Synonyms

Sexual reconviction; Sexual reoffending

Overview

Sexual recidivism is concerned with the reoffending of sexual offenders who have already had contact with the criminal justice system. This entry emphasizes the need to carefully define what is meant by recidivism and discusses some of the pitfalls in this area. It then focuses on recidivism rates, following on with a consideration of risk factors for recidivism, both static and dynamic, before commonly used risk scores are introduced. A discussion on specialization and glances towards possible developments in this area concludes the section.

Fundamentals

This entry is concerned with sexual recidivism, that is, the "persistence" of sexual offending once an offender has been arrested or convicted and addresses the future risks posed to the public by sex offenders after conviction.

Defining Recidivism

To begin, definitional aspects of recidivism and its measurement are considered, including the outcome measure, the type of recidivism, the time horizon, and the definition of what constitutes a sexual offense.

Recidivism: Recidivism is defined as the reoffending of a known offender; however, Falshaw et al. (2003) have noted that "there is little consistency in the way this term is used and the specific behaviour it refers to." They remind the reader that Maltz, in his classic book on recidivism, pointed to the use of nine different indicators of recidivism across a total of 90 studies in the United States, i.e., absconding, arrest, incarceration, parole violation, parole suspension, parole revocation, reoffense, reconviction, and probation violation.

Focusing explicitly on sexual recidivism, Falshaw et al. (2003) distinguished between sexual reconviction, sexual reoffending, and sexual recidivism. Their view was that recidivism is primarily concerned with lapsing into previous patterns of behavior and thus encompassed other forms of potential sexual-offense-related behavior such as loitering outside a school. They defined sexual reconviction as a subsequent conviction for a sexual offense, sexual reoffending as the perpetration of another illegal sexual act (whether caught or not), and sexual recidivism as the commission of a behavior related to a sexual offense, legal or illegal, with a clear sexual motivation. A more common use of the term sexual recidivism in the literature and one which is used in this entry, however, is some kind of official contact with the criminal justice system for a sexual offense, whether it be arrest, charge, or reconviction.

There is an implicit hierarchy within these distinctions. A "sexual reconviction" is the strictest measure as, to count, one needs the endorsement of a court of law. "Sexual recidivism" is a broader measure and may include arrests or charges as well as convictions for a sexual offense. "Sexual offending" has difficult counting and legal implications as it includes illegal sexual acts, whether caught or not. It is crucial to understand the importance of such analytical distinctions as the use of different outcome measures can produce very different results.

Type of Recidivism: Many studies on the recidivism of sexual offenders use as their outcome measure any form of recidivism – a general measure of subsequent contact with the criminal justice system for *any* offense. Others are interested in whether *sexual* recidivism has taken place, whereas yet others are concerned with recidivism for *dangerous* offenses which is usually taken to be sexual or violent recidivism.

Time Horizon for Follow-Up: Some studies have a fixed time horizon or a fixed series of time gates whereby recidivism rates, say, 5 or 10 years after release can be established. Other studies use an average follow-up time – these are less valuable as their results cannot be generalized in systematic reviews.

Nature of the Sample Taken: Some recidivism studies relate to those incarcerated in prison or in a treatment facility; others involve those with community sentences as well. Other aspects are also important – are females as well as males included, and is the sample restricted to a particular age range? Specifically, are juvenile offenders included?

Definition of a Sexual Offense: Normally, legal statutes which categorize sexual offenses (e.g., rape, indecent assault, exhibitionism) are used, but these can differ from country to country and from US state to US state. Most of these differences currently relate to laws against consensual homosexual activity (e.g., Malaysia, Zimbabwe). In addition, the age of sexual consent varies from country to country, varying from 12 (e.g., parts of Mexico) to 20 (Tunisia), and in some countries sexual behavior outside marriage is illegal (e.g., Saudi Arabia, UAE). The age of consent also varies from state to state in the USA and in Australia. There is a further issue relating to long-term or historical recidivism studies in that the definition of what is a sexual offense will change over time. A specific example relates to the laws of sodomy, or "unnatural" sex, which was in effect a legal prohibition in 14 US states until 2003. This makes comparison of recidivism rates across time, across countries, and across states problematic.

There are two further issues relating to whether an offense can be classified as sexual. Some offenses may be classified as a sexual offense but may indeed have no sexual motivation. For example, some might regard "bigamy," which until recently was classified by the Home Office as a sexual offense in England and Wales, as more of a deception than a sexual offense. In contrast, other offenses captured under "theft" (e.g., stealing underwear) could be regarded as more indicative of a sexual than acquisitive motivation but are unlikely to be included. Less well recognized is the fact that most reconviction studies are based on the principal offense committed. Hence, someone convicted of both murder and rape, for example, is recorded for murder as the principal offense, while the offense of rape is masked.

Risk and Prediction: A *risk* is a chance or probability that some event (usually undesirable) will happen in the future. Thus, one can talk about the risk of a sexual offender being reconvicted for a sexual offense in the next 5 years on release from an English prison. Good risk statements should include some element of location (risks for offenders in the Netherlands may well be lower than in the UK) and some indication of a future time horizon (the next year, the next 10 years, etc.) – however, these are sometimes left implicit, leaving the reader to judge what the statement means. A *prediction* usually relates to a particular person and uses the risk measure to make a judgment about an individual. This prediction may, in turn, be acted upon and some judgment made about the individual based on the prediction. Mostly, the assessment of risk in criminology is about potential dangerousness.

The Risk of Sexual and General Recidivism

Both large numbers and a long-term follow-up are thought to be crucial in the quest for a definitive study about recidivism rates. Although systematic reviews suggest that the observed sexual recidivism rates are only 10–15 % after 5 years (Hanson and Bussière 1998), the rates continue to increase gradually with extended follow-up periods. The study by Prentky et al. (1997), using a follow-up to 25 years from a treatment center in Massachusetts, demonstrated that, if they had restricted the follow-up to less than 24 months, they would have missed up to 45 % of new charges. While even with a 5-year follow-up period, they would still miss 30 % of the charges they finally identified. In fact, they examined the cumulative failure rates for new charges for sexual offenses only as well as for new charges of any offense. They used nine time gates, broken down by charge, conviction, and imprisonment. Table 1 shows the recidivism rate for new *sexual* charges.

As Table 1 shows, the conviction rates after 2, 5, 10, and 25 years were 6 %, 11 %, 16 %, and 24 % for rapists, while the comparable figures for

Sexual Recidivism, Table 1 Cumulative sexual recidivism rates over nine time gates

Rate at given time gate									
Type of recidivism	1 year	2 years	3 years	4 years	5 years	10 years	15 years	20 years	25 years
Rapists ($N = 136$)									
Sexual reoffense charge	.09	.12	.15	.17	.19	.26	.31	.36	.39
Sexual offense conviction	.04	.06	.08	.09	.11	.16	.20	.23	.24
Sexual offense conviction with prison disposal	.04	.06	.07	.08	.10	.14	.17	.19	.19
Child molesters ($N = 115$)									
Sexual reoffense charge	.06	.10	.14	.17	.19	.30	.39	.46	.52
Sexual offense conviction	.04	.07	.10	.12	.14	.23	.31	.37	.41
Sexual offense conviction with prison disposal	.04	.07	.09	.11	.13	.21	.28	.33	.37

Source: Prentky et al. (1997)

child molesters were 7 %, 14 %, 23 %, and 41 %. The work of Prentky and his colleagues provides a very clear case in demonstrating the importance of long-term follow-ups.

More recently, the results of Prentky et al. (1997) have been validated by Cann et al. (2004), who followed up all 419 male sexual offenders discharged from prison in 1979 in England and Wales until 2000, giving a follow-up period of 21 years. The sexual reconviction rates after 2, 5, 10, and 20 years were 10 %,16 %, 20 %, and 25 %; the equivalent figures for general reconviction were 34 %, 49 %, 56 %, and 62 %. The sexual conviction rates are higher at the 2-year point than either of Prentky et al.'s subsamples, but after that point, the reconviction rates are very similar.

Risk Factors and Sexual Recidivism

As already stated, the risk of recidivism is the probability or chance that the offender, who has already offended once, will take place again in the future within some time horizon. The risk will depend on characteristics of the offender, and it is therefore important to identify a set of factors or variables which are known to be associated with the risk of recidivism. Five such factors are highlighted below.

Sexual Recidivism and Gender

The extent of female sex recidivism is still under-researched; however, differences between male and female sexual offenders in terms of recidivism have been observed. Freeman and Sandler (2008) took a matched series of 780 female and male sex offenders in New York State and demonstrated that male sex offenders were significantly more likely than female sex offenders to be rearrested for both sexual and nonsexual offenses. A later study by the same authors (Sandler and Freeman 2009) extended this work and took 1,466 female offenders who were then followed up for 5 years. The 5-year rearrest rate for these offenders was a very low 1.8 % for a sexual offense and 26.6 % for any offense. Cortoni et al. (2010) concurred with the general conclusion of low rates for female sexual recidivism and, in a meta-analysis using 10 studies, found that the rates were typically under 3 % with an average follow-up of six and a half years.

Sexual Recidivism and Age

The age variable is also theoretically very relevant, particularly in relation to developmental psychology. For instance, Hanson (2002) identifies three broad factors relevant to sexual offending – deviant sexual interests (motivation), opportunity, and low self-control – and uses these to help explain the variation in the recidivism rates of various offenses. So, he maintains that, for rapists, all three factors should decline with age – "self-control should increase in young adulthood, deviant sexual drives should decrease in late adulthood, and opportunities should gradually decline throughout the life span" (Hanson 2002). Consequently, Hanson is not surprised that most rapists are young and that their recidivism rate steadily decreases with age. In contrast, in explaining that child molesters are generally older than rapists, he points to competing factors influencing recidivism risk during early to middle adulthood with, for instance, self-control probably improving but the opportunities for child molesting may well be increasing.

Thornton (2006) has noted that "sexual offenders released at a younger age tended to be more general criminals while those released at an older age tended to be sexual specialists." But Barbaree et al. (2003), focusing more specifically on sexual recidivism, produce an extra twist. They argue that "if libido [seen as one of the important determinants of sexual aggression] decreases with aging, then it follows that sexual aggression should show similar aging effects." Certainly their results suggested that "offenders released at an older age were less likely to recommit sexual offences and that sexual recidivism decreased as a linear function of age-at-release" (Barbaree et al. 2003).

Following reviews and meta-analyses, the consensus is that there is an inverse relationship between sexual offenders' age at the time of their release from incarceration and their sexual recidivism risk (Thornton 2006; Hanson 2002; Hanson and Bussière 1998). However, Doren (2006) notes some recent challenges to this "iron law" – Doren found a series of "study-specific conclusions . . . that were often mutually exclusive." Reanalysis of existing data showed numerous potential interacting variables, such as participation in treatment, type of risk measure used, type of sexual offender, jurisdiction, and even a different measure of offender age. In other words, to explain the wide disparity of findings among the studies he reviewed, there were perhaps confounding variables in all of the reviewed research. While the age variable is definitely on the agenda, Doren concludes that "we have a lot of work to do before we can say we understand how to consider offender age in sexual recidivism assessments" (p. 156).

Sexual Recidivism of Juveniles

In law and policy, the age divide between juveniles and adults is particularly crucial. However, the activity of juvenile sex offending has only comparatively recently attracted attention and research interest. In fact, over the past decade or so, sexually abusive juveniles/adolescents have increasingly been distinguished from adult offending. Worling and Långström (2003) provide a useful and detailed review of studies indicating criminal recidivism risk with adolescents who have offended sexually. They identify, for example, that their own study on 117 sexual adolescents reported a 30 % sexual reconviction rate after a mean follow-up of 9.5 years. Such rates are higher than the Prentky et al.'s 10-year reconviction rates reported earlier in this entry.

An important counterweight to the concern that juvenile sex offenders are likely to be particularly dangerous is provided by Caldwell (2007). Caldwell compared 249 juvenile sex offenders and 1,780 nonsexual offending delinquents who were released from secured custody and contrasted the sexual charge recidivism figures for juvenile sexual offenders and nonsexual offenders and found nonsignificant differences – 6.8 % compared to 5.7 % after a 5-year follow-up. This result has important implications for policy concerns. Quite simply, most juvenile sex offenders may not be the future threat that many might have expected.

The low rates of sexual recidivism among juveniles and adolescents are certainly noteworthy. Vandiver (2006) confirms how nonsexual offenses predominate in recidivism among juvenile sex offenders. Vandiver focuses on 300 registered male sex offenders who were juveniles at the time of their initial arrest for a sex offense. The series is followed through for 3–6 years after they reached adulthood, and while more than half of the series is arrested at least once for a nonsexual offense during this adult period, only 13 (or 4 %) were rearrested for a sex offense. Similar results are portrayed in Nisbet et al. (2004) showing relatively low rates of detected adult sexual recidivism but high rates of detected nonsexual recidivism, among young men who committed sexual offenses as adolescents. Hence, one is identifying relatively stable patterns of general antisocial conduct in adolescent sex offenders, but continuing aberrant *sexual* behavior is not much in evidence. Curiously, with this study, while age at assessment was found to predict sexual recidivism, rather counterintuitively, it was an older age at assessment that predicted adult sexual offense charges. In fact, "the likelihood of being charged with sexual offences as an adult increased by 60 % with each year increase in age at assessment" (p. 230). This is an important finding as it confirms that very early sexual crime is generally unlikely to be a precursor to persistent sexual offending in adult life.

Sexual Recidivism and Type of Sexual Offending

In general, large numbers of sex offenders are needed when testing the notion that different types of sex offenders have different kinds of outcome. Earlier work such as Prentky et al. (1997) had already hinted that some types of sex offenders were more likely to commit new *sexual* crimes than others, suggesting that child molesters have a substantially higher sexual recidivism rate compared to rapists. Other authors have disagreed with this conclusion. For example, Serin et al. (2001) have indicated that recidivism rates are higher for rapists than child molesters. Hanson (2002) notes that "rapists were younger than child molesters, and the recidivism risk of rapists steadily decreased with age." Also differences in recidivism within the same kind of sex offense have been noted – for example, pedophiliac versus non-pedophiliac child molesters.

