the same time, Antwerp policemen could only take 1 day of rest and 3 days of leave a year at the end of the nineteenth century, and lost them in case of punishment or illness. In 1907, however, this last rule was withdrawn and the number of days of leave was increased by four. By 1912, working hours had been reduced to an average of 8 h and 25 min a day. The most definite improvement in the conditions of service before the First World War was realized through the gradual introduction of higher wage levels and a retirement pension, paid by the city (from 1886). It has to be noted, however, that the rise in wage rates achieved by 1914 was considerably accentuated by the fact that initially, at the end of the nineteenth century, wages had simply been ridiculously low. By 1914, the pay of Antwerp constables had come close to that of a concierge, while wage rates in Brussels slightly exceeded those of the lower civilian personnel of the city (De Koster 2008).

Although they were relatively limited, these improvements in the conditions of service had an immediate effect on recruitment. Belgian municipal police forces experienced much less troubles in finding candidates for the jobs: A greater number of applications followed and rates of dismissals and resignations fell, which raised the standard among the recruits. Overall, the municipal police gradually became a more permanent place of employment for a growing number of people and the composition of these forces gradually shifted to a corps of more experienced policemen. However, the adaptation of a growing number of officers to the new institution was accompanied by what the police still considered to be a high departure rate. Scores of young policemen left the municipal police every year to seek their fortune elsewhere, and although those who left were generally soon replaced, the authorities were not always happy with the general quality of the new recruits. Possibly, the police were not able to attract suitable personnel in sufficient numbers to offset the annual wastage and meet the high manpower demands of the force, and had to accept recruits below the prescribed norms (Keunings 2009). Antwerp provides a good example for the subsequent attempts by Belgian municipal authorities and police administrations to improve the policeman's qualifications during the first decade of the twentieth century. In order to obtain better qualified personnel, a "police school" was set up, the cost of which was covered by the city. It was relatively small, however, and few policemen were sent to it. Despite these efforts, there remained a considerable lack of professional training (De Koster 2008).

However, there were other significant signs of police professionalization in Belgium. The turn of the twentieth century saw a formidable increase in the number of police manuals and handbooks being published. A set of standardized examinations was devised, which candidates for promotion were obliged to pass at almost every stage in their career. Promotion to superior ranks was thus made dependent on climbing the rungs of the police hierarchy. In terms of equipment, the municipal police also knew considerable improvements, especially in Brussels, where the police disposed of not only a telegraph (1873), straitjackets (1883), and solid helmets (1897), but from the early twentieth century onward also revolvers (1902), bicycles and the famous white traffic batons (1910), a police dog brigade (1907) – copied from the Ghent police (1899), who was the first in the world to introduce this – and even police cars (1914). A parallel development, spurred to a large extent by the first police unions ("associations," from 1881 onwards), was the creation of specialized units within the largest urban police forces: antigambling brigades, vice squads, traffic police, port police, and criminal investigation departments. All these developments went hand in hand with a militarization of police culture, most police officials being drawn from commissioned army officers (Keunings 2009).

In Prussia, the institutional layout of the police resembled the one in France although major differences existed. During the so-called Prussian reform period at the beginning of the nineteenth century, Prussia established the police as a state prerogative, allowing the Prussian state to establish state polices in Prussian cities, but allowing the Prussian state as well to commission cities with the establishment and the direction of communal or municipal police forces, establishing state police forces in a few cities only. The Prussian state established during the first half of the nineteenth century state polices only in those cities, which were seen as hotspots of political opposition and dissent. While the state polices were on the budgets of the Prussian state, it were the municipalities themselves which had to pay for their municipal police. During the 1860s, the Prussian state withdrew its state polices from a number of cities, leaving it to the municipalities to police them with municipal polices, the reason for this withdrawal being a mixture of budgetary considerations and changed security evaluations by the Prussian government. In these cities, the mayor represented the prerogative by being the official head of the local or municipal police. While the mayor was the head of the municipal administration, elected by the city council, he was at the same time, with respect to his duties as head of the police in the respective city, executing state functions and had thus to obey state orders. Due to these specific patterns of police organization, the Prussian state could theoretically intervene in everyday municipal matters, although in practice, the cities had many possibilities for diverting or impeding such interventions (Funk 1986; Jessen 1991; Reinke 1993; Spencer 1992).

Who could become a member of the police force in Prussia? There are some resemblances to patterns to be observed in France during the nineteenth century. In theory, previous service in the Prussian army up to 12 years was an absolute prerequisite for being recruited into the uniformed Police in Prussia. Thus, the ranks of the uniformed policemen on the beat were supposed to be filled with noncommissioned officers (NCO). Military service as a prerequisite for admission to the police served several functions: The NCO policeman was supposed to represent king and state in the everyday life of the citizen. His superiors expected him to show his derived authority, and, if necessary, to compel compliance to this authority from the public. On the other hand, long training within the military hierarchy was supposed to have made him an obedient servant to his superiors and a reliable instrument for maintaining law and order. But, in reality, this recruitment pattern worked partially only. Although the civil service did have a high social ranking, the position of a uniformed patrolman had a low ranking on this list. Getting a job in the police was not what an army NCO necessarily looked for after years of military service. For many NCOs, the job of a policeman was only a transitory phase on the way to a quieter existence in the civil service than the police service could offer. In Berlin for example, whose royal police was to serve as an example for other polices in Prussia, more than 2,000 policemen left the police force during the 1890s. The Berlin police force totaled about 4,000 men in the middle of the 1890s. A quarter of those who left the police went into other positions within the civil service. Due to these turnover rates, a large number of police posts were permanently vacant (Funk 1986). Not only Berlin, but other Prussian cities also had to cope with this situation (Funk 1986; Roth 1997; Spencer; 1992). During the 1890s and again during the first decade after the turn of the century, the Prussian state administration tried to solve the turnover problem by reducing the military service requirements for employment in the police force. As a result, more men were drawn into the police service. The nine- to twelve-year military service remained nevertheless the idea requirement looked for when conceiving a real Prussian patrolman on the beat. Those policemen who had acquired their post on the basis of the reduced requirements were often considered as some sort of second-class policeman.

Vacancies in the civil service, the police included, were announced and advertized by state and city administrations in public lists and journals. But the police posts offered regularly outnumbered applicants from the NCO's ranks. Cities with municipal police forces therefore reduced their employment requirements by recruiting men for the police service who had only fulfilled their obligatory military service after conscription, rather than service as regulars (Jessen 1991; Spencer 1992). By the 1880s, and much more so after 1890, cities in the West of Prussia, along the Rhine and in the Ruhr, did find it increasingly difficult to recruit candidates with the adequate military background. While some cities reported during the 1890s that they were still managing to staff the municipal police positions accordingly, other cities found the supply of candidates with the requisite military experience falling even more short of their needs. By 1911, the police department in Düsseldorf, one of the largest cities in the Prussian West, with 46 patrolmen's positions to fill, reported that of 500–600 applicants, only 22 had the adequate military background. Thus, despite persistent pressure from the Prussian state to seek out NCOs for police service, the cities in the Prussian West turned increasingly to the local wage-earning population for recruits. Urban administrators usually did so reluctantly, sometimes continuing to see the ideal policeman not just as someone shaped by long years of military discipline but also as someone from the outside, preferably of rural or small town origin. But the reality was that most applicants were local residents with only minimal military experience. As a consequence, the possibility of recruiting of policemen having personal contacts with organized workers loomed ever more threatening (Jessen 1991; Spencer 1992).

The training of policemen was carried out on the job and was oriented along the practical requirements of the man's on the beat everyday activities. The patrolman had to get acquainted with his precinct and with the things he was supposed to look after when on the beat. A number of "formalities" were also briefly taught, such as some basic ideas about the penal code of the Empire, the police ordinances that had been issued for the respective city or community, etc. Apart from that, the writing of dictations was part of the training. Often this was essential because the men's ability to write seems to have suffered considerably during the long years of military service. But all in all, serious training did not take place. Around the turn of the century, the Prussian state government as well as municipal police administrations acknowledged an urgent need for an improvement in the policeman's qualifications. Police schools were set up, and additionally, the military habits of the ordinary policeman were no longer deemed sufficient for the handling of the everyday problems the police encountered in the growing urban contexts. The more Prussian cities grew and the more complex urban society became, the more qualifications were required from the policeman beyond his authoritarian and military attitude. In 1899, the first police school was established in Prussia, as a school for the gendarmerie. The gendarmerie took the initiative, since for this force, which was still part of the military, the problem was the most urgent. In 1901, the first police school for municipal police personnel was set up in Düsseldorf. The costs of the schools were covered by those municipalities who sent their policemen there. In general, municipal administrations accepted the necessity for improving the qualifications of their police personnel, but for financial reasons, however, they limited the number of men they sent to these schools (Jessen 1991; Reinke 1993; Spencer 1992).

Similar institutions were being established in other Prussian districts as well at about the same time, beginning with Berlin in 1895. Police schools were intended not only to impart necessary knowledge and approved attitudes but also to raise police prestige. Increased formal training (whatever its content) would help lessen the gulf between policemen and respected representatives of the Prussian state. In Düsseldorf, the course for patrolmen lasted 2 months, that for senior officers for 3 months. Students were required to live at the school so that its influence could prevail around the dock. The cities paid the costs for the patrolmen, fearing that if the men were required to use their own resources, they would fall into debt, a situation policemen were strongly encouraged to avoid. The senior officers, expected to come from somewhat more well-off families, had to pay for their own instruction. Cities tried to protect their investment in the candidates by stipulating that those who left their departments after less than 5 years had to repay all or part of the costs of their schooling. Also, attendance at the school was typically reserved for those recruits who had already completed 6–12 months of service. As justification for this fiscally prudent move, police administrators argued that schooling was more meaningful if it followed a substantial period of practical experience. By 1906, the state district administration in the Prussian had stipulated that in cities of 10,000 or more, patrolmen either had to attend the police school or pass an examination before being confirmed in their posts. Supporters of the Düsseldorf school were dismayed to find that many communal police departments, to save the cost of instruction, either tried to hire recruits who had already attended a police school elsewhere or else encouraged the taking of the examination. To make certain that the Düsseldorf school had enough students to pay for itself, the Prussian provincial administration before the war was contemplating eliminating the examination option. As a step toward making municipal policemen more credible as rule enforcers by increasing the likelihood that they knew and understood the rules and what they were doing and for what purposes, the Düsseldorf police school represented only a hesitant beginning (Jessen 1991; Spencer 1992).

"Professional" Police Knowledge

Throughout most of the nineteenth century, a coherent and exclusive stock of police knowledge did not exist. This stock of police knowledge emerged only gradually, acquired empirically, and further elaborated during the last decades of the nineteenth century via the huge data collections, which police headquarters in European capitals (Berlin, London, Paris, etc.) started assembling during this late nineteenth century period. There rather existed different layers of police knowledge, which spread according to the functions and tasks different strata of policemen fulfilled. At the turn of the nineteenth century, a comprehensive stock of knowledge had been assembled, but this stock incorporated a pronounced ideological bias, focusing – in the wording of the contemporary discourse – on a "social defense" modus, i.e., focusing on those threatening the values of bourgeois society and "property" as its *Leitmotiv*.

During the first half of the nineteenth century, uniformed policemen started with no knowledge at all. They simply were looking at people, things, and circumstances, when on the beat or on patrol. It has been argued that a specific empiricist police gaze developed gradually, which categorized people as disorderly, deviant, or as potential criminal perpetrators. Parallel to this emergence to a empiricist police gaze existed a flourishing publication market, consisting of police handbooks. Especially in Central Europe, these handbooks were connected significantly to the Central European continuity of "Polizey," thereby conceiving police beyond law-and-order maintenance in a narrower sense. These handbooks were very much meant to give guidelines for protecting the state against those threatening it, thereby mixing the handling and the control of the economic and social challenges developing already during the first half of the nineteenth century with the control of political dissent and opposition, threatening the political regimes of the nineteenth century postrevolutionary period. Both layers, the results of the patrolman's gaze when on the beat and guidelines of the handbooks, were connected loosely only – if at all.

As patrolmen on the beat remained some sort of general factotum until the beginning of the First World War, specialized police knowledge could not develop on that level. The small handbooks and notice books, which were brought on the market, which were published parallel to the establishment of police schools since the end of the nineteenth century, mirrored this, since they were rather designed for guiding in – what we would see nowadays – general administrative matters than in law-and-order maintenance. But another layer became more significant during this period. As a follow-up to rising anxieties about crime and disorder, especially since industrialization and urbanization accelerated its pace since the middle of the nineteenth century, immense data collections on those threatening bourgeois society and particularly "property" were assembled. These data collections, especially the data collected about the body or parts of the body of suspects or perpetrators (bertillonage, dactylography) and immensely growing number of photos taken, brought the policeman's gaze close to contemporary scientific methods and adopted them. But the data collections, or rather the way these data collections were organized, mirrored the threats the police was to handle. The data collections at the Berlin police headquarters reflected this: The core collection there consisted of an extremely detailed collection on theft, indicating not only contemporary anxieties but urban opportunity structures as well (Roth 1997; Wagner 1996).

Professional Policing and Crime Investigation

The second half of the nineteenth century saw in many European countries the rise of specialized criminal investigation departments, which has been perceived as an answer to urban growth and problems related to urbanization patterns during that period. The Berlin police headquarters established a separate and specialized crime investigation branch at the beginning of the 1870s. There had been police officers investigating crime before, but now crime investigation became a specifically institutionalized branch. In 1878, the Metropolitan Police in London established the Criminal Investigation Department/CID, and the Police Judiciaire in Paris underwent significant reform efforts during that period as well. Detectives, Commissaires, and Kommissare had operated in these countries before (Emsley and Shpayer-Makov 2006; Kalifa and Karila-Cohen 2008; Roth 1997; Shpayer-Makov 2002), but henceforth, the establishment of new or reformed police branches, specialized on crime detection and investigation, was a response to similar patterns in very many European countries. Massive urbanization, occurring all across Europe, brought about significant changes in the social fabric of the cities. While urbanization was read on the one side as an indicator of progress during the nineteenth century, it nevertheless led to the anxieties and fears.

The complexities, created by these massive economic and social transformations, were in parts translated into fears of rising crime, to which the establishment of specific crime investigation units was a response. Similar secular trends are observable here in some European countries. Already contemporary nineteenth century observers argued from time to time that the rise in the fear of crime exceeded the rise of crime, but crime investigation departments expanded continuously during the nineteenth century, accompanied by a growth of its personnel. When recruiting for these new or restructured crime investigation units, the police in some European countries followed different recruitment patterns than those followed for the uniformed police. The Berlin police headquarters during the second half of the nineteenth century provide a good example for this trend: The recruitment and the career patterns at the crime investigation unit of Berlin police headquarters, the *Kriminalpolizei*, were increasingly based on expertise and specialized training than on military background. This expertise became – not only in Berlin – the more urgent the more the complexity of the expanding cities grew, accompanied by a growing diversification of opportunity structures allowing for theft. Some governments and some police forces in Europe answered to this growing complexity by diversifying its recruitment criteria when hiring men for the crime investigation branch. In order to catch up with this, the Berlin Kriminalpolizei became exempt to military recruitment obligation, to be observed when hiring men for the uniformed police. Among the members of the Berlin Kriminalpolizei were officers with very different backgrounds. There were former army officers of course, but academics as well, whose academic background comprised theology, the humanities, jurisprudence, medicine, and other disciplines. As these men were better paid than their counterparts in the uniformed police, the number of candidates for the detective force soon exceeded the vacancies (Funk 1986; Wagner 1996).

Police Associations and Police Unions

Between 1882 and the beginning of the Nazi regime in 1933, men from different polices in a number of German states founded approximately 100 police associations, representing the interests of its members. Very many of these associations (Berufsvereine) were very ephemeral, but they indicate the attempts of the police officers to organize and to engage in interest politics, to fight for better pay, for better work conditions, and increasingly for an improved training. Due to the local character of very many polices in Prussia, most of the foundations of these associations before the turn of the century were accordingly of local origin. It was quite often before the First World War only that the police officers managed to organize themselves nationwise or statewise. In quite a number of European countries (Belgium, England, France, the Netherlands, Prussia, and other countries), first attempts were made by police officers to organize. These associations mostly took the form of benevolent societies, as policemen were not allowed to create syndicates, i.e., formal unions or to join them. Policemen in most European countries were forbidden to organize these associations or societies as unions (Keunings 2009; Emsley 1991, 2000; Shpayer-Makov 2002; Berlière and Lévy 2011; van der Wal 2007; Jessen 1991). That is one of the reasons, that, although strike and protest action had been carried out in England in particular in London during the 1870s and the 1880s already, attempts to unionize did fail around 1890. This was taken up again shortly before the First World War, when a police union had established itself firmly within the London Metropolitan Police (Emsley 1991, 2000; Reiner 1978; Shpayer-Makov 2002). But this organization had to be clandestine, as policemen were still not allowed to organize in unions. Police officers had to join secretly. The establishment at the Metropolitan police was probably very much inspired by the successful efforts of members of the Paris police, who had founded a professional association in 1912 (Berliére and Lévy 2011). The growth, from 1905 onward, of trade unionism among the police, observable in many European countries was not only meant as a strategy for improving the conditions of pay and work, but included a more general, professional purpose: The more the police perceived themselves as professionalized, the more they regarded themselves as autonomous vis-à-vis nonprofessionals, vis-à-vis the politicians, for example. This purpose gained momentum within many European polices in particular during the 1920s.

Concluding Remarks

The scope of the development of the police as a profession and of members of the policed as professionals remained limited throughout the nineteenth century. Recruitment patterns for uniformed patrolmen, moving away from military recruitment to civil recruitment, changed gradually only. Institutionalized training facilities (police schools) were established, but the number of these facilities remained low in most European countries before the First World War, indicating nevertheless a beginning. Besides the question, whether the police is rather a "bureaucracy" than a "profession," a question today's research is still dealing with (Reiner 1978; Reiner 2000), is another feature of early nineteenth and twentieth century policing which can be seen as a major obstacle for conceiving "police" as "profession," up until today: Uniformed policemen remained throughout the nineteenth and well into the twentieth century a general factotum (Emsley 1991), serving a vast array of functions beyond law-and-order maintenance in a more narrow sense. The late nineteenth century saw in many countries the advent of specialized police branches, specializing on crime investigation, detection, and control. This branch acquired a public prominence already during the last decades of the nineteenth century, when rising fears of crime and disorder enhanced the demands for professional crime fighting. The social defense modus of crime fighting during the decades before and after the turn of the century, focusing on criminal perpetrators threatening "property," served a very specific, ideologically loaded notion of crime. In addition with the high level of public prominence allotted to this ideologically focused crime investigation work, the (societal) status and prestige of the work of uniformed policemen decreased, whereby crime investigation acquired the status of "real" police work, although, seen from a quantitative perspective, crime detection is a minor part of overall police activity.

A final remark: The development of professional police work is quite often seen as a linear and positive process, where professionalism within the police moves from very small beginnings to "real" and successful professionalism throughout the decades of the twentieth century. There is a remarkable a-historical bias in this conceptualization of professionalization along the time axis. A significant number of European policemen, which saw themselves as professionals during the 1930s already, participated actively and very much driven by own initiatives in mass murder or in the preparation of mass murder during the years of dictatorship and war in the 1930s and 1940s.

A Note on the Historiography of Police as a Profession

Early historical research on the history of the police, in particular research carried out by English-language historians during the 1970s, has started by conceptualizing the police as the strong and effective arm of the state. This conceptualization of the police as "state" was very much guided by an understanding of state, quite often orientated toward Marxist notions of "state," as efficiently controlling, supervising, and directing. This approach left little room for asking questions about the quality of police work, which qualifications policemen had for doing police work, and what the quality of police work meant for the control aspirations of the state.

This top-down-perspective, the research had taken when analyzing the police, has changed for a bottom-up perspective only gradually. Within the field of the history of the police as a profession, this change occurred when the historical police research broadened its scope and started to examine in a more detailed way: How police practices were carried out in local and urban contexts, who the men had been, where they came from, how they were trained and paid, and how effectively they performed their control functions in terms of the expectations attached to the police as an efficient control instrument, the expectations attached to the police as law-and-order-maintainers, as professional crime fighters or as "thief-takers." This research demonstrated not only how contradictory and how slow these patterns developed during the nineteenth century, but also shed light on the extent, to which policemen engaged themselves in efforts to increase the performance of police work and that of individual police officers, and to improve the overall status of the police force. This bottom-up perspective not only contextualized the policemen's lot as workers, striving for the status as professionals, but also offered a multifaceted account of the police force as an institution of professionals. The available literature gives a detailed account of how different approaches and strategies (training, expertise, unionization, and status improvement) were applied as professionalization devices until the First World War. Some periods and contexts are still greatly underexplored, however. Only a limited stock of knowledge is available for the interwar years and the impact of their multifold crises on the police's strive for professionalization. Equally ignored by historians for a long time and becoming a research topic only very recently is the issue of what professional police expertise and performance – or the police's understanding of this – had meant for the police's participation in colonial regimes, for its role as being an essential part of dictatorships in many European countries since the 1920s, and for its active participation in murderous and genocidal practices, such as in the Soviet Union in the 1930s or such as under the Nazi regime in Germany after 1933 and in the countries occupied by the Germans between 1933 and 1945.

Inspired by a more recent model of professionalism (which however never replaced that of the professional crime-fighter or "thief-taker"), in which police serve, learn from, and are accountable to the community, historians have drawn on older strands of sociological participatory research on police practices to shift their attention more to police relationships with the public, and to one of the basic issues with regard to the role of the police in Western urban society: the conflict between professional autonomy and popular control. In other words, the bottom-up perspective gradually went hand in hand with less police-centered research, whereby the profession and notions of professionalism are examined in their interactions with society and (the demands and attitudes of) the citizen.

In a similar way, inspired by a shifting emphasis in attempts at increased police professionalization from the late twentieth century onward from a primacy of personnel reform (recruitment, training, pay, etc.) to one of technological managerial reform (whereby ultimately the drive for new efficiency and technology has become dominant over the search for a new policeman), historians have increasingly begun to examine the historical antecedents of "scientific" and "intelligence-led" policing and the use and impact of new technologies on professional practices.

History of the Self-Report Delinquency Surveys

Janne Kivivuori

Synonyms

Hidden crime survey; Offender-based crime survey; Self-report delinquency survey

Overview

Criminologists use survey methods in order to study the full extent of crime, including both unrecorded crimes and crimes recorded by the criminal justice system and related official agencies. The self-report delinquency survey is one of the two major survey instruments currently used by criminologists to that effect (the other one being the victim survey). This entry presents a history of the offender-based self-report delinquency survey. The invention of the research method is described. In addition, the rise of the self-report survey is explained by reference to internal and external factors influencing criminology.

The main scientifically *internal* factor was the problem of unrecorded crime which haunted the age of moral statistics (early criminology) from 1820s to 1930s. The researchers of this era despaired over the impossibility of breaking the official control barrier of crime measurement. The barrier was finally broken by the groundbreaking self-report delinquency survey studies published in 1943 by Austin Larimore Porterfield, professor of sociology at the Texas

Christian University. This moment signifies the end of the moral statistics era and the beginning of scientific criminology because with the survey method criminology became independent of the official control and medical agencies.

While the current use of the self-report method is based on research showing its reliability and validity, the initial rise of the method took place in a specific historical context. Its rise was influenced by the following *external* factors: religious practices and ideologies, populist perception of hidden depravity among the middle classes, the legislative activism of the Progressive Era, suspicion of control biases in an ethnically diverse society, and the largely successful attempt of sociology to take over the field of criminology from the previously hegemonic psy-sciences. Inspired by this historical context of discovery, the first generation of self-report researchers sought to normalize crime by redescribing it as normal, thus giving empirical support for Émile Durkheim's notion that "crime is normal." In addition to these cultural factors, there were also a number of necessary conditions for the widespread deployment of the quantitative and typically self-administered delinquency survey, such as mass literacy and compulsory basic education.

Of the three basic quantitative methods of measuring crime independently of the criminal justice or clinical statistics, the *offender-based self-report survey* (asking offenders to tell about their crimes) preceded the rise of the *victim survey* (asking victims to tell about their experiences) but came after various *proxy report* methods (asking someone who knows offenders) were tried. The modern self-report delinquency survey has three basic features. First, it is based on standardized questions which are identical for the respondents. Second, the instrument is used to produce quantitative data in samples systematically selected by the researcher according to a clearly defined procedure; the samples are not self-selected (as in clinical data), selected by control agents (as in official control data), or unsystematically selected (as in qualitative studies or journalism). Third, the self-report survey is based on confession: the respondents are asked to report, typically anonymously, about the crimes they have committed. This entry presents the history of the modern self-report delinquency survey (for a more detailed description, see Kivivuori 2011).

Moral Statistics and the Official Control Barrier

Within criminology as a discipline, the history and invention of the self-report delinquency is intimately related to the problem of unrecorded crime. That problem was born in the early nineteenth century when European states started to publish the so-called moral statistics, including crime statistics. It was immediately recognized that a major problem with such crime statistics was that they excluded undetected and unrecorded offenses. The immediate solution was the so-called *constant ratio doctrine*. Formulated by Adolphe Quetelet, this doctrine stated that the ratio of hidden crime to known crime was stable, meaning that official statistics was a valid proxy measure for real crime (Beirne 1993, p. 80).

The moral statisticians were never naïve about the problem of hidden crime; they intensely felt that reliance on official statistics was a serious limitation. The concept of "dark figure," coined by the Japanese lawyer Shigema Oba in 1908 (Oba 1908), was thus a continuation of long self-critical reflection in the then almost century-old moral statistics tradition. What ensued was a gradual shift of emphasis in the kind of official statistics which was seen as most valid: the craft of moral statistics moved down the ladder of criminal justice institutions in search for more valid indicators of criminal behavior: from the courts and prosecutors to the police, and within the police statistics, from ascertained to reported crimes and to arrests. Thus, the researchers of the moral statistics era were moving closer to the offense as it looked for means to measure the extent and patterns of crime more precisely. Towards the 1920s and 1930s, the police statistics were prevailing as crime indicators, but this appeared to be the end of the road. There appeared to be no way of proceeding even closer to the offense. By the early decades of the twentieth century, it was typical of crime researchers to despair about the impossibility of direct measures of crime. In recent historical scholarship (Kivivuori 2011), this obstacle and the associated sense of despair has been described as the *official control barrier* of crime measurement. That barrier was almost like the Heisenberg uncertainty principle in physics: empirical observation seemed to be fundamentally warped by it.

Non-survey Responses to the Problem of Hidden Crime

There were however no shortage of attempts at breaking the official control barrier. The self-report survey was not the only (or first) attempt to that effect. Various methods which were subsequently eclipsed by the survey were tried. Often these methods were based on *proxy reports* by informants who for some reason knew about crime; such informants included the police, philanthropic services, medical sources, insurance companies, banking associations, and private firms as sources of information. Some of the proxy report solutions were developed very early; thus, in the 1880s Charles Booth conducted the first "social survey" of the London poor by employing school board visitors as proxy reporters; the social survey tradition was also interested in the morals of neighborhoods. In the early part of the twentieth century, multiple local crime surveys were conducted in various areas of the USA. It is important to observe that in these early stages, the word survey (as in "social survey movement" or "Illinois crime survey," etc.) stood for local fact-finding missions using multiple data sources but not anything like the modern self-report or victim surveys. They were thus non-survey methods of crime measurement. Some proxy report studies used the reporting propensity of institutional victims to derive a multiplier which was then used to estimate the true crime rate from the number of recorded crimes. Other methods included direct observation as in the UK Mass Observation project during the 1930s (Willcock 1949). Some of the early qualitative sociology in the Chicago School style was similarly a means of studying deviance directly, without any intermediaries, following the example of earlier social reports by continental European intellectuals giving first-hand descriptions of "underworlds."

Early Attempts at Systematic Use of Self-Reports

The above-described early solutions to the riddle of the official control barrier often resulted in an anecdotal style of reporting. In contrast, the distinctive feature of the modern criminological self-report delinquency survey is that data collection is based on standardized (identical) questions and clearly defined target group selected by the researcher. Before the first deployment of the full-blown modern self-report survey in 1940, there were occasional incidents were such standardization was attempted.

The surveys of W. E. B. Du Bois (1868–1963) in Atlanta are among the "anticipators" of criminological surveys. In the 1904 Atlanta survey, he asked young people about their contacts with the courts and the police (in any role). While there was no explicit or stated aim of measuring the extent of unrecorded crime, the Du Bois survey represents an early attempt to bypass the criminal justice system in gathering criminological data (Du Bois 1904). At the same time, important developments were taking place in Europe. The surveys of homosexual behavior conducted in Amsterdam (1901) and Berlin (1903–1904) by Lucien von Römer (1873–1965) and Magnus Hirschfeld (1868–1935), respectively, are among the more important anticipations of the discovery of the systematic self-report delinquency survey. Today of course homosexuality is not a crime in most developed nations, but a century ago it was, making the von Römer and Hirschfeld surveys count as among the earliest systematic self-report delinquency surveys. Both the Dutch and the German surveys were connected to the activities of Hirschfeld's Scientific-Humanitarian Committee, a liberal pressure group which aimed at normalizing sexual deviance by showing its huge prevalence.

Römer and Hirschfeld were both trained in medicine. Interestingly, Hirschfeld referred to the Catholic practice of confession as a source of inspiration in the development of the self-report survey. Other sources of inspiration included early US educational sociologists making surveys in schools. Typically for self-report delinquency research, both pioneers used student samples, but Hirschfeld additionally surveyed blue-collar workers by mail survey. Fifty years later, the Kinsey research team observed that Hirschfeld deserves "considerable credit for having tried on a larger scale than anyone had before to ascertain the facts on a matter that has always been difficult to survey" (Kinsey et al. 1948, p. 620).

Within psychology, the 1920s witnessed the development of what is today called the social desirability scale. The social desirability scales are used to control for the validity of survey responding. However, the development of the social desirability measures remained largely separate from the work that led to the modern self-report delinquency survey.

Approaching Takeoff: The Sutherland Experiments

In 1931, Thorsten Sellin formulated the axiom which later became known as Sellin's law, stating that "Due to a number of variable elements represented by changes in administrative policies and efficiency, the value of a crime rate for index purposes decreases as the distance from the crime itself in terms of procedure increases" (Sellin 1931–1932, p. 346). At about the same time, a century of reliance on official criminal justice statistics climaxed in a sequence of local crime surveys in various US cities and states. These were surveys in the old meaning of the word (fact-finding missions), but they were all "moving towards the offense" as stipulated by Sellin. In many ways, the most sophisticated old-style local delinquency survey was the one conducted in New York by Sophia Moses Robison, published as *Can Delinquency Be Measured* (1936). Her idea was to collect statistics from all kinds of control and philanthropic institutions, not only the police. She thus shifted the boundary of recorded and unrecorded crime by including more records, a strategy that still remained within the paradigm of moral statistics. Sophia Moses Robison (1888–1969) was however aware of these limitations; she suggested that delinquency data could be collected by asking people about it; indeed, it was known to her that Edwin H. Sutherland was trying to do something like that.