Sexual Recidivism and Prior Criminal History

The final risk factor highlighted is that of the offender's prior criminal history. There are many ways of summarizing such information, but interest has been focused on the number of prior convictions, the number of prior sexual convictions, the age of criminal career onset, and the relationship between the victim and the offender of prior sexual offending. In general, such measures have been incorporated into risk scores, and criminal history is discussed more fully below.

Risk Scores and Sexual Recidivism

A sexual recidivism risk score, put simply, identifies the risk of future recidivism of a sex offender based on a set of risk factors. For example, the risk score might classify a typical offender with a set of characteristics into one of five categories – highly unlikely to reoffend, unlikely to reoffend, equally likely to reoffend or not, likely to reoffend, and highly likely to reoffend. A prediction of recidivism, in contrast, is using that risk probability or score (and possibly other information) to make a judgment as to whether one particular person will reoffend. Less commonly, a prediction might estimate how many of a group of offenders will reoffend. Thus, a prediction might be made that a male sex offender in California released from prison who has three prior sexual convictions has a 40 % chance of reoffending with another sexual offense in the next 5 years. Based on this prediction, a decision might be made on the form of post-release supervision needed by the offender.

Actuarial and Clinical Assessment Tools

There are two methods of assessing the risk of an individual for subsequent sexual recidivism. Actuarial measures use summary measures of criminal career data on a large set of offenders together with other information about the age, gender, and circumstance of the offender to estimate a risk score. The offenders are followed up for the required period of time, and each offender is then identified as a recidivist or not. This risk score estimate is made though the application of statistical modeling methods such as logistic regression or other score-building models. The performance of the measure can be assessed by dividing the set of offenders into two – using one part of the data to build the risk score and the second part to assess how well the measure performs.

Clinical risk assessment, on the other hand, takes the judgment of professionals such as psychiatrists, probation officers, or parole board members to make a relatively informal judgment on the likelihood of an offender to reoffend. Tools such as the Violence Risk Score for Sexual Offenders can be used to guide the judgment. Although these professionals will have access to the same information on past criminal career history, they will also take into account a whole set of personal factors such as degree of remorse, demeanor, family support, stable residential status, etc., to determine risk (Milner and Campbell 1995).

Both measures would tend to be used at the start of some process – for example, in presentence reports presented to the court or in considering release from an indeterminate prison sentence. Which of these two approaches appears to give better predictions? An important study by Grove and Meehl took 136 separate studies – a mix of clinical and actuarial studies. In general, the clinical studies had a great deal of extra information available compared to the actuarial studies (Grove and Meehl 1996). Their study came to two important conclusions. Firstly, in studies which compared practitioners, there was little agreement between them. Secondly, despite using less information, the actuarial studies were either equal or superior to clinical risk assessment.

However, there have been criticisms of the actuarial approach (Quinsey et al. 1995). Firstly, it can categorize whole groups of individuals as high risk – even though it is recognized that personal circumstances will mean that some individuals are at low risk within a high-risk group. Furthermore, actuarial measures fail to take account of factors such as the intention of the offender to desist from crime. There are also other criminological arguments which need to be considered – that actuarial risk measures focus on the individual to the exclusion of other causes of crime, notably economic and social deprivation. Nevertheless, actuarial measures are perceived by many as providing a reliable estimate of risk and are increasingly used in daily criminal justice practice. For dangerous offenders, current practice relies increasingly on some combination of a structured clinical judgment and actuarial measures.

"Static" Versus "Dynamic" Factors

The main focus in predicting recidivism risk from its outset has been on historical, or "static," factors. These are factors relating to the prior criminal history of the offender such as age of first conviction; the number of previous sexual and nonsexual convictions; demographic factors, such as age and gender; historical factors in the early life of the offender such as whether both parents were present when the offender was a child; as well as victim characteristics (stranger, familial) and type of offending (child molestation, rape, etc.). Age is regarded as a "static" factor as it is taken at some fixed point in time, such as conviction or date of release from prison or treatment center. As such factors are "static," it is not possible to intervene and to change these to improve outcome.

Dynamic factors, in contrast, are subject to intervention. They can be divided into stable dynamic factors, which change slowly over time (such as job responsibility and attitudes to the opposite sex), and acute dynamic factors, which can vary day by day or hour by hour (such as day to day drinking behavior).

Building Risk Scores

Many risk scores in common use will apply statistical techniques to build a recidivism risk score. Data on a cohort of sex offenders is collected and each offender in the sample is followed up for a fixed period of time – typically 2 or 5 years – although longer follow-up periods can also be used. Typically, official data is used to assess whether the offender has recidivated by looking at arrest or court conviction records. Information on offender characteristics is also collected. These can be obtained from the criminal history of case notes of the offender. For scores involving dynamic factors, in addition, psychometric tests (e.g., for psychopathy) may need to be administered as they often contribute to the recidivism test score. Typically, logistic regression is then used to build a score and to determine the important risk factors. If follow-up times vary, then Cox regression may be used.

Once the score is built, its performance on new samples of offenders is assessed. Performance is usually measured by estimating the receiver operating characteristic curve of the score and calculating the AUC (area under the curve) which is expressed as a proportion or percentage. The AUC can be interpreted as follows: if two offenders are taken at random – one reconvicted and one not reconvicted – then the AUC gives the probability that the reconvicted offender will have a higher risk score than the unconvicted offender. Most risk scores used in assessing sexual recidivism have AUCs of around 0.70 or 70 %.

Risk Scores for Sexual Recidivism

Table 2 presents the sexual recidivism risk scores in common use, together with typical items which make up the score. As can be seen, four of the seven scores presented consist solely of static items, and only three scores attempt in addition to include dynamic factors.

Three measures are highlighted: the Risk Matrix 2000/Sexual (RM2000/S), the Rapid Risk Assessment of Sexual Offense Recidivism (RRASOR), and the Violence Risk Score for Sexual Offenders (VRS-SO).

The RM2000/S score consists of seven static items which relate to previous criminal history

Sexual Recidivism, Table 2 Some commonly used risk scores for assessing sexual recidivism for sex offenders

Measure	Full name	Number of items	Examples of items	Developers	Year
Static-99	Static-99	10 static	Conviction and sexual conviction history, relationship to victim, victim gender, lack of long-term intimate relationship, aged under 25	Hanson and Thornton	2000
RM2000/S	Risk Matrix 2000/Sexual	7 static	Conviction and sexual conviction history, age at release, relationship to victim, victim gender, marital status	Thornton, Mann, Webster, Blud, Travers, Friendship, and Erickson	2003
SORAG	Sex Offender Risk Appraisal Guide	12 static 2 dynamic	Age at offense, criminal history, failure on prior release, marital status, history of alcohol abuse, psychopathy score, phallometric test	Quinsey, Harris, Rice, and Cornier	1998, 2006
RRASOR	Rapid Risk Assessment of Sexual Offense Recidivism	4 static	Prior sexual offenses, age at release, relationship to victim, victim gender	Hanson	1997
MnSOST-R	Minnesota Sex Offender Screening Tool – Revised	17 static	Sexual and nonsexual criminal history, substance abuse, discipline history and sex offender treatment history, age at release	Epperson, Kau, and Hesselton	1998
VRS-SO	Violence Risk Score for Sex Offenders	7 static 17 dynamic	Conviction and sexual conviction history; age at release; age of first conviction; sexual deviance, criminality, treatment responsivity	Wong, Olver, Nicholaichuk, Gordon	2003
J-SOAP	Juvenile Sex Offender Assessment Protocol	23 dynamic	Sexual drive; impulsive, antisocial behavior; clinical; community adjustment	Prentky, Harris, Frizzel, and Righthand	2000

(number of previous court appearances, number of previous court appearances for sexual offenses, any conviction for a sexual offense against a male and against a stranger, any conviction for a noncontact sexual offense) together with measures of age at assessment and marital status. The test yields four risk categories – very high, high, medium, and low. The score is easy to administer and is used extensively by the UK Prison Service. AUC values of 0.75–0.77 have been reported.

RRASOR is an even briefer score and consists solely of four items and is, as its name suggests, easy to administer. The items are the number of prior sexual offenses, age of offender, gender of victim, and relationship to victim. AUC values of between 0.65 and 0.79 have been reported by various authors.

More recently, risk scores involving both static and dynamic factors have started to be introduced. The VRS-SO is one example of this development. The score includes both static items (conviction and sexual conviction history, age at release, age of first conviction) and a range of 17 dynamic items (sexual deviant lifestyle, sexual compulsivity, interpersonal aggression, and cognitive distortions are four of the items). The 17 dynamic items represent three underlying components of sexual deviancy, criminality, and treatment responsivity, together with additional items for intimacy deficits and emotional control. Theoretically, it uses "stages of change" to assess sexual-offending-related attitudes and behaviors and is administered twice, for example, pretreatment and posttreatment. The VRS-SO developers highlight its sensitivity to treatment-related change as well as to other forms of intervention. In terms of predictive validity at the time of development, AUC values ranged from 0.66 to 0.74. Beggs and Grace (2010) recently assessed the score and reported an AUC of 0.80 and also stated that the dynamic items provided additional predictive power after controlling for the static items. However, it needs to be stressed that researchers need training in the use of the instrument and the administration of the instrument is lengthy.

Researchers are divided about the utility of including dynamic measures in a risk score. The developers of VRS-SO argue that dynamic variables do not necessarily have to add to the predictive efficacy of static variables to be useful, stressing that their utility in treatment and in assessing risk change is also important.

Another area of controversy is whether age needs to be included in a risk score which includes dynamic items. The argument is that as most databases used to construct tests are cross-sectional, then age differences in the sample may represent birth cohort effects as well as age, and the distinct contribution of age cannot be determined (Harris and Rice 2007). An additional concern is that the dynamic items include measures of self-control, antisocial traits, and sexual potency, which will decline with age; hence, the inclusion of age in addition to these trait measures will overpredict sexual recidivism. However, Barbaree et al. (2009) have determined that age provides additional explanatory power over antisocial and sexual deviance measures in assessing recidivism.

In general, the choice of score depends on whether assessors have the skill, training, and time to assess offenders on the dynamic items. Scores involving dynamic items are best suited to those offenders who are incarcerated where there may be an interest in possible change, while court-based assessment is probably carried out more efficiently by using a static measure.

Recidivism and Specialization

A separate but related debate to sexual recidivism is that of specialization, which is defined as the tendency to commit the same type of offense. Specialist sexual offenders therefore have a tendency to recidivate with another sexual offense to a greater extent than the average offender.

Lussier (2005) explains that two major hypotheses have been put forward to describe the criminal activity of sexual offenders in adulthood. The first of these states that sexual offenders are specialists who tend to repeat sexual crimes. The second describes sexual offenders as generalists who are versatile in their offending. He goes on to state that the current state of knowledge provides empirical support for both the specialization and the generality hypothesis. A recent study has examined the specialization of sexual offenders both pre- and post-commitment (Harris et al. 2011). They found strong evidence of versatility but also found that those offenders who specialized prerelease were more likely than versatile offenders to specialize in sexual offending on release. They also found that child molesters were more likely to specialize than rapists or incest offenders.

The results suggest that sexual offenders are both versatile and specialist – a hypothesis originally suggested by Soothill et al. (2000). This study compared the criminal records of the 6,097 males convicted in 1973 in England and Wales of one of four offense categories – indecent assault against a female, indecent assault against a male, indecency between males, and unlawful sexual intercourse (USI) with a girl under 13 – over a 32-year observation period looking backward 10 years and forward 22 years, and very different patterns emerged for the four groups (Soothill et al. 2000). It showed that each offense group had very different criminality patterns in terms of their likelihood of being convicted of any (general) offense on another occasion – ranging from 37 % of those convicted of indecency between males to 76 % for those convicted of USI under 16. These sex offenders were shown to differ greatly in terms of general offending behavior – a *higher* proportion of those committing *heterosexual* offenses (i.e., indecent assault on female or USI with a girl under 16) tend to be convicted for violence against the person, property offenses, and criminal damage compared with the other two groups; however, a *lower* proportion of these offenders commit *sexual* offenses on other occasions. In contrast, those committing *homosexual* offenses (i.e., indecent assault on a male or indecency between males) are the mirror image. They are much less likely, compared with other sex offenders, to be convicted of violence or property offenses, while those committing indecent assault on a male are much more likely to be convicted of sexual offenses on other occasions.

At one level, therefore, sexual offenders may or may not specialize within their general criminal career, while at a more specific level offenders may or may not specialize in specific kinds of sex offending within their sexual criminal career. These two levels may act quite independently insofar that an offender could be a specialist at one level and a generalist at another. Miethe et al. (2006) have confirmed this picture by identifying, within low levels of general specialization, that 37 % of serial child molesters and 27 % of serial rapists were identified as specialists, offending with their specific types of sexual crime in the early middle and late third of their criminal careers.

Future Directions in Risk and Sexual Recidivism

This entry concludes with an indication of possible future directions in the study of sexual recidivism, focusing on new data sources, improvements in the methodology of risk score building, and better understanding of the criminal careers of sex offenders.

New Data Sources: One major difficulty with the construction of risk scores is that, in general, they are both constructed and validated on data sets containing a relatively small number of cases. Risk scores are, moreover, often built on specific samples such as sexual offenders in prison. However, the potential is there to construct longitudinal data sets through record linkage which would take complete birth cohorts of sex offenders and follow them up in terms of their conviction or arrest records for long periods of time. For example, one potential source for such data would be the population registers of the Scandinavian countries, which, when linked together, would provide information on police contacts, convictions, employment, income, and demographic variables.

New Methodologies for Assessing Recidivism: Improved data sets will allow more sophistication in the type of models which can be built to explain recidivism. Firstly, new forms of dynamic factors can be introduced. Marital status, for example, is currently included as a static variable, but having dynamic information on changes of marital status, as well as changes in job status and responsibility for children, will provide additional explanatory power which may prove useful. Modeling techniques such as the Cox discrete-time model can help to build prediction scores with time-varying covariates. Secondly, group-based trajectory modeling, which has proved its worth in identifying latent trajectories of offending frequency over the criminal history, and group membership of such classes is starting to be used as a predictor for future recidivism (Lussier et al. 2010). Thirdly, new methods of prediction from the machine-learning and data-mining disciplines (neural networks, support vector machines, random forests) will offer additional sophistication which can deal with the inherent nonlinearity of covariates on recidivism outcome.

Specialization and Recidivism: Most work on specialization and sexual offending has dealt with the whole of the criminal career. However, alternative methods are now available which propose that offenders may favor certain offense types during the short term, largely because of opportunity structures, but that because of changing situations and contexts over the life course, their offending profiles aggregate to versatility over their criminal career as a whole. This notion has not been considered specifically for sex offending. However, it seems possible that offenders may well have particular sex crime preferences in relatively narrow time periods and then transition to other kinds of behavior over time.

Reintegration into the Community: Recently, work has been carried out on how long after sentence or release general offenders become similar to non-offenders in their propensity to commit crime (e.g., Bushway et al. 2011). This idea of redemption and reintegration is important as it can help to determine policy such as how long DNA samples or old criminal records are kept for. This work needs to be extended into sexual offending, and the risk or hazard of future offending for different lengths of arrest or conviction-free periods needs to be determined and compared with non-offenders. Such results should inform the length of time sexual offenders are placed on sex offender registers.

Apart from these specific developments, it is important to realize that societal factors as well as personal and individual factors will affect sexual offending and recidivism. Indeed, it can be argued that changes in society rather than individual upbringing and attitudes have affected the long-term trends in sexual offending and changes in rates of recidivism. The focus of research into sexual recidivism in the last 20 years has focused on the individual; the next 20 years needs to focus more on society and community effects.

Shame in Criminological Theory

Nathan Harris
Regulatory Institutions Network, Australian
National University, Acton, ACT, Australia

Overview

The end of the 1980s marked a rediscovery of shaming in criminology. Criminological theories, and most particularly John Braithwaite's theory of reintegrative shaming, reintroduced the concept of shaming into the criminological debate. At around the same time, criminal justice systems experimented with new interventions, such as restorative justice and shaming penalties, which both draw on notions of shaming, albeit in very different ways. While these developments are principally concerned with actions that are taken by authorities, or broader communities, towards offenders, they also highlight the importance of shame as an emotion. Use of the word shaming implies that the corresponding emotion is in some way critical, but what shame is and what its benefits are for social control are less clearly articulated. The application of shaming within criminal justice is not without controversy, and the merits of shame as an emotion have provoked considerable debate. The concept of shame management and an ethical identity conception of shame have both been proposed to clarify the nature of the emotion as well as its implications for criminology.

The Rediscovery of Shaming in Criminology

The relevance of shaming to the regulation of crime has a long history. Shaming is central to accounts of social control in anthropological descriptions of Polynesian and Asian societies as well as analyses of European criminal justice practices in earlier centuries. Equally well documented is a move away from shaming practices in European-based criminal justice systems during the century and a half until the 1970s. However, in 1980s and 1990s, interest in shaming underwent something of a revival, most particularly through the publication of reintegrative shaming theory, the rise of restorative justice, and an interest in the judicial use of shaming punishments.

Reintegrative Shaming Theory

A focal point for the revival of interest in shaming was publication of John Braithwaite's (1989) book *Crime, Shame and Reintegration*. In this book it is argued that institutions of criminal justice as well as criminological theory have underestimated the importance of social disapproval. Braithwaite argues that to understand crime rates, we need to look beyond official mechanisms, such as penalties that are imposed by criminal justice systems, to the degree to which societies express disapproval of crimes. Strong social norms against criminality, which arise through community activism, are seen as critical to low crime rates because they engender a culture in which crime is unthinkable because people come to see it as abhorrent. The concept that is central to Braithwaite analysis is shaming, which he defines as "... all societal processes of expressing social disapproval which have the intention or effect of invoking remorse in the person being shamed and/or condemnation by others who become aware of the shaming" (Braithwaite 1989, p. 100). An important characteristic of this definition is that it does not limit itself to demeaning or humiliating forms of disapproval but seeks to encompass the full spectrum of ways in which disapproval might be expressed.

The fundamental distinction the theory makes is between stigmatization and reintegration. Stigmatization occurs when disapproval is directed at the person as well as at the offensive behavior, when the person is not treated with respect, when there is no ceremony to decertify the individual's deviant status, and where deviance is allowed to become a master status trait. As with labeling theories, it is predicted that stigmatization of offenders leads to greater re-offending. Being charged with a crime, found guilty of it in a court, and then sanctioned imposes a deviant identity on an individual because it ceremonially changes the position of the person within society and has important social implications, such as reduced employment opportunities. This critique of criminal justice asserts that once imposed, a deviant identity becomes a self-fulfilling prophecy and is almost irreversible: marginalization reduces the individual's access to legitimate opportunities while increasing perceptions of injustice and the attractiveness of supportive subcultures.

However, in identifying reintegrative shaming as an alternative, Braithwaite diverges from the labeling tradition by rejecting the idea that stigmatization is an inevitable product of social disapproval. Reintegration can be seen to have occurred when shaming is respectful, distinguishes between the person and their actions, concludes with forgiveness or decertification of deviance, and does not allow them to take on a negative master status trait. One context in which this often occurs is in family life and the disciplining of children, where research shows that authoritative approaches are more effective than either permissiveness or authoritarianism. Another example Braithwaite cites is Japanese society, which is both high in shaming and high in reintegrative traditions and which has a remarkably low crime rate.

In arguing for the positive effects of reintegrative shaming, Braithwaite highlights two mechanisms. One of these is that reintegrative shaming is an effective deterrent, particularly when it comes from those who the individual is close to, because it poses a threat to relationships that are valued. Yet, reintegrative shaming also transcends the rational actor model of deterrence. The second mechanism, which Braithwaite suggests is more important, is that reintegrative shaming communicates that certain behaviors are morally wrong and thus builds internalized controls or conscience. Braithwaite (1989, p. 72) argues:

> Shaming is more pregnant with symbolic content than punishment. Punishment is a denial of confidence in the morality of the offender by reducing norm compliance to a crude cost-benefit calculation; shaming can be a reaffirmation of the morality of the offender by expressing personal disappointment that the offender should do something so out of character.

Restorative Justice

Shaming has also been an important concept in the development of restorative justice programs, which exploded in popularity during the 1990s, and is now found in criminal justice, child protection, school, and prison systems in many parts of the world. Restorative justice is an alternative to the criminal justice system that redefines the goals of justice as well as the way in which it is carried out. A defining principle of restorative justice is that an offense creates an obligation for offenders to repair the harm that has been caused (Zehr 1990). Unlike the principles of traditional justice that emphasize the importance of consistent and proportional punishment, the aim of restoration focuses attention on apology, reparation, and reconciliation. While Braithwaite's concept of shaming can be applied to many different kinds of interventions, restorative justice quickly came to be seen as the principle way of implementing reintegrative shaming. The broad goals of restorative justice as well as the practices associated with it are consistent with reintegrating offenders, and there is evidence that offenders perceive it as more reintegrative.

The dynamics of restorative justice interventions, such as family group conferences, victim offender mediation, or healing circles, are rich contexts for shaming. Family group conferences, for example, involve semiformal meetings between the offender(s), people who are close to them, the victim(s), and their supporters. The focus of a conference is on finding out what happened and how the incident has affected all of the parties as well as coming to an agreement about what needs to be done to repair the harms that are identified. As a consequence, they involve communities in the kinds of conversations about the negative consequences of crime that Braithwaite argues are critical to developing individual conscience and commitment to the law. Empirical observations suggest that shame dynamics do play an important role in conferences and that well-run programs have the potential to assist in resolving these feelings (Retzinger and Scheff 1996).

Judicial Shaming

Finally, the explicit use of shaming by courts has also seen the rise of "shaming" practices that are completely contrary to the restorative approaches discussed above. Recent examples have occurred, particularly in American criminal justice, where shaming has been used in the court system as a deterrent or punishment for convicted offenders. Offenders have been ordered to complete "shame sentences" relevant to the crime they commit instead of spending time in jail. Shoplifters have been ordered to stand out the front of shops holding signs declaring that they stole, drink drivers are ordered to attach "DUI" stickers to their cars, while those convicted of soliciting sex are ordered to sweep the streets. An explicit aim of this kind of shaming is to humiliate offenders (see Kahan 1996). The significance that feelings of shame hold as a deterrent is exploited by these approaches, but the shaming they impart is explicitly stigmatizing. Another area of American criminal justice which reputedly incorporates shaming are boot camps where offenders are subject to military-style discipline but are also publicly confronted with their offense.

Concerns About Shaming

While awareness of shaming has increased, so too have concerns about the explicit use of shaming to control or respond to crime. Shaming punishments, in particular, have been seen by some as a regressive step which demeans the dignity of offenders while failing to protect basic human rights or allow for rehabilitation. Massaro (1997) argues that this "modern" kind of shaming is one that outcasts certain segments of society in a way that does not protect the individual and undermines the dignity of the whole community. In addition to arguing against the decency of this approach, she argues that the complexity of the emotion of shame is such that courts are ill-equipped to employ shaming and that the effect on offenders would be difficult to predict. Martha Nussbaum (2004) identifies five arguments in the literature against the use of shaming punishments: that they are an offense against human dignity, that they are a form of mob justice, that they are unreliable, that they don't hold the deterrent potential that they are supposed to, and that they are potentially net widening.

While it is not surprising that questions have been raised about these overt forms of humiliation, the appropriateness of shaming within more reintegrative forums such as restorative justice has also been questioned. Maxwell and Morris (2002) and others have argued that overt disapproval is not an aim of restorative practices, suggesting instead that they are oriented towards exploring the consequences that an offense has on its victims, with the aim of provoking empathy. They argue that shaming is a dangerous proposition in restorative justice because even with the best of intentions, shaming might be interpreted by offenders as stigmatizing. Shaming a young offender may exacerbate problems rather than prevent re-offending, particularly if offenses have been committed as a consequence of low self-esteem, which has occurred as a consequence of an absence of emotional support or a difficult past.

This critique of shaming is based in part on doubt as to whether shame is a positive emotion for offenders to feel. A number of scholars have argued that the more important mechanism in restorative justice is the eliciting of remorse, which occurs as a consequence of the offender coming to understand the impact that their actions had on the victims. Empathy, as understood by Maxwell and Morris, aids in this process. Shame, on the other hand, is said to be a dangerous emotion to invoke in offenders because it is a threat to the offender's sense of self-worth and is potentially destructive. These questions reflect a broader debate about the virtues of shame as an emotion, in which there is a clear division between scholars who are pessimistic about the role the emotion plays and those who are more optimistic.

Conceptions of Shame in Criminology

As just illustrated, various ideas about shaming, both positive and negative, are based on assumptions, often implicit, about the nature of the emotion that shaming invokes. This raises the following questions: what is shame, and what are its characteristics? While it is not possible to provide a neat typology because of the disparate manner in which theoretical approaches to the emotion have advanced, three broad characterizations of shame have been identified in the literature (Harris 2001). Each of these characterizations is reflected within criminological research.

Shame as a Social Threat

The first of these conceptions of shame conceives of the emotion as a response to social threat, which is precipitated by the individual's perception that they have been rejected or disapproved of in some way. This conception of shame is apparent in early anthropological perspectives which describe shame cultures as those that rely for social control on the sensitivity of individuals to negative perceptions of others, rather than through the development of conscience. This idea has been elaborated in various ways in contemporary research. While these approaches have varied in their explanations of why people are sensitive to social evaluation, they all emphasize the need to be accepted by others either because the need to have strong personal ties is a basic human motive or because there is an evolutionary need to maintain status or because shame is related to the person's perception of his or her own self-worth. An important characteristic of this conception is that it describes shame as exterior to individuals and as constraining. The individual feels shame as a result of another's decision to reject. If others do not reject in the face of the same actions, no shame is felt. Shame, or the fear of shame, is described as a powerful motivation for the individual to continually monitor and work on personal relationships and to comply with social expectations at a broader level.

As a consequence a fear of shame has been seen as a strong motivator for law-abiding behavior, and this assumption is explicitly made in early anthropological research on shame cultures. More recently, criminologists have drawn on this understanding of shame to argue that informal social sanctions represent a significant deterrent to crime (e.g., Grasmick and Bursik 1990). A number of empirical studies, which place shame within a rational choice perspective, suggest that expectations of feeling shame are associated with lower self-reported projections of offending and in some cases that the effect is comparable with, or greater than, official sanctions.

Shame as Personal Failure

A second way in which shame is described in the literature is as a response to perceptions of personal failure. This is based upon the proposition that shame occurs when an individual perceives that they have failed to live up to an ideal or standard that they uphold and that the consequence of this is the perception that the "whole" self is a failure. This proposition has been explained using a number of theoretical frameworks including psychoanalysis, attribution theory, and affect theory. Shame is contrasted with guilt because the focus of attention is the self rather than an act or omission. Unlike the social threat conception described above, perceptions of failure are not necessarily prompted by disapproval, but can occur in isolation and in relation to personal ideals.

Research that explores the impact of a disposition to feel shame as defined by personal failure has been applied to criminology. June Tangney and her colleagues, in particular, have argued that a disposition to feel shame is far less adaptive than a disposition to feel guilt because shame involves an overwhelming negative evaluation of the self that prevents individuals from responding positively. An extensive program of research shows that individuals who are shame prone are more likely to feel anger and hostility, are less likely to feel empathy for others, and are more likely to suffer from psychopathology (see Tangney and Dearing 2002). When applied to inmate populations, shame proneness is correlated with substance abuse and does not seem to play the same protective role that guilt proneness does (Tangney et al. 2011).

Shame as Ethical Threat

The third conception of shame cuts across these two literatures by incorporating the notion that shame occurs when wrongdoing is recognized by the individual and their community. Shame in this view is connected, unlike embarrassment, with serious transgression as well as the idea of fault. The individual feels shame for having intentionally committed a wrong. This is implicit in William's (1993) description of the precondition for shame being one in which a respected other, defined in ethical terms, would think badly of us. Taylor (1985) argues that shame is tied to the loss of self-respect, which defines what the individual feels is tolerable and what is not. Thus, unlike the social threat conception, shame is seen as occurring in response to the violation of internalized values, and the discomfort associated with the emotion concerns perceptions of the self. However, in emphasizing the ethical character of the emotion, this approach acknowledges the degree to which individual rely on others in forming their beliefs about what is right and wrong. Judgments about what is shameful are not externally imposed or arrived at in isolation, but they are socially negotiated.