It is apparent that Sutherland (1883–1950) was conducting self-report experiments among his students. Throughout the mid-1930s his writings and speeches occasionally refer to efforts at breaking the official control barrier of crime measurement. Speaking to the Milwaukee police in 1936, he described one such experiment as follows: "Of a class of forty, ten did not hand in papers, and since I had no signatures, I could not tell whether they were lily whites or had so many and so serious thefts that they refused to tell. Of those who did hand in reports, only one insisted that he could remember no thefts" (Sutherland 1936, in Snodgrass 1972, p. 222). This experiment had most aspects of the standard SR survey: standardized question, researcher-selected population, and confessional logic. The results revealed a very high lifetime prevalence of theft (97 %, N = 30). Sutherland used these survey experiments to press the point that crime was very prevalent and therefore normal (see also Sutherland 1973 [1936], p. 143 and 1972 [1937], p. 213).

Breaking the Official Control Barrier of Crime Measurement

Austin Larimore Porterfield

The first modern criminological self-report delinquency survey was conducted in 1940–1941 by the Texan sociologist Austin L. Porterfield (1896–1979). The year 1940 can thus be seen as the moment when the official control barrier of crime measurement was finally broken. The result of the survey was first published as the article "Delinquency and Its Outcome in Court and College" (Porterfield 1943) but became more widely known as part of his monograph *Youth in Trouble* (1946). Porterfield's discovery marks the moment when the discipline of moral statistics was transformed into the science of criminology, because at that point the empirical study of crime became independent from data created by agencies of the state.

Porterfield tried to make his questions about crime as similar as possible to the repertory of the offenses defined by the law. In two consecutive data collections in three Texan educational institutions (1940–1941 and 1941–1942), he targeted both precollege and college students about their crimes; the total number of respondents was 337. The results showed a "universal prevalence of past delinquency among college men and women" (Porterfield 1946, p. 38). More than one in five males had driven when drunk, while 62 % had participated in ordinary fighting. Ten percent had shoplifted. At the time, these figures where shockingly high. Like Hirschfeld, Porterfield interpreted his findings by underscoring the high prevalence and hence *normality* of crime. Delinquents were "not a sub-species of Homo Sapiens"; they were like all of us (Porterfield 1946, p. 45). Anticipating problems related to this interpretive frame, he however noted that incidence measures of crime might show different results, marking essential differences between nondelinquents and delinquents (Porterfield 1946, p. 42). Otherwise his take-home message was that delinquency was normal. He rejected the notion that delinquents are fundamentally different from the "law-abiding" citizen. He was a strong critic of what he called the "we-they" fallacy, the tendency to see a black-and-white distinction between supposedly "abnormal" criminals and a (putatively) law-abiding majority (Porterfield 1957, p. 46). The great importance of Porterfield's work was not immediately recognized, but already in the 1950s his work became known as the initiator of the self-report delinquency survey tradition.

Porterfield's style of writing and analysis was satirical. He critiqued the hypocrisy of the local elites by first exposing how their punitivity was compromised by their hidden delinquency. Characters such as store managers, middle-class parents, drunken police chiefs, and members of the Ku Klux Klan were satirically exposed as hypocrites. The breakthrough phase of the self-report delinquency survey thus combined quantitative analysis and social critique.

The Randen Foundation Crime Survey

Apart from Porterfield's groundbreaking studies, the second most important early self-report delinquency survey was Randen Foundation Crime Survey, the results of which were published in 1947 by James S. Wallerstein (1910–1990) and Clement J. Wyle (1903–1991). The title of their seminal paper was typically satirical, like many other early self-report studies: "Our Law-abiding Law-breakers" (Wallestein and Wyle 1953 [1947]). This study expanded the application of the newly invented method to adult population in contrast to student samples used by Sutherland and Porterfield. The data collection took place in the state of New York, with 1,698 respondents in the final dataset (response rate not known). As in other pioneering self-report surveys, the main finding was that lifetime participation in criminal activity was much more prevalent than typically expected. Nearly half of the male respondents reported "assault," while one in six admitted to burglary. Wallerstein and Wyle duly noted that some of the high figures may have reflected people's broad conceptions as to what "assault" means. However, the main finding was that unrecorded criminality was very prevalent in the population. Like other pioneers of the self-report survey, Wallerstein and Wyle underscored the high prevalence and therefore the normality of (occasional) crime. They also developed the random control argument, suggesting that being registered for crimes might reflect chance events more than criminality as such. Like Porterfield, they also critiqued the punitive mind-set of the putatively law-abiding people. During the late 1940s, Wallerstein published several articles using the normal-because-prevalent argument to critique punitivist attitudes.

Cambridge-Somerville Youth Study

When the early tradition of self-report delinquency surveys was shaped, a third important study was the Cambridge-Somerville Youth Study (CSYS). Its main goal was to asses in an experimental setting the efficacy of social work in the prevention of crime (Powers 1949). During the course of the project, much first-hand information was collected from the boys who participated in the experiment. In an article published in 1946, the CSYS workers reported the very high prevalence of unrecorded crime among the project subjects (Murphy et al. 1946). They concluded that because of the great frequency of undetected crime, changes in the efficacy of social control could drastically influence crime trends based on official statistics. In so arguing they thus presented a strong empirical critique of the constant ratio doctrine. Later on these findings were also interpreted from the point of view of normal-because-prevalent argument (Powers 1949, p. 82). While the Murphy et al. study was and is often cited as one of the first hidden crime studies, it remains a borderline case with respect to the modern self-report delinquency survey. Based on the psychiatric case worker data collection, its level of standardization remained comparatively obscure. The inclusion of boys who were known to come from disadvantaged backgrounds was also unique for this project. This was important because it enabled the CSYS researchers to conclude that boys with higher intensity of offending were more likely to be prosecuted and convicted. This finding was a crack in the moral framework based on the alleged normality of offending, something that was immediately recognized by Porterfield (1947, pp. 425–426).

External Factors Influencing the Rise of the Self-Report Survey

From the perspective of the internal development of criminology as a science, the self-report survey was a way of breaking the official control barrier in crime measurement. The survey enabled the systematic quantitative study of offenses which are not known to criminal justice or medical authorities. The invention of the self-report survey in 1940 thus marks the moment when moral statistics was transformed into scientific criminology because at that time criminology became independent of the control system of society.

Like all scientific innovations, the invention of the self-report delinquency survey took place in a specific historical context involving a constellation of social, cultural, technological, and policy-related influences. In science studies, the difference between internal scientific developments and external influences is often conceptualized with the so-called context distinction which separates the context of justification and the context of discovery when explaining an innovation in science (Schickore and Steinle 2006). The context of discovery captures all external influences which are not strictly internal to science. In what follows, the major external influences defining the context of the rise of the self-report delinquency survey are described.

Religious Influences

Previously, it has been suggested that the rise of the self-report survey was linked to the punitivist mind-set of the American Puritan tradition, which would have made scholars very interested to study minor infractions. Recent historical research (Kivivuori 2011) has definitely refuted this thesis by showing that the first-generation self-report researchers were typically liberals attacking punitivist attitudes by empirically showing the high prevalence and hence normality of crime. But it is correct that there is a religious substratum in the relevant paradigm shift. Hirschfeld's early work was inspired by confession as a religious practice. But more importantly, the generation of US scholars who pioneered the self-report method came from backgrounds influenced by the so-called Christian Sociology and the Social Gospel movement. From the end of the nineteenth century, these traditions sensitized scholars to the notion that seemingly law-abiding persons could be hidden offenders. In the beginning, this was associated with corporate offenders and "criminaloids" who were later renamed as white-collar offenders. Books such as *Sin and Society* (1907) by the sociologist Edward Alsworth Ross were influential bridges between religious and secular types of populism (see below). More generally, the critique of hypocrisy was based on the latent religious notion that since we are all offenders, it is wrong to judge harshly those who are detected offenders. Thus, many first-generation self-report researchers were inspired by the Biblical dictum "He who is without sin among you, let him throw the first stone" (John 8:3–7). This is pronounced in writers such as Porterfield, Wallerstein, and especially among the Nordic pioneers of the self-report survey.

Populist Traditions

The US populist tradition, which can be seen as a secular offshoot of the Social Gospel movement, was also an important part of the context which sensitized a generation of sociologists to see hidden criminality. The critique of "robber barons" transformed into the study of (the largely unrecorded) crimes of the white-collar offenders. It is no coincidence that Sutherland continued this tradition in his classic *White Collar Crime* (1948) while simultaneously experimenting with the self-report method. Both endeavors were based (or intended to show) that crime was committed by persons who were psychologically perfectly normal. Indeed, in its early phases, the self-report delinquency survey was regarded as part of the more general subfield of "white-collar crime studies", and this lasted at least until the 1950s. The US populist and Progressive Era also impacted criminology by initiating a period of intense legislative activism. As new behaviors were defined as crimes, the need to replace official statistics as the most important data source of criminology became very acute.

Suspicion of Biased Control in Ethnically Diverse Society

One of the contextual factors that sensitized US scholars to the artificiality of the official crime data as a social construction was the treatment of minorities. Scholars such as W. E. B. Du Bois wanted to know whether rising figures of recorded crimes reflected the increasing "efficacy of the judicial system in ferreting out and punishing crime" and concluded that crime statistics are "too mingled with extra-moral causes to be trustworthy" (Du Bois 1904, p. 10; Du Bois and Dill 1914, p. 11). Thorsten Sellin was also motivated by the same problem in his efforts to improve crime indexes.

Disciplinary Conflict

A very important external factor in the rise of the self-report survey was the disciplinary warfare between sociology and the psy-sciences (psychiatry and psychology). The abnormality paradigm of the psy-sciences had been hegemonic in criminology since the times of Lombroso. In contrast, the self-report survey was invented and supported by sociologists. They used this new empirical instrument to show that criminal behavior was so prevalent that it was impossible to see it as a sign of abnormality. This gave empirical boost to Émile Durkheim's early notion of crime as a "normal" social phenomenon. Sutherland especially was known as a long-standing critic of psychiatry and psychology; his link to normal-because-prevalent argument is part of that picture. Key sociological mandarins of the mid-twentieth century period, such as Robert K. Merton, used the earliest self-report surveys in arguing against psychology and psychiatry. The high cultural salience of Freudian psychoanalysis during the Post-War era in the USA probably helped to disseminate the notion that deep down, every person is deviant. This may have supported the acceptance (though not the invention) of the self-report delinquency survey. Indeed, it can be argued that the normality notion was the single most important part of the context of discovery in which the self-report delinquency survey was invented. This was so especially in the original discovery and in the second phase when the Nordic countries applied the method from the late 1950s.

Attack Against Punitivity

The first generation of self-report researchers used quantitative social analysis to attack notions which would today be described as "right wing" or "punitivist." Porterfield, Wallerstein and Wyle, and especially the Nordic self-report pioneers strongly critiqued harsh punishments. They argued that since everyone commits crimes, it is unjust to be harsh towards the few who are detected. This argument was intimately connected to subterranean religious traditions, and it was also possible to combine it with populism. From the perspective of disciplinary conflict, the empirical proof of the normality of crime was used both against the psy-sciences (crime is normal) and lawyers (punishments are unfair and ineffective). In critiquing outdated normative and repressive regulation with reference to high prevalence of "deviant" behaviors, the first generation of self-report delinquency researchers spearheaded the kind of argumentation which was also evident in the more famous Kinsey report of sexual behavior (Kinsey et al. 1948).

Other External Preconditions

The self-report survey was a means of breaking the official control barrier of crime measurement. Its success in this task was context dependent and socially embedded in multiple ways. First, the deployment of the survey in large populations required the rise of mass literacy. The historical link of the survey with educational institutions is thus very strong: the rise of basic education created the conditions of the survey by disseminating literacy and by additionally constituting an institutional basis for the survey as much of the early work was targeted at students. The crucial importance of the rise of the state-sponsored literacy is testified by Hirschfeld's ability to conduct a self-report mail survey among German blue-collar workers in the early years of the twentieth century.

Later on, the closely related development of newspaper publishing, opinion survey techniques, and improvements in sampling theory further helped in the creation of techniques that would later be applied in criminology as well (Converse 2009). An important precondition was also the existence of a critical mass of empirically oriented social science researchers and sufficient research funding. These factors were probably decisive in explaining why the official control barrier was broken in the United States as opposed to Europe.

In sum, the slow development of crime indicators during the long century of moral statistics from 1820s to 1930s cannot be attributed to a lack of insight among the moral statisticians. For much of that period, the necessary external preconditions of quantitative and literacy-based mass surveys were simply not in existence. When the required conditions emerged, cutting-edge scientists were quick to break the official control barrier. The time and place where this happened (the USA in the 1930s) was additionally influenced by the cultural movements described above.

Developments After Initial Discovery

The above narrative describes how the self-report delinquency survey was initially invented as response to an internal problem of crime measurement. The breakthrough took place roughly between 1930 and 1950 in the United States. While there were multiple external factors which influenced this process, it is important to underscore that the continued scientific use of the method was soon disconnected from the heavily morally driven context of its original historical discovery. Today criminologists use the self-report delinquency survey because its reliability and validity is ascertained in independent methodological research. Indeed, recent historical research has shown that much of the post-1950 development of the survey ironically produced results which were not expected nor anticipated by the generation that first started using the method. The notion of normality is a case in point. When the incidence measures of the surveys were improved, the small minority of "abnormal" or "chronic" offenders made a spectacular comeback, and this time his existence could not be denied by the claim that he was a social construction created by biased control. This shows that it is important to use the analytic distinction of context of discovery and context of justification in the historical analysis of science.

Mainstream Departs from the Normality Framework

The Post-War era witnessed what has been described as the Americanization of social sciences (a process that took place in the USA and elsewhere, see Haney 2009). This process involved a detachment from moral- and politics-oriented research and a move towards a more positivist style research based on incremental accumulation of knowledge. The development of the self-report delinquency survey since the 1950 was no exception to this trend. The work of James F. Short and F. Ivan Nye concentrated on the scale development of self-report instruments and then moved towards analysis of delinquency causation. Harrison Gough, Walter C. Reckless, Simon Dinitz, and others also shared these goals. Starting from this period, validation studies increasingly suggested that official control may be biased but not random with respect to criminality.

Nordic Revival of the Normality Framework

The first geographical dissemination phase of the self-report delinquency survey involved the Nordic countries. For a long time and until the early 1980s, it was possible for observers to comment that "most studies of self-reported delinquency have been American or Scandinavian" (West 1982, p. 20). Ultimately, this reflects the close ties of Nordics with the USA after the Second World War. The first pilot studies were initiated in 1959 by the Norwegians. Soon after that the Nordic Research Council of Criminology created an ambitious all-Nordic effort known as the Nordic Draftee Research project. The NDR project was globally the first internationally comparative self-report delinquency survey and kept this pioneering position for a very long time. The findings of the NDR were similar to the US precedents, and the Nordic scholars enthusiastically underscored the normal-because-prevalent argument, using it to critique the psy-sciences and the old-school lawyers for ungrounded punitivism. Today, self-report delinquency research remains one of the focal areas of Nordic criminology (Kivivuori and Bernburg 2011).

Subsequent Developments

During the 1960s and early 1970s, the self-report delinquency survey started to spread to areas outside the US and the Nordic area. The sheer volume of research increased as its flexibility in testing theories was fully recognized (Krohn et al. 2010). The 1960s witnessed several countries making efforts towards nationally representative youth samples, and self-report measures were being incorporated to longitudinal projects such as the *Cambridge Study in Delinquent Development* (West and Farrington 1973). After that, there was a period of slower dissemination and, in some countries, even stagnation (Aebi 2009, pp. 31–32). This partially reflected the reemerging interest in register-based studies. After all, the self-report delinquency survey had itself corroborated that the frequent offender existed and that, furthermore, the frequent offender was more likely to be arrested than others. This result supported the feasibility of register-based data in crime analysis. The classic monograph *Delinquency in a Birth Cohort* by Wolfgang et al., published in 1972, is a case in point. Additionally, for some time since the late 1960s, the energies of survey-based researchers were directed to the development of the victim survey as distinct from the offender-based self-report survey. These developments may partially explain, for instance, why the first full-blown international self-report project became reality only in the early 1990s when the *International Self-Reported Delinquency Survey* was launched at the initiative of Josine Junger-Tas. With the partial exception of the Nordic experience in the 1960s, all these developments took place in the neutral framework of crime measurement. The offender-based survey had become a regular and objective methodological tool of criminology with no connections to the morally loaded period of the initial discovery phase.

Further Readings and Research Needs

The history of the self-report delinquency survey method in criminology has been recently described in greater detail in the monograph *Discovery of Hidden Crime* (Kivivuori 2011) which covers both the original discovery phase in the US and the Nordic sequel. Krohn et al. (2011) provide an insightful overview of how the self-report delinquency survey has influenced theoretical developments in criminology. An in-depth description of the first internationally comparative self-report delinquency survey, the Nordic Draftee Research program, is also available (Kivivuori and Bernburg 2011). While the history of criminology has evoked more scholarly interest over the recent years, several important research problems call for further scrutiny. The prehistory of the self-report delinquency surveys probably goes further back in time than the von Römer and Hirschfeld studies and remains to be charted. Studies of survey history would also benefit from a closer look at the relationship of sexology and criminology because before the historically recent relaxation of moral legislation, sex surveys may have contained questions on criminalized behaviors. It is also known that the Kinsey survey influenced US criminologists. While the Kinsey report came after (1948) the key breakthroughs of criminological self-report studies, there were earlier sex surveys which may have influenced criminologists. The criminological work also influenced sex research as scholars like Porterfield were active in both fields.

Furthermore, more historical and archival work is needed on the period which immediately precedes the Porterfield breakthrough. Furthermore, it might be of some interest to know more about the strange role of the polymath and novelist James S. Wallerstein whose article “Our Law-abiding Law-breakers” (1947), coauthored with Clement J. Wyle, was very influential in criminology. On a more general level, an in-depth history of the victim-based survey remains to be written; such an enterprise might benefit from explicit comparison with the (historically earlier) rise of the offender-based self-report delinquency survey. The history of the self-report delinquency survey provides an important lesson generally for science studies: while the discovery of the method was strongly embedded in specific moral and policy framework (normality of crime), its deployment yielded empirical results which partially contradicted that very framework. Observation was initially theory laden, but empirical findings forced researchers to modify their theoretical framework. This also means that “theory history” and “methods history” cannot be separated.

Overview

This entry provides an account of the history of statistics and its relation to criminal justice and criminology. It describes how the "Law of Errors," initially based on astronomical observations, was adopted to explain "social physics" and in particular, the relative constancy of crime. Analytic methods that were developed to uncover patterns in data, which were not apparent prior to the utilization of the new methods, are described. Frequentist and Bayesian views of statistics are discussed, as well as issues surrounding some of the analytical methods used in criminology and criminal justice, including the concept of "statistical significance"; these issues are often glossed over by those who apply them.

Introduction

When a researcher in criminology and criminal justice does statistical analysis nowadays, all too often it goes like this. S/he:

- Gets permission to access a data set – for example, the National Longitudinal Survey of Youth (NLSY), the National Longitudinal Study of Adolescent Health (AdHealth), and the Project on Human Development in Chicago Neighborhoods (PHDCN)
- Then develops a "model" [*about which* Freedman (1985: 348) *noted: In social-science regression analysis, usually the idea is to fit a curve to the data, rather than figuring out the process that generated the data. As a matter of fact, investigators often talk about 'modeling the data.' This is almost perverse: surely the object is to model the phenomenon, and the data are interesting only because they contain information about that phenomenon. Whatever it is that most social scientists are doing when they construct regression models, discovering natural laws does not seem to be uppermost in their minds*]
- Calls it into one of the four Ss (SAS, SPSS, Stata, Systat) or some other collection of canned statistical routines
- Tweaks the model
- Looks for an encouraging p-value and starts writing.

This process was not always the case. First, data were hard to come by, and the researchers themselves often had to laboriously collect them. Second, and the topic of this entry, there were very few methods available to perform the analyses. The early statisticians had to develop these methods – and perform the calculations without the aid of even a calculator.

This entry describes the history of statistics and its relation to criminal justice, the analytic methods that were developed to uncover patterns in the data, and issues surrounding the analytical methods. The first section describes the early history of statistics used in demography. Section 2 describes the development of the "error law." Section 3 then details how the "error law" was misapplied to criminal justice data. Sections 4 and 5 describe the development of new analytic methods in the early twentieth century as well as the development of statistical analysis in the field of criminology. Section 6 discusses how these methods lead to hypothesis testing and statistical significance.

Early History

The practice of searching extant records for patterns seems to have been initiated over three centuries ago by John Graunt (Hacking 1975: 102). Church records, not state records, were the original source of demographic information. While examining London's church records of births and deaths (called Bills of Mortality), Graunt generated mortality tables that calculated the likelihood of an individual surviving to any age. These statistics were then used to estimate the number of London males eligible for military duty. As a result of this use of the Bills of Mortality, a number of European governments mandated that they be collected and provided to them (Hacking 1975: 102). One of Graunt's contemporaries, William Petty, "was a man who wanted to put statistics to the service of the state" (Hacking 1975: 105); he termed this use of data "political arithmetic" (Porter 1986: 19). The word "statistics" (*statistik* in German) was coined by Gottfried Achenwall in 1749 (Hacking 1990: 24), and soon replaced Perry's invention.

The first to use the Bills of Mortality for analytic purposes appears to be John Arbuthnot, who gathered data on birth cohorts at the end of the seventeenth century. He found that the ratio of male to female births was stable across years and location and wrote a monograph entitled "An argument for Divine Providence, taken from the regularity observed in the birth of both sexes" (Stigler 1986: 225). In other words, he equated this particular year-to-year regularity of an unequal number of births between males and females as proof of the existence of God. Since men lived lives that likely led to an early death, more men needed to be born each year compared to women.

[Of course, a statistician would point out that tossing a coin provides the same regularity, but perhaps s/he would not attribute this regularity to divine providence. Not only that, but ironically it took a Czech monk, Gregor Mendel, to show (in 1865) that even in genetics, a probabilistic model would suffice.]

Even earlier, in 1713, Jacob Bernoulli sought to explain such regularities in more detail. He determined that as the number of trials increased, the uncertainty about an event's true proportion of successes would decrease. Bernoulli tested his propositions by considering an urn that contained a number of two different colored balls in regard to the chance of pulling a certain colored ball out of the urn. He later applied these ideas to real-life examples (Stigler 1986: 65). Instead of ascribing this regularity to divine providence, Bernoulli showed that as the number of births (or other binomial phenomena) increases, the true proportion will be approached, which is why there was stability in the proportion of births over 80 years of data (Stigler 1986: 64ff).

Twenty years later, Abraham De Moivre made a significant contribution to Bernoulli's work on binomial statistics. He developed a formula that approximated the binomial probability distribution for a fair coin ($p = 0.5$), which resembles the symmetrical normal distribution of today. He showed that as the number of observations increases, the binomial distribution becomes a smooth curve which is highest at the true proportion (p) and whose logarithm drops off proportional to the square of the deviation from the mean. This led him to develop a concept similar to the central limit theorem, which was later refined by Pierre-Simon Laplace in 1781 (Stigler 1986: 136). These advances eventually led to the consideration of the concept and characteristics of statistical distributions since, although a particular value of p was the most likely outcome, values near p were also very likely.

A parallel effort in matters probabilistic was undertaken by Thomas Bayes in 1763. His eponymous theorem showed the way to update an estimate of a probability distribution or set of statistical parameters after one has obtained new data. His formula,

$$\text{posterior probability} = \text{likelihood} \times \text{prior probability}$$

stands in contrast to the frequentist view of statistics, based on sampling theory, that provides a probability estimate of the *data* rather than of the parameters. As Lindley (1992: 360) noted,

> [T]he concept of a significance level or a confidence coefficient, although probability statements, are [sic] not about the hypotheses nor the parameters, but about the data. It is this failure to use probability for hypotheses and parameters that distinguishes the frequentist, sampling-theory approach to statistics from the fully-coherent Bayesian approach.

The prior probability refers to the initial belief of the probability of an event occurring, while the likelihood is the probability that other observations will occur given some new data, and finally the posterior probability is the new belief based on the prior and the likelihood. Over time, Bayes' theorem has been advanced by many mathematicians and statisticians and had undergone serious critique but yet never disappeared (McGrayne 2011). In criminology it has been used in estimating recidivism parameters (Maltz 1984: 150) and in studying rational choice and deterrence (Anwar and Loughran 2011).

The "Law of Errors"

[This section relies heavily on Stigler (1986).] Concepts related to statistical distributions were also found when considering measurement error. When repeated observations are made, for example, of the angle between the horizon and a star for navigational purposes, they rarely produce the same number. Dealing with the variation in these observations was an important statistical issue in the eighteenth century, especially for seaborne navigation out of sight of land. Building on De Moivre's work, Thomas Simpson decided not to concentrate on the distribution of the *observations* but rather on the *deviations* between the observations and the true value or the errors (Stigler 1986: 90). While this may seem obvious now, at the time this was a major step forward since it moved away from the actual event, the observation itself, to an abstract quantity, the error, and its distributional properties.

Simpson made a number of simplifying assumptions about the error distribution and about the law of large numbers but was able to provide useful advice to astronomers that improved the way they dealt with error. But he (and Laplace after him) showed that the error curve was relatively symmetrical, and as the size of the error increases, the probability of it being that large should decrease monotonically away from zero.

Subsequent work by Carl Friedrich Gauss and Adrien-Marie Legendre showed that the mean of a series of observations minimized the sum of squares of the errors from the mean. Further, Gauss posited that the normal distribution (also known as the Gaussian distribution) was the appropriate distribution to use. His argument

> was essentially both circular and non sequitur. In outline its three steps ran as follows: The arithmetic mean (a special, but major, case of the method of least squares) is only 'most probable' if the errors are normally distributed; the arithmetic mean is 'generally acknowledged' as an excellent way of combining observations so that errors may be taken as normally distributed (as if the 'general' scientific mind had already read Gauss!); finally, the supposition that errors are normally distributed leads back to least squares. (Stigler 1986: 141)

The Error Law, Crime, and "Social Physics"

In the nineteenth century, a Belgian physicist, Adolphe Quetelet, began to apply these new statistical tools to social data. France had begun to collect criminal justice statistics in 1825, and Quetelet noted the relative constancy in the number of persons accused of crime and the percent convicted (Stigler 1986: 179). Of course, there may have been other reasons for this constancy – police, prosecutorial, or judicial manpower limitations, arrest quotas, and a limited prison capacity – but these were not considered.

Instead, Quetelet saw in this statistical regularity "signs of a deeper social reality" and wrote of the "average moral man (*l'homme moyen morale*)." While considering how the repeated flipping of a coin with probability p would produce a distribution of outcomes centered on p, he posited that the same would hold for humans; there was a fixed value for social phenomena as well, deviations from this value being error. He surmised that "[I]f an individual at any given epoch of society possessed all the qualities of the average man, he would represent all that is great, good, or beautiful" (quoted in Stigler 1986: 171). And based on a mistake in the data, he noted a gradual decrease in the annual conviction rate and assumed that the population was getting more moral over time.

Simeon-Denis Poisson had a different view of the conviction process. Using corrected data, he modeled jury decision-making as a binomial process and found that the variation in rates over time was "not so large as to support a belief that there has been a notable change in the causes" (Stigler 1986: 190). In other words, the year-to-year variation was not, in current terminology, "statistically significant."

Back to Quetelet essentially inverted the logic behind the "error law." That is, he implicitly assumed that if errors are generally normally distributed, then whenever we find a distribution that is normally distributed we can safely assume that there is an underlying "truth." This "truth" is a trait common to all persons but corrupted by errors. Quetelet called this truth a population's *penchant au crime*: he wrote "Society prepares the crimes and the guilty person is only the instrument," implying that "free will exists only in theory" (Hacking 1990: 116).

This idea that a population had fixed social characteristics, and that individual differences were due only to natural variation, continued to be believed. Emile Durkheim also concluded that there were social laws that acted on all individuals "with the same inexorable power as the law of gravity" (Hacking 1991: 82; see also Duncan 1984: 99). For example, he wrote of "suicidogenetic currents" in society, as if there was an innate propensity of the same magnitude for suicide within every individual (Hacking 1990: 158).

Others, especially Francis Galton (1889), criticized this approach. He saw variation as natural and desirable and criticized those who focused on averages as being "as dull to the charm of variety as that of the native of one of our flat English counties, whose retrospect of Switzerland was that, if its mountains could be thrown into its lakes, two nuisances would be got rid of at once" (quoted in Porter 1986: 129). Yet Galton's view was not shared by most of the social scientists of the time. In fact, there was widespread belief that those far from the mean were deviant in the pejorative sense of the word and that they were "errors." Statistics was not seen then so much as the science of variation (Duncan 1984: 224) as it was the science of averages.

Vestiges of this belief continue to this day (Savage 2009). In criminology, the General Theory of Crime (Gottfredson and Hirschi 1990) attributes all criminality to be generated by a single cause: lack of self-control. A lack of self-control may indeed lead a pedophile, a person engaged in insider trading, a serial killer, a drug dealer, and a pickpocket to perform criminal acts. However, making that assertion is no more useful than attributing all cancer to the same cause, uncontrolled cell growth: bone, breast, colon, lung, and prostate cancer have different etiologies, and each should be dealt with differently. They should not be looked upon as variations on a single theme.

Early Analytic Methods

Following in Galton's footsteps, Karl Pearson made further improvements in statistical methods and helped to bring statistics into the social sciences. Pearson, in 1900, embraced the centrality of the normal curve in statistical theory by asserting that any measurement that was three standard deviations from the mean was significantly different from the mean. This new concept became known as the "rule of three." Significance levels led way to early conceptions of hypothesis testing, which would eventually lead to the multitude of tests we have today (Ziliak and McClosky 2008).

In the 1920s Ronald Fisher introduced the concept of random sampling and controlled experiments. He accounted for individual variation and argued that control and experimental groups were needed to test treatments. The two groups needed to be generated by random assignment to one or the other from the study population, since each subject should have an equal and independent chance of being selected for either group. This would make it very likely (but not certain) that a representative sample populated both experimental and control groups.

Fisher also placed guidelines on determining a sample size. It is necessary to have a certain sample size based on characteristics of the groups in order to get reliable results. Nowadays power analysis software is used to determine the appropriate sample size for each group.

Fisher also promoted formal hypothesis testing and generated statistical tables for use by researchers to determine the level of "significance" of a finding. The "rule of 3" suggested by Pearson was not sufficient, and Fisher recommended setting an alpha level (often at 0.05) to determine "statistical significance." The alpha level is the probability that the hypothesis (of "no difference" between, say, experimental and control groups) is correct. If this hypothesis is rejected, then it is concluded that there is a difference.

There is a controversy over significance testing that continues to this day (e.g., Cohen 1990, 1994; Loftus 1993; Maltz 1994a; Savage 2009; Wilkinson et al. 1999; Ziliak and McClosky 2008), due in part to the use of the term "significance." Alfred Blumstein has suggested that the word "significance" be replaced with "discernibility," since the nonstatistical meaning of the word "significance" is "importance"; many *statistically* significant findings are far from *substantively* significant, and what the tests actually show is the extent to which one measurement is discernible from another.

Experiments can be costly, and one cannot always generate a large enough sample to invoke the central limit theorem and the assumption of normality. William Gosset found this to be the case while working at the Guinness brewing company. Since his employers did not want their competitors to see how his statistical findings could benefit them, Gosset published his findings under the name "Student", in 1908. He found that he could not use the standard z-score tables, which were based on the normal distribution. Instead, he developed a distribution useful for hypothesis testing with a small sample. Later on, Fisher would adjust the formula, and the Student's t-distribution was created (Ziliak and McClosky 2008).

The accomplishments of these statisticians should not be underestimated. They had to deal with data that needed to be collected, often by themselves, with no computing aids except for statistical tables compiled with an enormous expenditure of time and patience. They were positing crude models that they hoped would give them insights into patterns of complicated processes. Their focus on means and variances was doubtless due to the fact that in order to develop findings of any value, they had to use summary statistics to characterize the distributions. That they succeeded so well in these endeavors is a testament to their perseverance and ingenuity.

The Twentieth Century and the Birth of Criminology

In the 1920s, however, another way of looking at data was developed by University of Chicago sociologists (the "Chicago school" of sociology).

Rather than base their analyses on a data set's distributional properties (mean, standard deviation), they focused on its geographical variation. Two types of data emerged from this era: neighborhood data and ethnographic data.

Building on the work of Park and Burgess in *The City* (1925), Shaw and McKay (1942) collected data on the variation in juvenile delinquency rates in different neighborhoods in Chicago over several time periods and mapped the data. They then looked at the distribution of these rates and noticed that neighborhoods nearest the city center had the highest rates of delinquency, and as one moved away from the center, crime rates declined. In order to understand the reasons for the varying crime rates, they also gathered data on residential mobility, racial heterogeneity, and socioeconomic status. Shaw and McKay found that in areas with high crime rates, there was a large amount of residential turnover, racial heterogeneity, and low socioeconomic status, all of which decreased in places farther from the city center. Their findings supported the ecological perspective proposed by Park and Burgess. The methods of Shaw and McKay were highly influential and opened up the use of qualitative analysis in criminology (Noaks and Wincup 2004). It set the stage as well for geographical analyses in criminology, including computer-based crime mapping (Maltz et al. 1991) and hot spot analysis (Sherman and Weisburd 1995).

Another method of analysis used by the Chicago school was ethnographic analysis. In particular, the Chicago school is known for its use of life histories. In this method, a person is interviewed about his/her own personal history to understand the events in life that may have triggered crime and delinquency. One well-known life history study is *The Jack Roller* (1930) by Shaw, who interviewed a boy that had been institutionalized. Using official records, Shaw conducted the interview to fill in the story around each police interaction. Eventually an in-depth story was put into a book that followed this boy's delinquent career. This type of method allows the criminologist, or any researcher, to reach new causal hypotheses than can be further tested with data. Although ethnographies are qualitative and not statistical analyses, they can help derive new theoretical insight that can be studied with quantitative methods (Sampson and Laub 1993).

Hypothesis Testing and Statistical Significance

There has been a growing discontent with the (over)use of hypothesis testing and the search for statistically significant findings in the social sciences (e.g., Cohen 1990, 1994; Loftus 1993; Maltz 1994a). As a consequence, the American Psychological Association formed a committee, the Task Force on Statistical Inference (TFSI), to deal with it (Wilkinson et al. 1999), and various books (Lieberson 1985; Savage 2009; Ziliak and McClosky 2008) have taken up the cause as well.

In addition, there is growing evidence that many such findings may not be replicable, and often the initial finding turns out to be less "significant" due to regression to the mean. Moreover, journals are not interested in insignificant findings since they "show nothing." Unfortunately, many interesting articles go unpublished that could have useful findings, since a null finding may have its own policy implications (Lehrer 2010).

These hypothesis tests are often based on a comparison of mean values. Using the mean assumes that there is a unimodal distribution based around the average of the sample; however, it is often the case that more than one type of behavior is present. [For example, there are many different homicide syndromes (Block and Block 1995: 29), each of which would have its own set of characteristics.] Nowadays there are a number of methods and techniques to deal with this, but these tests were first proposed when the costs of data collection and analysis, both in time and money, were substantially greater than today. Analyses that took days to accomplish can now be done in microseconds.

Moreover, the data analysis landscape has changed over the past few decades. We now have oceans of data to analyze, collected for us by criminal justice agencies and other organizations. Additional techniques, based on exploratory data analysis (Tukey 1977), have been brought to bear on data. A wealth of computer programs is at our disposal to facilitate the use of scores of analytic and visualization methods. As Tukey (1992: 444) noted, "If one technique of data analysis were to be exalted above all others . . ., there is little doubt which one would be chosen. The simple graph has brought more information to the data analyst's mind than any other device."

These innovations have brought data analysis into the mainstream of social science, while at the same time, they have made it so easy to deal with data that the assumptions that undergird the statistical methods are too often ignored. As described above, there is now a great deal of data available for analysis using tried-and-true (as well as tired and not-quite-true) methods.

Summary

As noted above, the data landscape has changed considerably over the past few decades. Courtesy of the US Department of Justice, we now have the FBI's Uniform Crime Reports (UCR, from 1960) and the Bureau of Justice Statistics' (BJS) National Crime Victimization Survey (NCVS, from 1973), each of which has provided researchers with useful information about the study of crime, criminal behavior, and official (and unofficial) responses to these acts. And courtesy of other federal agencies and other grant-giving organizations, we also have other survey-based data sets (NLSY, AdHealth, PHDCN) to test hypotheses and find relationships. Having these data sets publicly available provides researchers with the raw material on which to apply their statistical tools.

The statistical/methodological picture has also changed over the same time period, although not as quickly nor as much. Many still cling to methods developed long ago when reliable data were hard to come by. As can be seen by perusing the table of contents of this encyclopedia, a host of new ways of analyzing data has been developed more recently.

It is important to understand the premises and assumptions that undergird whichever method one uses in research. Although very useful and innovative when they were first developed, hypothesis testing and its partner statistical significance may have outlived (most of) their usefulness. Their limitations, described in the cited papers and books by Cohen, Leiberson, Loftus, Maltz, Wilkinson, and Ziliak and McCloskey, are too often ignored by those who apply them. It is hoped that this review of their origins will lead to more their careful application and that greater (and appropriate) use is made of the methods described in other entries.

Acknowledgments The authors thank Laura Dugan for her helpful comments. This entry borrows liberally from Maltz (1994a, b).

► Drug Abuse and Alcohol Dependence Among Inmates

HIV in the Correctional System

Anne C. Spaulding, Shawnta L. Lloyd and
Lauren C. Messina
Rollins School of Public Health, Emory
University, Atlanta, GA, USA

Overview

The United States has witnessed a significant rise in the number of incarcerated men and women since the 1970s. In the more recent years of this "epidemic of incarceration," the epidemic of the human immunodeficiency virus (HIV) has hit the correctional system especially hard (Spaulding et al. 2002). Many persons first learn of their HIV infection through jail- or prison-based screening (de Voux et al. 2012). Among Americans living with HIV, about one in five are unaware of their HIV status (Centers for Disease Control and Prevention 2010; Centers for Disease Control and Prevention 2012). As the HIV prevalence among US prisoners is more than three times higher than that of the general population (Maruschak 2008), implementing more HIV testing in correctional facilities would provide an opportunity to identify new cases of HIV.

Integrating HIV care into standard medical care in all healthcare venues "normalizes" the disease and may encourage persons with known HIV diagnoses to disclose their status. Additional programs are needed to link HIV-positive individuals to HIV treatment and other medical care, as well as to HIV/AIDS education, both in correctional facilities and upon release. The criminal justice system has the opportunity to not only promote public safety, but to lessen health disparities found in the populations passing in and out of correctional facilities.

Dual Epidemics: Incarceration and HIV

The United States has the highest incarceration rates in the world (International Centre for Prison Studies), accounting for approximately 2.3 million Americans serving time behind bars (Glaze 2010). In comparison to the general population, individuals in correctional facilities are more likely to be living with mental illness, tuberculosis, viral hepatitis, substance use disorders, and/or sexually transmitted diseases (STDs) (Rich et al. 2011). Incarcerated individuals are considerably more likely to be living with HIV disease at all stages, including late stage and symptomatic HIV [otherwise known as acquired immunodeficiency syndrome (AIDS)] compared to the general population; approximately 17 % of all Americans living with HIV pass through correctional facilities at least once in a given year (Spaulding et al. 2009).

Minorities are over-represented in both the correctional population and the HIV-positive population. Non-Hispanic Blacks and Latinos are represented disproportionately among those inmates held in prisons and jails. In addition to exceedingly high incarceration rates, Blacks and Latinos are disproportionately affected by HIV. Although Blacks represent only 14 % of the total US population, they account for 46 % of people living with HIV. Latinos represent 16 % of the total US population and account for 17 % of people living with HIV (Centers for Disease Control and Prevention 2012). HIV infection affects those incarcerated as well as the communities to which these people return.

HIV can be transmitted through sexual fluids or blood, placing individuals who participate in unprotected sex, particularly unprotected anal sex, or injection drug use at an increased risk of becoming infected with HIV in comparison to those who do not. When the HIV epidemic began in the United States, gay, primarily white, men were the first persons infected with the virus. As time went on, the epidemic spread to those who participated in injection drug use and unprotected heterosexual sexual intercourse. Additionally, HIV infections were identified among blood transfusion recipients and newborns with an HIV-positive mother. Many injection drug users lived in urban communities and were well acquainted with the criminal justice system. During the time of the HIV transition into a new population, the United States criminal justice system was ballooning, due to the declared "war on drugs" (Spaulding et al. 2002). Drugs users were incarcerated at rising rates, increasing the number of HIV-infected persons in correctional facilities.

HIV Screening

Why Is Screening Necessary?

Most incarcerated men and women who are infected with HIV acquired their infection while in the community, before entering a correctional facility (Jurgens et al. 2009; Centers For Disease Control and Prevention 2009). High-risk behaviors such as unprotected sexual encounters and drug use and lifestyles linked with HIV are common among persons who subsequently enter a correctional facility (Braithwaite and Arriola 2003). Substance abuse besides injection drug use can lead to disinhibiting behavior which promotes high-risk behavior, making alcohol, cocaine, and methamphetamine abusers as vulnerable to HIV infection as injection drug users. Social factors epidemiologically associated with high HIV risk include poverty and homelessness (Braithwaite and Arriola 2003). HIV testing of asymptomatic persons has the ability to identify cases that may otherwise go undiagnosed and untreated. Since 18–20 % of Americans are unaware of their HIV status (Centers for Disease Control and Prevention 2010; Centers For Disease Control and Prevention 2012) and the incarcerated population are known to participate in high-risk behaviors associated with HIV infection, there may be a large number of undiagnosed HIV-positive individuals in correctional facilities.

After learning their status, HIV-positive persons tend to decrease unsafe sexual risk behavior and needle sharing; the prevalence of unprotected anal and vaginal intercourse can drop by more than 50 % after HIV diagnosis (Marks et al. 2005). The same phenomenon has been observed among inmates who tested HIV positive during incarceration; receipt of an HIV diagnosis is associated with lower rates of anal intercourse among male inmates (Jafa et al. 2009). HIV testing in correctional facilities, either during or after entry, not only benefits those incarcerated, but also those in the community as well. Partner Services conducted by the local health department (Altice et al. 2010) may be able to locate former sexual and injecting drug partners of incarcerated HIV-positive individuals, allowing those in the communities to seek testing; if positive, these individuals can obtain clinical care and HIV/AIDS education. This is an opportunity to decrease the transmission of HIV/AIDS and to increase HIV/AIDS knowledge in the communities, extending the potential benefits of HIV testing in the correctional system.

Testing Procedures

The Center for Disease Control and Prevention (CDC) published the *HIV Testing Implementation Guidance for Correctional Setting*s in 2009. The CDC recommends the adoption of a universal, routine, opt-out testing approach to improve HIV detection among the incarcerated population. This approach includes incorporating consent for HIV treatment into the general consent form for medical services within the institution, meaning that all inmates should be tested for HIV unless an inmate refuses to have the test completed. Studies of jail detainees newly diagnosed with HIV reveal that the majority had no risk for HIV acquisition other than heterosexual sexual relations (Macgowan et al. 2009). Thus, limiting HIV screening to those who report injection drug use or men who have sex with men is less effective in identifying HIV cases compared to universal testing. A large proportion of individuals moving through the correctional system may be offered screening and tested before being released into the community or transported to another facility undiagnosed. Inmates should be given information about HIV/AIDS before testing occurs, and the decision to test must be noncoercive (Centers For Disease Control and Prevention 2009). Medical staff should note when an inmate declines HIV testing because he or she may accept a repeat offer in a subsequent medical encounter. Reasons why inmates may refuse testing include fear of needles, conflict with another activity, lack of knowledge of risk behaviors, and/or an upcoming release date (Altice et al. 2010). Routine opt-out testing has the ability to standardize HIV testing in correctional facilities, reducing the stigma and fear associated with HIV testing. Universal opt-out testing may not be perceived as an option in some facilities when budgets are tight or where custody staff are unable to provide security services for a prolonged medical encounter at entry. Alternatives to the optimal approach of universal testing by nursing at entry include risk-based screening or screening during subsequent medical encounters. Risk-based screening constitutes offering HIV testing to inmates who have had high-risk characteristics (injection drug use, men who have sex with men, sex with an at-risk partner, transactional sex, multiple sex/drug partners, and STDs) within the last 12 months. These approaches allow correctional facilities to test those individuals that may be at the highest risk of HIV infections. However, as noted above, an important study showed that the most common risk factor for undiagnosed HIV among those entering a correctional facility is heterosexual sexual behavior (Macgowan et al. 2009). Thus, targeted testing will miss most infected persons.

Traditional testing consists of an HIV enzyme immunoassay (EIA). When traditional HIV testing is performed, the specimen is processed in an external laboratory; it can take several days for the result to be returned to the staff of the correctional facility. It is still a practical option for inmates with a longer length of stay such as those found in prisons. As of mid-2012, any positive HIV screening test is followed by a second confirmatory test using a Western blot assay (Centers for Disease Control and Prevention 2009). The algorithm for confirming positive tests may be changing in the near future.

In correctional facilities with rapid population turnover such as jails, new "rapid HIV tests" can offer several advantages. Most rapid tests have been approved to be used at the "point of care"; processing does not require sending the specimen to a laboratory. The median length of stay in many jails is 48 h or less (Spaulding et al. in press-a), which means half of the population may have left the facility before conventional HIV tests return. Training for conducting rapid, point-of-care tests is not extensive. With an oral swab or a finger stick for a rapid test, medical staff can complete the HIV tests in as little as 10–30 min (Altice et al. 2010). Medical staff are therefore able to quickly inform inmates of their HIV status shortly after the testing, rather than bringing the person back to the healthcare setting at a later time. Rapid testing offers the advantage of producing a preliminary result quickly; further testing can take place during the same visit, at the clinician's discretion.

Some facilities do not have access to resources to offer opt-out testing and linkage to appropriate medical care. Partnerships with local health departments and/or community-based organizations can aid in carrying out HIV testing and counseling in correctional facilities where further resources are needed. Additionally, academic institutions have the capacity to assist with testing and clinical care. Professionals with expertise in various disciplines such epidemiology, sociology, and criminology can provide the criminal justice system with data collection and analytic skills to aid in the improvement of testing and clinical care (Rich et al. 2011).

Testing Permits Treatment and Prevention

HIV in the incarcerated population is diagnosed at a younger age and earlier stage of disease than in the general population, factors leading to better HIV/AIDS health outcomes (Spaulding et al. 2002; de Voux et al. 2012). Prompt diagnosis after infection and treatment has the ability to save lives. HIV testing is crucial in the correctional system to identify HIV-positive cases or allow individuals to reveal their HIV-positive status, if previously diagnosed. Upon diagnosis, treatment options can be explored and safer behaviors can be implemented to slow disease progression and prevent transmission to others, leading to longer, healthier lives.

Once an HIV-positive status is known, the first step to treatment is HIV education to ensure that the inmate is aware of necessary lifestyle changes and the importance of adherence to treatment (U.S. Department of Health and Human Services 2011). Before initiating antiviral medications, untreated infected persons should have their virus tested to determine what drugs would be most likely to suppress it. This test of susceptibility should be reviewed with a healthcare provider experienced in treating HIV to determine the appropriate therapeutic regimen. In some cases, HIV-infected persons may need to be referred to an outside HIV specialist depending on the complexity of the inmate's medical issues. Medical staff in some correctional facilities may lack HIV specialists or persons with adequate HIV experience and education on site; these facilities can develop links to HIV specialists in the community and contract with providers to provide the necessary consultative care (Centers for Disease Control and Prevention 2009). Those inmates who disclose their known HIV-positive status and have been prescribed antiretroviral medication should continue or resume treatments under the direction of a provider with HIV experience. Previous medical records should be consulted.

The two methods of administering HIV medications in facilities are directly observed therapy (DOT) and keep-on-person (KOP) therapy. The DOT system requires staff members to administer medications; patients are known to have better adherence using this system, but an inmate may fear the loss of confidentiality. Conversely, KOP therapy requires an inmate to be responsible for administering his/her own medication: the inmate is not monitored by the medical staff and adherence to medical treatment is often unknown. However, this method can aid in adherence of HIV treatment after release (U.S. Department of Health and Human Services 2011).

Since many inmates have co-occurring illnesses, the treatment of disease can become complex. Adherence to HIV medication is essential to decrease viral loads and increase CD4 lymphocyte (CD4+) counts. It is common for inmates, including HIV-positive inmates, to have multiple medical conditions such as substance abuse or mental health conditions. Inmates should receive treatment for co-occurring issues while receiving HIV medication to ensure that they are in a state of mind to understand how to properly take the medication and maintain a healthy lifestyle. Additionally, medical staff need to learn how to identify side effects to HIV treatment and schedule follow-up visits during the first weeks of therapy to monitor adherence and potential side effects (U.S. Department of Health and Human Services 2011).

Treatment: Specific Issues for Prisons

Correctional facilities have become a significant provider of HIV medical care and treatment due to the high number of HIV-infected persons transitioning through the criminal justice system. Additionally, HIV-positive persons incarcerated in prisons have sentences longer than a year unlike those in jails, providing adequate time to receive testing, results, and antiretroviral therapy. The introduction of highly active antiretroviral treatment (HAART) in correctional facilities has aided in the suppression of viral loads and increased CD4+ counts in HIV-infected inmates (Springer and Altice 2005). Sustaining HIV treatment allows HIV-infected individuals to achieve undetectable viral loads, which can greatly decrease the risk of HIV transmission to sexual or drug injection partners. An increased CD4+ count in an HIV-infected person allows preservation of the immune system to help the infected person avoid life-threatening medical conditions. Accordingly, AIDS-related deaths among all deaths in state prisons decreased from 34.2 % to 4.6 % between 1995 and 2006 (Maruschak 2008). This massive decrease in AIDS-related deaths mirrors the decrease of HIV-/AIDS-related deaths nationwide.

Incarceration can be an opportunity for prisoners to receive quality healthcare from medical staff; adherence to medical treatment may be facilitated in a controlled environment. When individuals in correctional facilities are provided with adequate care, health outcomes can be comparable to those in the community setting; however, due to the variation of healthcare services currently offered in correctional facilities, health outcomes vary from facility to facility. A study completed in Texas found that only one-third of HIV-infected inmates who were eligible to be treated based on the Department of Health and Human Services criteria for initiation of HAART were on HAART therapy (Baillargeon et al. 2000). While treatment of HIV infection in correctional facilities can be successful, inmates have the right to refuse treatment and not all inmates take advantage of the possible medical treatments for reasons such as adverse side effects or poor prognosis.

Diagnosis and Treatment Is Feasible in Jails

HIV testing and treatment rates in jails tend to be lower than those in prisons (Culbert 2011). However, due to the success rates observed in some prison settings, jails have the potential to produce successful declines in HIV complications. On a given day, 750,000 persons are incarcerated in jails, most only staying for a short period of time (Spaulding et al. 2009). Jails provide a setting to offer HIV testing and treatment, if necessary, to thousands of persons daily. Inmates may not have access to adequate healthcare in the community and may not pursue testing on their own. Without testing, undiagnosed HIV-positive individuals will continue to engage in risky behaviors and may transmit the virus while incarcerated and/or in the community.

Given the rapid turnover of inmates and chaotic environment of jails, traditional HIV testing was challenging, but rapid testing has made HIV testing feasible in jail settings. However, if a rapid test produces a positive result, results of confirmatory testing may take 1–10 days to arrive at a correctional facility. Some inmates may be released from jail by the time the test result returns. However, community-based organizations can aid correctional facilities in contacting former inmates regarding their HIV status and offer linkage to medical treatment, if needed. An oral fluid HIV test can offer an alternative to blood tests, especially for persons who fear needles; confirmatory results will arrive in 3–5 business days (Altice et al. 2010).

In 2003, the states of Florida, Louisiana, New York, and Wisconsin received funding from the CDC to conduct HIV testing in jails. These four programs successfully performed 33,211 tests and identified 269 new HIV cases. With the use of rapid HIV testing, 99.9 % inmates received their test results. These testing programs also demonstrated the feasibility of universal opt-out testing. Of those who received a reactive rapid HIV test, rates were particularly high among persons who did not report risk behaviors (3.1 %), including injection drug use, male-to-male sex, transactional sex, sexual assault, STDs, heterosexual behavior, or sex with an at-risk partner. Incarcerated men who did not report risk behaviors were more than four times likely to be diagnosed with HIV than incarcerated men who reported heterosexual behavior. Therefore, new cases may be missed if inmates were only offered testing based on risk behaviors. A total of 440 known and newly diagnosed HIV-positive inmates with a reactive rapid HIV test were referred to medical care, treatment, and prevention services (Macgowan et al. 2009), demonstrating that HIV testing and linkage to medical care and treatment is feasible in the fast pace environment of jails.

In a jail setting, inmates may be released soon after being diagnosed as HIV positive; therefore, inmates may not have the opportunity to receive a pretreatment evaluation and begin antiretroviral treatment in jail. Linkage to HIV medical care and treatment in the community is critical to ensure that these HIV-positive individuals begin treatment as soon as possible after release. For those individuals with a longer length of stay in jail, pretreatment evaluation can be completed and the appropriate antiretroviral treatment can begin. Many newly diagnosed HIV-positive inmates start HIV treatment while in a correctional facility, receiving HIV medical care for the first time. Additionally, inmates and former inmates may be able to resume HIV therapy previously interrupted in jail and through linkage to care after discharge. Considering the short length of stay for most jail inmates, the cost of treatment for those with a longer length of stay should be minimal (de Voux et al. 2012).

Trust and Confidentiality

Although HIV/AIDS diagnosis in the correctional system has its benefits, some inmates may delay or refuse HIV/AIDS-related services in correctional facilities for reasons such as mistrust of staff and/or fear of discrimination from peers. Routine and opt-out testing has the capacity to reduce the stigma associated with HIV/AIDS. Inmates can be provided with literature on various health topics to deter others from learning about their medical conditions. In many facilities, HIV testing is provided only upon request. In a harsh environment such as a correctional facility, inmates may not feel comfortable requesting an HIV test. Inmates may feel more comfortable releasing medical information and completing care during medical assessments when the testing is common practice in correctional facilities (Centers for Disease Control and Prevention 2009).

HIV treatment in correctional facilities can lead to issues regarding confidentiality, as inmates have little privacy while incarcerated. It is important for facilities to create methods to guarantee inmates' medical confidentiality during HIV treatment delivery. In a setting where HIV may be stigmatized and the risks of violent acts are high, inmates may not feel safe while disclosing and receiving medical care from the medical staff. To receive medications, inmates may have to be escorted to another area in the correctional facility. When HIV-positive inmates are segregated, adherence to medication may be reduced and confidentiality compromised. Methods as small as allowing the doors to be closed while medical staff are disclosing information to the inmates may decrease the amount of information overheard by other staff and inmates as well as gain the trust of the inmates. All medical records should be under lock and key with access to only select personnel. The trust between the staff and inmates is vital to encourage the treatment of HIV and persuade HIV-positive inmates to initiate and adhere to the recommended treatments during their sentence and when released back into the community (Centers for Disease Control and Prevention 2009; Wakeman and Rich 2010). Ultimately, the medical staff and the custody staff must work as a team to keep inmates being tested for HIV safe.

HIV Prevention Inside Correctional Facilities

More risk behaviors usually take place in the community than while incarcerated (Braithwaite and Arriola 2003); however, the risk behaviors and potential to transmit HIV and other infectious agents to others during incarceration should not be overlooked. A study completed in Georgia found new cases of HIV during incarceration among inmates who tested negative during entry HIV testing (Jafa et al. 2009). There is evidence that transmission of HIV occurs in correctional facilities; however, the frequency of its occurrence and method of transmission is not absolutely known. The incidence of HIV transmission may vary in different facilities.

Existing data and research provide evidence that high-risk behaviors associated with HIV, including sexual intercourse and injection drug use are present in correctional facilities, even though these activities may be banned. The World Health Organization and the Joint United Nations Programme on HIV/AIDS strongly recommend the use of harm reduction strategies in correctional facilities. Condom distribution in correctional facilities has the capacity to reduce HIV transmission during penetrative sexual intercourse. Additionally, distribution of clean needles and syringes or diluted bleach along with instructions for cleaning injection equipment has the ability to reduce HIV transmission during drug injection, tattooing, and skin piercing (The World Health Organization and The Joint United Nations Programme on HIV/AIDS 2006). Most US correctional facilities have resisted adopting HIV prevention policies and practices such as condom distribution, needle and syringe programs, and decontamination strategies for injection equipment to reduce the transmission of HIV, because adoption of the UN standards is perceived as condoning such behavior. Items such as condoms and needles are viewed as contraband in jails and prisons, and inmates are not allowed to possess them while incarcerated (Tucker et al. 2007; Jurgens et al. 2009). Condoms are available in state prisons in only two states, Vermont and Mississippi, and in jails in five large urban jails (New York City, Philadelphia, San Francisco, Los Angeles, and Washington D.C.) (Braithwaite and Arriola 2003). Controversy surrounds the issue of providing inmates with harm reduction strategies such as condoms and clean needles due to the conflict between risk behaviors and rules in correctional facilities. Many administrators of correctional facilities do not want to acknowledge that risk behaviors continue to take place in their facilities since rules have been established in an attempt to prevent such occurrences. Even though some correctional officials may be aware of the needs for HIV prevention and medical care among the incarcerated population and wish to provide these populations with harm reduction equipment and knowledge, limited resources and decreased funds may replace the health of inmates with custody and security issues on the list of priorities (Braithwaite and Arriola 2003; Tucker et al. 2007). To decrease the concern that some HIV prevention programs may contradict the rules and policies of the correctional system, it has been recommended that messages and education to reduce HIV transmission be presented in a way as it applies to HIV prevention once released from a correctional facility (Braithwaite and Arriola 2003). In this way, correctional officials would not have to deviate from the rules in their facilities, and inmates would have the opportunity to learn how to protect themselves and sexual and/or drug injection partners from HIV transmission.

Unintended Consequences of Incarceration: Concurrency in the Community

The criminal justice system removes individuals away from the community, friends, family, and intimate partners. Once sexual or injection drug partners are separated, new partners may be introduced into the relationship; partners left in the community may engage in sexual intercourse and injection drug use with new partners. When the number of sexual or drug injection partners are increased, the risk of becoming infected with HIV and other sexually transmitted diseases increases. While incarcerated, inmates may engage in sexual activities with new partners, either by choice or coercion. Injection and tattooing equipment may be shared with other inmates. Due to the large number of incarcerated black males, black women are disproportionately represented in the community. This increases the opportunity for men in the community to have relationships with multiple women and decreases the number of potential long-term male partners for women (Pouget et al. 2010). Men and women in the community and those in correctional facilities are placed at a higher risk becoming infected with HIV.

Among recently incarcerated males, high-risk sex partnerships are likely to be reported. A study of men, aged 15–44 years old, found that incarceration may impact sexual behavior between both users and nonusers of illicit drugs. Multiple and concurrent partnerships were strongly associated with recently incarcerated men; however, the introduction of illicit drugs heightened risk behaviors with multiple or concurrent partners. Drugs enable individuals to engage in risky sexual intercourse and further drug use without sound judgment (Khan et al. 2009). The correctional system has a significant impact on those incarcerated and those left behind in the community.

Linkage to Medical Care After Release

After being released from a correctional facility, individuals need to be integrated back into the community. Former inmates may encounter a host of social and medical challenges upon release. In a population with an exceedingly high number of substance abusers and individuals suffering from mental illness, relapse to addiction and untreated medical illness is common upon release, respectively. Though there is a particularly high prevalence of mental illness in the correctional system, including 60 % in state prisons, 45 % in federal prisons, and 64 % in jails, only 25 % of inmates with psychiatric conditions received medications. Mental conditions left untreated can lead to a low adherence to antiretroviral therapy and reentry into a correctional facility (Rich et al. 2011). In states with a high rates of opiate abuse, drug overdose has been noted as a leading cause of death in the immediate post-release period (Binswanger et al. 2007). Homelessness and poverty often burden releases. It is possible for some inmates to lose Medicaid benefits during their sentence, resulting in an average interruption of 3 months in insurance coverage while the individual reapplies (Wakeman et al. 2009). Individuals convicted of drug-related charges are banned from receiving food stamps or federal assistance under the Welfare Reform Act and can be denied public housing under the Anti-Drug Abuse Act of 1988 (Pogorzelski et al. 2005). Antiretroviral therapy in correctional facilities has been successful in a few states; however, the improvements in an inmate's health observed during incarceration may quickly diminish if adequate care and treatment is not continued (Rich et al. 2011). Medical services offered during incarceration may be the individual's first link to primary healthcare and HIV/AIDS care. It is common for incarcerated persons to return to poor communities with little or inadequate access to HIV medical care. As there are a considerable number of obstacles presenting themselves, adhering to HIV treatments may not be a high priority for many releasees while trying to gain stability in the community. Release from a correctional facility has been associated with poor HIV treatment adherence: only 5.4 % of released HIV-positive inmates filled their antiretroviral prescriptions within 10 days, 17.7 % after 30 days, and 30.0 % after 60 days (Baillargeon et al. 2009). Poor adherence can lead to disease progression and emergence of drug–resistant viral HIV strains. Therefore, prerelease discharge planning, case management, and linkage to care are crucial to ensure that former inmates initiate and continue HIV/AIDS care and treatment. Non-adherence to HIV treatment upon release from a correctional facility may also be linked to inadequate discharge planning (Culbert 2011).

Prerelease discharge planning allows inmates to develop a plan to access medical care and treatment while incarcerated to reduce the burdens faced by inmates upon reentry into the community. Many agree that discharge planning is a legally and ethically mandated standard of care for those in the criminal justice system. During discharge planning, inmates can be provided with (a) a list of medical providers in the community, (b) an appointment with a community care provider, (c) education about the importance of adherence to medications, (d) transfer of medical records, (e) assistance with insurance applications, and (f) linkage to HIV case management services. Upon release, former inmates should be provided with an adequate supply of medication to avoid interruption in treatment until the initial appointment in the community (Centers for Disease Control and Prevention 2009).

HIV case management services have the ability to assist with discharge planning to link recent releases to healthcare and other resources in the community; case managers provide a link between former inmates and healthcare facilities to make access to healthcare easier. Inmates who participate in adequate discharge planning may be more likely to sustain their health and avoid reentry into correctional facilities (Culbert 2011). Although case managers can be beneficial to recent releasees, there are shortcomings that come with using just case management programs to ensure that adherence to HIV treatment and non-detectable viral loads are continued upon release, and that linkage to medical services is established. Discharge planning and HIV case management should not only involve linkage to HIV medical services and treatment, but also to organizations that can alleviate social burdens upon release as well such as health insurance, housing, and substance abuse treatment to reduce the number of burdens that releasees face. In the face of social burdens, HIV-positive releasees may disregard adherence to medication.