This conception of shame is most clearly represented in criminological theory in Braithwaite's theory of reintegrative shaming. Reintegrative shaming according to Braithwaite is "conceived as a tool to allure and inveigle the citizen to attend to the moral claims of the criminal law, to coax and caress compliance, to reason and remonstrate with him over the harmfulness of his conduct" (Braithwaite 1989, p. 9). This suggests that shaming is important because of its educative value in developing or reinforcing beliefs about what is wrong. While the theory suggests that shaming can have a deterrent effect, as an informal sanction that threatens the loss of respect by valued other, this is considered secondary to its moralizing qualities. Braithwaite argues that the primary reason individuals do not commit crime is because they have commitments to shared moral norms and social institutions. Punishment is irrelevant to most people because committing serious crime is simply unthinkable to them. The socialization of children in families and schools about moral norms leads to a broad consensus about what acts should be crimes. In social contexts where there is a broad consensus that particular behavior is wrong and individuals are interdependent because of strong communities, those behaviors will be shameful. Individuals will feel ashamed for violating these values because, consistent with an ethical conception of shame, they have subscribed to these values.

Another approach that has likewise focused on shame's moral qualities is Wikström's (2004) situational action theory of crime, which argues that the emotion is a protective factor in preventing offending. Shame in this framework reflects the individual's commitment to do the right thing, which in turn influences their perception of the choices available in a given context. A number of studies have shown that juveniles who report that they would feel shame in front of others (e.g., friends) if they committed a crime also reported lower levels of delinquency.

Shame Management: The Different Faces of Shame

Evidence that feeling bad about one's actions can have both positive and negative consequences has turned attention to understanding why shame is a constructive emotion in some situations but is counterproductive in others. Why do we hope that some individuals feel shame for offenses they commit, yet also experience unease at the idea of imposing shame within criminal justice? A long tradition of research on shame emotions has explored variation in how individuals experience the emotion, and this, like more contemporary research on dispositions, has recently been drawn on to explore the notion of shame management (Ahmed et al. 2001). This theoretical perspective suggests that when confronted with feeling ashamed for their actions, individuals can manage or respond to the emotion in different ways and that this has important implication for criminal justice institutions.

Evidence of differences in shame experiences was first captured in the seminal work of psychiatrist Helen Block Lewis (1971). In her research with patients, Lewis identified three different forms of shame. The first, "acknowledged shame," involves the recognition that one feels shame and awareness of the feeling associated with it. "Overt-unidentified" shame describes the experience of feeling the negative emotion associated with shame but not recognizing it as shame and thus mislabeling it. "Bypassed" shame involves an awareness that an event may be shameful and doubt about how others see the self, but the emotion is bypassed leaving the person with "… an insoluble, plaguing dilemma of guilt thought which will not be solved" (Lewis 1971, p. 134).

One of the important findings from this work for understanding the implications of shame is that unacknowledged forms of shame are associated with feeling of anger and hostility towards others. Scheff and Retzinger (1991) extended Lewis's analysis by arguing that shame is a signal that the bond between the individual and others is threatened. When feelings of hurt associated with rejection are not acknowledged by the individual, as is the case in unacknowledged forms of shame (bypassed and overt-unidentified), then this emotion becomes redirected as anger towards the self and others. According to Scheff and Retzinger, this is the cause of humiliated fury and helps to explains not just individual anger but also conflict between nations. In both Lewis's and Scheff's accounts of shame, it is evident that when shame is not acknowledged, it manifests itself in an unhealthy reaction.

Eliza Ahmed and her colleagues (2001) have described the various manifestations of shame through the concept of shame management. This captures the notion that when confronted with a shame-inducing situation, individuals can manage the negative feelings in a variety of ways and that this is influenced by both individual characteristics and the social context. Acknowledged shame occurs when the individual accepts that they are responsible and thus acknowledges the emotion. It is argued that when shame is acknowledged, the person is more likely to make amends, feels less anger towards others, and is more likely to discharge the negative feelings. In contrast, unacknowledged shame, which Ahmed describes as displaced shame, occurs when the person does not accept that they are responsible. Failure to resolve the emotion, because of the tension between the disapproval of others and this denial of responsibility, results in shame being displaced into anger towards others.

There is growing empirical evidence that shame management predicts both bullying and criminal behaviors. Ahmed's own research in Australia and Bangladesh shows that children who are bullies are more likely to displace shame compared to children who haven't bullied, who are more likely to acknowledge shame feelings (Ahmed and Braithwaite 2006; Ahmed et al. 2001). These results have been partially supported in a study by Ttofi and Farrington (2008) which showed that displaced shame was a predictor of bullying, but did not demonstrate the expected relationship between shame acknowledgement and lower bullying. A similar result was found by Murphy and Harris (2007) in the context of white-collar crime. In this study, shame displacement predicted recidivism, but the relationship between shame acknowledgement and recidivism was mediated through a measure of remorse.

This research on shame management has significant implications for reintegrative shaming theory and has prompted a revision of the theory (Ahmed et al. 2001). While the revision does not alter the theory's prediction that reintegrative shaming reduces offending (while stigmatic shaming increases offending), it does clarify why this is the case as well as the role that shame plays. The original formulation of the theory implies that the benefit of reintegrative shaming is that it leads to greater feelings of shame in offenders. However, the implication of shame management is that reintegrative shaming reduces offending in most cases because it allows offenders to manage feeling of shame more constructively. Reintegration is more likely to result in offenders acknowledging shame, feeling remorseful for what has happened, and making amends. Stigmatization, on the other hand, is more likely to result in offenders displacing shame and feeling anger towards others. Thus it would seem, somewhat ironically, that the benefit of reintegrative shaming is that it allows offenders to resolve and diminish any shame that they feel.

The implication for criminal justice procedures that have drawn on reintegrative shaming theory, like restorative justice, is that the kinds of shaming or disapproval that are effective in those setting do not involve explicit attempts to shame offenders (Retzinger and Scheff 1996). Overt forms of disapproval, such as a focus on participants expressing their dislike of the behavior, may undermine the offender's ability to acknowledge and resolve feelings of shame. This may be exacerbated in those situations where it is culturally inappropriate to overtly disapprove of another or where offenders have already acknowledged wrongdoing. Processes like family group conferences instead focus on discussion of the consequences of the offenses for all parties. By focusing on how people have been hurt, they avoid stigmatization of the offender and allow them to express remorse and to make amends. Both of these behaviors, as well as acknowledgement and forgiveness by others, are important mechanisms for resolving shame.

An Ethical-Identity Conception of Shame

A critique of the empirical research on shame is that it fails to adequately explain the complex relationship between the individual and the social contexts in which shame occurs, either conceptualizing shame as a response to values that are extrinsic to the person (social threat conception) or having little to say about the social context at all (personal failure conception). Neither of these conceptions adequately accounts for repeated observations that shame is both intimately tied to identity and sensitive to disapproval of others.

To better explain the social context in which shame occurs, as reflected in the empirical research conducted on shame management, an ethical-identity theory of shame has been proposed, which draws on both the ethical conception of shame discussed earlier as well as insights from social psychology (Harris 2011).

The central claim of this approach is that the defining characteristic of shame is that it occurs when we experience a threat to our ethical identity. The precondition for this to occur is an awareness that we violated an ethical value that we subscribe to: we realize that we have behaved in a way that we feel is wrong or at least have significant doubts about how acceptable our behavior was. Even though shame is experienced in reference to internalized values, it is also sensitive to the opinions of others, firstly in making us aware that we might have violated a value that is important to our sense of self, but also because the opinions of others (those whose views we respect) contribute to our interpretation of our behavior.

Research on social influence and conformity suggests that a simple dichotomy between our own and others' values is too crude. A long history of research in social science demonstrates that values, attitudes, and beliefs held by individuals are influenced by others (Turner et al. 1987). Others' opinions are important because, as is illustrated by social identity theory, our values, attitudes, and beliefs, all part of our identities, are often shared with others. We expect to agree with those people whom we see as similar to ourselves, and it is disconcerting when we do not. The reason why disapproval results in shame is because it acts as a form of social validation, either reinforcing the belief that what we did was shameful or undermining the assumption that it was not.

Shame is linked to identity because violating one of our values only leads to shame if it undermines our sense of who we are. This threat to our ethical identity occurs because there is a reciprocal relationship between our values and who we think we are. Holding certain values is at the heart of personal or social identities because identities are defined in large part by sets of beliefs (e.g., "being nurturing" would be an important value if "mother" was an important identity). It follows that when we become aware that we have acted contrary to our values, our identity is called into question. The painful feelings of self-awareness, anger at ourself, and confusion that are associated with shame occur because the contradiction between our values and our behavior cannot be easily reconciled.

An important characteristic of shame is that it motivates us to resolve this dissonance between our actions and how we think of ourselves, and we are able to do so in a variety of ways. We can resolve the threat to our ethical identity by diminishing the significance of our behavior (either by concluding that there was a good excuse or reason for what we did or by making up for it in some way); we can respond by perceiving ourselves as having an alternative identity that is consistent with our behavior and in doing so rejecting any disapproval, or we may perceive ourselves as defective because we have failed to live up to our values.

It is hypothesized that the way in which we resolve this threat to ethical identity will also be influenced by the social validation we receive from others. This explains why individuals react differently to reintegrative shaming and to stigmatizing shaming. Disapproval of our behavior that is reintegrative, when it comes from those whom we respect, can reaffirm a positive ethical identity and thus encourage us to apologize and repair what we've done so as put our misdeeds within a larger positive story about ourself (Maruna 2001). Stigmatization makes this less likely because the message from others is that there is something defective about who we are. In this situation we are more likely to defend our ethical identity by deciding we had a valid reason for our behavior, we might feel very bad about ourself, or we might even decide that we have fundamentally different values to those who disapprove of us and embrace a deviant identity.

Conclusion

An important issue that has been at the center of emerging research on shame is whether it should be understood as a productive and useful emotion that allows offenders to reconsider their behavior or whether it is a dangerous and unhelpful emotion that may even promote greater offending. This question has been complicated by the various notions about what shame is and the various ways in which it has been incorporated into criminological research. However, it does seem clear that the answer is unlikely to be simply one or the other. This is unsurprising once we accept that shame is integrally connected to our belief systems, to our identities, and to our relationships with those around us. Research on shame management and an ethical-identity conception of the emotion of shame have sought to delineate the various ways in which individuals can respond to shame and have examined the consequences of these responses for both the individual and society.

Overview

Shaming plays a critical role in crime and punishment. Within the context of criminological theories, there are two different styles of shaming: stigmatizing and reintegrative. Shaming that stigmatizes is known as labeling. Through labeling theory, it has been widely recognized within criminological circles that having a negative criminal label (a stigma) contributes to the formation of a deviant self-image, which pushes offenders into criminal subcultures, facilitates the internalization of the deviant identity, and leads to secondary deviance (Becker 1973; Lemert 1951). In contrast, reintegrative shaming combines punishment with compassion and aims to rehabilitate and reintegrate individual offenders and restore broken relationships. While both types of approaches to crime and punishment have been practiced throughout human history, only relatively recently (since the 1980s) has restorative justice and reintegrative shaming caught the attention of scholars and policy makers in Western countries such as in the Unites States.

This entry first defines and describes shaming and its different forms. It then examines unique social conditions that are conducive to reintegrative shaming. Research has shown that unique social conditions, such as a high interdependency among individuals and communitarianism within a society, facilitate the use of reintegrative shaming (Braithwaite 1989). Asian countries, such as China and Japan, have been widely regarded as communitarian societies, and shaming has played an important role both in informal and formal social settings. To help illustrate the characteristics and nature of reintegrative shaming practiced in Asia, crime prevention and control programs, such as *bang-jiao* in China and *bizai shobun* in Japan, are assessed within the context of the individualism and communitarianism debate.

Shame and Reintegration

Within the context of criminology, shame refers to the disapproval of deviant acts and/or criminal wrongdoings by others and often in public. Shaming can take different forms. It can be as subtle as a frown, a slight shake of the head, or gossip. It can also be as direct as a verbal confrontation, a media broadcast, or an official pronouncement by a judge (Braithwaite 1989). Shame serves as an effective social control on two levels: (1) shame deters future criminal behavior through internally building conscience (guilt induction) and (2) shame also deters future criminal behavior by public disapproval through external referents (e.g., family members, teachers, neighbors, police officers) that set boundaries and reaffirms rules.

Developmental psychologists sometimes make the distinction between shame and guilt by depicting shame as a reaction to criticisms by others such as parents and neighbors, whereas guilt is induced internally after a wrongdoing (Braithwaite 1989). Others regard shaming and guilt induction as inextricably part of the same social process. They both imply certain moral expectations of the individual and the community.

Scholars argue that a culture that has a high set of moral expectations and reinforces these moral expectations through shaming will have a more effective social control than a culture that seeks control through strict law and punishment (Braithwaite 1989). This is because shaming implies that citizens have the responsibility to express public disapproval of behaviors that harm the community. The potency of this form of self-policing lies in its swiftness (in time) and intimacy (both in physical distance and social distance).

A new form of shaming – online shaming – takes shaming to the virtual world. Witnesses of an immoral/deviant incident, often out of frustration and outrage, may take pictures and post them online. For example, pictures of a South Korean woman who refused to clean up after her dog defecated on a train were posted online. This resulted in her being “shamed” by bloggers from all over the world. This newly emerged shaming obviously grew from modern technology but also out of the growing diversity, mobility, and fear of disorder and crime shared in modern societies. Online shaming essentially serves the function of peer surveillance, or lateral surveillance, and may help deter deviant behaviors and reaffirm moral boundaries (Skoric et al. 2010).