To create an effective discharge planning program, a considerable amount of money and face-to-face time is required in addition to the development and continuance of partnerships within the communities in which former inmates reside upon release. However, budget cuts and transfer of correctional healthcare services into the private sector have reduced partnerships with community-based organizations (Culbert 2011). Although there are challenges and resources may be limited in some facilities, an effort can be made to increase adequate discharge planning and case management programs in the correctional system.

Starting in 2006, the Rollins School of Public Health at Emory University and Abt Associates, Inc. coordinated the evaluation of the Enhancing Linkages to HIV Primary Care and Services in Jail Settings Initiative (EnhanceLink). This initiative successfully provided HIV testing in 20 US jails, resulting in 822 new diagnoses out of 212,464 inmates who agreed to HIV testing. Services were provided to not only address linkage to medical care but also to social needs upon release such as mental health and substance abuse treatment and linkage to housing. Transitional services were accepted by 82 % of HIV-positive persons in the program offered services (Spaulding et al. in press-a). At 6 months follow-up, 26 % of releasees had suppression of their HIV viral load (Spaulding et al. in press-b). In a jail setting, HIV testing and linkage to care after release are feasible. With adequate program planning, successful testing and transitional programs can be implemented in jails and prisons throughout the United States.

Conclusion

The prevalence of HIV is high in the correctional population, but HIV disease needs to be understood in context. Men and women entering the correctional system are also disproportionately affected by low socioeconomic status, violence, mental illness, substance abuse, chronic disease, and infectious disease. With a large proportion of HIV-positive individuals passing through the correctional system, these facilities have the opportunity to play an instrumental role in the diagnosis and clinical care of HIV/AIDS patients. Known HIV-positive persons would be able to receive HIV medication and avoid interruption of therapy. Undiagnosed HIV-positive persons could learn of their HIV status and begin treatment; access to HIV testing may be suboptimal after release. Treatment of HIV with antiretroviral therapy is needed to lower viral loads and restore the immune system, allowing HIV-infected persons to live a healthier life. Correctional facilities are settings where HIV-positive persons might control their HIV for the first time.

Furthermore, due to the poorer health status and higher incarceration rates of people of color, the criminal justice system has the opportunity to significantly decrease health disparities. If HIV medical services are not provided to the incarcerated and released population, poor health outcomes could continue to devastate communities plagued by poverty and high crime rates. The incarcerated have a right to adequate medical care. Many individuals transitioning through a correctional facility do not have access to adequate healthcare, prior to receiving healthcare in a correctional facility. An effort has to be made to develop more partnerships between the correctional system and the community-based organizations.

Medical care in the criminal justice system provides medical and public health professionals the opportunity to work with a vulnerable and underserved population. In order to continue to have a supply of providers sensitive to the needs of inmate patients, medical schools and residency programs should consider providing mentored training opportunities in correctional facilities. The correctional setting provides opportunities in a challenging environment to reach a large underserved population, while developing skills in areas such as working with patients with co-occurring medical conditions and dealing with a high turnover rate of patients. There are many practice and research opportunities available in correctional facilities to address and aid in the needs of the incarcerated. The criminal justice system has the capacity to be a wonderful training ground for future health professionals.

Correctional healthcare, if administered well, can have a positive impact on the lives of HIV-positive inmates. There is an opportunity to enhance HIV medical care in correctional facilities. Correctional healthcare can mitigate the disparities among a poor, underserved population. Improved HIV educational programs, HIV testing, and linkage to care is needed to ensure that better health outcomes are observed in the incarcerated population and after release to the community. Failing to address health disparities is an additional punishment.

Overview

This entry focuses on homegrown terrorism in the United States. There are many terrorism definitions. Indeed, Schmid and Jongman (1988) identified over 100 definitions that differed over whether they included 1 of 22 elements. Nonetheless, Freilich et al. (2009a, b) demonstrate that almost all definitions require a violent, ideologically motivated illegal act committed by a political extremist, and this definition is used here. The Congressional Research Service (Bjelopera and Randol 2010, p. 1) defines homegrown terrorism as a "terrorist activity or plots perpetuated within the United States or abroad by American citizens, permanent legal residents, or visitors radicalized largely within the United States."

A review of the empirical literature demonstrates that homegrown terrorists currently pose a threat to public safety. These threats are dynamic however and change over time. In addition, policy interventions and strategic tactics often have unintended consequences. Sometimes these interventions have created backlash effects that led to greater numbers of crimes. This entry first discusses how homegrown extremists pose a threat and then illustrates how it has changed over time. Second, the entry outlines the nature and scope of the current danger posed by homegrown terrorists and extremists. It then discusses how policy makers, law enforcement personnel, and crime analysts should carefully monitor the homegrown threat and consider the unintended consequences of their proposed responses to these extremists. Finally, note that this entry includes new material and draws from materials published in two 2009 articles (Freilich et al. 2009a, b).

Key Issues

Homegrown terrorists and extremists pose a risk to the American community. Recently, attention has focused on American supporters of Al-Qaeda and related ideologies, because of the devastating attacks committed on September 11 and its desire to strike again within the United States. However, LaFree et al. (2006) found that the United States also faces other homegrown threats. Hewitt (2003; see also Smith 1994) found that between 1954 and 2000, over 3,000 terrorist incidents were perpetrated in the United States, many by non-Islamic jihadist homegrown terrorists such as far-rightists, Puerto Rican nationalists, Jewish extremists, Black nationalists, and animal and ecoterrorists. These acts claimed over 700 lives and caused hundreds of millions of dollars in damage. More recent research indicates that the number of incidents occurring in the United States might be higher (Freilich et al. 2012).

A review of the accumulated empirical evidence finds that homegrown terrorist threats are not static. Smith's (1994) study of terrorist strikes in the United States found homegrown far-left groups to be the most active in the 1970s. Carlson (1995) surveyed police chiefs in large-sized American cities (>100,000) in the early 1990s. He asked the chiefs to rank the top four groups that, in their opinion, were most likely to commit a terrorist act within the next 2 years. Despite the celebrated nature of the 1993 Trade Center bombing, police chiefs did not think that Middle Eastern terrorists posed the greatest threat. Instead, homegrown antiabortion perpetrators and white supremacists were rated the two greatest threats. Riley and Hoffman's (1995) RAND survey of state and local agencies over 2 years in the early 1990s similarly found that issue-specific homegrown organizations (e.g., antiabortion) and right-wing groups posed the greatest terrorist threat. Freilich et al. (2009) more recent survey of state police agencies found that almost all respondents strongly agreed that Islamic jihadists and their American supporters were the top national security threat and most strongly agreed or agreed that they were a significant threat to state security. Importantly, far-right and animal/environmental rights homegrown extremist movements were also seen as representing a severe threat to both national security and to the security of individual states.

These results demonstrate that homegrown terrorism threats change over time. Carlson's research from almost 15 years ago identified homegrown antiabortion activists as the greatest threat. Freilich et al. (2009) found that state police agencies, however, do not currently rate antiabortion activists as posing a great threat to either national security or their state's security. The attacks of September 11 have clearly impacted concerns about the potential threat of Islamic extremists in the United States. While Smith's (1994) domestic terrorism study found homegrown far-left groups to be the most active in the 1970s, currently state police agencies do not rate far-left groups as a major threat on either the national or state level.

Relatedly, the strength of individual groups and the larger homegrown movements they belong to also evolves over time. These extremist and terrorist groups and their external environment are dynamic. For example, research finds that the homegrown far-right militia movement was impacted by the Oklahoma City bombing, forcing many individuals to leave the movement, others to join, and some to go underground or seek other extremist organizations in fear of government infiltration (Chermak 2002). Extremist organizations and terrorist groups must adapt to changes occurring in their external environment. Research (Freilich et al. 2009; Rapoport 1992) shows that most terrorist and extremist groups are unable to adapt and therefore fail in a relatively short time.

Empirical evidence also finds that the rise and fall of homegrown extremist organizations are linked to critical events and organizational-level variables that enhance or disrupt the group. Freilich et al. (2009) identified factors that produced growth and decline within four homegrown far-right extremist organizations (the National Alliance, the Aryan Brotherhood, Public Enemy Number 1, and the Oklahoma Constitutional Militia). The groups that grew did do because they (1) had able leadership that set forth a clear ideological message and goals, (2) undertook concrete actions to further their ideology and goals and had the finances necessary, (3) took advantage of political opportunities, and (4) were internally cohesive. However, the groups declined because of organizational instability and/or responses by law enforcement and nonstate actors, such as watch groups. The fall/decline of a particular group likely affects other groups or supporters in the same movement. For example, the decline of one far-right group often provides political openings for another extremist organization to grow and prosper. Another example is law enforcement operations that eliminate violent extremists. Such actions could unintentionally outrage and further radicalize other extremist groups to turn to violence (Freilich et al. 2009).

Current Threat

The United States Extremist Crime Database (ECDB) is a unique, open-source, relational database. The ECDB is funded by the Department of Homeland Security through the National Consortium for the Study of Terrorism and Responses to Terrorism (START). It tracks ideologically motivated and routine/nonideological violent and financial crimes committed by homegrown movements seen as representing the greatest threat to American public safety: far-rightists, Al-Qaeda supporters, and animal and environmental rights extremists (Freilich et al. 2009). Definitions/descriptions of these movements are set forth in Freilich et al (in press) work and are available upon request. The ECDB collects information on multiple units of analysis. The ECDB's inclusion criteria are based upon a criminological approach, and the ECDB is different than other terrorism databases because it includes a broader array of illegal acts. For an incident to be included in the ECDB, it must satisfy a two-prong test. The first prong is behavioral and requires that an illegal violent act or financial scheme must have been committed inside the United States. The second prong is attitudinal and requires that, at the time of the incident or scheme, at least one of the suspects who committed the act must have subscribed to a far-right, Al-Qaeda-influenced, or extremist animal or environmental rights belief system (Freilich et al. in press).

The ECDB has identified thousands of criminal incidents committed by homegrown far-right extremists between 1990 and 2010. These crimes range in important ways, such as the level of violence imposed on victims, the number of suspects involved, and the motivational circumstances underlying each incident. Far-right extremist crimes include hate crimes, attacks on abortion providers, and foiled terrorist plots, as well as financial crimes and cases involving illegal firearms and other weapons.

According to the ECDB, homegrown far-right extremists committed over 370 homicide incidents in the period spanned by the data. Over 40 % of these homicide events were ideologically motivated (and thus most akin to terrorist attacks), and another 20 % were nonideological but were still movement related (such as an internal killing over drugs or a woman). These homicides varied both spatially and temporally. Homegrown far-rightists also killed close to 50 law enforcement officials in the line of duty between 1990 and 2010. These incidents involved federal, state, or local police officers, correctional officers, private security guards, and a judge (Freilich et al. in press).

Smith and Damphousse's (2009) American Terrorism Study (ATS) documents the tremendous property damage and financial losses that environmental and animal rights attacks have caused in the United States. Indeed, one group "The Family" committed 21 arson and "ecotage" attacks between 1995 and 2001. The group's most serious act was an arson attack at the Vail ski resort in the late 1990s that caused over $25 million dollars in damage.

The ECDB was still involved in data collection on crimes committed by eco – and animal rights extremists when this entry was being prepared, and thus the results are not finalized. Nonetheless, a preliminary examination indicates that these homegrown extremists have committed over 230 violent (i.e., bombing and arsons) incidents between 1995 and the present (Freilich et al. 2012). In addition, the ECDB is investigating a few violent acts committed by possible supporters of extremist animal and environmental rights movements that targeted persons. This is important because many academics and others conclude that this type of homegrown extremist has intentionally avoided harming persons (Amster 2006; Cothren et al. 2008; Taylor 1995). These incidents that may have involved animal and environmental rights extremists who targeted persons include the Unabomber's letter bomb attacks, the murder of a Red Bluff police officer by a self-proclaimed anarchist who also criticized corporate malfeasance including their harmful actions against the environment, a car bomb attempted murder of a veterinary officer, and the firebombing of a car belonging to a University of California, Santa Cruz scientist that resulted in injuries to both of his feet.

Importantly though, a review of the empirical literature thus far indicates that research on homegrown terrorists has focused mostly on Al-Qaeda supporters and other similar extremists (see below) or far-right extremists. Gruenewald et al. (2009) identified over 320 studies on far-right-wing extremism and political crimes in the fields of criminology, political science, sociology, and terrorism, and most of the current studies focus on Al-Qaeda supporting networks. Conversely, a review found many fewer studies on animal/environmental rights extremists. Future research needs to focus on eco – and animal rights homegrown extremists and study them more systematically.

Again, the ECDB also tracks crimes committed by supporters of Al-Qaeda and groups involved in local jihads across the globe. Many of the perpetrators of these crimes are homegrown extremists. Here too, the ECDB is still involved in data collection. But, a preliminary examination indicates that these extremists have committed over 25 fatal (i.e., the suspect killed others, was killed by police, or committed suicide) incidents since 1990. In addition, in this period, the ECDB identified a few honor-killing incidents, as well as scores of foiled plots in the United States (Freilich et al. in press).

In addition to ideologically motivated violent crimes, homegrown extremists have also committed nonviolent crimes that have harmed US security. Far-right homegrown extremists committed over 430 "financial schemes," while Al-Qaeda and other similar extremists committed over 100 financial or material support schemes since 1995. These schemes were worth over 600 million dollars. Since data collection and coding is ongoing, this number may change (Freilich et al. in press).

A preliminary descriptive analysis of ECDB data of financial schemes prosecuted in federal court in 2004 reveals that far-right and Al-Qaeda-influenced and similar extremists in the USA engage in different types of financial schemes, follow distinct modus operandi, and are prosecuted for a variety of both financial and nonfinancial crimes (Belli 2011). Despite these differences, a common trend was identified, that is, the involvement of non-extremist accomplices who provided useful resources for the crime commission process.

With respect to the far-right, the findings suggest that these may be individuals with specialized skills and know-how who provided professional services and expertise on a variety of issues (e.g., tax preparation, business ventures, financial and legal counseling). Al-Qaeda-influenced and similar extremists seem to have relied on non-extremist accomplices for a diverse set of reasons, for example, as middlemen to conduct wire transfers and manage bank accounts, couriers for cash smuggling, and nominees to set up storefront businesses (Belli 2011).

A comparison of financial schemes, crimes, and techniques revealed significant differences in the financial criminality of far-rightists and Islamic extremists. Far-rightists engaged mostly in tax avoidance schemes as a form of antigovernment protest. These schemes were perpetrated using techniques that require both proactive and passive behaviors. Proactive behaviors included filing false tax documents, underreporting income, marketing antitax packages, using bogus trusts, and setting up offshore "shell" corporations. Passive behaviors included ideologically motivated tax refusal, that is, a popular crime of omission that involves the failure to file an income return or to pay employment taxes on the basis of misinterpretations of tax laws and the constitution, usually rejected as "frivolous arguments" by US courts.

The majority of Al-Qaeda-influenced and similar extremist-related schemes involved "money-dirtying" and money-laundering strategies for self-financing purposes. Money dirtying (the reverse of money laundering) refers to the process of using money raised legitimately (e.g., through donations or legitimate investments) for illicit purposes (e.g., terrorism financing). Although there are some similarities between money-laundering and money-dirtying strategies, there are also at least two important differences: (1) the source of the money, that is, criminal in the former (e.g., drug dealing, tax evasion, cigarette smuggling) as opposed to either legitimate or criminal in the latter (e.g., legitimate business revenues, charitable donations), and (2) the goal, that is, transforming "dirty" money into expendable income as opposed to channeling funds of any origin to individuals or groups to enable acts of terrorism. To carry out these schemes, Al-Qaeda-influenced and other Islamic extremists made ample use of traditional money transfer mechanisms both domestically and internationally (e.g., wire transfers, cash deposits, checks). They also used simpler methods that avoid leaving paper trails, like conducting transactions in cash and physically transporting money across borders.

There were also differences in the way far-right and Islamic extremist financial crime cases were handled by federal prosecutors. Comparing criminal charges in federal indictments revealed that far-right cases were usually prosecuted for typical financial crime offenses (e.g., tax evasion, mail fraud, money laundering), whereas suspects in alleged terrorism financing cases were indicted for a variety of criminal offenses, ranging from money laundering to providing material support to a foreign terrorist organization (FTO), immigration fraud, RICO conspiracy, and false statements.

Finally, a recent report using ECDB data compared the organizational differences between violent and nonviolent hate groups (Chermak et al. 2013). This study used the Southern Poverty Law Center's (SPLC) annual Intelligence Report and Klan Watch publications to produce a list of hate groups in the United States (over 6,000 hate groups) and then focused on organizations that existed for at least 3 consecutive years (over 500 groups). Two hundred seventy-five (275) groups were then randomly selected to study in depth. Groups were categorized as violent or nonviolent.

The research revealed that 21 % of the 275 far-right hate groups included in the study had members who had committed at least one violent criminal act. Based on findings from a number of statistical models, there appear to be several indicators that were related to a group's propensity for violence even when controlling for other significant predictors. Age and size were related to a group's propensity for violence. That is, as groups increased in the number of years in existence or in the number of their members, the likelihood of them being involved in violence increased. This result makes sense as groups have an opportunity to learn over time. The significance of group size may be that simply having more members increases the odds that at least one individual will be linked to a violent act. Larger organizations also have a more diverse body of members who bring different skills and expertise, and this diversity may allow them to evade capture for a longer period of time and thus provide the opportunity to commit more violent crimes.

Groups that published ideological literature, such as newsletters or pamphlets, were significantly *less likely* to be involved in violence. Such literature is used to attract potential members to the organization, and perhaps these groups realize that the publication of their rhetoric will bring increased attention to their group and thus decrease the likelihood of being involved in violence. Groups that had some specific conflict with another group, had charismatic leaders, advocated for leaderless resistance tactics, and were headquartered in the West and Northeast (compared to groups in the South) were significantly more likely to be involved in violence. *Policy makers must carefully monitor political extremists and consider the unintended consequences of their proposed interventions.*

These findings suggest that law enforcement intelligence and analysis have an important role to play in countering terrorism. First, the ECDB's preliminary financial findings have important policy implications. They provide evidence that political extremists today engage in criminal behaviors that have traditionally been associated with profit-driven crime for various reasons and using different methods. In addition, the differences in the modus operandi and goals pursued highlight the importance of conducting systematic analyses of crime patterns using an "all-crimes/all-threats" approach to improve threat assessment and prioritization strategies. Lastly, they highlight the need to investigate the role of non-extremists as well as the nature and scope of their interactions with political extremists, as they may provide crucial resources in the form of knowledge, skills, and contacts.

Again, another important obstacle for law enforcement and analysts to overcome is to understand that identifying the homegrown threats that should be prioritized is like hitting a moving target. Analysts must engage in dynamic analyses (Freilich et al. 2009b; Smith 1994). Changes in contextual and organizational factors may cause a homegrown movement to increase or decrease in strength and potential to commit violent acts. Paying attention to such changes will allow law enforcement to better assess a movement's threat level as it changes, differentiate between truly dangerous groups and less dangerous groups, differentiate between immediate versus potential future threats, and develop policies to best address these threats (Chermak et al. 2009; Duffy and Brantley 1997; McGarrell et al. 2007).

Presently, different types of counterterrorism strategies have been implemented to reduce the number of terrorism attacks in the United States and abroad. Most strategies are "hard control" measures, such as retaliatory attacks, increasing punishments and using law enforcement measures to "crack down" on certain active groups. Lum et al. (2006, p. 22) conclude in their systematic review that there are few positive results: "Many effects are close to, or cannot be statistically discerned from, a zero effect."

A review of recent empirical research supports two conclusions. First, previous studies have found that responses by both the state and non-state actors may contribute to the decline of *specific* homegrown terrorist or extremist groups. Smith (1994, p. 91; see also Hamm 1993) concludes that homegrown far-right skinhead groups declined in the United States in the 1980s because of a "double barreled blast of aggressive federal criminal prosecutions and private civil rights attorneys." Hamm (2007) reached similar conclusions about the demise of the homegrown Arizona Patriots (see also Hewitt 2003).

Importantly, such responses, although contributing to declines in these groups, may also have unintended consequences. For example, Hamm's (2007) important analysis examining terrorist involvement in traditional crime discusses how terrorist groups seek traditional means of funding until such funding is unavailable. Groups then adapt and seek other sources of revenue. Hamm examines the effects of a crackdown on the IRA's efforts to raise money. In the 1970s, law enforcement shut down the IRA's fund-raising efforts in the United States, but this success increased their reliance on other sources of revenue. This shift may have also increased the harm caused by the organization as it moved to more traditional criminal and organized crime activities to finance operations, including bank robberies, smuggling goods and weapons, and extortion.

Lum et al. (2006, p. 26) systematic review evaluates several types of counterterrorism measures and also finds that such interventions often produce unintended and counterintuitive findings. For example, the implementation of metal detectors in airports were effective in decreasing airport hijackings, but caused displacement effects and increased the use of other types of terrorism, such as kidnappings, assassinations, and bombings.

Similarly, Freilich et al. (2009a) found that after the homegrown far-right National Alliance and the Aryan Brotherhood imploded for various reasons after the deaths of their well-known leaders, other groups, such as skinhead organizations, seemed to benefit. They concluded that groups within a larger movement are interrelated. Strategies that might mitigate activities against only one part of a movement may result in unanticipated consequences to other parts of that movement.

Relatedly, it seems obvious that successful law enforcement operations can eliminate a group or individuals that have engaged in crimes. This appears to bolster deterrence and incapacitation views that call for harsh responses to extremist groups. Many watch groups call for firm government actions against extremist organizations (Chermak 2002; Freilich 2003).

A review of empirical research in this area also suggests that there are sometimes unintended consequences to law enforcement responses. Perceived harsh government and police actions may lead to consciousness raising (Dobratz and Shanks-Meile 1997) that outrages the wider homegrown movement and causes a backlash. Other extremist groups and the movement at large may grow, and individuals and groups may become further radicalized and turn to violence. A growing number of studies find that harsh government responses to terrorism often have no deterrent impact and sometimes lead to a backlash (LaFree et al. 2009; Pridemore and Freilich 2007). For example, Lum et al. (2006) systematic review of the impact of counterterrorism strategies concluded that retaliatory strikes after a terrorist incident (i.e., the United States attack on Libya in 1986 in response to a bombing in Berlin) actually led to additional attacks.

Similarly, Freilich et al. (2009a) found that the racist Aryan Nations group capitalized on the killings of Gordon Kahl and Robert Mathews by law enforcement in the 1980s and the organization's popularity increased. In addition, Mathews partially created the notorious group "The Order" – the premiere domestic terrorist group in the 1980s (responsible for five murders and spectacular armored car robberies) because of anger over Kahl's death. The National Alliance, the militia movement, and other far-right groups grew in reaction to the government's excesses at Waco and Ruby Ridge in the early 1990s.

Alternative Policies

Based upon a review of the empirical findings in this area, we conclude that the authorities must strike a careful equilibrium. The government must balance a carefully calibrated campaign that eliminates dangerous homegrown groups and stresses that violence will not be tolerated, with responses that avoid outraging and possibly increasing crime from the larger movement. There are several options to consider. First, law enforcement should only use deadly or harsh responses as a last resort. For instance, harsh government actions at Waco and Ruby Ridge in the early 1990s that led to the death of homegrown cult members and far-rightists outraged the antigovernment far-right. Most observers conclude that these harsh policies led to a backlash and fueled the growth of the paramilitary right (Chermak 2002; Freilich 2003). Conversely, the ADL (2003) explains that law enforcement's nuanced and patient response that allowed far-right extremists to save face led to a peaceful resolution of sieges in Montana in 1996 and in Texas in 1997.

The government should consider accompanying harsh law enforcement actions against violent groups with "outreach" programs to nonviolent wings of extremist movements. These strategies should encourage members of the movement to forsake illegal behaviors in favor of participation in the political system or other legal activities. Jones and Libicki's study found that 43 % of 268 terrorist groups worldwide – the largest category – ended because of a transition to the political process. Significantly, F.B.I. agents charged with monitoring domestic extremists have made similar arguments. Agents Duffy and Brantley (1997) created a typology of four categories of homegrown far-right militia groups that ranged from noncriminal to organizations that conducted serious – for example, homicide and bombings – crimes. Duffy and Brantley (1997, p. 2) urged local police to open a dialogue with leaders from the two nonviolent categories "so that the two sides can voice their concerns and discuss relevant issues in a non-confrontational way."

These strategies should be used more frequently, especially when law enforcement is involved in crackdowns on specific movements. These outreach policies could be modeled after law enforcement efforts to build bridges in immigrant communities that are suspicious of the government (Clarke and Newman 2006; Freilich and Chermak 2009). Newman and Clarke (2008) recently set forth steps that police agencies could take to reduce tension with migrant communities that have come under suspicion because a few terrorists, such as the 9/11 hijackers, used them to fit in. These steps included assigning community police agents to solely work with migrant communities, taking advantage of ethnic media outlets to communicate with the larger community, and clearly publicizing the police agency's mission and policies. Similar strategies could be undertaken with the more moderate portion of homegrown extremist movements. In addition to initiating dialogue with nonviolent groups, agencies could assign officers to appear on extremist media outlets. Such campaigns should explain the government response and note that it is only directed at those who commit crimes. Authorities should reassure noncriminal members of the movement that their rights will be protected and encourage them to focus on lawful activities while stressing that violence will not be tolerated.

While there are hard-core individuals who have no interest in pursuing change through legitimate processes, it is also true that most extremist individuals and groups do not engage in violence or terrorism themselves. Further, some who end up engaging in terrorism are reluctant participants and are not strongly committed to an extremist ideology. McGarrell et al. (2007) discuss how most (nearly 70 %) of the individuals who were detained as terrorists or linked to a series of bombings were not ideologically committed.

Finally, backlash effects are usually found when a government takes action *after* a crime or terrorist act has been committed. Strategies that prevent these crimes from happening by such methods as using situational crime prevention to prevent groups from raising funds and furthering their objectives (Clarke and Newman 2006; Freilich and Newman 2009; Hamm 2007; Newman and Clarke 2008) may preempt the harsh police responses to these crimes and thus avoid backlash effects.

Conclusion

This entry provides an overview of the threat of homegrown terrorism in the United States. Despite the considerable investment in the study of the terrorism that has occurred following the

September 11 attacks, there is still little known about attacks occurring in the United States and the extent to which group dynamics might function similarly or differently when comparing at-home to abroad attacks. What has been documented provides evidence that there is a significant threat, that it is a constantly evolving threat, and that extremists of different ideologies are involved in a significant number of violent and financial crimes. Similarly, although there have been some lessons learned about how to best respond to such terrorism, there is much that is unknown and needs to be discovered. The need for additional research examining the etiology of homegrown terrorism is critical to understand the successes and failures of different types of responses.

Overview

"Is biology really relevant to criminology? After all, criminal behavior is learned, right? People aren't just born criminals; that's ridiculous." Critics of the biosocial perspective still use this sort of reasoning to raise doubts about the role of biology in crime causation. However, such thinking overlooks evidence that many personality traits and even human interests and preferences are genetically *influenced* to a substantial degree (Bouchard and McGue 2003; Kreek et al. 2005; Schermer and Vernon 2008). There is also considerable evidence that all human learning boils down to neurochemical processes that vary from one individual to another (Lawson 2003). Consequently, even though criminality is learned, biology still affects *how* we learn. To set the stage for examining this line of reasoning further, this entry will describe the role of a class of biochemicals called *hormones* in learning criminal behavior. But before doing so, a little background on biosocial criminology is in order.

Criminology's Biosocial Perspective

The first scientist to make the case for biological influences on criminality was an Italian physician named *Cesare Lombroso*. Writing in the mid-1800s, he is most famous for having argued that persistent criminals were *atavistic*, meaning that they were "throwbacks" to an earlier stage in human evolution.

Today, criminologists' opinions about the relevance of biology to understanding criminal behavior have gone far beyond Lombroso's concept of *atavism*. These opinions can be organized into three rather extreme categories:

1. Criminal behavior is almost completely determined by biological forces.
2. Biology and the social environment interact to influence criminal behavior.
3. Criminality is determined almost entirely by social factors.

According to surveys conducted in recent years, no criminologists subscribe to the first statement, although critics of the biosocial perspective often imply otherwise. About 20 % of criminologists subscribe to the second option, i.e., biological and social factors *interact* to affect criminal behavior. The remaining 80 % of criminologists still believing that biology has little or nothing to do with people's involvement in crime (the third option). So, the biosocial perspective remains a minority position among criminologists, although it does seem to have gained a little in popularity in recent decades (Cooper et al. 2010).

As other entries in this *biosocial section* illustrate, a great deal of progress has been made in recent decades deciphering biological influences not only on criminality but also on several related behaviors (e.g., aggression, risk taking, and susceptibility to alcohol and drug addiction). What has emerged from this research is *not* the conclusion that people are "hard wired" to be murderers, thieves, robbers, or rapists. Instead, the following four interrelated principles have become part of how biosocial theorists reason:

1. All human actions are controlled by the functioning of the brain.
2. Genes and other biological factors profoundly affect how the brain functions in response to whatever environment it encounters.
3. By affecting brain responses to the environment, biological factors can alter the probability of individuals running afoul of the law.
4. Hormones are among the most important biological factors influencing brain functioning.

About Hormones

Hormones are substances produced primarily in one part of the body (such as various glands) that travel to other parts of the body (usually by way of the blood system) where they have their greatest effects. The brain is one of the main targets of hormones.

This entry focuses on two types of hormones. One type is called *sex hormones* because they exist in greater quantities in one sex than in the other. The other is known as *stress hormones* because they tend to be produced in greater quantities when individuals are experiencing stress and anxiety.

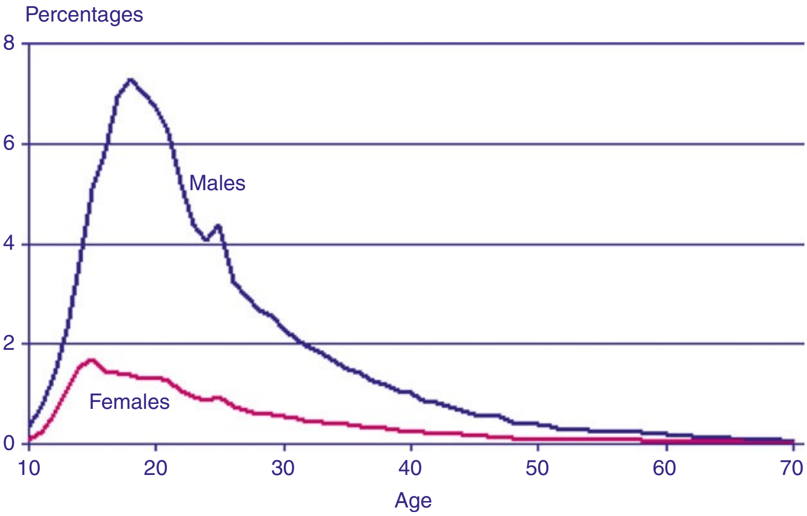
Androgens: The Hormones from Hell

Those familiar with farm animals – be they cattle, horses, hogs, sheep, or even chickens – know that males are nearly always more belligerent and combative than their female counterparts. What "barnyard culture" is responsible for such a sex difference? Of course, culture is *not* the culprit; biology is. Even though this is a rather obvious conclusion, think about how quickly people attribute male-female differences in belligerency and combativeness to cultural learning in *humans* while still recognizing that culture is not responsible for the same sex difference in other animals.

Scientists and farmers alike have learned that sex differences in belligerency and combativeness have hormonal underpinnings partly because they have identified how to eliminate the sex differences using a procedure called *castration*. This simple operation involves removing the testicles, glandular organs that specialize in producing hormones known as *androgens* (which collectively refers to all sex hormones that males produce in higher quantities than do females). Within a few months after being castrated, males nearly always become much more passive, like their female counterparts.

Studies have shown that the most influential androgen regarding physically aggression is *testosterone*. While most androgens are produced by the male testicles, smaller amounts are also synthesized by the adrenal glands (that both sexes have) as well as by the female ovaries. Therefore, even though androgens are called "*male* sex hormones," one should keep in mind that females also produce them, only in lower quantities.

Hormones, the Brain, and Criminality, Fig. 1 Crime according to age and gender



Linking Androgens to Criminality. If testosterone and other androgens are responsible for average sex differences in belligerency and combativeness, could these hormones also contribute to criminality? Nearly all biosocial criminologists believe the answer is yes. After all, many crimes have distinctive aggressive elements, especially those crimes committed primarily by males.

Before going further, it is important to note that no one seriously argues that because androgens contribute to criminality, the "solution" to the crime problem is castration! Even so, the fact that castration can dramatically reduce aggression in farm animals provides additional evidence that androgens deserve research attention by criminologists.

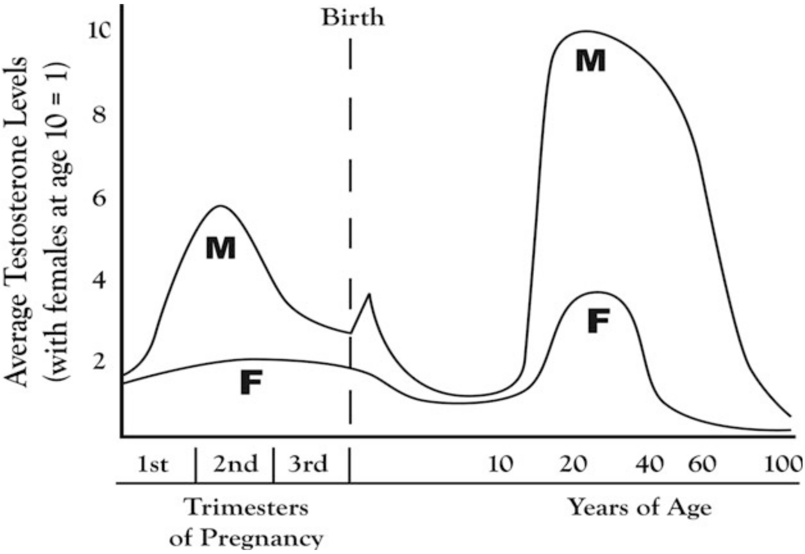
One way to think about the potential influence of androgens on criminality involves tracking crime rates over the course of a human lifetime. In this regard, not only are males much more criminal than females, but most male offenses occur between the ages of 13 and 30. The relationships between sex, age, and criminality are illustrated in Fig. 1. This particular graph is based on persons convicted of serious offenses in England and Wales during 2000, but almost exactly the same pattern can be found anywhere else in the world (Ellis et al. 2009, pp. 17–20).

Keep in mind this sex-age-crime relationship shown in Fig. 1 and then look at Fig. 2. This second graph represents the average levels of testosterone in the human body throughout life (adjusted for body weight). This second graph traces testosterone all the way back to conception (for reasons to be explained shortly), but for now simply notice how the rise in testosterone closely parallels a rise in the probabilities of criminal convictions for males as well as for females. These two graphs along with research on how androgens affect the brain provide support for the argument that androgens contribute to criminality. Some of this research will be briefly reviewed.

How Androgens Work. As already noted, androgens appear to affect behavior by altering the brain. But one should add that these alterations primarily occur in two developmental stages, not just one. The first, called the *perinatal* (or *organizational*) *stage*, takes place before and shortly following birth. Refer back to Fig. 2, and notice how males are producing considerably more testosterone than females throughout gestation and for a month or two after birth.

It is during this perinatal stage that the brain becomes irreversibly *sexed*, i.e., made to be either masculine or feminine, although to widely varying degrees. In the simplest of terms, if androgens are present in low amounts, the brain will be left in its "neutral" or "default" form, which in mammals is feminine. On the other hand, if androgens are present in high amounts, the brain (along with

Hormones, the Brain, and Criminality, Fig. 2 Lifelong testosterone



the rest of the body) will be masculinized. (As an aside, the fact that the "default sex" is female explains why males have nonfunctional nipples, testes that are really modified ovaries, and penises that are essentially enlarged clitorises.)

The second stage of brain sexing begins at puberty and continues throughout adulthood as shown in Fig. 2. Basically, to the extent that the male brain is exposed to androgens following the onset of puberty, it begins to function in a fully masculine mode. This second state is referred to as the *postpubertal* (or *activational*) *stage* (Sisk and Zehr 2005). However, it is important to realize that the *potential* for fully masculine behavior was laid down during the first stage; the second stage merely "turns on" the behavior.

Because female brains receive lower exposure to androgens than do the brains of males, their behavior tends to be much less "androgen influenced." Nevertheless, there is no simple straightforward relationship between high testosterone at a given point in time and the probability of someone robbing a bank or assaulting a neighbor. This fact has been demonstrated by studies that have correlated postpubertal testosterone levels in the blood or saliva with involvement in crime. The relationships tend to be quite modest (Ellis et al. 2009, pp. 208–210). However, one should keep in mind that neither the blood nor saliva provides a very good indication of how much testosterone is in the brain. Overall, the cause-and-effect relationship between androgens and criminality is complex even though it is still quite real.

Some Detailed Behavioral Effects of Androgens

Let us consider the behavioral consequences of high androgen exposure in greater detail because it is not just aggression that is affected. In other words, what types of behavior besides those that are illegal and violent are promoted by exposing the brain to androgens?

Competitive-Victimizing (CV) Behavior. Numerous animal experiments have carefully manipulated both perinatal and postpubertal influences of androgens on behavior. These experiments have shown that animals with high exposure exhibit more aggressive and combative tendencies, especially when their access to resources or mates is challenged or blocked (Archer 1994). Regarding the timing of the androgen exposure, it appears that perinatal exposure is actually more important than postpubertal exposure (Romeo et al. 2003).

Studies suggest that the effects of exposing the brain to androgens are similar to the effects in other mammals. Collectively, the behavioral effects of androgen exposure can be described as *competitive-victimizing (CV) behavior*

(Ellis et al. 2008). CV behavior primarily consists of elevated aggression and competitiveness, even in the face of considerable personal risk (Booth et al. 2006; McDermott et al. 2007). In humans, one manifestation of CV behavior is criminality, especially regarding violent and property offenses. The fact that males have higher levels of androgens than females offers a scientific explanation for why males are much more criminal than females throughout the world (Ellis et al. 2009; McDermott et al. 2007; van Bokhoven et al. 2006).

The idea that brain exposure to androgens is a major cause of sex differences in criminality and for the dramatic rise in male offending in the teenage years is visible when one compares Figs. 1 and 2. However, there is one interesting discrepancy revealed when comparing these two graphs. Notice that after age 30 or so, male offending rates drop off dramatically (Fig. 1) even though testosterone levels remain quite high (Fig. 2). How can this inconsistency be explained?

One proposal has been that the discrepancy reflects the influence that learning has on criminality (Ellis 2005). In particular, to the extent that males learn how to compete for resources and mates in ways that minimize the risk of retaliation by victims, their offending rates will rapidly decline. Thus, males with difficulty learning will have longer criminal "careers" than males who learn quickly.

Imagine two hypothetical males whose brains have been equally androgenized. Assume that one of these boys is able to learn quickly and the other one requires much more time. Theoretically, they should both be involved in some degree of delinquency during adolescents. However, the quick-learning boy should transition within a year or so into a socially responsible citizen who is able to compete for resources without violating the law. The slow learner, on the other hand, may take decades to finally "settle down."

One criminologist made the essential distinction between two types of offenders. She termed one "adolescent limited" and the other "life-course persistent" (Moffitt 1993). Both types engage in delinquency during their teenage years, but only the latter continues to offend as full adults. This distinction can be merged with the idea that androgens contribute to criminal activity by noting that both types of offenders will still be predominantly males. The males who become life-course-persistent offenders will be mainly those who have the greatest difficulties learning (nearly always due to some underlying neuropathology). This line of reasoning is supported by numerous studies documenting lower IQ scores, more learning disabilities, and higher school dropout rates among the most serious and persistent offenders (Ellis et al. 2009, pp. 150–159).

Did Criminal Behavior Evolve?

Another aspect of biosocial criminology has involved exploring the possibility that criminality has evolutionary roots. This means that the commission of crime could be part of how many individuals, particularly males, pass their genes on to subsequent generations (Ellis 2008; Rowe 1996).

At the heart of the argument is that over countless generations, females who have chosen mates who are unusually ambitious and competitive have left more of their (and their mate's) offspring in subsequent generations than is true for females who use other criteria when choosing mates. As a result, males may have evolved tendencies to victimize others, including in ways that most people deem criminal.

Hormones and Stress

Not all hormones are involved in sexual differentiation. Some hormones are released into the blood system primarily during times of stress. These are known as *stress hormones*. One stress hormone, called *cortisol*, has been repeatedly found associated with persistent criminal behavior (Ellis et al. 2009, pp. 210–213). However, unlike androgens that tend to be positively correlated with offending rates, cortisol levels are inversely correlated. In other words, criminals usually exhibit lower levels of cortisol levels than do persons in general.

How might the relationship between low cortisol and criminality be explained? Most proposals have reasoned as follows: Having elevated levels of cortisol tends to be relatively unpleasant. Individuals with high cortisol levels, or with cortisol levels that rise rapidly whenever they begin to experience stress, will be more easily deterred from engaging in whatever behavior is associated with elevated cortisol.

Consistent with such reasoning, low levels of cortisol have been found associated not only with criminality but also with childhood conduct disorders, persistent childhood aggression, and attention deficit hyperactivity disorders (Pajer et al. 2001). It is not very surprising to learn that all of these childhood traits have been found to be statistically associated with involvement in criminal behavior later in life (Ellis et al. 2009, p. 213).

Overall, persons who are most likely to exhibit these behavior patterns have lower “resting” levels of cortisol, or, when they experience stressful events, their cortisol levels rise very little (Gordis et al. 2006). Consequently, individuals who happen to be “hyporesponsive” to stress in terms of cortisol levels are more likely to be involved in crime.

Why do people vary in cortisol levels, especially in response to stress? Studies based on twins have revealed that genetic factors are important (Bartels et al. 2003; Wüst et al. 2000). There is also evidence that cortisol may actually interact with testosterone to affect offending behavior (Terburg et al. 2009). Ultimately, no matter what causes low cortisol levels and high androgen levels to be associated with criminality, their relationships provide further evidence that criminology without biology is incomplete. Biosocial criminologists are in a unique position to help bring these two important disciplines closer together.

Conclusions

Unlike the majority of criminologists who still argue that *only* learning and social variables are needed to explain criminal behavior, biosocial criminologists incorporate biological factors into their theories and research. This chapter has provided a thumbnail sketch of how two types of hormones appear to be relevant to understanding criminal behavior – sex hormones and stress hormones.

Regarding sex hormones, androgens appear to be central to the sexual differentiation of both the brain and the rest of the body. By affecting the brain, androgens increase the chances of many forms of competitive/victimizing behavior. Several extreme types of such behavior have been criminalized in all societies. Because male brains are exposed to higher levels of androgens, their contribution to crime is considerably greater than that of females.

At least one type of stress hormone – cortisol – has also been found associated with involvement in criminal behavior. Unlike androgens, it is unusually low levels of cortisol that are linked with criminality.

Despite the simplicity of the idea that both sex hormones and stress hormones are associated with criminality, one should appreciate that there are complex chains of events that still need to be considered as one attempts to understand the connections. For instance, most effects of hormones on behavior appear to be mediated by neurotransmitters (chemicals in the brain that help transmit signals from one nerve cell to another) (Birger et al. 2003).

Will biosocial criminology ultimately help reduce the crime problem? In all likelihood, yes (Archer 1994; Ellis 2008; MacGillivray 1997). Some critics of biosocial criminology fear that this perspective could reopen the door to Nazi-style “solutions” to crime and other social problems (Mitchell and Richard 1998). However, the risks are low in democratic societies where people insist on balancing concerns about public safety with respect for individual freedom and liberty. Also, most people understand that human behavior is much too complex to ever be easily manipulated exclusively at biological levels.

Overview

Over the past two decades, a series of rigorous evaluations have suggested that police can be effective in addressing crime and disorder when they focus in on small units of geography with high rates of crime (see Braga et al. in press; National Research Council [NRC] 2004; Weisburd and Eck 2004). These areas are typically referred to as hot spots, and policing strategies and tactics focused on these areas are usually referred to as hot spots policing or place-based policing. This place-based focus stands in contrast to traditional notions of policing and crime prevention more generally, which have often focused primarily on people (see Weisburd 2008). For example, police work often begins with a response to citizens who call the police, and police are very focused on identifying and arresting offenders who commit crimes. While hot spots policing does not ignore the offenders found within crime hot spots, the focus is very much on the places where crime is occurring.

Police, of course, have never ignored geography entirely. Police beats, precincts, and districts determine the allocation of police resources and dictate how police respond to calls and patrol the city. With place-based policing, however, the concern is with much smaller units of geography than the police have typically focused on. Places here refer to specific locations within the larger social environments of communities and neighborhoods, such as addresses or street blocks. Crime prevention effectiveness is maximized when police focus their resources on these micro-units of geography.

The evidence suggesting the effectiveness of place-based policing efforts is detailed in the sections that follow. A definition of crime hot spots is first discussed followed by a review of research suggesting that crime is highly concentrated at micro-units of geography, and these concentrations remain stable over time. Hot spots policing is then defined, and the strategies place-based policing can entail are discussed. The extent to which hot spots policing has diffused across American policing is also examined. The empirical evidence for hot spots policing and the different approaches to addressing high crime places are then reviewed. Finally, some suggestions for future research are presented.

Defining Crime Hot Spots and the Concentration of Crime at Place

Defining Crime Hot Spots

Crime hot spots are small units of geography with high rates of criminal activity. The specific geographic area that makes up a hot spot varies across studies, ranging from individual addresses or buildings (e.g., Sherman et al. 1989), to single street segments (i.e., both sides of a street from intersection to intersection; e.g., Sherman and Weisburd 1995), to small groups of street segments with similar crime problems such as a drug market (e.g., Weisburd et al. 2006). Hot spots are smaller than the units that police departments typically use for dividing up patrol resources such as patrol beats, zones, or sectors. Hot spots can be viewed as micro-places, to differentiate them from larger geographic units such as communities and neighborhoods that have traditionally been of interest to criminologists discussing crime and place (see Weisburd 2008).

There is also no firm rule as to how much crime must be found in a micro-place before it can be categorized as a hot spot. This will vary across studies and contexts, based on the overall rate of crime in a jurisdiction. In the studies of hot spots policing described below, hot spots are typically defined by drawing upon a rank ordered list of the highest crime locations (e.g., addresses or streets) in the city based on calls for service or crime incidents. Thus, places are not defined as crime hot spots by reaching an absolute threshold of crime, but instead because of extremely high levels of criminal activity relative to other places in the city.

Crime Concentration at Hot Spots

Regardless of how hot spots are defined, a number of studies over the past 20 to 30 years have found that a relatively small number of micro-places are responsible for a significant amount of total crime in a city (e.g., see Weisburd and Mazerolle 2000; Weisburd et al. 2004). The hottest spots in a city, regardless of the specific unit of analysis chosen, are responsible for a large chunk of a jurisdiction's crime problem. Perhaps the most influential of these studies was Sherman et al.'s (1989) analysis of emergency calls to street addresses over a single year. Sherman et al. found that only 3.3 % of the addresses in Minneapolis, Minnesota, produced just over 50 % of all calls to the police. If crime were randomly distributed across the 115,000 addresses in Minneapolis, one would not expect any places to have 15 or more calls in a single year. Instead, Sherman et al. found 3,841 such addresses, indicating that crime is far more concentrated than would be expected by chance.

A study conducted by Weisburd et al. (2012) not only confirms the concentration of crime, but also the stability of such concentrations across a long time span. Weisburd et al. examined street segments in the city of Seattle from 1989 through 2004. They found that each year, 50 % of crime incidents occurred on between 4.7 and 6.1 % of the street segments. These data overall illustrate a kind of "law of concentration" for crime, suggesting that crime is heavily clustered in cities with fewer than 5 or 10 % of addresses, street segments, or small clusters of addresses and street segments accounting for a majority of crime in a city each year (Weisburd et al. 2012). Thus, police can target a sizable proportion of citywide crime by focusing in on a small number of places.

Sherman (1995) argues that such clustering of crime at places is even greater than the concentration of crime among individuals. Comparing the concentration of calls in Minneapolis to the concentration of offending in the Philadelphia birth cohort study, he notes that future crime is "six times more predictable by the address of the occurrence than by the identity of the offender" (1995: 36-37). Sherman asks, "Why aren't we thinking more about wheredunit, rather than just whodunit?"

The Stability of Crime Hot Spots

Concentration by itself has important implications for the effectiveness of hot spots policing. However, it is also important to examine the stability of crime hot spots over time. If hot spots of crime shift rapidly from place to place each year, it makes little sense to focus crime control resources at such locations, because they would naturally become free of crime without any criminal justice intervention (Spelman 1995).

Data on crime stability suggests that hot places tend to remain hot over time. Spelman (1995), for example, examined calls for service at schools, public housing projects, subway stations, and parks and playgrounds in Boston. He found evidence of a very high degree of stability of crime at the "worst" of these places over a 3-year period. Spelman concluded that it "makes sense for the people who live and work in high-risk locations, and the police officers and other government officials who serve them, to spend the time they need to identify, analyze and solve their recurring problems" (1995: 131).

The most comprehensive examination of the stability of crime at place over time was conducted by Weisburd et al. (2012) in their study of crime incidents at street segments in Seattle. Using group-based trajectory analysis to categorize street segments according to similar developmental patterns, they identified 22 specific trajectory groups. The most important finding in their study was that crime remained fairly stable at places over time, particularly in a small group of high crime segments they refer to as the "chronic group." These street segments remained among the hottest in the city throughout the 16-year study period. Representing just 1 % of the street segments in Seattle, the chronic streets accounted for 22 % of the crime in the city. Hot spots of crime thus appear to remain hot over long periods of time. This can be contrasted with developmental studies of individual offending where there is often tremendous change across relatively short periods, especially for high-rate offenders (see Horney et al. 1995), and a great deal of variability across the life-course as many high-rate "hot" offenders in adolescence age out of crime and cool off in adulthood.

The Distribution of Crime Hot Spots

How are hot spots of crime distributed geographically across cities? This question is important to explore, because it gets at the issue of whether it is necessary for police to focus in on micro-places for hot spots policing. For example, if all the crime hot spots were concentrated in only one or two neighborhoods in a city, then neighborhood or beat-level initiatives might be just as effective as hot spots approaches in addressing crime concentrations.

Evidence to date suggests that crime hot spots can be found throughout a city. Weisburd and Mazerolle (2000), for example, identified 56 drug markets in Jersey City, New Jersey. Although the drug markets were more concentrated in socially disadvantaged areas, they could even be found in areas that were generally seen as more established and better off. Weisburd and Mazerolle argued that even "good" neighborhoods can have "bad" places. Importantly, most places even in very disadvantaged neighborhoods were relatively free of serious drug problems.

Groff et al. (2010) examined the distribution of all crime hot spots in Seattle. While hot spots may be more likely in high activity places in the city like the central business district, they tend to be found in a variety of different neighborhoods, and even neighborhoods with higher concentration of hot spots tend to have a sizable proportion of crime free locations. Groff et al. (2010) conclude that much information about crime would be missed by focusing on larger units such as neighborhoods. These findings overall suggest the usefulness of a policing approach that narrows the focus to hot street segments or micro-places as opposed to hot neighborhoods or hot communities.

Place Risk Factors

Research by Weisburd and colleagues (2012) provides new insights into the key risk factors that help explain whether places become hot spots or not. They overall find that social and opportunity factors are very highly concentrated at the street block level, and these concentrations are generally very closely linked to concentrations of crime. This suggests that certain factors may contribute to street segments remaining hot spots of crime over time, and hence could be viewed as criminogenic risk factors for a street becoming (and remaining) a crime hot spot.

Some of these factors present opportunities for the police in addressing crime at chronic hot spot streets. For example, the number of employees working on a block is a strong predictor of a street segment being a chronic hot spot. While the police have little control over the number of people working on a block, they can control the level of guardianship they provide on each block and how they approach the potential crime attractors and generators on each block (e.g., working to install CCTV in parking areas on streets with many employees to address car break-ins). As another example, higher numbers of high-risk juveniles (defined as those with high rates of truancy or poor school performance) on a block substantially increased the likelihood a street would be a chronic hot spot. Increased enforcement from police could reduce levels of truancy and limit the amount of time these juveniles spend on their street unsupervised.

Current State of Hot Spots Policing

What Is Hot Spots Policing?

Hot spots policing, also sometimes referred to as place-based policing (see Weisburd 2008),

Hot Spots and Place-Based Policing, Table 1 Percentage of police agencies using computers for specific tasks by population served (Adopted from Tables 22 and 25 of Reaves 2010)

Population served	Crime analysis	Crime mapping	Hot spot identification	Providing crime maps to officers in-field
1,000,000+	100	100	92	31
500,000–999,999	100	100	100	29
250,000–499,999	100	100	80	48
100,000–249,999	96	94	66	32
50,000–99,999	88	82	56	31
25,000–49,999	69	60	31	16
10,000–24,999	53	41	19	11
2,500–9,999	37	23	9	9
Less than 2,500	21	11	5	8
All sizes	38	27	13	11

covers a range of police responses that all share in common, a focus of resources on the locations where crime is highly concentrated. Just as the definition of hot spots varies across studies and contexts, so do the specific tactics police use to address high crime places. There is no one way to implement hot spots policing. As Weisburd (2008) notes, approaches can range rather dramatically across interventions.

For example, the strategies of place-based policing can be as simple as dramatically increasing officer time spent at hot spots patrol, as was the case in the Minneapolis Hot Spots Policing Experiment (Sherman and Weisburd 1995). But place-based policing can also take a much more complex approach to the amelioration of crime problems. In the Jersey City Drug Market Analysis Project (Weisburd and Green 1995), for example, a three-step program (including identifying and analyzing problems, developing tailored responses, and maintaining crime control gains) was used to reduce problems at drug hot spots. In the Jersey City Problem-Oriented Policing Project (Braga et al. 1999), a problem-oriented policing approach was taken in developing a specific strategy for each of the small areas defined as violent crime hot spots. The results of these interventions are discussed more in the next section.

Are Agencies Using Hot Spots Policing?

To what extent are police agencies using hot spots policing in practice? To answer this, data from the 2007 Law Enforcement Management and Administrative Statistics (LEMAS) data were examined (see Reaves 2010), as well as survey data that asked police agencies about hot spots policing. While data on specific tactics are limited in the LEMAS survey, there are a number of questions related to police technology (see Table 1). Crime analysis and crime mapping, in particular, are very important for the successful implementation of hot spots policing. The results overall suggest widespread use of these technologies in larger departments but not in smaller ones. For example, while over 90 % of the largest agencies are using computers for hot spot identification, just 13 % of departments overall are. Even in moderately sized cities (population 100,000–249,999), just 56 % of departments use computers to identify hot spots. When it comes to using computers for crime analysis and crime mapping, results are similar. One hundred percent of the largest departments make use of computers for such tasks, but only 38 % of agencies overall use computers for crime analysis, and 27 % use computers for crime mapping. In terms of patrol officer's access to crime data, just 31 % of the largest agencies and 11 % of agencies overall provide officers access to crime maps in their patrol cars.

The use of computers for crime mapping and analysis has increased since the 2003 LEMAS survey. For example, the percentage of officers working in a department that uses computers for crime mapping jumped from 57 % in 2003 to 75 % in 2007 and for hot spot identification the increase was from 45 % in 2003 to 58 % in 2007 (Reaves 2010). Research by Weisburd and Lum (2005) suggests that the use of crime mapping diffused quickly across policing from the mid-1990s through 2001. They note that the adoption of crime mapping was closely linked to the use of hot spots policing. When agencies were asked why they developed crime mapping in the department, the largest response category was "to facilitate hot spots policing." Kochel (2011: 352) cites similar statistics, noting "Within 15 years, hot spots policing had diffused almost completely throughout large U.S. police departments." These latest LEMAS data suggest that the use of crime mapping continues to increase, but smaller agencies are lagging behind.

Data on the adoption of hot spots policing also come from a Police Executive Research Forum (PERF) survey of 176 policing agencies of various sizes on their efforts to reduce violent crime (Koper 2008). Responses showed close to two-thirds (63 %) of agencies used hot spots policing to reduce violent crime. This was by far the most popular response to the question of how to address violence. When asked what sort of places the agency defines as a hot spot, the majority of respondents noted addresses or intersections (61 %) or clusters of addresses (58 %). However, a majority of respondents (57 %) also identified neighborhoods as potential hot spots and a sizable minority pointed to patrol beats (41 %) as the sort of place that would be defined as a hot spot. Crime is not as highly concentrated at these larger units of geography, so focusing on them may not produce the same crime control benefits as using more micro-units of analysis.

The PERF survey also provides data on what tactics agencies are using to respond to homicide, robbery, assault, gang violence, and drug crime hot spots. While agencies identified a number of different potential responses to hot spots, the top responses in each category tended to be some combination of problem solving and analysis, directed patrol, community policing/partnerships, and targeting known offenders (Koper 2008). These strategies and the empirical evidence supporting them are discussed more below, focusing, in particular, on problem solving and directed patrol.

It is important to note that while the data discussed above provide an estimate of the extent to which police agencies have adopted hot spots policing, they do not make clear how frequently agencies are actually using hot spots policing in practice. In other words, while it appears that a substantial portion of larger agencies are using computers to identify crime hot spots, what percentage of officer time is actually being spent on hot spots policing in these agencies? Data on the level of implementation of hot spots policing is not available at the department level, but such data would be important to better understand to what extent hot spots policing is becoming a primary tactic in police agencies.

Empirical Evidence on the Effectiveness of Hot Spots Strategies

The evidence base for the effectiveness of hot spots policing in reducing crime and disorder is particularly strong. As the NRC (2004: 250) review of police effectiveness noted, "studies that focused police resources on crime hot spots provided the strongest collective evidence of police effectiveness that is now available." The Braga et al. (in press) systematic review came to a similar conclusion; although not every hot spots study has shown statistically significant findings, the vast majority of such studies have (20 of 25 tests from 19 experimental or quasi-experimental evaluations reported noteworthy crime or disorder reductions), suggesting that when police focus in on crime hot spots, they can have a significant beneficial impact on crime in these areas. In Braga and colleagues' (in press) meta-analysis, they found an overall mean effect size of 0.184, suggesting a significant benefit of the hot spots approach in treatment compared to control areas. As Braga (2007: 18) concluded "extant evaluation research seems to provide fairly robust evidence that hot spots policing is an effective crime prevention strategy."

Importantly, there was little or no evidence to suggest that spatial displacement was a major concern in hot spots interventions. Spatial crime displacement is the notion that efforts to eliminate specific crimes at a place will simply cause criminal activity to move elsewhere, thus negating any crime control gains. Braga et al. (in press) found significant evidence of spatial displacement in only one study (Ratcliffe et al. 2011) and even here the amount of displacement was far less than the main crime prevention benefit of the intervention. Thus, in nearly every study, crime did not simply shift from hot spots to nearby areas (see also Weisburd et al. 2006). Indeed, a more likely outcome of such interventions was a diffusion of crime control benefits (Clarke and Weisburd 1994) in which areas surrounding the target hot spots also showed a crime and disorder decrease. Displacement is not inevitable, in part, because hot spots tend to have specific features that make them attractive targets for criminal activity, and these same features may not exist on neighboring blocks. For example, in the Weisburd et al. (2006) study, the prostitution hot spot targeted by police had few homes and many vacant buildings, making it an attractive site for prostitution activity. In contrast, one of the catchment areas near the target site had many more residences, making it more likely that the police would be called when prostitution occurred. In this context, prostitutes could not easily move their illegal activity to areas nearby.

The experimental evidence on hot spots policing is discussed below, focusing when possible on what tactics seem to be most effective in addressing crime hot spots. The literature has not provided the same level of guidance on what specifically police officers should be doing at hot spots to most effectively reduce crime. As Braga (2007: 19) notes "Unfortunately, the results of this review provide criminal justice policy makers and practitioners with little insight on what types of policing strategies are most preferable in controlling crime hot spots." The update to Braga's (2007) review by Braga and colleagues (in press) does provide some additional guidance, suggesting that problem-oriented hot spots interventions may be somewhat more effective than simply increasing police presence, although the authors caution these comparisons are based on a small number of studies.

The first randomized experiment on hot spots policing, the Minneapolis Hot Spots Patrol Experiment (Sherman and Weisburd 1995), used computerized mapping of crime calls to identify 110 hot spots of roughly street-block length. Police patrol was doubled on average for the experimental sites over a 10-month period. Officers in Minneapolis were not given specific instructions on what activities to engage in while present in hot spots. They simply were told to increase patrol time in the treatment hot spots, and the activities they engaged in ranged a good deal from more proactive problem-solving efforts to simply sitting in the car parked in the center of a hot spot street segment. The study found that the experimental as compared with the control hot spots experienced statistically significant reductions in crime calls and observed disorder. The significant decline in calls for service was driven largely by a decline in soft crime calls (e.g., disturbances, drunks, noise, and vandalism). While soft crime calls declined 7.2–15.9 % in the treatment group relative to the control group, depending on the time period examined, hard crime calls, (e.g. burglaries, auto thefts, and assaults) declined a non-statistically significant 2.6–5.9 %.

The results overall though suggested increased police presence could have a significant effect on crime, particularly disorder and less serious crime. This marked a major change from the conventional wisdom about the impact the police could have on crime. The most influential prior study of police patrol at the time was the Kansas City Preventive Patrol Experiment (Kelling et al. 1974), which found that neither doubling nor removing preventive patrol in a beat had a significant impact on crime or victimization. The finding that police randomly patrolling beats is not an effective crime deterrent makes sense based on the review of the crime concentration literature above. Since crime is very concentrated across cities, it makes little sense from an effectiveness and efficiency standpoint to respond with a strategy relying on the random distribution of police resources across large geographic areas. The Minneapolis study and the other hot spots studies described below suggested police could have an impact on crime by appropriately focusing their resources on the locations where crime was highly concentrated.

Significant crime and disorder declines are also reported in five other randomized controlled experiments that tested a more tailored, problem-oriented approach (see Braga and Weisburd 2010) to dealing with crime hot spots. In the Jersey City Problem-Oriented Policing in Violent Places experiment (Braga et al. 1999), the exact response varied by hot spot, but the responses all included some aspect of aggressive order maintenance and most included efforts to make physical improvements to the area (e.g., removing trash, improving lighting) and drug enforcement. Strong statistically significant reductions in total crime incidents and total crime calls were found in the treatment hot spots relative to the control hot spots. Social and physical observation data showed improvement in visible disorder in 10 of the 11 treatment areas compared to the control sites after the intervention.