There are two types of shaming: reintegrative and stigmatizing. A reintegrative type of shaming has two essential components: (1) shame (public expressions of community disapproval) and (2) reintegration (efforts to reaccept the offender into the community). Community disapproval can range from a mild rebuke to a strong disapproval within a formal ceremony. Also, efforts at reintegration can range from a simple smile expressing forgiveness and love to a formal ceremony to decertify the offender as a deviant. Shaming is more potent when expressed and administered by significant others – parents, friends, and neighbors. This is because significant others tended to have a continuing and meaningful relationship with the deviants; thus, their opinions bear more importance to the deviants than would a stranger's or an institution's (i.e., the police, court officials). In addition, shaming is more effective when there is a goal of reintegration and restoration, rather than stigmatization and rejection. The best place to witness reintegrative shaming is the loving family. Within a loving family, disapproval is expressed while bonds of respect are maintained. Condemnation is made toward the deviant act, not the deviant family member. More important is the forgiveness and genuine gesture of reacceptance that leads to reintegration back into the family (Braithwaite 1989).

The stigmatizing type of shaming is disintegrative. It typically involves attaching a deviant label to the offender. Labeling is stigmatizing because it focuses on the public degradation process, the labeling of the deviant, yet with little attention on delabeling and reintegration. The deviant person, once labeled and stigmatized, is likely to become an outcast and pushed into the criminal subculture. The deviant behavior becomes their master status. A master status is a characteristic(s) that defines an individual. For example, a person could be a good athlete or a good student, but if they are caught for engaging in delinquent behavior and are labeled, this label trumps what they were characterized as being before. Consequently, it precipitates the outcast to internalize a criminal identity and reject any attempts at shaming and reintegration. This self-fulfilling prophecy happens as a response to shaming that dramatizes the offenders' evil.

Criminologists of divergent perspectives (e.g., rational choice, social learning, labeling) now recognize that most criminals do not reject criminal law outright. Instead, they rationalize their deviant actions by shifting the blame of their deviance onto others (e.g., "it's the victims' fault," "everybody else is doing it," "I did not mean it"). The ability to rationalize their deviant behavior allows the deviants to temporarily suspend their commitment to the law and insulates them from shame. In this process of rationalization, criminal subcultures provide the much-needed social support for the deviant behavior, particularly when legitimate opportunities are blocked due to negative labels. Within the world of criminal subcultures, deviant actions are rationalized as a defensible lifestyle – against the injustice and stigma often felt inflicted upon the outcasts. Deviance thus becomes a way of life. The more attempts that are made to reform the outcasts, the worse it becomes (Braithwaite 1989; Becker 1973; Lemert 1951).

Some societies are prone to reintegration, whereas other societies prefer punishment as a way of social control. In general, societies characterized as communitarian, with reciprocal relationships among its citizens, are more likely to shame reintegratively. Shaming within this context is likely to be more potent, resulting in lower crime rates, because disapproval is unlikely to be rejected. In contrast, societies characterized as individualistic, with its citizens interacting only out of necessity and convenience, are more likely to resort to punishment. Shaming in this context is less effective because stigmatization and punishment are likely to cut off the deviants' interdependencies with their mainstream social relations and push them into the criminal subcultural world.

In addition, shaming is culture specific. Similar public expressions of disapproval of a deviant act may be perceived differently. In the United States, for example, the same outward disapproval of a delinquent act in an Asian culture setting may be received differently than it would in an African American culture setting. This is based on the concept that the ideals and attitudes held by different cultures are not the same in regards to legal justice, norm violations, and the extent of the impact by external forces (Braithwaite 1989). Even within the same cultural context, different social organizations (i.e., family, neighborhood) may deliver various degrees/kinds of shaming. For example, a study on Chinese urban residents found that family members generally use shaming and reintegration highly when a family member deviated because acts of deviance reflect badly on the rest of the family and their ancestors. With the economic development since the 1980s, Chinese neighborhoods are transforming to be become more transient. The study found that residential mobility affected shaming practices in the neighborhood (making shaming less reintegrative) much more significantly than shaming practices within the family (Lu et al. 2002).

In sum, reintegrative shaming is likely to label only the deviant acts, whereas stigmatizing shaming is likely to label the actor. Reintegrative shaming is more effective at crime control than stigmatizing shaming, because reintegrative shaming minimizes the risks of pushing deviants into criminal subcultures, whereas stigmatizing shaming increases these risks. In addition, deviants who are embedded in relationships that are overwhelmingly characterized by social approval are more likely to respond positively to shame. In contrast, deviants, who are not in these types of relationships, are more likely to reject shaming and make it criminogenic rather than crime inhibiting.

Shame and Communitarianism

The effectiveness of shaming depends upon two interrelated social conditions: interdependency and communitarianism. Interdependency refers to the interrelationship among individuals. It is an individual level variable. Individuals with more interdependencies are more susceptible to shaming; thus, they are less likely to commit crime.

There is an overwhelming consensus among criminologists regarding factors critical to an individual's interdependent relationships. These factors include, but are not limited to, age, gender, marital status, education, and employment status. For example, studies have found that the most important correlate of interdependency is stage in the life cycle. Individuals are mostly likely to become a deviant between 15 and 25 years of age. The two life-defining events for deviants to go straight are getting married and having children (Braithwaite 1989).

Communitarianism is the antithesis of individualism. It is the combination of a dense network of individual interdependencies with strong cultural commitments to mutuality of obligation. There are three basic elements to communitarianism: (1) interdependencies densely enmeshed in all spheres of social life, (2) interdependencies characterized by mutual obligation and trust, and (3) interdependencies built upon group loyalty (Braithwaite 1989). Thus, while numerous interdependencies are a necessary condition for communitarianism, mere interactions among group members are not sufficient for the group/society to be characterized as communitarian.

In communitarian societies, communities are typically defined by social ties, such as in family or neighborhood, as well as other significant relationships such as fellow students and coworkers. These communities are held together by mutual dependency and the need for cooperative endeavor (typically in a strict hierarchical order based on an individual's group status and/or social roles) to function. Countries and/or tribes in many parts of the world, such as Asia and Africa, can be characterized as communitarian. Most Western societies may be identified as more individualistic rather than communitarian. As the economy progresses, societies become more urbanized, mobile, diverse, and individualized. While there may be an abundant amount of interdependent relationships in highly developed areas (i.e., Western societies), because of increasing economic activities (i.e., landlords and tenants, bank tellers and customers) and other activities accompanying the economic growths (i.e., the police and criminals), these interdependencies may be more out of necessities and convenience, opposed to mutual obligation and trust. Within this context of high individualism, shaming by communities becomes particularly challenging. This is because "As a society becomes more role-differentiated [as in a modern society], the potential for effective shaming increases in important ways, but so does the potential for stigmatization that cuts off effective shaming" (Braithwaite 1993, p. 15).

Shaming can be administered by private individuals (i.e., communitarian-based shaming), and it can also be administered by the state (i.e., state-sanctioned shaming). In most developed Western countries, shaming is handled by the state via the criminal-justice system. In contrast, communitarian based shaming is dominant in many developing nations where legal systems are not fully developed and accessible.

Studies have found that communitarian-based shaming is more effective than state-sanctioned shaming in two aspects. First, shaming delivered by people of high interdependency and within a communitarian society (i.e., family, friends) is more potent than when it is delivered by an impersonal state because of the constant contact the intimates have with the individual. Second, shaming by significant others is more likely to be expressed in ways that is reintegrative, compared to the shaming by an impersonal state. Offenders are less likely to be stigmatized and adopt an outcast master status. In this context, a communitarian society resembles an enlarged loving family, where reintegrative shaming works best.

Reintegrative Shaming and Its Effectiveness

Since its publication in 1989, the theory of reintegrative shaming has aroused great interest among scholars and policy makers. Several studies tested this theory in a variety of settings.

A study using adolescents (ages from 14 to 17) from a single urban area in a southwestern state of the United States examined the relationship between the adolescents' perceptions of their parents' sanctioning methods (reintegrative vs. stigmatizing) and their reports of predatory delinquency (Hay 2001). Findings of this study are largely consistent with Braithwaite's theory of reintegrative shaming in that the level of interdependency of the adolescent with the parents and the use of reintegration by the parent were statistically significant. Parental sanctions are a way to reinforce a close relationship within families that have strong interdependent relationships between parents and children.

Reintegrative shaming theory has been used as a valuable interpretive framework in some experimental studies. For example, a study on a drug court in a southwest state of the United States revealed that drug courts were perceived to follow more of the reintegrative shaming type of model than a traditional court that offered more of an assembly line type of service. However, drug court participants had a higher recidivism risk than nondrug court participants. A compelling explanation for the failure of drug courts is because the presumed comparability with RST in process and structure is not necessarily true. Drug courts may be more stigmatizing than general courts based on field observation data (i.e., the initial and second appearances in courts resembled more of a public degradation ceremony than reintegrative shaming). In addition, disapproval expressed by the judge may not be potent. Judges represent an impersonal state and may not be regarded by offenders as someone respectable or important. Furthermore, judges do not continue to have relationships with the drug users after seeing them in court (Miethe et al. 2000). In sum, the RST can be used to guide programs that are intended to restore offenders back into the community and can help those who manage and evaluate the programs to make them more successful.

Several studies examined family group conferences in Australia using reintegrative shaming theory. For example, a study examined basic conditions for a successful restorative/

reintegrative family conference and identified a list of key factors. First is separating the event and the offender. While the event may be defined as irresponsible, wrong, or criminal, the offender is ought to be supported and viewed as a whole person. Second, those who administer reintegrative shaming must represent all the interests involved (i.e., offender, victim, and the law) to mete out a fair and effective solution to the problem (i.e., the final goal is reintegration and restoration). Third, apology, repentance, and forgiveness must occur in order to terminate the separation of the offender and victim and to enforce reintegration rituals (Braithwaite and Mugford 1994). Another study on restorative justice conferences suggests that these types of conferences tended to have a greater and positive psychological impact on participants' view on the legitimacy of the law (Tyler et al. 2007).

Reintegrative shaming theory has also been applied to a study on nursing homes' compliance to regulatory rules in Australia. The study showed that the nursing homes that had inspection teams who had a reintegrative shaming philosophy (high disapproval and high reintegration scores) showed greater improvement in regulatory compliance, compared to inspection teams having other philosophies (i.e., tolerance [low on disapproval and high on reintegration] or stigmatizing [high on disapproval and low on reintegration]). In addition, the more interdependency between regulators and the nursing home managers, the more compliant the nursing home managers are toward the regulations (Makkai and Braithwaite 1994).

Despite the vastly different social conditions in Western and Eastern countries, scholars have also attempted to examine the validity of the claims made by reintegrative shaming theory in Asian countries. Using a sample of 1,725 adolescents (ages 11–17) in China, one study attempted to identify the general effect of reintegrative shaming theory and the predictive effect of delinquency disapproval (shaming) and forgiveness (reintegration) on delinquency involvement. The study found that parental shaming, parental forgiveness, and peer shaming had reduced the involvement of predatory offenses. However, when the interactive effect of shaming and forgiveness was introduced in the multivariate analysis, reintegrative shaming theory (represented by the interaction term of shaming and reintegration) did not appear to be a significant predictor of predatory offense involvement (Zhang and Zhang 2004).

The study in China, described above, generated somewhat mixed results about the theory. Nevertheless, it is generally believed that Asian cultures, such as in China and Japan, which are influenced by Confucianism and centered on family, frequently use shaming and guilt induction as means of informal and formal social control (Braithwaite 1989). This widespread use of shaming within the family model has been regarded as contributing to the low crime rates in these countries. In the next section, two unique crime prevention and control programs, *bang-jiao* in China and *bizai shobun* in Japan, are described in order to illustrate how the principles of reintegrative shaming work in these unique sociocultural contexts.

Reintegrative Shaming in Asia

Compared to individualism shown in Western countries, many of the countries in Asia are based on ideas of communitarianism. Due to strong Confucian influence, Southeast Asia in particular (e.g., China, Japan, Korea, Taiwan) holds high regards for social status, hierarchy, order, peace, and harmony. These values help promote conformity and submission to group interests. In contrast, the values fundamental to Western ideas of individualism – individual rights and freedom – are only placed in a relative context in these Asian countries.

As a result, a communitarian society prefers informal social control to formal social control. Collective citizen action is considered an effective strategy for maintaining peace and harmony, solving disputes, controlling crime, and reducing the fear of crime. To foster an effective informal social control, citizens are taught these social responsibilities through socialization, which is to behave appropriately according to group/social norms and rules. This takes place first and foremost within the family, then at school, in the neighborhood, and in the workplace. In addition, citizens are expected to help others observe the rules of ritual propriety and help educate and correct behaviors that deviate from the norms. This network of informal social control is largely operated on reciprocal interdependencies with mutual respect. The *bang-jiao* program widely practiced throughout urban neighborhoods in China represents such an informal social control model.

Bang-jiao and Reintegrative Shaming in China

One of the major differences between social control in China and Western countries is that the Chinese attempt to control both the behavior and minds of the people. In contrast to the Western concept of original sin, Confucianism assumes the goodness in people. Crime is thus viewed as the result of the environmental influence. To offset the negative influence of the environment and help individuals get in touch with the good of their inner selves, Confucius and his followers believed in the importance of the rule of *li* (moral code). This was because *li* was viewed as essential in fostering an internationalization of the basic moral principles, promoting voluntary compliance to the rule, and being virtuous and good. Confucius also believed in the power of education in shaping people's thoughts and behaviors. Moral awakening through thought education is considered the primary stabilizer of society (Chen 2002).

In this process of moral education, shaming is regarded as playing a critical role – a role that calls attention to the damage the deviant/criminal has done to the victim/community and a moral imperative to correct the wrongs and amend the broken relationships caused by the deviant/criminal act. To the Chinese, shaming can generate both negative (e.g., stigma) and positive (e.g., deterrence, rehabilitation) results, depending on the strategies (Chen 2002).

One strategy is early intervention. Nipping crime in the bud is common wisdom rooted in Chinese philosophy. Early intervention only requires a small dosage of shaming and small educational efforts could result in full reintegration. Even though early intervention may run the risks of intrusion into other people's lives, it is taken for granted and viewed not as meddling, but caring.

Another strategy is popular participation. Chinese social control is from the bottom up, not the top down. The Chinese prefer to handle their own crime and delinquency problems in their community rather than leaving them to the professionals. The popular participation approach ensures a swifter and more effective crime control service because those who deliver the service presumably have more intimate knowledge about the deviant person as well as the act and have more stakes in the quality of service.

The total approach is yet another strategy used in crime prevention and control. As China moves toward legalization and professionalization, greater emphasis is given to law and the legal professionals in addressing major legal issues such as crime. Nevertheless, legal professionals, such as the police and judicial officers, are expected to use all sorts of means (e.g., legal, administrative, and social) to prevent crime and reintegrate offenders. *Bang-jiao* in urban neighborhoods of China represents one such program.

Bang-jiao literally means, assisting, helping, guiding, and directing offenders, especially juvenile offenders (Zhang et al. 1996). It is a community-based program that utilizes remedial and preventative measures for controlling crime. Even though no particular group of individuals are excluded from the objects of *bang-jiao*, *bang-jiao* typically handles predelinquents, delinquents, deviants, and offenders who have committed minor offenses and are without a prior record. These groups of people are targeted, because they are the mostly likely to be "helped" (*bang*) and "educated" (*jiao*) successfully (13–28 years of age). Most *bang-jiao* programs are situated in urban neighborhoods, and they consist of parents, relatives, neighbors, teachers, coworkers, resident committee members, and/or local police who work as a team in carrying out *bang-jiao*.

Even though *bang-jiao* is community based and represents an extra legal measure to crime prevention and control, it still has some basic principles guiding its program. According to the Juvenile Delinquency Prevention Law (1991), *bang-jiao* must be conducted based on the following principles: (1) fairness and equality, (2) practical guidance, and (3) response to genuine repentance with love, emotional support, and sincere acceptance of deviants back into the community (Zhang et al. 1996).

The characteristics and process of a typical *bang-jiao* intervention can be illustrated with the following example. A teenage boy is sent to a work-study school for rehabilitation because of repeated thefts. After recommendations from his *bang-jiao* team and work-study school principals, he was transferred to a normal school. Every day he came home after dark, because he was too ashamed to be seen by his neighbors. The boy's mother finally talked to the *bang-jiao* team members. The team members visited the neighbors and found out that the neighbors wanted to communicate with the boy, not ridicule him, but did not know how. The *bang-jiao* team discussed how to overcome these barriers with the neighbors and decided to hold a community event in which they knew the boy was interested in and would participant in (community painting exhibition). They boy was invited and at the event he was highly praised for his work. This experience changed the boy, and he started being involved with community events and being a part of the community (Braithwaite 2002).

From a theoretical standpoint, reintegrative shaming facilitates this process of *bang-jiao*. Although little empirical research has examined the effectiveness of *bang-jiao* in deterring crimes and reducing recidivism rates, one study based on self-report data suggests there is a significant negative relationship based on reports by inmates living in communities with a *bang-jiao* program (Zhang et al. 1996). More specifically, the inmates who lived in neighborhoods with an active *bang-jiao* program reported a significantly lower likelihood of recidivism compared to those who lived in neighborhoods without an active *bang-jiao* program.

Even though crime rates, including juvenile delinquency rates, have surged since the economic reforms in the 1980s in China, the majority of juvenile delinquents were able to successfully have their deviant label removed and be reintegrated back into the community. This was supported with the low recidivism rate of between 8 % and 15 % annually in recent years (Chen 2002).

Bizai Shobun and Reintegrative Shaming in Japan

Similar to the Chinese view of the relationship between the individual and society, the Japanese see individuals not as an isolated entity, but as part of the network. There is a kind of social web that binds individuals into a collective. Within this largely communitarian society, punishment is not geared toward retribution, but rehabilitation and restoration.

Due to the importance of status and family to an individual, shaming has different meanings in the Japanese culture. Its potency can be different as well, particularly when compared with Western countries.

When assessing punishment, one of the criteria used in Western culture is severity of punishment (proportionality of punishment to crime), typically measured by the length of prison sentences and/or the amount of monetary fines imposed on the convicted offenders. In Japan, however, the focus is different. Contrary to isolation and punishment of the individual wrongdoer, the Japanese prefer restitution and restoration. Numerous terms, such as benevolent, paternalistic, and familiar, have been used to describe this reintegrative shaming practice unique to the Japanese. Among these different terms, an individualized decision-making model seems to best capture the Japanese crime control and prevention practice (Foote 1992).

The Japanese criminal-justice system is benevolent in that its goal is to achieve reformation and reintegration of offenders into society through lenient sanctions tailored to the offender's particular circumstances (Foote 1992). This benevolent-paternalism model emphasizes love and mutual respect so that the best interest of the offender and his/her rehabilitation is the focus of any decisions. The success of this family model depends on officers' use of widespread power of discretion. It not only permits but also expects public officials to use discretion and take a preventive approach to crime and disorder. The major factors officers consider include family circumstances, employment status, and other types of support mechanisms available to the offender and, to a lesser extent, satisfaction of the victim.

Central to the Japanese practice of restoration and reintegrative shaming are concepts of apology, repentance, and forgiveness. To apologize, the wrongdoer must first confess to the crime. The importance of confession in the Japanese criminal-justice system can hardly be overstated. Numerous scholars of the Japanese legal system concur that confession, apology, and begging for forgiveness are essential elements at virtually every stage of the criminal process in Japan. Confession and admission of guilt are not used as part of the plea bargain, but are regarded as a gesture of complete submission to authorities in Japan. Confession, accompanied by sincere apology and remorsefulness, is viewed as having both the probative and correctional value. It aids the police, the judge, and the correctional officers to better achieve the goals of holding criminal offenders accountable for their wrongdoings and reforming them into law-abiding citizens.

The ability of legal officials to exercise widespread discretionary power lies in the great faith that is bestowed on public officials. Legal officials enjoy great autonomy and widespread power sometimes beyond the legal spheres in Japan. When dealing with an offender, the classification scheme of legal (e.g., offense severity, prior criminal record) vs. extralegal (e.g., age, gender, employment) factors commonly used in Western countries may not be relevant in Japan. Instead, means of punishment/treatment will be considered favorably if they are least disruptive to the deviants'/criminals' life, fit individual circumstances, and most likely lead to the successful reintegration back into the community.

Reintegrative shaming as a punishment philosophy has been institutionalized in Japan. All three authorities in the criminal-justice system are given widespread discretion when disposing of cases. For example, the police have the authority not to report minor offenses (*bizai shobun*) (Code of /Criminal Procedure, art. 246), the prosecutors have the authority to suspend prosecution (Code of Criminal Procedure), and the courts have the authority to suspend execution of sentences (Criminal Code, art. 25).

Below the practice of *bizai shobun* is summarized to show how the police, in exercising their discretionary power, translate the philosophy of reintegrative shaming into practice.

The Japanese police enjoy widespread discretion when performing their crime prevention and law enforcement duties. For example, the Japanese local police have the authority to conduct residential surveys twice a year for the purpose of getting to know the residents, registering new comers, and preventing future crimes. The Japanese police officers may stop and question anyone in public without reasonable suspicion or probable cause. They also have the authority to interrogate a criminal suspect for a lengthy period of time without a warrant. The relative "crime-free society," combined with high citizen respect and cooperation in Japan, make the police even more powerful and free in using the tools at their disposal when dealing with criminal suspects. The Japanese police have a "quasi-judicial" function, especially when dealing with simple cases or cases involving petty offenses. One such power is discretion to drop trivial cases from further investigation and charges.

Bizai shobun is rationalized based on two principles: (1) when involving minor offenses, the police shall not put victims under undue psychological stress with an unnecessarily punitive punishment of offenders and (2) to enhance efficiency of the police work, police should focus on more serious crimes and use informal means in dealing with the less serious crimes (Arakawa 1987).

To maintain jurisdictional consistency, the police power of *bizai shobun* is granted by the prosecutor. Typically the supervising prosecutor's office will issue an order for specific types of trivial offenses to be dropped from further processing by the police. These trivial offenses commonly include assault, theft, fraud, embezzlement, and gambling. For example, in the early 1990s there were instructions for theft cases to be dropped under three conditions: (1) if the value of stolen goods did not exceed 10,000 yen ($85); (2) if the offender had a fixed residency, which excluded transients (particularly foreigners); and (3) if the offender repented (Johnson 2002).

It was estimated that up to 40 % of criminal suspects arrested by the police are released without any charges. Many of these cases were resolved through negotiation, apology, compensation, and forgiveness between the offender and the victim. Furthermore, victims, their family, and their community are critical in the police decision to employ *bizai shobun*, because they must be willing to accept the offender's apology and to forgive him/her. This is to ensure the successful reintegration of the offender back into the community.

Limitations of Reintegrative Shaming

One of the most fundamental criticisms of reintegrative shaming theory is its incomplete conceptualization of sanctions (Hay 2001). Braithwaite depicts sanctions as shaming, either reintegrative or stigmatizing, and makes the assumption that all deviance is detected and reacted to with some type of corrective action. However, deleterious reactions (no reaction) to deviance are common. Even if existing, some reactions to deviance may only intend to evoke fear of further punishment, rather than trying to evoke remorse/shame. Reintegrative shaming theory is thus regarded as incomplete, because shaming is not the only form of corrective reaction.

The concept of reintegrative shaming has the obvious strengths of maintaining continuous and interdependent relationships. However, shaming in communitarian societies (e.g., Confucian culture) may become too powerful and overwhelming, thus, having the risk of destroying robust individuation within secure social bonds. An example of the danger associated with engulfment of the individual is the high suicide rate in Japan and, to a certain degree, in China (Braithwaite 1989)

Reintegrative shaming theory is also limited in scope to personal and property offenses where there is a clear consensus regarding their moral wrongfulness (Hay 2001). In cases where societal consensus is unclear, such as white-collar crime, drug offenses, and public order offenses (e.g., prostitution, gambling), shaming may not take place (either not expressed by the public or dismissed by the wrongdoer), let alone reintegration.

Besides these conceptual challenges, reintegrative shaming theory faces difficulties of empirical validation. Some of the key concepts such as shame and reintegration are difficult to operationalize and measure with empirical data (Zhang 1995; Zhang and Zhang 2004). In addition, major moderating and mediating factors that may indirectly affect the potency of reintegrative shaming have yet to be established. For example, a study found that procedural justice (i.e., a sense of being treated fairly) affected how well offenders responded to efforts of reintegrative shaming (Tyler et al. 2007).

These issues of measurement are magnified particularly in cross-cultural settings where definitions and perceptions of shame may diverge markedly. A successful shaming program in one type of society (e.g., communitarian) may not work well in another type of society (e.g., individualistic).

Last, but not the least, shaming may run the risk of civil vigilantism. It is especially noteworthy of its potentially massive invasions of personal privacy in the online environment. An example involves the growing popularity of the "Human-Flesh Search" (*renrou sousuo*) in China where individuals' private records were dug out and posted on the website by Internet users for a variety of reasons such as personal revenge and resentment to corrupt public officials and celebrity. This counters the very intent of maintaining a civil and orderly society (Skoric et al. 2010). Within the criminal-justice system, reintegrative shaming programs may run the risk of widening the net of social control and blurring the line between moral and legal issues.

Conclusions

Reintegrative shaming, as practiced in China and Japan, place great faith on public officials – their personal morality, skills, and judgment – in making important decisions about law and order. By using extralegal means in dealing with essentially a legal matter, these criminal-justice systems runs the risk of corruption and undermining procedural transparency and the predictability and fairness of the decisions. Despite of these potential limitations, reintegrative shaming provides a plausible, alternative means for crime control and prevention. Reintegrative shaming has been demonstrated theoretically, and to a certain degree, empirically, to be more effective and efficient than the traditional means of social control.

Shoplifting

Jason Davis
Criminal Justice, Clayton State University,
Morrow, GA, USA

Overview

Shoplifting refers to the theft of retail merchandise during hours of operation (Clarke 2003; Hayes and Cardone 2006). This form of larceny is viewed as a minor offense that does not generate significant public outrage or fear. Furthermore, it lacks the sensational appeal that necessitates extensive media coverage or immediate legislative responses (Cromwell et al. 2006; Klemke 1992). Notwithstanding these perceptions, retail theft imposes significant financial and social harms. Each year, shoplifting costs companies billions of dollars in lost revenues or merchandise. Beyond these losses, however, retail theft entails additional financial costs. Companies allocate millions of dollars each year for security personnel and measures to help deter shoplifting (Tonglet 2002; Gills et al. 1999; Cox et al. 1993). In some cases, retailers pay higher insurance premiums because they experience high rates of theft (Burrows 1998; Finklea 2011). Shoplifting can also adversely affect honest patrons. To offset financial losses, companies levy a "consumer tax" in which merchandise prices of commonly pilfered items are substantially increased (Cox et al. 1993; Schwartz and Wood 1991). Customers can also be inconvenienced by cumbersome security measures such as cable locks, key controlled glass cabinets, or other equipment that limits accessibility to merchandise (Tonglet 2002; Cox et al. 1993; Dawson 1993). Finally, state governments and local communities lose tax revenues that could be generated from stolen merchandise.

Beyond the financial tolls, shoplifting can prompt safety and domestic security problems. Unsuspecting customers or employees can be injured by fleeing or aggressive shoplifters attempting to avoid apprehension (Axelrod and Elkind 1976). A 2011 survey found that 13 % of retail crime apprehensions involved some level of physical assault or battery (National Retail Foundation 2011). When perishable goods such as infant formula and over-the-counter drugs are shoplifted, fraudulently repackaged, and sold on the open market, customers can unknowingly consume outdated or spoiled products (Finklea 2011; National Retail Foundation 2011). Finally, shoplifting by professional or organized retail theft (ORT) rings has been linked to money laundering, organized criminal syndicates, and the funding of terrorist activity (National Retail Federation 2011; Finklea 2011).

This entry provides a general overview of shoplifting. Specifically, it discusses the financial losses associated with shoplifting and how these figures likely underestimate the true costs of shoplifting. Next, a typology of shoplifters will be offered with primary attention given to amateur and professional shoplifters. A discussion of common shoplifting targets and techniques will follow as well as an examination of the theoretical explanations used to help understand why offenders engage in shoplifting. Finally, this entry will review common antishoplifting measures utilized within the retail industry and summarize their effectiveness.