In the Jersey City Drug Market Analysis Program experiment (Weisburd and Green 1995), a step-wise problem-solving model was compared to generalized enforcement in drug hot spots. The treatment group received a three-stage intervention. In the planning stage, officers collected data on the physical, social, and criminal characteristics of each area; in the implementation stage, officers coordinated efforts to conduct a crackdown at the hot spot and used other relevant responses to address underlying problems; and finally, in the maintenance stage, officers attempted to maintain the positive impact of the crackdown. The experimental sites had significantly smaller increases in disorder calls compared to the control sites. In particular, the project had a positive impact on calls related to public morals and suspicious persons.

In the Oakland Beat Health study, Mazerolle and colleagues (2000) evaluated a civil remedies initiative to deal with high crime addresses and blocks. The intervention involved a police officer and police service technician visiting a site to identify and analyze the problem and to make contact with the property owner or place manager to try to address the problems. The intervention typically involved pressuring third parties (e.g., the landlord of a problem apartment building) to make changes to improve property conditions or face the possibility of civil action. Results showed significant reductions in drug calls for service at the treatment hot spots relative to the controls.

In Lowell, Massachusetts, a problem-oriented policing intervention to address disorder was associated with a statistically significant 20 % reduction in crime and disorder calls for service at the treatment hot spots compared to the control hot spots (Braga and Bond 2008). Systematic observations confirmed the official crime data results, showing significant reductions in social and physical disorder at the treatment places relative to the control places.

The Braga and Bond (2008) experiment also included a mediation analysis to assess which hot spots strategies were most effective in reducing crime. Results suggested that situational prevention strategies had the strongest impact on crime and disorder. Situational strategies are concerned with the physical, organizational, and social environments that make crime possible, and they focus on efforts to disrupt situational dynamics that allow crime to occur by, for example, increasing risks or effort for potential offenders or reducing the attractiveness of potential targets. Such approaches are often a prominent part of hot spots interventions, particularly those involving problem solving and include things like securing lots, razing abandoned buildings, and cleaning up graffiti. Increases in misdemeanor arrests made some contribution to the crime control gains in the treatment hot spots, but were not as influential as the situational efforts. Social service interventions did not have a significant impact on crime and disorder. These findings suggest not only the importance of situational crime prevention as a strategy for addressing crime facilitators in hot spots, but also that aggressive order maintenance through increases in misdemeanor arrests may not be the most effective way of addressing high disorder places. The potential negative consequences of intensive enforcement in the form of decreased perceptions of police legitimacy are discussed below (see Braga and Weisburd 2010).

More recently, in an important experimental study in Jacksonville, Florida, Taylor et al. (2011) were the first to compare different hot spot treatments in the same study with one treatment group receiving a more standard saturation patrol response and the second receiving a problem-oriented response that focused on officers analyzing problems in the hot spot and responding with a more tailored solution. Results showed a decrease in crime (though not a statistically significant decrease) in the saturation patrol hot spots, but this decrease lasted only during the intervention period and disappeared quickly thereafter. In the problem-oriented policing hot spots, there was no significant crime decline during the intervention period, but in the 90 days after the experiment, street violence declined by 33 % (a statistically significant decline). These results offer the first experimental evidence suggesting that problem-oriented approaches to dealing with crime hot spots may be more effective than simply increasing patrols in high crime areas. They also suggest that problem-solving approaches may take more time to show beneficial results, but any successes that come from a problem-oriented framework may be more long-lasting in nature.

Braga and Weisburd (2010) detail the desirability of problem-oriented policing as a strategy for long-term crime reduction in chronic hot spots. They recognize that even when agencies use problem-solving approaches, they often tend to prioritize more traditional, enforcement-oriented responses. Drawing upon the results of Braga and Bond (2008) and other hot spots studies, they argue that "situational" problem-oriented policing is not only more innovative but also more likely to produce significant crime control benefits. As they conclude "based on the available empirical evidence, we believe that police departments should strive to develop situational prevention strategies to deal with crime hot spots. Careful analyses of crime problems at crime hot spots seem likely to yield prevention strategies that will be well positioned to change the situations and dynamics that cause crime to cluster at specific locations" (Braga and Weisburd 2010: 182–183).

Two other recent experiments shed new light on the effectiveness of particular approaches to dealing with crime hot spots. While the initial Minneapolis study did not include a systematic examination of officer activities in the hot spots, subsequent analyses by Koper (1995) provide some insight into how much time officers should be spending in hot spots to maximize residual deterrence. Koper analyzed observational data on nearly 17,000 instances when police drove through or stopped at a hot spot and examined the time from when the officer(s) left the location until the next occurrence of criminal or disorderly behavior. Using survival analysis techniques, he found that each additional minute of time officers spent in a hot spot increased survival time by 23 %. Survival time here refers to the amount of time after officers departed a hot spot before disorderly activity occurred. The ideal deal time spent in the hot spot was 14 to 15 min; after about 15 min, there were diminishing returns and increased time did not lead to greater improvements in residual deterrence. This phenomenon is often referred to as the "Koper curve" as graphing the duration response curve shows the benefits of increased officer time spent in the hot spot until a plateau point is reached at around 15 min (see Koper 1995, Fig. 1). As Koper (1995: 668) notes "police can maximize crime and disorder reduction at hot spots by making proactive, medium-length stops at these locations on a random, intermittent basis." Koper (1995) argues for an approach in which police travel between hot spots, spending about 15 min in each hot spot to maximize residual deterrence, and moving from hot spot to hot spot in an unpredictable order, so that potential offenders recognize a greater cost of offending in these areas because police enforcement could increase at any moment.

These recommendations suggest a potential reason why an experimental hot spots intervention at crack houses in Kansas City had quickly decaying effects (Sherman and Rogan 1995). The crackdowns on drug locations led to significant but modest improvements in the experimental street blocks, but these crackdowns were only one-time events and hence, residual deterrence was limited. Within a few weeks, crime on the streets where crack houses were located returned to pre-crackdown levels.

Koper's (1995) recommendations were recently applied to the design of a hot spots policing experiment in Sacramento, California. Officers were explicitly instructed to rotate between treatment group hot spots and to spend about 15 min in each hot spot. Results suggest the Koper (1995) approach to hot spots policing had a significant impact on crime. Treatment group hot spots had significantly fewer calls for service and Part I crime incidents than control group hot spots when comparing the 3-month period of the experiment in 2011 to the same period in 2010 (Telep et al. in press).

Ratcliffe and colleagues (2011) evaluated the impact of foot patrol in crime hot spots in a randomized experiment in Philadelphia. Foot patrol has traditionally been viewed as an effective strategy for reducing fear of crime, not actual crime. Results suggested significant declines in violence in the treatment hot spots compared to the control sites. The intervention was particularly effective for hot spots that reached a threshold of violence (i.e., the hottest hot spots). Overall, the 12-week intervention prevented a net total of 53 violent crimes in the target areas. These findings suggest the importance of reconsidering the effectiveness of foot patrol when intensive foot patrol is used in high crime micro-places.

Hot Spots Policing and Police Legitimacy

In sum, the empirical research is highly supportive of the effectiveness of hot spots policing in reducing crime and disorder. The effectiveness of policing, however, is also dependent on public perceptions of the legitimacy of police actions (NRC 2004; Tyler 1990). The police need the support and cooperation of the public to effectively combat crime and maintain social order in public spaces. Legitimacy here refers to the public belief that there is a responsibility and obligation to voluntarily accept and defer to the decisions made by authorities (Tyler 1990). A number of scholars have recently argued that intensive police interventions such as hot spots policing may erode citizen perceptions of the police (e.g., see Kochel 2011; Rosenbaum 2006). Rosenbaum (2006), for example, argues that enforcement-oriented hot spots policing runs the risk of weakening police-community relations. Aggressive tactics can drive a wedge between the police and communities, as the latter can begin to feel like targets rather than partners. This is particularly relevant in high crime minority communities where perceptions of the police already tend to be negative. This has implications for the crime control effectiveness of hot spots policing as Tyler (1990) has argued that legitimacy is an important predictor of long-term compliance with the law. If hot spots policing interventions weaken perceptions of legitimacy, then the short-term crime control gains from the intervention might be offset by long-term increases in criminal offending.

Despite arguments that intensive interventions such as hot spots policing will have negative impacts on police legitimacy, the limited evidence available from such interventions tends to suggest that citizens living in targeted areas welcome the increased police presence. Recent research from three cities in San Bernardino County, California, for example, found that a broken windows style intervention in street segments had no impact on resident perceptions of police legitimacy (Weisburd et al. 2011). It would also be useful to assess the views of residents of areas nearby hot spots and target sites to assess whether such interventions have spillover effects (either positive or negative) on legitimacy perceptions. Additionally, research to date has not attempted to measure how the individuals who were stopped and searched by the police perceive such programs. Ideally, a study would compare the perceptions of individuals stopped as part of a hot spots intervention to those stopped under standard routine preventive patrol. Braga and Weisburd (2010) describe a community-oriented approach to hot spots policing focused on community consultation on the tactics used in hot spots and efforts to ensure that hot spots policing strategies do not reduce levels of police legitimacy. The knowledge base on this important topic of how police fairness and effectiveness intersect in hot spots policing remains limited.

Conclusions and Future Research

Overall this entry suggests that significant crime control benefits can result from the use of hot spots policing and place-based policing. Basic research suggests that the action of crime is at very small geographic units of analysis, such as street segments or small groups of street blocks. Such places also offer a stable target for police interventions, as contrasted with the constantly moving targets of criminal offenders. Crime at place is not simply a proxy for larger area or community effects; indeed, the basic research evidence suggests that much of the action of crime occurs at very small geographic units of place. This basic research is reinforced by a strong body of experimental evidence for the effectiveness of place-based policing in reducing crime and disorder without simply displacing crime to areas nearby. Additionally, rigorous evaluation research in policing suggests that place-based interventions, including hot spots policing, tend to be more effective than interventions focused on people (Weisburd and Eck 2004).

While hot spots policing already has a larger evidence base than many police interventions, there are still areas where future research can shed new light. First, as noted above, additional research is needed on how hot spots policing impacts perceptions of police legitimacy in hot spot locations and the implications this has for the long-term effects of intensive police efforts. In particular, studies to date have not adequately examined the perceptions of offenders arrested or stopped in hot spot areas. Second, nearly all hot spots studies have taken place in highly populated urban areas. While smaller departments with only a few officers are unlikely to have a significant quantity of street-block size hot spots, future research should better examine the applicability of hot spots policing across varying contexts. Third, there are no studies that examine the long-term effects of hot spots interventions. In some respects, this makes sense. Hot spots interventions that focus on increasing patrol time to maximize deterrence are not expected to have an impact long after the police have left. But more problem-oriented hot spots approaches are designed to have longer-term impacts by changing the dynamics of places and so longer follow-up periods would be desirable in future projects. Fourth and in a related way, there should be more research that examines how police can disrupt long-term crime concentrations. In other words, can police address certain criminogenic factors that would stop the same places from appearing in the chronic trajectory group year after year as they did in Seattle? Fifth, further study on the importance of time in understanding crime hot spots is needed. To date, researchers have typically focused on annual data to generate hot spot locations, but the year may not be the most appropriate temporal unit. Police agencies must find a balance between targeting areas that have shown some stability in crime rates over time, while also allowing for flexibility in shifting resources when data suggest the movement of hot spots or the emergence of new hot spots. Sixth, future research should consider the cost-effectiveness of hot spots policing. How much is crime reduced per dollar spent or unit of officer time devoted to hot spots policing? How does the cost-effectiveness of hot spots policing compare to other policing strategies such as random preventive patrol? Assessing cost-effectiveness is particularly important in times like the present when many police agencies are facing budget cuts.

Finally, there is a need for better data on what agencies are doing in the field. LEMAS, for example, suggests the largest agencies have many of the capabilities and technologies needed for properly implementing hot spots policing, but many smaller agencies still lag behind. LEMAS is limited though in providing data on what departments are engaged in day-to-day. Because it is a massive national survey, there are limits to the number of questions that can be asked about daily practices, and even with additional questions, the LEMAS data reflect the survey responses of only certain individuals in the department, who may not always have sufficient knowledge about daily practices to provide reliable data. Qualitative studies could potentially provide greater insight into what policing looks like at the street level.

Qualitative or mixed methods approaches could help better assess to what extent departments are actually engaging in hot spots policing.

Housing Choice Vouchers and Escaping Neighborhood Crime

Ronald E. Wilson and Brent D. Mast
Office of Policy Development and Research,
U.S. Department of Housing and Urban
Development, Washington, DC, USA

Overview

The Housing Choice Voucher Program (HCVP) provides relocation opportunities for low-income families to find better places to live. In examining why HCVP, participants want to relocate research generally focuses on the "pull" factors of why low-income families want to relocate. Most reasons for relocation are related to some benefit the new neighborhood offers, such as access to better schools, jobs, housing stock, and other amenities to improve their lives. Often overlooked are the "push" factors that drive residents from a neighborhood. Much research on these push factors has focused on life-course changes in family structure, career options, or some financial gain. One significant push factor that uniformly effects residential satisfaction is how safe families feel with respect to witnessing or being victims of crime in their neighborhood. Families who use a voucher to relocate are no exception to this concept and have stated across numerous studies that the primary reason for wanting to leave their neighborhood is to escape chronic problems with crime. Numerous studies and reports have documented low levels of residential satisfaction by families in impoverished neighborhoods, primarily driven by violence, drugs, and gangs in the neighborhood. Research across several disciplines is consolidated in this entry about why families in impoverished neighborhoods want to leave their current residences for new neighborhoods, many of which use vouchers to escape crime.

Introduction

Many factors known to cause delinquency, social exclusion, antisocial behavior, violence, poor health, and low academic performance in youth come from living in distressed places (Buck 2001; Overman 2002; Friedrichs and Blasius 2003; Musterd et al. 2003; Sharkey 2008). Project-based public housing communities are usually located in places that exhibit a confluence of these factors. Families in these neighborhoods often have little means to escape and must withstand regular exposure to these factors reducing their neighborhood satisfaction in a multitude of ways. While there are family and peer factors that contribute to the prevalence of these factors, simply relocating out of these places can help diminish the negative effects of living in distressed places.

In 1974, the US Department of Housing and Urban Development (HUD) launched the Housing Choice Voucher Program (HCVP) to financially assist low-income families to relocate to neighborhoods of their choice. In 2010 alone, approximately 2.1 million families received assistance through the program (U.S. Department of Housing & Urban Development 2010). The HCVP is a "tenant-based" residential assistance program resulting from the Community Development Act (CDA). Other HUD assistance programs are "project based" and require participants to move to campuses, high-rise complexes, or other centrally located housing. Participants in the HCVP use a voucher to seek rental housing anywhere within the local housing market and pay at least 30 % of their own income toward rent and utilities; the remainder is paid by HUD through a local housing authority. HCVP participants can come from any neighborhood, not just project-based sites. Prior to the HCVP, residential choice for assisted families was limited to a small number of centrally located project-based sites.

Success of the HCVP is contingent on participants' searching for and finding housing that satisfies program requirements as well as their own preferences. The program's main intent is to provide access to safe and sanitary housing that must pass housing quality inspections. But HCVP descriptions commonly emphasize neighborhood as much as dwelling. This language implies a dual objective of finding both a dwelling and a neighborhood. With the HCVP, choice of where to live becomes more than just about the quality of housing stock and is inexplicably tied to the neighborhood the dwelling is located within. A key outcome of the HCVP design is that households have a maximized spatial mobility choice in selecting where to live (Winnick 1995). Place, then, is a central factor in the voucher recipient decision-making process, and (Ross 2011) found evidence that HCVP tenants were more likely to look at neighborhoods before housing units.

The growth and popularity of the HCVP is fueled by its distinct advantage in allowing a participant's locational needs and preferences to become the driving factor in choosing a place to live. As such, low-income families have an impetus for applying to the program to escape the often impoverished places they currently live, particularly when crime is a constant threat to their safety and their children.

Establishing the Idea of Place for Understanding the HCVP

Place is a central concept to understanding the HCVP. In housing studies, the term "place" often refers to project-based sites. Other social science disciplines also tend to geographically limit the term "place" to an address or nothing larger than a street block, which in geography is usually associated with the concept of "location." When limited to such small units, the concept of place is constrained to understanding why individuals, families, and households select certain environments to live and leave based on what occurs in that household or on that street. Decisions to move from environmental conditions are seldom limited to that scale. In geography, place is a scalable term that represents a delineated area that is distinguishable from other areas. Under this definition, a "place" could be a room, building, street block, neighborhood, section of a city/county, metropolitan area, or even a region. Place, whatever the scale, can be used as a framework that is inclusive of a location and its surrounding environment in which to examine individual, peer, and family interaction within a larger geography as part of a complete context.

Locations are focal points within a larger geography that situates *where* something is positioned or an event occurs. Locations exhibit specific characteristics that make them relatively fixed entities, represented accurately with an X and Y coordinate pair. Environments exert influence on the characteristics of that location contributing to its condition. Change the environment and the characteristics of a location will likely change. Changing a location's characteristics can also cause the surrounding environment to also change. As such, using locations as unit of analysis can constrain a more complete measurement of individuals, families, or households interactions. A "place" is representative of the scale that captures the influence of conditions and events occurring between a collection of locations in their larger environment.

Neighborhoods form an appropriate definition of place in studies of urban crime as opposed to locations. Neighborhoods matter as "places" that frame the interactions between individuals, peer, and families while accounting for the impact the environment has on them and them on it. Most crime clusters within a larger area than at a single address or set of addresses. Limiting place to such a small area, then, reduces the opportunity to understand the full impact of the neighborhood crime on residential satisfaction. People situate their locations within the larger neighborhood they live in and reference the features, events, and changes that occur within that space on how they feel. As such, separating the location from the neighborhood does not permit the ability to fully measure the factors that makes a resident satisfied with the neighborhood, i.e., the research cannot disentangle internal characteristics from external influences.

Crime is a deeply personal experience for victims. The traumatization associated with crime can stem from both personal victimization but also with place. Residents who witness or hear about crime in their neighborhood are also affected through the transmission of conditions and other events that occur in the neighborhood. Whether victim, witness, or simply "hearing" about crime in the neighborhood negative feelings about place can lead to behavior modification – of which leaving the neighborhood is one – based on anticipated fear of being victimized. This fear does not manifest itself from just incidents in buildings, addresses, street blocks, or a public housing sites, but emerges as product of the location and the larger environment. As such, location will not suffice in understanding crime in place for those using a voucher to relocate. In this entry, the term "place" refers to the dwelling and the neighborhood unless otherwise specified.

Wanting to Leave the Neighborhood for a Better Place

There are many reasons families relocate. Most reasons are brought on by life-course turning points in family status that entails changes in job opportunities, school quality, housing needs, or desirable neighborhood amenities. But decisions to move can result from factors related to satisfaction with neighborhood conditions (Wolpert 1965; Rossi 1980; Galster 1987; Lu 1999; Basolo and Strong 2002). For low-income families, neighborhood conditions may be more important than life-course events when deciding to apply to the HCVP to relocate. Participants applying to the HCVP program are looking to more often escape negative "life-altering" events that result from living in neighborhoods characterized as socially disorganized (Shaw and McKay 1942).

Social disorganization is the result of concentrated economic disadvantage and social isolation in place. These places are bleak geographies that exhibit higher levels of residential turnover, unemployment, single-headed households, uneducated populace, low quality businesses, poverty, and poor quality housing stock. Social networks and local organizational ties in these places are weak because of collapsed informal neighborhood relationships that leave residents unable to actualize common values – maintenance of a healthy, safe, and attractive residential environment – that contribute to higher levels of crime (Wilson, and Kelling 1982; Sampson and Groves 1989; Bursik and Grasmick 1993; Krivo and Peterson 1996; Sampson et al. 2002; Fagan and Davies 2004; Weisburd et al. 2004). Many HCVP applicants live in these types of neighborhoods.

Across the 1960s, 1970s, and 1980s, the quality of life in many public housing communities severely declined in the form of concentrated poverty (Banks and Banks 2004), resulting in socially disorganized places. Residents of these communities repeatedly cited crime as one of their greatest concerns among numerous neighborhood problems. Crime concerns grew so prominent that in 1989, Congress created the National Commission on Severely Distressed Public Housing (NCSDPH) to identify the national extent of the problem. This effort was the result of an earlier HUD study (Jones et al. 1979) that identified a set of indicators to measure the severity of social problems residents in public housing reported. The Commission used four broad areas to measure distress levels in public housing. Violent crime was one of those areas and was the first direct national-level acknowledgement that crime was a critical component of social and economic disadvantage in specific places.

Following the Commission's report, Lawrence Vale, a prominent scholar on housing issues, wrote a critical piece (1995) on the NCSDPH final report with several discussion points about crime and place. Vale made a key point about the spatial connection public housing developments share with their surrounding environment, noting they were at risk of becoming future problems partly due to their neighborhoods they were situated within. Responding to Vale's commentary, Jeffery Lines (1995), a consultant on the NCSDPH report, acknowledged crime was one of the most pervasive problems that made public housing residents perceive their neighborhood was severely distressed. These negative feelings toward the neighborhood appeared to be the cornerstone of residential dissatisfaction by most public housing residents and not just within their housing project. Vale's main argument was that a focus on too small of geographies limited the understanding, measurement, and interventions of crime in public housing. Both Vale and Lines stated that if analyses were limited to such small geographies, the likelihood of revitalizing public housing would not be fruitful because the problem must be solved inclusive of the surrounding neighborhoods.

In 1998, the Bureau of Justice Statistics (BJS) produced a report that provided more evidence that neighborhood crime was one of the most important aspects to residents with respect to neighborhood satisfaction. Using six waves of American Housing Survey (AHS) data between 1985 and 1995, BJS statisticians examined resident perceptions of neighborhood crime (DeFrances and Smith 1998). Across all six waves, 25 % of black and 13 % of white public housing respondents cited crime as a problem in the neighborhood where they lived. For overall households, 5 % white and 14 % black reported crime to be a problem. Of the public housing respondents, 18 % (24 % black and 13 % white) perceived crime so "objectionable" that it caused them to consider moving. The authors also used the 1998 National Crime Victimization Survey (NCVS) and found that even though crime victimization was the same in public housing as it was outside of public housing (23.8 % vs. 23.4 % respectively), the percentage of residents who expressed the desire to relocate was substantially higher for those in public housing communities. The analysis also revealed that, comparable to crime, black residents had equal concerns about other neighborhood problems, such as disliking neighbors, too many people, and loitering. Central city white households 15 % reported these "people" problems as a neighborhood problem whereas 13 % reported crime as the most pressing problem. While not being able to determine if these reasons were related to concerns of safety, other researches have noted these minor incivilities contribute to perceptions of safety in the neighborhood.

In 1999, Dugan used four waves of the National Crime Victim Survey (NCVS) between 1986 and 1990 to examine if victimization prompted neighborhood residents to relocate. Dugan found a 12 % increase in the probability a resident will move after the first victimization is experienced or known. Equally important was the finding that knowledge of criminal offenses outside the neighborhood had no effect on prompting residents to move, indicating the immediate neighborhood affected perceptions of safety that would prompt a consideration to move.

In examining relocation preferences from the Chicago Area Survey Project, Harris (2001) measured black and white preferences in neighborhood relocation and found crime and disorder to be of most concern to neighborhood choices. Specifically, the results showed that residents' perceptions of "big" crime problems lead to a significant decrease (.40 and .65 standard deviation unit reduction) in residential satisfaction for both whites and blacks, respectively. School quality and neighborhood deterioration were also found to be significant determinants of resident satisfaction.

Basolo and Strong (2002) surveyed residents of low-income neighborhoods in New Orleans as part of a revitalization initiative evaluation and found crime to be the greatest concern for potential home buyers. The authors examined questions that determine both neighborhood and housing satisfaction along several dimensions. Respondents stated their decision to purchase a house in a neighborhood was based on housing condition but safety was the strongest factor, the absence of crime was the most important factor toward being satisfied with the surrounding neighborhood. The authors found that 40 % of respondents who were renters cited poor housing conditions and crime as the primary reasons they would not buy a house in a neighborhood if they had the opportunity.

Hipp (2009) used the American Housing Survey data between 1987 and 1999 in 24 metropolitan areas to identify the determinants of neighborhood satisfaction. He extended the earlier BJS study by conducting a multilevel analysis for individual and neighborhood effects and found that perceived disorder and other social disorganization factors were related to increases in neighborhood dissatisfaction. Overwhelming, perceived crime was an accelerant to being dissatisfied with a neighborhood. A key aspect of Hipp's study was that he linked the elements of social disorganization with the desirability of neighborhoods.

In 1994 and 1995, several thousand residents in Chicago were surveyed for Project Human Development in Chicago Neighborhood (PHDCN) to examine how families, schools, and neighborhoods affected child and adolescent development (Earls et al. 1995). Numerous survey questions revolved around residential satisfaction, many questions related to crime. One question asked respondents to indicate the reasons they might move. Sixty four percent of respondents listed living in a safer neighborhood as a reason they might move, 62 % cited crime, and 60 % cited drug problems. Wanting to get their children away from bad influences (50.4 %) and lower housing/rental costs (49.9 %) were cited as the next top reasons. All other reasons amounted to less than 35 %. These results indicate crime is a driving factor in residential satisfaction and wanting to relocate.

Surveys of HCVP participants also showed crime was a major determinant of tenant satisfaction. Buron and Patrabansh (2008) examined data from an HCVP customer satisfaction survey and found that respondents rated crime as the most important quality of life factor. Fifty percent of respondents who rated their neighborhood as low quality cited crime as "a big problem," while other neighborhood conditions were of much less concern. Residents who rated their neighborhood of higher quality also cited crimes as their greatest concern. The correlation between crime and neighborhood rating was −0.62, indicating that perceived neighborhood quality declined with increased perceptions of crime problems. The Voucher Homeownership Assessment (VHA) program also showed that proximity to high-crime areas was among the two main negative features reported to the surveyors (Turnham et al. 2003).

Studies have shown that when given the opportunity to relocate, publically assisted families tend to move into neighborhoods with lower poverty and less crime (Austin et al. 2002; Fauth et al. 2004). Two particular housing initiatives examined the effects of low-income families in severely distressed public housing using HUD vouchers to relocate. The first was the *Gautreaux* program, a court ordered initiative to remedy racial discrimination in Chicago's public housing communities. The second was the *Moving to Opportunity* (MTO) experiment in five cities by the US Department of Housing and Urban Development. The intent of Gautreaux and MTO was to give public housing residents the option to move to new neighborhood of their choice for the purpose of improving access to opportunity. Participants in both programs stated that crime was one of the most prominent reasons they wanted to relocate (Popkin et al. 2003; Goering and Feins 2003). With MTO an average of 53 % of participants across all five cities cited getting away from drugs and gangs as the most important reason for wanting to move (Goering and Feins 2003). The second most important reason was to get their children into better schools (30 %). Follow-up research on Gautreaux and MTO consistently showed that participants saw improvements in the conditions of their neighborhoods with regard to health, economy, and safety

(Varady and Preiser 1998; Katz et al. 2001; Orr et al. 2003; Fauth et al. 2004; Kling et al. 2004; Gilderbloom et al. 2005; Keels et al. 2005; and Briggs et al. 2010). These studies indicated that even after relocation, crime was still a primary determinant of residential satisfaction for HCVP tenants. Long-term positive effects on the participants, however, have shown to be less than desired.

Varady et al. (2001) examined survey and neighborhood-level data across four US cities to determine if counseling led to more successful housing searches by HCVP participants. The authors found that perceived neighborhood safety was the strongest driver (coefficient for safety was 0.315) of housing satisfaction compared to 12 other factors. Distance also played a significant role, with participants wanting to remain in close proximity to their previous neighborhood while simultaneously wanting to move to a new place offering a greater sense of safety. Their findings were consistent with previous studies that found that HCVP participants tended to feel safer after using a voucher to relocate.

Conclusion

Questions about the impacts of the HCVP on neighborhoods are an emerging policy issue. Sadly, little attention is paid to the crime aspect of housing vouchers and voucher mobility even though the evidence presented in this entry shows it is a major factor in the decision to move. The findings across these studies clearly show that for low-income families, regardless of receipt of rental assistance, crime is a central determinant of participant residential satisfaction.

Fear of crime is often a driving force behind residential dissatisfaction and the need for safety (Gibbs and Hanrahan 1993) that manifests itself in behavior modification. Studies from criminology have shown that the anxiety generated from anticipated victimization prompts neighborhood residents to take protective actions, such as altering daily routines to minimize chances of being victimized, fortifying their homes (Baumer 1980), limiting children's activities (Kling et al. 2004), avoidance of walking outside (Roman and Chalfin 2008), and moving to a safer place (Skogan 1990; Rountree and Land 1996; Xie and McDowall 2008; Hipp et al. 2009). These behavior modifications clearly connect to the neighborhood and not just the location of their dwelling or street.

The combination of immediate location and the surrounding area is what constitutes place utility, upon which people make decisions to stay or move based on residential satisfaction (Wolpert 1965). Thus, using "place" offers an advantage over the separate use of "location" or "neighborhood" toward understanding of crime and place. The objectives of the HCVP emphasize the place utility concept and exemplify how the program is codependent on both people and place, with residential satisfaction as the link. Success for the HCVP participant is having a better place to live and work and for their children to grow, less fearful of crime. Success for the neighborhood is having residents that contribute to its well-being so that it is a desirable geography for people to live, work, attend school, socialize, and visit. Without place satisfaction, a resident may not contribute to the neighborhood and the neighborhood may not contribute to the resident's well-being.

The housing literature clearly shows a nexus with the study of crime and place. The thoughts and language used by residents in housing studies reveal that residents see their homes situated within a larger environment that contributes to their sense of satisfaction and safety. The housing literature identifies and discusses many of the same factors and conditions of social disorganization (residential turnover, unemployment, single-headed households, uneducated populace, low quality businesses, poverty, and poor quality housing stock) in project- and tenant-based programs that are used in the study of crime and place in criminology. There is a constant reference to "in and around" in the housing literature and indicates that residents and scholars understand there is an inseparable link between a home and its neighborhood. Housing scholars also use variables that go beyond the demographic structure that environmental criminologists have discussed and used, such as building conditions and values, land use, family structure changes, or business types. These housing scholars, though, do not often include social disorganization factors relevant to the understanding of crime in place. Some criminologists have been using some of these variables to inform the understanding of crime and place (see the Geographic Criminology entry of this encyclopedia). Both criminology and housing scholars could benefit from drawing upon evidence from both disciplines – and in particular, the theories and evidence from geography – regarding the effect of place on safety perceptions and the effect of safety perceptions on choice of place.

Mayor Robert Sabonjian of Waukegan, IL (a town north of Chicago), summed up the common sentiment about Section 8 housing in a local newspaper that highlights the unconscious understanding in policy-making that place is a key aspect to the success of the HCVP. Mayor Sabonjian stated that the problems associated with public housing "are not going to go away by getting rid of one problem building – it's going to have to be a systemic answer across the city" (Moran 2012). This statement demonstrates the recognition that a wide range of geographies are crucial to any solution to assisted housing. Briggs et al. (2010) stated that the success of relocation programs "hinge" on holders having proximal access to jobs and resources, i.e., the geography of opportunity model (Galster and Killen 1995). Research findings have made it quite clear that residential satisfaction includes the neighborhood, although there remains a debate about what constitutes the geography of a neighborhood (Wilson 2012). The studies presented in this entry present evidence of the larger role of neighborhoods in residential place satisfaction. Residents of high-poverty neighborhoods and public housing communities are often stuck in places exhibiting classic indicators of social disorganization in which crime is an everyday part of life. The HCVP plays a crucial role in promoting access to places with greater chances for residential satisfaction and socioeconomic opportunity, which are inextricably linked to the absence of crime.