Financial Estimates of Shoplifting

No other property crime including robbery, burglary, or auto theft can match the financial impact of shoplifting. Estimates have consistently shown that retailers lose anywhere between $10 and $50 billion dollars annually to shoplifting (National Association for Shoplifting Prevention 2012; National Retail Foundation 2011; Centre for Retail Research 2011; Clarke 2003). A recent study found that shoplifting cost US retailers approximately $12.1 billion (National Retail Federation 2011). In 2010, a global retail theft survey discovered that shoplifting incidents cost 1,187 retailers representing 43 countries $51.5 billion (Centre for Retail Research 2011). While the financial costs attributed to shoplifting are staggering, it is generally understood that these figures grossly underestimate the true extent of the problem (Burrows 1999; Dabney et al. 2004; Clarke 2003).

Dilemmas Associated with Shoplifting Estimates

Underreporting is a major problem associated with shoplifting data as only one-third of all thefts get reported to the police (Dabney et al. 2004; Clarke 2003). When shoplifting is officially reported, few incidents result in a formal record or prosecution (Klemke 1992; Dabney et al. 2004; Clarke 2003). Instead, law enforcement is more inclined to issue a warning or have the charges downgraded to a misdemeanor or violation offense (Dabney et al. 2004; Clarke 2003). Many retail companies are reluctant to formally report shoplifting and thus contribute to underreporting dilemmas (Burrows 1999). Part of the hesitancy may stem from legal obstacles. Stores may be unaware of shoplifting statutes, or they may be dissatisfied with the weak laws or outcomes that insufficiently punish offenders (Axelrod and Elkind 1976; Burrows 1999). In lieu of formal responses, companies more commonly seek civil restitution from the offenders. Companies may also be reticent about disclosing adverse shoplifting information (Burrows 1999). Publicity about shoplifting could alert potential offenders about a store's security vulnerabilities, alarm shareholders about potential crime problems, or signal that costly security measures are ineffective (Burrows 1999; Axelrod and Elkind 1976). Even if retailers suspect customers of shoplifting, they are apprehensive about accosting them because of a fear of litigation resulting from false arrest or imprisonment (Axelrod and Elkind 1976). Some stores are equally worried about the risk of embarrassment and loss of reputation that false arrests could yield. Collectively, there appears to be reluctance to report, classify, or respond to shoplifting as a serious felony offense.

Beyond underreporting dilemmas, sources of shoplifting information including police records, victimization or self-report surveys, and industry level data are problematic because they fail to directly measure shoplifting (Burrows 1998). For instance, shoplifting is coalesced into the larger category of larceny-theft in the Uniform Crime Report, and therefore, it is impossible to discern what percentage of thefts can be attributed to shoplifting. The National Crime Victimization Survey (NCVS) neglects shoplifting altogether since it focuses on individual victimization, not crimes committed against organizations (Burrows 1998). Store-generated data suffers similar measurement limitations. Since only a small percentage of offenders are detected at the time of the offense, store security managers or personnel must "guesstimate" what percentage of loss can be directly attributed to shoplifting (Dabney et al. 2004). Through the use of routine audits, companies measure the disparity between merchandise physically present in a particular store and financial statements regarding sold merchandise (DiLonardo 1997). Such audits determine levels of *inventory shrinkage* or shortages in inventory levels. The greater the amount of unaccounted merchandise, the more revenue lost. With the exception of employee theft, shoplifting is generally considered the second most common source of inventory loss (Hayes and Cardone 2006). In most cases, estimates maintain that roughly 33–43 % of all retail losses are caused by shoplifting (National Retail Foundation 2011; Centre for Retail Research 2011). Nevertheless, without direct observation, it is not feasible to parse out what percentage of inventory shrink is actually shoplifting related (Dabney et al. 2004). Indeed, a study relying on surveillance cameras observed more shoplifting incidents than were formally reported to law enforcement (Dabney et al. 2004). The authors concluded that shoplifting incidents from a single retail drug store approximated the total number of all larceny-theft cases reported to police in the metropolitan Atlanta area over the course of 1 year. Such findings call into question the reliability and validity of both formal and store-generated estimates regarding the prevalence and financial impact of shoplifting (Dabney et al. 2004).

Shoplifting Typology

Research has consistently identified two categories of shoplifting offenders: (a) amateur or opportunistic shoplifters and (b) professional shoplifters that generally operate as part of an organized retail crime (ORC) ring (Clarke 2003). To a lesser extent, studies have also acknowledged the existence of compulsive shoplifters known as kleptomaniacs (Blanco et al. 2008).

Amateur Shoplifters

The majority of shoplifters are considered amateurs who steal relatively inexpensive merchandise for the purpose of personal use or consumption (Cameron 1964; Cox et al. 1990;

Clarke 2003). In many cases, amateur shoplifters lack a clear motive for stealing as many offenders possess the resources to legitimately purchase merchandise or they may not have an immediate need or desire for the products they steal. Accordingly, amateur shoplifting is typically viewed as an opportunistic crime in which offenders steal goods when they perceive relatively easy opportunities to do so. Some amateurs envision shoplifting more as a challenge and thus steal to see if they can get away with it. Amateur shoplifting also tends to be impulsive and infrequent. Their acts of theft are generally unplanned, and many steal only a few times a year (Cameron 1964). Overall, amateurs are not committed to a criminal lifestyle (Cameron 1964; Clarke 2003). Formal detection or apprehension is generally enough to deter future offending (Cameron 1964).

Amateur shoplifting is not confined to a small subgroup of offenders (Cox et al. 1990). Instead, a sizeable number of people have shoplifted at some point in their life (Cameron 1964; Cromwell and Thurman 2003). According to the National Association for Shoplifting Prevention (2012), an estimated 1 out 11 people or 27 million people have shoplifted. Not surprisingly, there is not a prototypical profile of a shoplifter. Amateur shoplifters are a demographically diverse group. Various studies have concluded that men and women are equally likely to steal as are young and old and people of various ethnic backgrounds and social classes (Klemke 1992; Dabney et al. 2004; Blanco et al. 2008; Asquith and Bristow 2000; Dawson 1993; Tonglet 2002; Cromwell and Thurman 2003; Cromwell et al. 2006). While the influence of demographic characteristics has been inconclusive, behavioral clues may be stronger predictors of shoplifting. Shoppers who leave a store without purchasing an item, scan the store for security measures, or tamper with products are more likely to steal (Dabney et al. 2004).

Organized Retail Crime (ORC): Professional Shoplifting

Unlike amateurs, professional shoplifters are more inclined to steal merchandise for the purposes of reselling stolen goods for a profit (Cameron 1964; National Retail Federation 2011; Finklea 2011). This category of shoplifters tends to be more organized and skilled, steal merchandise more frequently, and target more expensive items. It is estimated that roughly one-quarter of shoplifting cases are committed by professional shoplifters (Finklea 2011). Professional thefts are generally part of a larger criminal network known as organized retail crime (ORC). At its core, ORC networks involve a relationship between *boosters* and *fences*. Boosters steal merchandise and sell these goods to fences for approximately 10–30 % of the retail value of a stolen product (Cameron 1964; Finklea 2011). For their part, fences purchase, conceal, or transport stolen merchandise. Fences use a variety of business such as small “mom and pop” community establishments, pawn shops, flea markets or swap meets, convenience stores, and online auctions to dispose stolen goods (Cromwell and Olson 2006; Finklea 2011). In some cases, the fences may represent organized crime or terrorist operations. Fences typically supply boosters with “fence sheets” that specify desired merchandise, the value or profit margin for stolen goods, and stores that commonly carry preferred items (Cromwell and Olson 2006). Some mid- or higher-level fences ostensibly operate legitimate warehouses that in reality remove security tags, store labels, repackage goods, or alter expiration dates from stolen merchandise (Finklea 2011; Cromwell and Olson 2006). The “cleaned” stolen goods are amalgamated with legitimately purchased merchandise and reintroduced on the open market. In addition to professional fences, there is the existence of part-time fences who occasionally buy stolen merchandise primarily for personal consumption. In other instances, barters exchange professional services or drugs for stolen merchandise. These nonprofessional fences do not purchase a high volume of stolen merchandise nor do they rely on fencing as their primary source of income (Cromwell and Olson 2006). The advent of online internet auction sites such as eBay has created another outlet for professional shoplifters to dispose stolen goods.

Known as *e-fencing*, this form of disposing stolen merchandise is potentially more lucrative as professional shoplifters can earn approximately 70 cents on the dollar for stolen goods (Finklea 2011).

Kleptomaniacs

While amateurs and professionals are the ubiquitous shoplifters, there is a smaller category of offenders known as kleptomaniacs who are unable to resist the temptation to steal and generally steal items they do not have a conceivable use for (Blanco et al. 2008). Historically, the term kleptomaniac was used to describe females who had an uncontrollable urge to pilfer (Hayes and Cardone 2006). More recently, kleptomania is considered a psychological disorder in which a person experiences intense feeling of anxiety prior to stealing and a sense of gratification or release after stealing (Blanco et al. 2008). It is generally believed that kleptomaniacs also suffer from other psychological disorders such as impulsivity, mood disorders, or obsessive-compulsive behaviors that compel them to steal.

Common Shoplifting Targets and Techniques

Common Shoplifting Targets

A general sample of items generally shoplifted include but are not limited to music, games, electronics, apparel, batteries, tobacco products, infant formula, and over-the-counter (OTC) medicines (Clarke 1999; Clarke 2003; Hayes and Cardone 2006; Finklea 2011). Clarke's (1999) CRAVED model focuses on six attributes that make certain targets vulnerable. In particular, items that are *concealable, removable, available, valuable, enjoyable, and disposable* are deemed *hot products*. On the whole, shoplifters commonly target merchandise that can be easily concealed and avoid stealing merchandise in large quantities or items too large to conceal for fear of attracting too much attention (Carroll and Weaver 1986). Both amateur and professional shoplifters will target widely available merchandise especially new attractive products such as cell phones, computers, video games, and apparel. While professional shoplifters typically steal merchandise that will garner greater profit margins, novices including adolescent offenders may be driven to steal merchandise that holds personal worth or cultural value. Finally, the CRAVED model predicts that shoplifters, particularly professional shoplifters, are more inclined to steal merchandise that is easy to sell or convert into cash.

Common Shoplifting Techniques

In its simplest form, shoplifting involves the illegal concealment of merchandise in one's clothing or hand. While some brazen shoplifters may simply grab goods and leave the store quickly, both amateur and professional shoplifters utilize a variety of methods to illegally pilfer retail merchandise. Research has noted that many shoplifters work in teams with some members serving as lookouts to alert the thieves about potential dangers (Hayes and Cardone 2006). Listed below are select shoplifting techniques commonly identified by researchers and practitioners (Hayes and Cardone 2006; Clarke 2003; Finklea 2011; DiLonardo 1997):

- **Booster boxes or bags**: Shoplifters use a special foil-lined dummy box or bag that has false bottoms or openings to hide stolen merchandise. The foil lining is designed to weaken electronic article surveillance (EAS) tag signals so that they do not activate or trigger the alarm upon departure from a store. In other situations, shoplifters will conceal stolen goods within a legitimately purchased boxes or bags including televisions boxes, computer boxes, sporting goods merchandise, suitcases, dog food bags, or safes.
- **Diversions**: Working in groups, one or more shoplifters will create some type of diversion (pretending to slip and fall, faking an illness or injury, dropping or breaking merchandise, knocking down a display cabinet or shelve, or triggering a fire alarm). While store employees are distracted, other shoplifters will steal merchandise.

- **Fitting room**: Shoplifters will take several items or garments into a fitting room where they will wear the stolen clothing or conceal items in a bag or purse.
- **Clothing or *crotchwalking*** This shoplifting method occurs when an offender wears large baggy clothing to hide merchandise. In some cases, shoplifters wear special clothing (i.e., coats, shirts, pants) that contains multiple hidden pockets to help conceal merchandise. Some female offenders will wear large maternity clothing to give the appearance of being pregnant while concealing merchandise.
- **Receipt manipulation**: In some instances, shoplifters will make a legitimate purchase and take the item to their vehicle. Thereafter, they will return to the store and steal the same item listed on the receipt. If stopped by employees or store detectives, the shoplifter can present the receipt as proof of a legitimate purchase. Days later, the shoplifter may return the legitimately purchased item for a full refund. In other cases, shoplifters may use discarded receipts found in the parking lot, trash bins, or store floor to steal the items listed on the receipt. The disposed receipts can also be used for refund purposes. The shoplifter may pick up the items listed on the dispensed receipt and seek a cash refund.
- **Smash and grab**: This form of theft occurs when a group of shoplifters typically steal a car or sports utility vehicle (SUV) and drive it through a storefront window. Once the vehicle has smashed through the store, shoplifters quickly grab and pack the car with as much merchandise as possible before driving away.
- **Price tag switching**: This refers to the fraudulent removal of price tags or bar codes from expensive merchandise and replacing them with cheaper price codes.

Theories of Shoplifting

Empirical studies have concluded that there is not a solitary factor that causes a person to engage in shoplifting (Cromwell et al. 2006; Tonglet 2002). Instead, shoplifting behaviors are shaped by a range of factors. Many view shopping as a crime of opportunity, while other perspectives assert that offenders view shoplifting as a trivial offense that does not cause harm. Some frameworks maintain that shoplifting is related to age-specific factors. Finally, research has argued that psychological needs or disorders may be a determinant of shoplifting behaviors.

Opportunity Perspectives

Some of the prevailing theories of shoplifting including routine activity theory (RAT) and opportunity structure for crime can be classified as theories of opportunity. Partially rooted in rational choice principles, these opportunity theories assert that would-be offenders take advantage of perceived easy opportunities to offend after careful consideration of the potential risks and rewards associated with a particular act (Clarke 1997). Opportunity theories also focus on the importance of the crime setting (Clarke 2003). In the context of shoplifting, opportunity theories are interested in understanding how the retail environment contributes to the prevalence of shoplifting. Shoplifters will seek stores with weak or ineffective security measures because they believe the benefits of shoplifting (procuring something for free) outweigh the risk of apprehension (Gills et al. 1999). Indeed, many shoplifters perceive retail pilfering as a low-risk offense that requires minimal effort, abundance of opportunities, and substantial gains (Tonglet 2002).