Acknowledgments We would like to thank John Markovic from the Community Oriented Policing Services Office (COPS) of the US Department of Justice, Paul Joice of the US Department of Housing & Urban Development, Mark Stallo of the Dallas Police Department, and Emma Wilson of Montgomery College for providing valuable comments toward improving the clarity of this entry. We would also like to thank Sue-Ming Yang for giving us the opportunity to include this work.

Human Rights Violations in Criminal Court

Joachim J. Savelsberg

Synonyms

Crimes against Humanity; Genocide; International Criminal Court; International Tribunals; War Crimes

Overview

Grave violations of human rights have become increasingly criminalized in recent decades. Chances that perpetrators will be charged in criminal courts, including international criminal courts, have grown. These developments culminated in the creation of the first permanent international criminal court, the International Criminal Court in 2002. This entry first provides a summary of the history of criminal justice intervention against perpetrators of human rights crimes. A brief discussion follows concerning the societal conditions that advanced this trend. A further section examines challenges of criminal justice intervention against human rights violators and issues of debate: the building of functioning international criminal courts, their institutional incentives and constraints, the scope of their jurisdiction, the question of individual versus collective liability, tension between political reason versus legal procedure, and finally actual chances to effectively reduce grave human rights violations. Selective examples from a growing and at times impressive new body of literature are cited.

Historic Roots and Fundamentals

Human rights, those civil, political, social and economic rights that are granted humans independently of their citizenship, are codified in the Universal Declaration of Human Rights (UDHR). The United Nations General Assembly passed this declaration on December 10th, 1948, in response to the atrocities committed by Nazi Germany. Human rights are associated with the right and obligation of the international community to intervene against offenses by national governments. They thus weaken the principle of national sovereignty, established by the Peace Treaty of Westphalia that ended the Thirty Years War in 1648. While most violations of human rights do not constitute crimes and while the principle of national sovereignty is still prominent, considerable change has occurred. It has been argued that many previous centuries can compete with the 20th with regard to the level of human rights abuses, but that the twentieth century is distinct as serious attempts have been undertaken to intervene in atrocities, to slow or prevent them (Minow 1998). Some even diagnose a "justice cascade" (Sikkink 2011).

The process began during the late nineteenth century when humanitarian law, or the law of wars, was first codified in a series of international conventions, known as the Geneva and Hague Conventions. The conventions were drafted by multinational conferences that initially sought to establish rules regarding the treatment of wounded soldiers and of prisoners of war. In 1949, rules were added against the deportation of individuals or groups, the taking of hostages, torture, collective punishment, "outrages upon personal dignity," the imposition of judicial sentences without due process, and discriminatory treatment. The Geneva Convention has garnered broad support across the world's nations as is indicated by the large number of 180 signatories.

While these conventions set binding international standards for situations of international conflict, they continue to respect national sovereignty. Yet, two subsequent Protocols of 1977 marked a weakening of sovereignty. Protocol I extended the protections of the Hague/Geneva Conventions to persons involved in wars of "self-determination," typically liberation wars which former colonies fought against colonial powers. Thus, violations of humanitarian principles could no longer be considered internal affairs of colonizers. Going one step further, Protocol II extended humanitarian protections to persons involved in severe civil conflicts, prohibiting collective punishment, torture, hostage taking, acts of terrorism, slavery, humiliating and degrading treatment, rape, and enforced prostitution. These Protocols have also found broad support, albeit weaker due to their more interventionist nature, with 150 and 145 signatories respectively.

Humanitarian law provided a foundation for judicial intervention. The International Military Tribunal in Nuremberg (IMT) against leading Nazis drew legitimacy from the conventions, as did the Tokyo trials against Japanese war criminals. Yet, the history of Nazism had shown that even the treatment of domestic populations should not remain unchecked by the international community. Unbearable in itself, mistreatment at home may prepare yet more horrendous offenses against foreign peoples. In Nazi Germany, for example, the gassing of mentally retarded German children and adults served as a training ground for the SS's work on the "final solution" against Europe's Jews and other groups

(Schmidt in Heberer and Matthäus 2008). The idea was thus born to extend rights that many countries guaranteed their own citizens (civil rights) to all humans (human rights), independently of their citizenship, and to certify these rights in a covenant, the UDHR, and a series of international treaties. Sovereign states would now be bound by a new and growing system of international law that was not limited to times of armed conflict.

In reaction to the Nazi crimes, The Convention on the Prevention and Punishment of the Crime of Genocide came into force on January 12th, 1951. Article 2 of the Convention defines genocide as: "…any of the following acts, committed with the intent to destroy, in whole or in part, a national, ethnical, racial or religious group, such as: Killing members of the group; causing serious bodily or mental harm to members of the group; deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; imposing measures intended to prevent births within the group; forcibly transferring children of the group to another group." Genocide, "whether committed in time of peace or in time of war, is a crime under international law which… [the contracting parties] undertake to prevent and to punish" (Article 1). Threatened with punishment are "constitutionally responsible rulers, public officials or private individuals" (Article 4).

Other conventions sought to protect the human rights of women (1979), children (1990) and indigenous peoples (1991), but only the Convention against Torture and Other Cruel, Inhumane and Degrading Treatment or Punishment (1987) applies standards of criminal liability, like the genocide convention and humanitarian law before it and the Rome Statute of 1998 that established the ICC.

Despite such progress, a recent review of the history of international human rights law and its enforcement cautions us. Enforcement of the growing number of international treatises tended to be weak at least through the 1980s (Sikkink 2011). Treaty bodies created by the UN General Assembly, such as the Human Rights Council, focus on states' legal accountability. They monitor violations and work toward solutions with accused governments, but with few enforcement powers. New regional courts, such as the European Court of Human Rights, the African Court of Human Rights, and the Inter-American Court of Human Rights also apply a state accountability model. Treaty Bodies and courts ask states to provide remedies when violations are recorded, including changes in policies and/or reparation payments to individuals victimized by past policies.

This situation partially changed during the 1990s. A new model of criminal liability began to supplement state accountability, even if preceded by the London Agreement through which the victorious powers of World War II had created the IMT. The IMT had marked the serious beginning of the construction of international criminal courts as central institutions in the fight against grave humanitarian law and human rights violations. The occupying powers had arrested and the IMT had charged the defendants with crimes against the peace (conducting illegal, aggressive war), war crimes and crimes against humanity. Yet, as the trial focused on offenses committed during the war it shied away from challenging the notion of national sovereignty. Pre-war offenses of the totalitarian Nazi regime against German citizens were not covered. Eventually, 12 defendants were sentenced to death and executed, 7 received prison terms, and 3 were acquitted (on related trials, including the famous "doctors'" and "lawyers' trials" see Heberer and Matthäus 2008).

After a long hiatus caused by the Cold War between the two super powers, only the breakdown of the Soviet Union allowed for new initiatives. Different from Nuremberg or Tokyo, these new courts did not grow out of military victory. Instead, the UN Security Council established both the ICTY in 1993 and the ICTR in 1994; and an international agreement, the Rome Statute of 1998 created the ICC, the first permanent international criminal court. The Rome Statute entered into force in 2002 when 60 countries had ratified. As of 2008 there were only 108 ratifications, with several powerful members of the international community opposed, including the US. The creation of new legal institutions corresponds with a quadrupling of trial activity, at the domestic and international levels, in only two decades from the early 1980s to the early part of the twenty-first century (Sikkink 2011). In addition to international courts, a diversity of other types are involved.

Hybrid courts, emerging from agreements between the UN and national governments, are staffed with groups of domestic and international judges applying domestic and international law. Recent examples include courts in Sierra Leone, East Timor, Kosovo, and Cambodia, the latter a much delayed response to the genocidal mass killings of the 1970s under the Khmer Rouge regime. Such trials, typically conducted in the countries where the crimes were perpetrated, allow for easier access to victims and witnesses than international courts, while international participation may reduce the risk of partisan abuses of trials as revenge mechanisms by post-transition regimes – or, in the alternative, obstruction by past perpetrators who managed to hold on to political power under the new regime. *Foreign courts* became famous through the Jerusalem trial against Adolf Eichmann in 1961. More recently, under the new doctrine of universal jurisdiction, a Spanish judge charged Chilean General Augusto Pinochet and (unsuccessfully) requested his extradition from the UK

Cases tried in foreign courts remain rare though, while *domestic courts* are a prominent part of international justice when they apply international humanitarian and human rights law, often in combination with domestic law. Importantly, domestic courts now operate under the shadow of the ICC. Its mere existence is likely to encourage domestic enforcement, as most countries prefer cases to be handled at the domestic level (Sikkink 2011; Roht-Arriaza 2005). Crucial here is the doctrine of complementarity that governs the ICC. The court can only take up cases if domestic courts are unable or unwilling to do so. Domestic courts, however, tend to try top leaders only after regime changes (e.g., Argentina, Chile, Iraq), while low-level defendants are targeted in cases of regime continuity. Examples are the cases of My Lai and the abuse and torture committed in the Abu Ghraib or Guantánamo Bay prisons. In addition, penalties in these cases tend to be either mild or greatly reduced after initial sentencing.

In short, the growing openness toward international intervention into domestic affairs comprises three processes:

- A universalization or globalization of human rights law, its institutionalization in international doctrines and organizations, including courts of law and its application by many nations in domestic courts
- An individualization of human rights law, allowing for grievances to be directed not just against governments or entire countries, but also against individuals acting on behalf of these countries (and filed by individuals) and
- A partial criminalization of human rights law, supplementing compensatory mechanisms with penal responses

Societal and Global Conditions of Change

Recent research explores structural and cultural conditions for these trends (Savelsberg 2010). On the cultural side scholars such as Emile Durkheim and Erving Goffman, in their classic works, alert us to the status of an individual's dignity in modern society. While it sets limits to the intensity and types of punishment, it simultaneously encourages the punishment of killers, including dictators who radically disregard the "sacred" status of individuals in modern society. Such reactions are intensified by the growing sensitivity to physical violence that accompanied the pacification of domestic life to which Norbert Elias's classical arguments about the civilizing process alert us.

In light of such cultural trends, the outrages of the Holocaust further advanced global consensus regarding the dignity of individuals. Through symbolic extension of the Shoah and psychological identification with the victims, members of a world audience became traumatized by an experience that they themselves had not shared

(Alexander in Alexander et al. 2004). In these terms, the punishment of leading Nazi perpetrators by the IMT and by subsequent trials was performative. It provided, consistent with a semiotic model of social life, images, symbols, totems, myths, stories, and it thus contributed to the formation of a collective memory of evil to which we shall return below.

Once it was established as universal evil, the Holocaust served "analogical bridging" to reinterpret later events in light of this earlier trauma (Alexander in Alexander et al. 2004: 245–249). Examples are the treatment of minorities in the United States or the victimization of millions in the Balkan wars during the 1990s. In the latter case, analogical bridging occurred famously through the image of an emaciated Bosnian concentration camp inmate behind barbed wire, published on the front pages of most international newspapers and magazines. Thus building a bridge from the Holocaust to the cruelties committed in Bosnia advanced diplomatic and military intervention and the establishment of the ICTY, with great potential at contributing to new international criminal law (Hagan 2003).

Structural changes also contribute to the growth of international criminal justice against human rights perpetrators. Especially shifts in the balance of power at the international and national levels opened the way to the prosecution of national leaders. Globalization with its internationalization of economic ties and modern technologies of communication and transportation created a new dependency of nation states, and their leaders, on the international community. This shift is supported by the establishment of international governmental organizations (IO) such as the UN and its many sub-organizations and by the multiplication of International Non-Governmental Organizations (INGOs), representing a form of civil society at the global level. Five times as many organizations worked on human rights in the 1990s, than in the 1950s. Specifically, Transnational Advocacy Networks (TANs) prove effective, especially when they raise issues involving bodily harm to vulnerable populations; when responsibility can be attached to specific actors; when networks are dense, involving many actors and providing reliable information flow; and finally when target actors show material or normative vulnerabilities (Keck and Sikkink 1998).

While structural changes in the balance of power have opened up opportunities for international criminal justice intervention, continuing imbalances of power still leave their mark. Powerful countries such as China, Russia and the United States, and their rulers, have been spared criminal justice intervention when they offended against human rights law. Further, for the most part, only *formerly* powerful leaders have been indicted, and their numbers are few (e.g., Charles Taylor and Saddam Hussein; but see Slobodan Milošević and Omar al-Bashir). Mostly, when current officials are prosecuted, typically in situations of regime stability, they tend to be low ranking officers, internationally and nationally.

Challenges and Debates

Criminal justice responses to grave human rights violations face several challenges and controversies, some of which are specific to international interventions while others apply at all levels. A short section is devoted to each of these themes.

Functioning of Courts, Forms of Capital, and Competition: The Case of the ICTY

Formal Security Council decisions or international treaties are only first and necessary steps toward creating international courts. Their actual functioning depends on multiple social actors and forces. Sociologist-criminologist John Hagan (2003) identifies, for the ICTY, a multitude of innovative actors in the judicial field, all with different strengths (or forms of capital) and exposure to various national legal traditions. These actors compete against and cooperate with others inside the court and in the world of diplomacy and international politics to make the court succeed. Two brief examples must suffice.

After the UN Security Council had established the ICTY, it appointed Richard Goldstone as chief prosecutor, a South African judge with impeccable human rights credentials but little criminal law experience. Goldstone first used his international contacts and continued media presence, to secure a $30 Million budget for the court. Later he gained, through his diplomatic contacts, access to CIA aerial images of mass graves around Srebrenica, allowing ICTY investigators to advance their massive exhumation project. Still, after 2 years and 70 indictments, only 6 suspects were in custody, and the court resorted to legally problematic hearings against defendants who were not in the custody of the court ("in absentia hearings"). Change came only after a new prosecutor with different forms of capital took over from Goldstone. Canadian jurist Louise Arbour's substantial expertise in criminal law then became crucial in transforming the "virtual tribunal" with its questionable "in absentia" hearings into a "real time tribunal" (Hagan 2003: 93–131). Arbour linked traditional tools of criminal law with the UN mandate by introducing sealed (secret) indictments and surprise arrests through NATO military forces. These strategies resulted in a substantial increase in the number of defendants in custody. In short, Security Council resolutions alone do not determine the success of a newly founded international criminal court. Innovative strategies, involving cooperating and competing legal actors, but also actors from the worlds of diplomacy and military, from national governments, IGOs and NGOs, unfold in the face of uncertain outcomes before a new type of international criminal legal practice can be established.

Incentives to Intervene: The Case of the ICC

The organization of a court and the institutional rules under which it operates determine the incentives to aggressively engage in the prosecution of grave human rights violations. The ICC, for example, determined by the Rome Statute, consists of several courts or "Chambers" with a total of 18 judges, each with non-renewable 9-year terms (see Schabas 2007). Trial and appeals chambers write opinions and thus specify future international criminal law. The prosecutor is also selected for one non-renewable 9-year term through an anonymous vote of the member states. Cases can be referred to the ICC prosecutor by individual citizens of member states, by states against one of their citizens, and by the UN Security Council. The latter, for example, referred the Darfur case to the ICC. In contrast, state parties referred cases against Uganda, the Central African Republic and the Democratic Republic of Congo to the ICC.

In light of these and additional conditions, the court will not be as activist and punitive as American criminal courts have been in recent decades. First, due to the principle of complementarity the ICC can only get involved with Security Council referral or if domestic courts are unable or unwilling to prosecute. Second, given the still relatively weak institutionalization of civil society at the world level, public moral outrage is less likely to promote prosecution than at the national level. Third, prosecutors and judges, holding tenured and non-renewable positions, are less likely to be responsive to moral outrage. Yet, public mobilization may advance Security Council actions as it did in the case of Darfur. Fourth, given the strong role of nation states among the court's constituents, the ICC's legal and procedural principles will often compete with diplomatic or military actors and outcome-oriented reasoning. Finally, massive power-asymmetries between states are likely to constrain the court's agenda. The United States, for example, has entered "Bilateral Immunity Agreements" with some 100 governments that agree not to extradite American citizens to the ICC, often in exchange for international aid.

Scope of Jurisdiction: More on the ICC

The ICC's jurisdiction includes only four crimes: genocide, crimes against humanity, aggression, and war crimes, committed after April 2002 in states that have ratified the Rome Statute. Some actors would like to substantially expand jurisdiction of the ICC or other criminal courts to include violations of all rights guaranteed by the UDHR. Scholar-activists have suggested, for example, that child poverty in a wealthy country could be conceived of as an offense against the Convention for the Rights of the Child. This should, in the eyes of some, result in sanctions against responsible states and in the expansion of individual criminal liability to those whose policies had advanced these violations of international human rights standards.

Such far-reaching demands are being challenged by others, even those who in principle support expanded international criminal law (Hagan and Levi 2007). They argue that that tort law may in many cases be at least as effective as criminal law, with lower burdens of proof; charging countries and their leaders in criminal court may isolate these countries from the international community, polarizing conflict, and resulting in a loss of international influence; and that criminal law is ill-suited to address larger structural and cultural forces that contribute to broader human rights violations. Finally, human rights problems such as large-scale homelessness among children may result from national policies enacted by legitimate governments and backed by majorities of the electorate. Who then is to be charged?

Individual Versus Collective Liability

Grave human rights violations, while always involving individual agency, are typically embedded in complex organizational settings, government agencies, police and military units, and actors at different levels of hierarchy. These complexities pose challenges to prosecution. In response, criminal law has developed the concept of conspiracy, rooted in American jurisprudence. The crime of conspiracy is defined as an agreement between two or more individuals, entered into for the purpose of committing an unlawful act. It is justified as a separate crime as it is conceived of as a threat to the public in itself. Conspiracy also encourages and eases additional criminal behavior. Law seeks to deter (by increasing the cost of membership) and to destabilize (by undermining trust among co-conspirators) (see Meierhenrich 2006). “Conspiracy” makes its way into international criminal law under different names.

Article 9 of the London Charter, for example, makes membership in a “criminal organization” punishable. The American chief prosecutor, Justice Robert Jackson, argued that criminal organizations will serve as carriers of criminal plans from one generation to the next if not delegitimized by criminal law. Later, at the ICTY, crimes that must be expected in the context of a “joint criminal enterprise” constitute individual criminal liability even if charged individuals are not themselves engaged in the execution of the crime. For instance, involvement in the planning of ethnic cleansing campaigns to be conducted by armed groups should result in charges of homicide and war crimes as such campaigns must be expected to result in the killing of civilians.

And yet, “conspiracy,” “criminal organizations,” and “joint criminal enterprise,” innovative attempts at resolving the legal dilemma of individual guilt in the context of collective action, face grave challenges. They raise the specter of guilt by association, thereby endangering the *nullum crimen sine lege* principle, and they thus create doubts regarding the rigor and impartiality of international criminal law.

An alternative option of collective punishment, following the US Sentencing Guidelines’ model of Corporate Probation, would face challenges as well. Court orders are hard to enforce if a hostile regime refuses to obey, a problem long faced by UN Treaty Bodies. Further, in cases of grave atrocities, a negotiated settlement with the perpetrating collectivities such as the Iraqi Republican Guards or the Nazi SS, is often inconceivable and may undermine the legitimacy of the court. Dissolution of corporate entities and punishment of their individual members are typically called for. Collective punishment also disregards considerable shades of culpability. It may open collectivities up to the lure of oppositional cultures, if it is directed against large populations or entire countries. Post-WWI German history taught lessons, and paths chosen after the victory over Nazi Germany took these lessons seriously.

Formal Procedure Versus Political Reasoning

Given the high stakes of trials against serious violations of human rights, practical consequences of a court’s rulings are considerable. Justice Jackson had argued that failure to legally denounce the organizations involved in the Nazi crimes would open the doors to a recurrence of massive genocide in the next generation, and that humankind would not survive a repeat of such horrors. And yet, some legal philosophers argue that formal principles, a "just desert" orientation and a focus on rights of the accused must trump policy in international criminal justice. Even the IMT has come under liberal attack for its breach of formal rules, despite general agreement regarding its relative success in producing justice. Landsman (2005), for example, critiques the IMT's breach of liberal legal principles, such as the admission of hearsay evidence. Such philosophical arguments are backed by the conviction that only strictly due process-oriented international criminal justice can earn legitimacy and that only a legitimate system can prevail in the long term.

Effectiveness of Criminal Court Intervention Against Human Rights Perpetrators

The effectiveness of criminal justice intervention in preventing grave human rights violations is hotly debated. Critics challenge, for example, the rise of universal jurisdiction, the power of domestic courts to try foreign citizens, summarized in the Princeton Principles of Universal Jurisdiction and justified by the recognition that human rights violations are offenses to all humanity. Domestic courts, they argue, may have little sense of the harm their prosecutions may cause in the affected foreign country. Amnesties, truth commissions and other transitional justice programs, and thus successful transitions to peace and democracy may be at risk.

The ICC and other international courts are further targets of critique. They are said to suppress the consideration of power, necessary to assess the consequences of intervention and to balance legal accountability with political costs. Critics argue that filing charges against Serb president Milošević by the prosecutors of the ICTY, for example, made it harder for NATO to reach a deal with Serbia at the time, thereby extending war and suffering in the Balkans in the summer of 1999. In 2011, critics challenged the ICC for its decision to charge Sudanese President al-Bashir with genocide, at a time where his role in stabilizing relations with the newly independent South Sudan may be crucial. In general, the concern is that perpetrators will not be willing to negotiate and cease power if they are threatened by criminal trials (see Snyder and Vinjamuri 2003/2004).

Challengers of these skeptics include political scientist Kathryn Sikkink (2011), who offers an impressive new data set with information on domestic truth commissions and domestic, foreign and international trials for a 26-year period (1979–2004), covering 192 countries and territories. Sikkink finds that transitional justice does not typically lead to the strengthening of old forces; the severity of offences and the likelihood of trials are highly correlated (decisions for trials are thus not made lightly); and, importantly, countries with more human rights trials show greater improvements of later human rights records. Such positive outcome was further improved where trials were coupled with truth commissions. More importantly, and contrary to skeptics' point of view, not a single case in Latin America shows that holding a trial contributed to violent conflict and dislodged the transition.

If the correlation between the use of transitional justice and improved human rights records shown by Sikkink is not just due to third factors (e.g., a past rule of law regime in the affected country), but if it does indeed constitute a causal relationship, the question remains how this relationship can be explained. Theoretical efforts toward understanding the link between trials and outcomes require us to open up the "black box" between intervention and human rights. Two processes may be at work. One is a deterrence mechanism, consistent with rational choice ideas; the other is a cultural mechanism, a thorough de-legitimization of gross human rights abuses, possibly to the point where they no longer appear as options in the decision trees of rational actors.

Rational choice ideas and deterrence research have a long tradition in criminology. One common conclusion of many studies is that the certainty of punishment is most likely to have a deterrent effect, more than its severity. White-collar crime literature suggests that deterrence is most likely to work for the powerful, as they are expected to act rationally. Sikkink's (2011) explanation of the positive correlation between transitional justice mechanisms and human rights records is consistent with this mode of thought: the next generation of military officers will remember the shaming their predecessors experienced as a result of criminal sanctions or truth commission reports and be reluctant to breach human rights. But what are the conditions under which past perpetration and subsequent sanctions are being remembered? Sophisticated rational choice arguments take learning about the past seriously, as such learning will affect what costs and benefits decision makers take into consideration.

Here a new line of academic work comes to play that examines the effects of trials and other mechanisms on collective memory (Osiel 1997; Savelsberg and King 2011). This work builds on classic sociological ideas and on arguments made by politicians and jurists such as President Franklin Roosevelt and Justice Robert Jackson. Judge Samuel Rosenman, Roosevelt's confidant reports about the president: "He was determined that the question of Hitler's guilt – and the guilt of his gangsters – must not be left open to future debate. The whole nauseating matter should be spread out on a permanent record under oath by witnesses and with all the written documents" (after Landsman 2005: 6). From a Durkheimian perspective, Osiel perceives the court room drama in cases about mass atrocities as a "'theatre of ideas,' where large questions of collective memory and even national identity are engaged" (Osiel 1997: 3).

A new idea is thus added to the traditional rationales for criminal trials and sanctions such as retribution, deterrence or incapacitation: a history writing function, the construction of a collective memory of past evil that, some argue, will reduce the likelihood of future offending. Collective memory is here understood as knowledge about the past that is shared, mutually acknowledged and reinforced by a collectivity. Its shape determines how a formerly charismatic leader, after the "degradation ceremony" of a criminal trial, will be remembered.

The hope invested in criminal trials' contribution to history writing and to the formation of collective memory, however, must be cautioned. Trials follow a particular logic. Evidentiary rules differ, for example, from those used by historians. Further, trials target individuals, not the social processes and cultural patterns sociologists might focus on when constructing the past. Actions trials address are further limited by legal classification systems; producers of inflammatory rhetoric may have played central roles, but they will typically not be criminally liable. Finally, following the binary logic of criminal law, the defendant is guilty or not guilty, a gross simplification by psychological standards.

A budding literature has thus begun to critically explore the consequences of trials for collective memory. Giesen (in Alexander et al. 2004), for example, argues that German criminal trials against former Nazis served a "decoupling" function. In light of such trials, the German people could take the position of the third party, while individual guilt was assigned to a few in the court of law. As individual perpetrators were ritually expelled, the majority of Germans were offered a chance to avoid acceptance of collective guilt. Osiel (1997) applies this insight to French history. President Charles De Gaulle urged that post-World War II trials were directed against a few elite actors of the Vichy regime that had collaborated with the Nazis. Here too decoupling succeeded. By attaching guilt to some individuals through legal rituals, memory could be cleansed of the collaboration of many, and attention could be redirected from questions about their past to the reconstruction of France following war and occupation.

The French case indicates further that trials after grave human rights violations, especially after regime change and military defeat, can only be understood in their political context. Just like the legal process was affected by political will in the French case, so were the Allied trials against German perpetrators (Landsman 2005: 111ff for the IMT). The Allies decided to focus on just a few major Nazi perpetrators, as prosecuting all who had become guilty might have destabilized the country and its budding democracy. This focus on few perpetrators, however, helped shape a view of history that saw the majority of Germans as victims of a small elite, thus repressing the memory of support and collaboration many had provided (Marrus in Heberer and Matthäus 2008).

Cases against high-level perpetrators have in common that trials follow conquest and/or regime change. Trials may construct very different collective memories though when past evil is processed in the context of regime continuity (Savelsberg and King 2011). The United States trial against perpetrators of My Lai, for example, where criminal guilt was attributed only to one low-ranked military, has contributed to the exculpation, not just of broader segments of the population, but also of political and military leadership in public memory. Research shows, for example, that most American history textbooks do not mention the My Lai case. Those that do, tend to present the massacre in line with the outcome of the trial, focusing on the one convict, Lt. Calley, but silencing the role played by higher ranks and their attempted cover up of the massacre. Such processing of past atrocities may have advanced uncritical attitudes toward the institution of the military and contributed to a willingness by American military in current conflicts to offend against norms of humanitarian law. The judicial handling of recent torture and illegal imprisonment cases is likely to further advance such attitudes.

Despite such misgivings, criminal justice mechanisms may still affect collective memory in ways that decreases the likelihood of future evil. First, the de-legitimization of past perpetrators may be crucial in transitions. Second, the selectivity of legal logic must not be overrated. After all, legal trials initiate the collection of evidence. While not all may be admitted in the court of law, such evidence nevertheless may be available to future historians, or it may be directly communicated to the public through mass media. Hagan (2003) documents the diversity of extra-legal expertise of forensic scientists, victim workers, journalists and social scientists, mobilized by the ICTY to uncover forensic and interview-based empirical evidence of the atrocities committed during the Balkan wars. News of recently opened mass graves and liberated concentration camps reached a broad public through journalistic reports, independent of the success of translating these materials into evidence in the court's proceedings. Investigatory evidence may also be used in future historical documentations, independently of its legal status at the trial (Bass 2000).

In short, through deterrence and collective memory functions, criminal trials may help transitions and prevent repetitions of past evil. Optimism, however, must be tempered by insights into the selectivity and inaccuracy of trial-based memories, by the focus on "small fish" in the absence of regime transitions and by transition problems that trials may cause in some contexts.

Alternatives, Supplements and Precursors to Criminal Justice Intervention

In light of the shortcomings of criminal courts, a balance of principles may be more realistically achieved through a mix of institutions, including UN Treaty bodies, creative new models, truth commission, reparation programs, vetting proceedings, apologies, commemorations and memorials, or amnesties. A few comments on four of these must suffice.

First, while the movement toward criminal justice and other mechanisms has partly been powered by a profound sense of frustration regarding the weak enforcement of human rights through UN Treaty Bodies such as the UN Human Rights Council and traditional international courts, the latter institutions still constitute one crucial component in the mix of mechanisms through which the international community responds to human rights violations.

Second, international courts, beyond criminal courts, include the International Court of Justice (ICJ), also called the "world court," and regional courts. The ICJ addresses disputes between states, and it provides the UN with advisory opinions. Regional courts such as the European Court of Human Rights (ECHR) and the Inter-American Court of Human Rights have somewhat stronger enforcement mechanisms.

Their judgments may demand reparation and force policy changes in member countries. Judgments also become binding law to nation-level courts.

Third, innovative experimentation with traditional justice mechanisms holds some promise. Reponses to the Rwanda genocide included a new institution, called *inkiko gacaca* (*gacaca*). The *gacaca*, while inspired by traditional justice forms, is a modern system of some 10,000 community-based judicial bodies, oriented toward retributive and restorative justice, and administered by the Rwandan state. By establishing the *gacaca*, the state responded to a desperate situation in which up to 120,000 detainees waited for their trials in overcrowded cells in this extremely poor country of just six million people (see Meyerstein 2007).

Finally, truth commissions (TC) have become important supplements, predecessors, or alternatives to criminal courts. They are bodies that focus on the past, investigate long-lasting patterns of abuses, are constituted for limited periods of time and conclude their work with a report. They are officially sanctioned and authorized by the state (Hayner 2001). The name "TC," of course, is often misleading, as the truth is frequently well known, while its acknowledgement is at stake. The Argentinean TC, for example, the National Commission on the Disappeared was created in 1983 per decree by President Raúl Alfonsin after 7 years of military dictatorship, during which tens of thousands endured arrest and torture and "were disappeared." Eventually, the commission turned its files over to the prosecutor's office and thus provided critical evidence for the cases against senior members of the military Junta. Importantly, TCs may contribute to accountability in ways not available to criminal courts. Instead of attributing responsibility to particular individuals alone, they examine broader patterns of abuse, thereby encouraging institutional reforms. They may thus also challenge broad sectors of society and segments of the population that carry some degree of responsibility, from bureaucrats to torturers and profiteers all the way to by-standers who refused to speak up.

Concluding Comment

Domestic, hybrid, foreign and international courts have increasingly applied international human rights law, especially since the end of the Cold War. International courts or tribunals, once created, require resourceful actors with different types of capital, to successfully fight challengers and to actually get a functioning court off the ground. The specific institutional forms courts take have massive implications for their functioning. Establishing and operating courts involved in human rights issues, even more than other courts, faces diverse fields of tension: between a formal-procedural versus a pragmatic outcome orientation, restricted versus expanded jurisdiction, and individual versus collective accountability. Criminal courts often face considerable challenges as human rights perpetration typically occurs in complex organizational and political contexts. Yet, recent research indicates the potential of positive outcomes. Both a deterrence function and the establishment of collective memories that delegitimize past inhumane practices appear to be at work. Finally, human rights courts are supplemented by other institutions such as lustration or truth commissions, at times thought of as alternatives, but often crucial supplements of criminal justice intervention.

[2]Department of Criminology, Faculty of Law, Erasmus University, Rotterdam, The Netherlands

Overview

The illegal movements of migrants across national borders have become a global issue. Human smuggling is defined as those activities that facilitate illicit crossing of national borders with consent of the individuals smuggled. It is therefore closely connected to international migration as such. The present entry discusses definitions as well as background factors and basic characteristics of the process of smuggling over time. Characteristics of human smugglers and those of smuggled migrants are presented. In addition, the ways in which states respond to the challenges of detecting and dealing with human smuggling are dealt with. The entry closes with a brief discussion of controversies and future directions including the paradox of combating human smuggling and tensions between migration control and crime policies.

Introduction: Human Smuggling and Its Definition

Human smuggling is currently often presented as one of the most profitable criminal activities worldwide. A formerly relatively minor transborder activity affecting few neighboring countries has become a global activity (Saricca 2005:8). Tragedies like Dover in 2001 and Morecambe Bay in 2004 every now and then throw a spotlight on the largely hidden human smuggling trade. This trade takes place between China and Europe, the Horn of Africa and South Africa, and Asia and Australia, only to name a few routes. Media coverage of incidents is high, and thanks to popular movies, "snakehead" has even become a familiar word in many countries.

Movement of people across borders is far from new, but it is only in the 1990s that human smuggling, human trafficking, organized crime, and illegal migration came to attract attention of policy makers and researchers alike (Salt 2000). In this first phase, scientific and policy debates were severely hampered by lack of clarity in definitions and by conceptual confusion. Over the years consensus over definitions seems to come nearer, but the field remains complex and politicized. Empirical research is almost inherently difficult and many publications are written primarily from the viewpoint of law enforcement.

Definitions

Human smuggling involves, put simply, those activities that facilitate illicit crossing of national borders with consent of the individuals smuggled, and it is therefore closely connected to migrants and international migration (Staring et al. 2005; Van Liempt and Doomernik 2006). The United Nations Protocol against the Smuggling of Migrants by Land, Sea, and Air, which supplements the Palermo Protocol, accounts for consent in its definition of human smuggling, by clarifying that the “Smuggling of migrants shall mean the procurement, in order to obtain, directly or indirectly, a financial or other material benefit, of the illegal entry of a person into a State Party of which the person is not a national or a permanent resident” (2011a:1). The protocol relates smuggling of migrants explicitly to the aim of obtaining financial benefits of the illegal entry of a person into a state (UNODC 2011a), thereby excluding helping a person to cross borders for humanitarian reasons.

Human smuggling and migration are often confused with trafficking in human beings (THB). These concepts have the following in common: they involve the movement of persons and they are all at least commonly associated with illegality, vulnerability, and exploitation. Yet, there are important differences between them. Crossing borders is not a necessary condition in the case of human trafficking (see chapter on THB by Smit and Van der Laan), where by contrast exploitation and lack of consent are crucial. Although the legal concepts are clearly different, there are also similarities and interconnections between human smuggling and human trafficking in practice, and one form can evolve into another (Aronowitz 2001). One could state that whereas human smuggling is perceived primarily in the context of international migration and organized crime, trafficking is, by and large, seen as an issue of (organized) crime as well as of human rights (with victims whose fundamental rights are violated). The idea that smuggled immigrants made a choice out of free will conflicts with notions of victimhood. Therefore, some researchers have made a case for a broader more sociological outlook on the phenomenon (Staring 2001; Van Liempt and Doomernik 2006). Migration scholars also stress that legal and illegal entry modes and flows of people are inextricably related. When facing restrictions, prospective immigrants employ an array of side doors and back doors in order to reach their destination, including the help of human smugglers (Castles and Miller 2009). In many instances, this does not have to involve criminal organizations.

Migrants who have been smuggled often become illegal immigrants once they enter the destination country. Several authors have criticized the use of the terms “illegal migrants” because of its connotations with criminality and called for replacing it by the term irregular migrants (for a discussion, see Koser 2005). Because in the end, all terms used may acquire similar connotations, the term “illegal” is used here despite its disadvantages (cf. Ngai 2003). It has the advantage that it refers to the way in which migrants relate to the construction of what is legal (Samers 2001).

Dimensions of illegal migration are entry, stay, work and, in a country like China, also exit (Van der Leun 2003). Exact regulations differ across jurisdictions. In case of human smuggling, the dimension of entry is crucial. Yet, what states consider as legitimate (legal) might not fully coincide with what individuals consider as such (Abraham and Van Schendel 2005). Transnational movements of people can be labeled illegal because they defy formal norms and authority, while in the participants’ view they can be acceptable, even licit.

Background Factors and Basic Characteristics

Global inequalities and integrated world markets shape push and pull factors for international mobility of people and, as such, also fuel processes of human smuggling. A number of factors can be identified in order to explain contemporary human smuggling, which in turn facilitates illegal migration. The globalization of communication means and transport routes are important ones: countries that have been once secluded are gradually becoming part of a global market and infrastructure. In addition, the availability of information and all forms of ties between individuals and communities brings societies closer together. Networks of immigrants and immigrant communities also play a crucial role in this respect (Massey et al. 1993). Restrictions on immigration, and sometimes on emigration, are meant to channel this mobility, but restrictions to some extent also create illegality and crime. At the same time, unregulated migration can involve social, financial, and political costs for the individuals, society, and governments alike.

Estimates of numbers of people and money involved have been made. At the end of the 1990s, IOM, for instance, estimated that four million people were smuggled across borders annually worldwide (IOM 1997). More recent UN assessments have suggested that total revenues of 10 billion dollars are involved, but these estimates are severely hampered by a lack of reliable data, conflicting perceptions and interests (Kyle and Koslowski 2011). Therefore, figures on human smuggling should be interpreted with care.

While some decades ago these forms of migration law violations and migration crime appeared to be phenomenon of the wealthier countries of the global north and west, they are now globally prevalent. Smuggling patterns have become more complex and in some cases also more dangerous.

Being smuggled is not without risks. Especially those migrants who are being smuggled by sea face high risks. Pugh (2004: 56) found that up to 3,000 people drowned in the Morocco-Spain crossings during the 1990s. More recently, in 2011, around 1,500 people are estimated to have drowned in the Mediterranean Sea only in an attempt to reach Europe (Strik 2012). Moving to the border between Mexico and the United States, it is acknowledged that due to the increased militarized security measures at the border, fewer migrants cross illegally. Rose poses that this militarization of the Mexican-American border leads smugglers and migrants to choose more dangerous and desolated routes through the desert. As a result, the number of migrants dying in these illegal crossings remains stable the last 10 years (Rose 2012). Grassroots organizations such as the Human Rights Coalition estimate the number of victims in the southern border regions of the United States among the smuggled migrants around 200 yearly (http://derechoshumanosaz.net). Apart from those who end up paying with their lives, smuggling can also be accompanied with other risks including violence.

Smuggling routes are highly diverse and constantly changing. At a global scale, Zhang (2007) has discerned four major smuggling routes to high-income regions and countries like Western Europe, Australia, and the United States: (1) from African countries through Spain and Italy to parts of Western Europe; (2) from Central Asia through countries like Kyrgyzstan, Turkmenistan, and Uzbekistan to Russia and then further to Western Europe through the Czech Republic, Slovakia, and Ukraine; (3) from the Middle East and Asia (China) to Australia and New Zealand; and finally (4) from Southern American countries or islands in the Caribbean via the Mexican-American border into the United States. The UNODC (2011a) classifies this perspective on human smuggling toward high-income countries as a rather traditional, western-centric vision, denying the dynamics and complex nature of people smuggling nowadays. Human smuggling networks do not only adapt routes and modus operandi in response to law enforcement, but smugglers have also developed routes toward West African countries, South Africa, and countries in the Middle East that also have economies that attract people from abroad (UNODC 2011a: 34–37).

Human Smugglers

Research has made it evidently clear that many illegal immigrants do not enter European countries through the help of human smuggling organizations but rather enter legally. These immigrants travel regularly and safely with tourist or business visa, guaranteed by the helping hands of relatives and friends living in the countries of destination. Only when they overstay their visa, they become illegal immigrants. Others were smuggled in by family or friends on their way back home from a holiday or visit in their home country. These transnational kinship-based networks can explain the arrival and further incorporation of illegal immigrants even in times of economic recession. This pattern coincides with what is referred to in the literature as chain migration, although in an irregular form (cf. MacDonald and MacDonald 1974). In these cases, financial gains are largely absent and a relative or friend of the illegal immigrant is often the human smuggler (Staring et al. 2005). Other prospective immigrants employ local smugglers or middleman during their travels from country to country without valid travel documents. They cross borders illegally by foot and by local means of transportation, or they pay local smugglers for difficult border crossings only. In the case of, for instance, the irregular trans-Saharan migration to North Africa and Europe, De Haas (2006) describes how local smugglers – often nomads or former immigrants – cooperate with local corrupt officials and intermediaries who have links to European employers. Finally, there are those international human smuggling networks that to a large extent dominate the media coverage and popular image as well as the political debate on combating irregular migration (Staring 2004; cf. Kleemans and van Brienen 2002): highly organized large-scale criminal organizations.

Several authors argue that the characterization of human smuggling in terms of international organized crime does not fit reality in most cases. Pastore et al. (2006) have demonstrated for Italy that the extent of organization is hugely overrated in popular belief. On the basis of a review of court cases, they argued that smuggling organizations in Italy are often little more than loose networks linking largely independent clusters of practical competencies, without a clear chain of command. Moving from Europe to the USA, Zhang (2008), a prominent expert on Chinese smuggling networks, stresses the fact that "snakeheads" should be perceived as opportunistic entrepreneurs who provide specific services in cooperation with other smugglers. They form flexible temporary business alliances rather than function in a stable organized setting. In line with these observations within Europe, Zhang's study based on fieldwork among Chinese snakeheads has smashed the popular image of snakeheads as members of well-organized mafia-like gangs. In the Netherlands, the Research and Documentation Centre of the Ministry of Justice and Safety continuously monitors organized crime by a two-yearly systematic analysis of closed investigations of criminal groups that are active in the Netherlands. In one of these monitors, the authors also concluded that human smuggling organizations show a huge diversity in terms or organizational structures (Kleemans and Van Brienen 2001). Other researchers who analyzed closed Dutch human smuggling investigations in the domain of organized crime stated that the majority of these human smuggling organizations showed more similarities with the image of small-scale informal entrepreneurship where economic motives intermingle with kinship-based loyalties. Large-scale, violent, and professionally organized human smuggling networks seem to be an exception rather than the rule (UNODC 2011a: 81).

Authorities and law enforcement agencies often claim that human smuggling is related to other forms of (organized) crime as document fraud and/or forgery, human trafficking, labor exploitation, money laundering, and terrorism. Among researchers this link between human smugglers and activities of organized crime groups is more controversial (UNODC 2011a). There is much more agreement on the existence of a shadow economy – especially in transit countries – surrounding human smuggling in which divergent facilitators operate. These include, for instance, forgers, burglars looking for identity documents, hairdressers, and beauty specialists for look-alikes; human smugglers sometimes do need local carriers and people safeguarding and taking care for the smuggled migrants in safe houses (Staring et al. 2005). Both informal economic activities and criminal activities take place within these shadow economies.

Smuggled Migrants

Migrants typically travel from relatively poor to richer areas, but the poorest people do not usually have the financial and social capital to move across borders. Those who are on the move are pushed by necessity and/or pulled by the prospect of a brighter future abroad *and* have the means to take action. As described before, many, probably most, illegal immigrants enter their country of destination in a legal manner and without the help of smugglers. Aronowitz (2001: 167) states that those "who fall prey to smugglers and traffickers are usually those most disadvantaged in their own countries: those with poor job skills or little chance of successful employment at home. They are often women and children." In other words, a selective segment of the population of illegal immigrants makes use of the services of smugglers. Whereas the majority of the illegal immigrants employ human smugglers out of a lack of other opportunities, there are also those immigrants who chose for the paid services of human smugglers in order to stay away from moral claims of relatives and friends. There is also evidence that significant proportions of asylum seekers in the United Kingdom and elsewhere in Western Europe have also been smuggled, thereby blurring the boundaries between asylum migration and illegal migration (Koser 2005).

On the whole, the literature currently available on smuggled migrants is scarce and has inherent methodological flaws. Moreover, it tends to focus on migrants from the perspective of the countries of destination and from the perspective of migration control. Qualitative sociological studies on living conditions of illegal immigrants in Europe and the USA (see, for instance, Düvell 2006; Mahler 1995; Staring 2001; Van der Leun 2003; Van Meeteren 2012) show that illegal immigrants make up a highly diverse category of people. Relatively young men between 20 and 40 years of age make up a large share, but the share of women appears to be growing. Social networks are pivotal for their opportunities. Without social resources, they risk marginalization. Deportation is a main fear and health problems including mental health problems are often found among smuggled migrants.

In literature which views smuggling of migrants primarily as a form of organized crime, migrants are often presented as "human cargo" or passive objects trapped and moved around by criminal networks. These studies also emphasize the risks involved, up to death on the way. Although this can be a realistic picture, as the figures mentioned before have illustrated, it is also biased. Studies departing from a more sociological viewpoint emphasize human agency and point to the selectivity of the other perspective. Violence and risks can indeed be involved, but human smuggling is in many cases also "just" a way of making migration possible when legal options fail. Many migrants, including many who have made use of the services of smugglers, are pursuing a project of bettering their lives. Finding a way of making a living is their top priority.

After arrival illegal migrants typically start looking for (informal) work. They are prepared to do the jobs that natives shun, many times under poor conditions, for wages usually lower than those of the legal residents (Calavita 2005: 15). Businesses in receiving countries are searching for cheap labor input, while private homeowners welcome the domestic workers that otherwise they might not afford. Certain economic sectors even only survive international completion by employing illegal workers (Van der Leun and Kloosterman 2006).

There are also instances in which exploitation takes place after arrival. Migrants who have initially consented with their smuggling have to pay high smuggling fees and later find out they have to work under exploitative conditions in order to pay the sum back. Migrants from China, for instance, appear to face a high risk of being exploited through these forms of debt bondage. These are the cases in which human smuggling can turn into human trafficking, which were briefly mentioned before.

State Policies

Tackling the smuggling of migrants requires a comprehensive approach, in which governments across the world invest in different ways, extents, and configurations. Since terrorist attacks in New York, Madrid, and many other places, the fight has become more intense. At the national level, border agencies such as customs, border police, and immigration services are responsible for the processing of people and goods at points of entry and exit as well as for the detection of human smuggling. Since the mid-1980s, EU and especially Schengen officials have been intensifying police and judicial cooperation to combat illegal or irregular migration in response to the diminishing of internal borders (Boswell 2003). This was followed by the externalization of migration control to countries outside the EU in the form of so-called pre-frontier control, or capacity building of migration management and asylum systems in transit countries, or the deployment of EU police to combat migrant trafficking in the western Balkans. In 1999 the European Council on Justice and Home Affairs has strengthened cooperation in the area of migration, asylum, and security. Five years later FRONTEX was established – the European Agency for the Management of Operational Cooperation at the External Borders of the Member States of the European Union. FRONTEX enables joint operations using member states' staff and equipment at external sea, land, and air borders.

At the international level, important steps have been taken since the late 1990s with the so-called Vienna process in response to concerns about the involvement of organized crime in international migration. This has led to the Protocol against the Smuggling of Migrants by Land, Sea, and Air, supplementing the United Nations Convention against Transnational Organized Crime (Smuggling of Migrants Protocol) which entered into force in 28 January 2004. In the whole multilevel playing field involved, a push toward a punitive approach is visible. The ultimate objective is dismantling organized crime networks that are active in migrant smuggling.

Controversies and Future Directions

Despite obvious successes, there is no convincing evidence that current policies to curb human smuggling are effective in doing what they should do (Kyle and Koslowski 2011). In fact, human smuggling is both adaptive and persistent (UNODC 2011b). Organized crime is not only feeding on and profiting by the phenomenon of illegal migration, but its activity also might be promoting it. This is partially the case because it does not influence root causes for international mobility. More effective long-term solutions to illegal migration and its facilitation would have to involve more legal opportunities for labor migration in receiving countries and diminishing economic differences between parts of the world, which have to be seen as long- and far-off-term aims. In the mean time governments still have to deal with international migration in many forms, including illicit forms.

Combating human smuggling will remain a challenging task, also in the future. Yet, law enforcement strategies and irregular migration policies are increasingly characterized by academics as not only ineffective but also inhumane because they lead to a race between law enforcement agencies, human smugglers, and the migrants. More militarization of and control at the borders will lead to new and more dangerous routes and as such will also contribute to an increasing number of victims and a lucrative market for organized crime. New technology might to some extent offer solutions, but it also will bring about new problems and adaptations. Engbersen and Broeders (2009) emphasize that the increasing digitalization of control within Europe has made the cat-and-mouse game between states and illegal migrants, pushing them further underground.

Many studies have demonstrated that rather than focussing on those behind human smuggling, many governments still, or even increasingly, see and treat smuggled individuals as criminals. In practice, people who are smuggled are often the ones to be arrested, detained, and expelled. This tendency appears to be strengthened by processes of crimmigration and securitization which puts the emphasis on "dangerous others" (Pugh 2004; Stumpf 2006). Yet, it should not be forgotten that protecting human rights is at the fundaments of the international protocols that underlie the fight against human smuggling. In line with international protocols, it is very clear that policies should focus on those behind human smuggling, rather than on those smuggled. Or as the recent UN Action Plan states: "Where migrants are simply detained and returned to countries of origin without investigating the actors involved in smuggling those migrants, the criminal processes at work continue unchallenged" (UNODC 2011b: 6).

Identification and the Development of Forensic Science

Pierre Margot
School of Criminal Justice, Institute of Forensic Science, University of Lausanne, Lausanne, Switzerland

Overview

Forensic science as a science and profession takes its roots in the industrial revolution and the Age of Enlightenment. Measurement, classification, and databases started on habitual criminals or recidivists, with criminal anthropometry introduced in Paris by Bertillon, but this was soon followed with fingerprinting or dactyloscopy. The scientific exploitation of traces as silent witnesses of crimes or clues to their understanding extended the capabilities of forensic science throughout the twentieth century. The story of identification sees a major development in 1985, with the advent of the analysis of DNA markers which allow current individualization, through their extreme diversity. Identity has always been a fuzzy notion. It is the need to identify criminals and recidivists that led to the concept of identity and individuality that currently influences the structure of large databases such as fingerprint or DNA, but also most measurements in biometry as well as administrative identities (security documents, electronic identity, etc.). These developments arose at the end of the nineteenth century around pioneers. This entry goes through the early discussions and controversies that established forensic science as a scientific endeavor.

Definitions, History, Administrative Identity, and Biological Identity

Early man may have used identification in rituals and in relation to gods (hand impressions, finger impressions). The process of identification and individualization became essential as soon as communities grew to a size when direct knowledge and recognition of familiars was not possible anymore. There is little reference to identification of persons in the earlier texts (such as Hammurabi's code, art 18 about the identification of the owner of slaves), but the early history of man describes impostors or

characters impersonating others to rob, cheat, or gain undue advantages or a hiatus around the identity (in religious early manuscripts such as Esau in the Genesis) that make the essence of theatre plots and great tragedies (such as Oedipus). Persons in organized societies started to have rights (community, legal, monetary) and duties needing administrative or civil identification, and supports were soon introduced in material forms such as church registries (recording birth, death, marriages, filiations) and magistrate logs.

Within organized societies, migrations created the need for legislation, classification, and identities. The use of "identifiers" such as a written signature (in Europe) or an apposed fingerprint (in Asia) strengthened the binding of terms in documents, engagements, etc., whereas official documents "*sauf-conduits*" were given to officialize the identity of the bearer for a safe passage. This led to the first passports that, incidentally, gave little information about the identification of the bearer but carried the power of the authority given by seals such as royal or imperial heraldic seals. Passports became personal identity papers for early royal messengers of the French King Louis XI in 1464 – early postmen. Associated to the passport, a registry of passports allowed tracking every journey made by messengers and a way of controlling back the activity and the effectiveness of delivery. The development of surveillance has become a whole part of the identification process in modern days, often in contradiction with other rights (privacy, data protection, etc.).

One can distinguish two types of identities: civil or administrative (surname, name, sex, filiation, date of birth, address, profession, function, etc.) and biological. The first may be variable over time and may depend on the observer's knowledge making this identity relative, whereas the biological identity (genome, DNA, fingerprint, biometry) is usually very stable over time with notable exceptions (like the extraction of a tooth in odontology).

Any new development such as identity documents has intrinsic weaknesses that will be abused by government (spies, etc.) and criminals (forgers, counterfeiters, mafias, etc.). Groebner (2007) makes a fascinating account of the historical developments around the needs and reasons for identification in Europe from the Middle Ages to modern times and technological developments and their risks. The need for identification becomes a major issue in our electronic world with the apparent distance between a person (identified, pseudo) and her activities through the electronic medium. Identity theft is not a new crime, but it has taken dimensions never attained before the twenty-first century.

Other needs arise for the recognition and identification of deceased persons (Gremaud 2010), an act necessary for a mourning family (particularly important for victims of disasters – Disaster Victims Identification teams or DVI teams are often deployed), but also for administrative reasons (pensions, heritage, insurances, etc.) or to establish the criminal act of genocide, or stop a criminal investigation against a disappeared person.

The use of court experts and expertise is documented in Antiquity, but the needs for the identification of persons became a real issue with the comparatively recent demographic explosion (humankind reached one billion in 1860 and sees the seven billion mark will overtaken in 2013!). This was compounded by the disappearance of many forms of arbitrary justice (based on torture and various forms of godly intervention, etc.), and punishments based on mutilations (from severe cuttings of limbs or disfiguration to marking the skin with a hot stamp). The century or Age of Enlightenment in France (siècle des Lumières – Diderot (1713–1784), Montesquieu (1689–1755), and Voltaire (1694–1778)) led to major changes (American Declaration of Independence, US Bill of Rights, French Revolution, Universal Declaration of Human Rights, etc.) that affected the way justice was done. Punishment (except for the death penalty) became pecuniary or imprisonment in Europe and countries under its influence. This led to a situation where habitual criminals could not be identified as such, unless arrested by the same policeman who could identify a recidivist under whichever name (pseudo) the criminal used. The need for authentication or verification was born, and the questions of how to recognize or identify a person previously condemned for a crime, what are the causes of crimes, is there a way to identify the signs from crimes, etc. became the focus of interest of both natural and social scientists. Many theories were based on pure prejudice and have led to tragic decisions and outcomes (racial theories, facial or body stigmata, genetic syndromes, psychological traits, etc. justifying exclusions, investigation methodologies, to the extreme of genocides) that still haunt us today. Except for specific types of madness, most crimes fall under categories of moral or conventional decisions that may vary over time, and some changes come about because some broke what they considered wrong laws (see the debate about passive or active euthanasia in this beginning of the twenty-first century).

The use of measurements and statistics helped develop selectivity of observed traits that may differentiate individuals or groups within populations or to observe relationships (whether causal or correlated) between societies and crime. Quételet (1796–1874), a versatile mathematician, decided to apply the newly developed statistics and probability to measure social phenomena a discipline that he called "social physics." It was a key factor in the development of both sociology and criminology. His work on the measurements of man, to determine the "average man" (still used in medicine in the form of the body mass index), was also the seed to the development of a fundamental aspect of forensic science: criminal anthropometry or bertillonnage.

Bertillon and Criminal Anthropometry

Bertillon (1853–1914) was what we would call a failed scientist, but he had a systematic and orderly mind, almost to an obsession. Highly influenced by a family of scientists, he obtained a clerical job at the Préfecture de Police in Paris in 1879 because of strings his influential father pulled. His main duties were to copy and file criminal records, created in 1848 after indications that many crimes were made by few individual repetitive offenders (recidivists). These records were mostly vague, nonsystematic, partially inaccurate, and with photos (when photos were available) taken in different lights, angles, sizes, etc. It was obvious that there was no way this data could be used to recognize or describe known criminals with any chance of success. The only recognized recidivists were recognized because they were known to the police officers that arrested them, often under different assumed names, the real birth name remaining unknown most of times with little chance of reconstructing the criminal career. The family background of Bertillon led him to obsessively search for a combination of measurements on each individual that would be selective to the extreme so that any recorded criminal, when arrested again could be identified to a recidivist with the same set of measurements, whatever the assumed name. This would be a process of authentication or verification that the person was already known and had a criminal record. The assumed names were identified to a set of crimes and not necessarily to a specified identity in the sense that we use with biometry now days (biological identity).

The principle was based on the measurement of fixed and stable features offered mostly by bone structures in adult persons. Nine bone measures offered 19,683 possible features that could be combined to obtain a highly selective classification. These included the stature and the spanning (from the left shoulder to the tip of the major of the right hand) (Bertillon 1893). Examples are given below: Fig. 1.

Various other descriptive features such as skin color, eye/iris color, face morphology, nose, hairline, forehead, and shin as well as accidental or added features (tattoos, warts, scars) offered complementary attributes that would characterize an individual.

Bertillon also introduced the standardization of the "mug shot" (position, lighting, size of face, and profile) that is still the feature of police file photographs. Initial success led to the systematic introduction of anthropometry, despite heavy administrative demands, error prone measurements, and the limited application to the sole recognition of habitual criminals.

Identification and the Development of Forensic Science, Fig. 1 Examples of anthropometric measurements of the Bertillon system

Herschel, Faulds, Galton, Vucetich, and the Lyon School of Forensic Medicine (Lacassagne)

William Herschel (1833–1917) and Henry Faulds (1843–1930) fought over the discovery of fingerprints as identifiers, although both had essential merits in the development of fingerprinting. Both members of the British Empire, they observed in India (Herschel was a British civil servant) and in Japan (where Faulds was a medical doctor, part of a Scottish mission) that fingerprints were locally used as binding seals in contracts, works of arts, and judgements and decided that these minute patterns and details of papillary ridges may be used for identification.

Herschel had the merit of studying the permanence as well as the diversity of ridge details and proposed through a letter to the British Government (the so-called Hooghly letter sent in 1887) that it could be used for the identification of recidivists (Herschel 1880). The proposal was indeed similar to Bertillon's anthropometric measurements, once recorded a recidivist can be identified by his fingerprints. Faulds, on the other hand, had noticed that the contact of fingerprints with objects left an image of the pattern and details (a finger mark) that could be used to identify the source of the mark (Faulds 1880). Here the identifier is not necessarily in a file but on the fingertip of the bearer and could be used to identify the source of a contact, even if this source is not a recidivist but identified through inquiry as a potential participant to a crime. Whereas Herschel and Bertillon considered the possibility of identifying using the basic relation "person to person," Faulds proposed the identification through a "trace to person" or "person to trace" relationship, thereby being able to solve crimes from trace elements. Faulds had addressed his findings to Charles Darwin, who passed it on to a relative, Francis Galton, who mostly ignored the submission and forwarded it to the Anthropological Society of London.

The awkwardness of the anthropometric system led to question its effectiveness as a law enforcement tool. A veterinary doctor Wilhelm Eber, who had observed many times his own fingerprints in animal blood, proposed to the Preussen ministry in Berlin the use of dactyloscopy (the study of fingerprints) in 1888 rather than anthropometry, and that same year, Galton was required to discuss the identification of criminals. This led him to study Bertillon's system and reminded him of Herschel and Faulds proposals. He started to study fingerprints from an anthropological point of view and was soon convinced of its usefulness and superior identifying power in law enforcement not only in the identification of recidivists but also in crime and trace investigation. This was published in a book, now considered a classic in forensic science (Galton 1892). Bertillon resisted all discussion with Galton, and Great Britain adopted initially a mix between anthropometry and dactyloscopy. An efficient classification system (Henry's system) soon demonstrated its ability to supersede most of what anthropometry was supposed to offer (Henry 1900). The active resistance of Bertillon internationally probably was instrumental in slowing down the development of dactyloscopy.

Vucetich (1858–1925), a Croatian immigrant in Argentina, anthropologist, and police official, was in charge of setting up the Argentinian police identification system at the end of the 1880s. He came across reports of Galton and communicated with him. Convinced of the superiority of dactyloscopy over any other system, he designed a classification system (the Vucetich system) based on Galton's work and was apparently the first to use finger marks to identify the author of a crime in 1892.

To move from an administrative system designed to recognize recidivists to a system that would allow the recognition of recidivists but also the identification of criminals based on traces left at scenes of crime accepted throughout the world approximately 25 years elapsed, and the death of Bertillon in 1914 saw the abandonment of his system as a whole except for a few administrative and peculiar feature.

Ironically, beside Bertillon in France, a professor of forensic medicine in Lyon, Alexandre Lacassagne (1843–1924) was a keen observer of nature, convinced of the validity of scientific methods, and was very critical of various theories about crimes and criminals. He was very critical of theories about the criminal man propounded by Lombroso (1887) where facial appearance became an indicator of criminal propensity and critically considered the systematic use of anthropometry. Indeed, he created and opened the scientific journal he founded in 1886, "*Les archives d'anthropologie criminelle*," to conflicting views and views he opposed. He developed an active research whose influence is still felt today. Locard was one of his students, but many others carried research on aspects of trace evidence to help identify authors of crimes or reconstruct criminal activity with many fundamental theses on subjects such as pattern marks in judiciary investigations (Coutagne and Florence 1889). Other examples include research on prints in general, with detection methods for invisible or poorly visible marks (Forgeot 1891), fingerprint patterns and as traces (Frécon 1889), and blood marks and patterns (Florence 1885). Many tests and procedures to detect and analyze blood, finger marks, semen, hair, etc. survived most of the first half of last century. Locard, although his initial research was dedicated to medicolegal history, was the first, early in the twentieth century, to consider forensic science (criminalistics) as a separate branch of knowledge rather than a part of forensic medicine or police work. The research and innovations of this group were largely overshadowed by the fact that their endeavor was provincial as compared to Bertillon's central position in Paris and the importance of anthropometry developed within police circles that would view the clerical and administrative aspects as secondary support to investigation.

Hans Gross and Archibald Rodolphe Reiss

Parallel to these activities in the police, scientific, and medical world, a scholar in criminal law, and part of the intelligentsia of the Austro-Hungarian Empire, Hans Gross (1847–1915) was fascinated by many scientific and medical discoveries and had contacts with personalities that had a huge importance in developments that influenced the whole twentieth century. These included Freud (psychoanalysis), Landsteiner (blood groups), Amoëdo (odontology), and other chemists, biologists, and engineers. Gross had the insight to realize the benefit that science could bring to the criminal investigator.

Austria had a continental legal system, inquisitorial in nature, with a magistrate responsible for criminal investigation: the investigating judge/magistrate. The responsibilities for this judge was (and still is) to collect and analyze all data to try to solve crimes and when faced with a suspect to determine all information in favor or against the suspect to build a case that is forwarded to a court and the public prosecutor. Gross imagined the immense resources afforded by scientific investigation and called for an academic discipline fundamental for all magistrates to be introduced in law schools: *Kriminalistik* (German name for criminalistics or forensic science). Gross considered that forensic science was the single fundamental investigative methodology for the investigating magistrate. This was epitomized in a book (Gross 1893) that became a best seller in a second edition, translated in multiple languages. A sixth edition was produced in 1913 by Gross himself and further editions updated by various authors have been published in German until the end of the twentieth century.