Routine activity theory maintains that crime occurs when a *motivated offender* comes into contact with *suitable targets* in the absence of *capable guardianship* (Cohen and Felson 1979). The convergence of these three factors in time and space represents a crime triangle. Routine activity theory is ideally suited for understanding shoplifting. Retail environments bring potential motivated offenders into contact with suitable targets including small, portable, and desirable goods that can be easily concealed. To the extent that retail environments lack adequate surveillance or security measures, motivated offenders will take advantage of the lack of guardianship and shoplift valuable targets.

Touted as an integrated theory that incorporates elements of environmental criminology, rational choice, lifestyle, and routine activity theory, Clarke's (1997) opportunity structure theory asserts that the physical environment influences opportunities for crime. Immediate situational or environmental factors dictate the supply of *targets* (objects), *victims* (vulnerable individuals), and *crime facilitators* (weapons) necessary for offending. To this end, retail environments play an important role in creating or reducing shoplifting opportunities. Through personal experiences, peer associations, or the media, would-be offenders learn the risks, effort, and rewards associated with specific stores, and they will target those with the greatest vulnerabilities or relatively easy opportunities to steal. In this context, retailers must manipulate the environment and implement target-hardening devices to decrease opportunities for offending. Research indicates that shoplifters do in fact evaluate store characteristics when deciding whether or not to steal (Carroll and Weaver 1986). In particular, experienced shoplifters assess store layouts for security devices, counter heights, or behavior of store staff in order to identify potential risks. The presence of these factors is enough to deter most expert shoplifters.

Techniques of Neutralization

Another explanation for why people shoplift is techniques of neutralization theory (Sykes and Matza 1957). This perspective asserts that most offenders hold conventional norms or attitudes, and they must rely on rationalizations to help neutralize the guilt and shame associated with offending. Potential offenders use a priori excuses that allow them to drift into criminality while temporarily suspending their moral convictions. In its original conception, Sykes and Matza (1957) identified five different techniques of neutralization that offenders use to justify criminal behavior including *denial of responsibility* (offending is beyond person's control), *denial of injury* (offending behavior is trivial and does not really harm anyone), *denial of victim* (victim deserved to have a crime committed against them), *condemnation of the condemners* (if authority figures engage in unethical behaviors with impunity, then others should be allowed to engage in similar acts), and *appeal to higher loyalties* (commitment to peers or peer pressure caused offending behavior). Recent research has identified at least seven other neutralizations including *defense of necessity* (offending is a matter of survival for basic or essential needs), *metaphor of the ledger* (crime offsets unfair conditions or can settle a grievance), *everyone else is doing it* (certain crimes are common), *denial of the necessity of the law* (laws are unfair), and *sense of entitlement* (offender should enjoy certain privileges) (Cromwell and Thurman 2003).

Studies have found that shoplifters typically use one or more justifications to help neutralize their illegal pilfering (Tonglet 2002; Cromwell and Thurman 2003; Clarke 2003). Many offenders hold proshoplifting attitudes and perceive pilfering as a relatively trivial offense that does not significantly harm the overall sustainability of profitable retailers (*denial of injury*). Some shoplifters imply that they had little control over their actions (Cromwell and Thurman 2003). This *denial of responsibility* neutralization would be consistent with shoplifters who suffer some psychological compulsion or addictive behavior to engage in theft. In other instances, offender attitudes are congruent with a *denial of victim* perspective. Many people view large organizations as wealthy and somewhat ruthless entities (Schwartz and Wood 1991; Clarke 2003; Dawson 1993). Accordingly, shoplifters are less likely to experience feeling of guilt, remorse, or shame about stealing from impersonal stores. Such antagonistic attitudes about retailers may also reflect a *metaphor of the ledger* justification in which they view shoplifting as a sense of entitlement or compensation for unfair treatment or price markups by indifferent companies (Schwartz and Wood 1991). Other shoplifters may utilize a *defense of necessity* justification in which offenders assert they had to steal in order to survive or because they did not possess the resources to make a legitimate purchase (Cox et al. 1990; Cox et al. 1993; Cromwell and Thurman 2003). A recent study identified two other neutralizations including *justification by comparison* and *postponement* (Cromwell and Thurman 2003). Offenders using the former rationalization maintain that if they were not shoplifting, they would be committing more serious offenses, while those exploiting the latter neutralization momentarily delay any thoughts about the offending behaviors. In essence, people that use postponement do not think about their crime.

Age-Specific Reasons

Motivations to shoplift can also be age specific. Studies of juvenile shoplifters have discovered that adolescents steal for thrill or novelty reasons (Cox et al. 1990; Cox et al. 1993). In addition, social desirability is a motivation for adolescent shoplifters. Juveniles steal popular merchandise including electronics or clothing in order to enhance their status among peers. In some cases, juveniles steal items that they are too young to legally purchase or too embarrassed to buy such as cigarettes, alcohol, or condoms (Cox et al. 1990). Interestingly, there is little evidence to suggest that juvenile shoplifters are directly affected by peer pressure, dares, or status attainment (Cox et al. 1993). There is also evidence that juvenile shoplifters may not be deterred by antishoplifting security measures or formal apprehension (Klemke 1992). Apprehension by parents, store personnel, or the police can actually increase the likelihood of future shoplifting for adolescent shoplifters presumably because deviant labels propel the offender, particularly female shoplifters, to commit future acts of pilfering (Klemke 1992).

Psychological Factors

Some argue that shoplifting represents coping mechanism to address stressful life events or psychological problems including depression, anxiety, bulimia, anorexia, substance addiction, financial hardship, or relationship problems (Lamontagne et al. 2000; Blanco et al. 2008; Schwartz and Wood 1991). For instance, bulimics may steal food to address eating disorders, while people who suffer from anorexia may steal clothing or beauty products to enhance their physical appearance (Schwartz and Wood 1991). Stress can also contribute to shoplifting behaviors. There is evidence that people who are experiencing stressful life events like marital problems, employment or financial problems, or health issues shoplift as a coping mechanism (Schwartz and Wood 1991). These psychological perspectives assert that shoplifting generates excitement and produces an adrenaline rush or high that temporarily subdue feelings of anger, frustration, or depression (Blanco et al. 2008). Shoplifters may also suffer some sort of psychiatric disorder generally related to pathological gambling, bipolar disease, nicotine dependency, or alcohol abuse. In support of psychological perspectives, research has noted that shoplifters are indeed more likely to seek mental health treatment compared to nonshoplifters (Blanco et al. 2008).

Common Antishoplifting Measures and Their Effectiveness

In accordance with the basic tenets of opportunity theories, many antishoplifting measures focus on manipulation of retail environment or target-hardening measures. Clarke's (1997) situational crime prevention model proposes 16 different techniques designed to make crime opportunities less attractive. The various techniques are designed to (a) increase the effort associated with offending, (b) increase the perceived risks of crime, (c) reduce the anticipated rewards of criminality, and (d) remove the excuses to offend. Some of the crime reducing-measures include target-hardening devices, formal and natural surveillance, access control, entry and exit screening, ink security tags, property identification, and warning signs. Several of these techniques are well established within the retail industry. Stores commonly use target-hardening devices like locks, safes, cabinets, mechanical cables, security tags, or benefit denial tags. Most retailers employ various forms of formal surveillance such as store security officers, employees, closed-circuit televisions (CCTVs), or dressing room attendants. Stores display dummy products or empty boxes as a means of removing the benefits of shoplifting. Finally, companies use warning signs about the prosecution of apprehended offenders or signs that indicate a store is under formal surveillance. Collectively, these security measures emphasize the importance of physical store layout, staff and security personnel, and target-hardening devices that help monitor, detect, and apprehend potential shoplifters.

Physical Store Layout

In many ways, the physical layout of a store can facilitate the commission of shoplifting (Carroll and Weaver 1986; Burrows 1998). Most store layouts openly display merchandise and encourage self-service. In addition, the size of most stores makes it difficult to effectively monitor all merchandise and customers simultaneously. Stores typically have multiple exit points, display merchandise near exits, or have high shelves that obstruct viewing angles. Therefore, retail stores provide easy access to valuable and concealable goods in the absence of effective surveillance (Clarke 2003; Tonglet 2002; Cox et al. 1993).

Accordingly, retailers employ a variety of techniques intended to manipulate the store environment, increase the level of surveillance, and reduce the opportunities to steal. For instance, stores create wide aisles to help alleviate congestion and create clear sight lines for employees to easily monitor customer behavior. Stores use convex mirrors and adequate lighting that enables staff to monitor the store from multiple angles. Merchants commonly monitor entry or exit points with employees, detectives, CCTVs, or audible alarm antennas. Smaller items are placed near checkout counters for increased visibility. Finally, stores like to maintain neatly ordered or arranged shelves so that employees can easily notice irregularities (Clarke 2003). While the presence of various security measures is necessary, retailers face the challenge of balancing a customer-friendly environment with an overly intrusive security atmosphere. The inclusion of too many cumbersome, intrusive, or highly visible crime prevention tools can make legitimate customers feel uncomfortable or alienated (Dawson 1993).

Staff and Security Personnel

Research indicates that employees and security personnel are the most important factor in reducing shoplifting (Gills et al. 1999; Clarke 2003; Hollinger and Dabney 1994; Dawson 1993). When sales associates immediately approach and greet customers, make eye contact with them, or consistently offer assistance, it sends a signal to would-be shoplifters that they have been noticed and are being monitored. Indeed, shoplifters report that they are less likely to steal if they believe they are being closely scrutinized or watched by alert employees or store detectives (Gills et al. 1999). Not surprisingly, shoplifters prefer environments in which workers are disinterested in providing quality customer service. They also prefer stores that are routinely understaffed so that employees are too busy to monitor customer behaviors. Furthermore, stores that have high turnover rates or rely heavily on part-time workers undermine effective shoplifting surveillance efforts (Hollinger and Dabney 1994). In these situations, workers are less committed to the company, lack security training, and have limited experience or awareness of shoplifting clues. To be sure, company commitment to equitable treatment of its employees and low turnovers significantly lower levels of inventory loss (Hollinger and Dabney 1994).

However, misuse or abusive employee surveillance can lead to lawsuits. Since untrained employees may misinterpret customer behaviors, they may inadvertently confront and detain innocent customers (Axelrod and Elkind 1976). In addition, employee racial biases or prejudices can affect surveillance efforts. For example, several retail companies including Eddie Bauer, Lord & Taylor, and The Children's Place have settled civil suits amid accusations that store security personnel unfairly monitored, accosted, or apprehended ethnic customers.

These high-profile cases have drawn attention to a phenomena of *consumer racial profiling* (CRP) in which employees and store detectives target shoppers, primarily African Americans, on the basis of race and ethnicity, not necessarily suspicious customer behavior (Gabbidon and Higgins 2007; Asquith and Bristow 2000). Several African Americans report that they have been victims of retail racism in terms of poor service, excessive monitoring, or being looked upon with suspicion by employees or security personnel (Gabbidon and Higgins 2007). Such practices overlook white customers who are equally as prone to shoplift as other customers.

Target-Hardening Devices: Electronic Article Surveillance (EAS) Tags

Introduced in the late 1960s, EAS tags are antishoplifting protection systems that have been widely adopted by the apparel, music, and general retail industries. In general, EAS tags are detachable devices affixed or pinned to merchandise that must be removed or deactivated by a sales associate at the time of purchase. Transmitter stands strategically placed near exit doors are designed to trigger an audible or silent alarm if a customer passes through the transmitter with an active EAS tag. Not only do EAS tags provide physical obstacles to shoplifting, they provide a psychological deterrent as potential offenders are reluctant to risk activating an alarm that alerts store security or employees (DiLonardo 1997; Dawson 1993). A multiyear study of several retail apparel stores found that stores that used EAS tags experienced significant declines in inventory shrinkage, while shortages among retailers without EAS tags actually increased by 30 % during the same time period (DiLonardo 1997). Overall, shoplifting and inventory shrinkage rates have been successfully reduced by 35–75 % after the introduction of EAS systems (DiLonardo 1997).

Other studies, however, have found that EAS tags do not deter shoplifters. Many shoplifters note that EAS tags are easy to remove with pliers or other tools (Gills et al. 1999). In some instances, shoplifters are able to use specially designed foiled bags that stunt the ability of transmitters to sound an audible alarm. More brazen shoplifters simply walk out of the store even if the alarm is sounded. The errant functioning of EAS tags can also contribute to their ineffectiveness. Stores that experience a high number of false alarms triggered by system malfunction or sales associates that fail to remove or deactivate sensor tags risk the potential of offending customers and losing their patronage (Dawson 1993). Legitimate customers are likely to feel embarrassed, annoyed, or upset by inadvertent EAS alarms. Perhaps more importantly, customers may be subject to unwarranted suspicion or scrutiny from security personnel and other customers. Beyond the potential of tarnishing a retailer's image and reputation, false alarms can levy financial costs in the form litigation and punitive damages (Dawson 1993). Another consequence of errant EAS tags is related to the fact that customers, staff, and security may, over time, become desensitized to the alarms.

Despite the best efforts of retailers, evidence suggests few antishoplifting measures including cameras, security tags, mirrors, or prosecution warning signs effectively deter the motivation of pilfers (Gills et al. 1999; DiLonardo 1997). Closed-circuit televisions (CCTVs) are considered ineffective by many shoplifters because they cannot capture quality indisputable images (Gills et al. 1999). Furthermore, shoplifters maintain that most stores have natural blind spots that make it impossible for cameras to monitor. Warning signs that imply all shoplifters will be prosecuted if detected similarly have little impact on the motivation to steal. Shoplifters typically believe the most stores will not go through the trouble of going to court or legal proceeding to recoup relatively inexpensive merchandise (Gills et al. 1999). While some shoplifters acknowledge that ink tags are more challenging to defeat, offenders will still target dye-tagged merchandise primarily because they lack an audible alarm. Once shoplifters effectively remove the merchandise from stores, they have plenty of time to carefully remove the tag (Gills et al. 1999). Even if shoplifters are deterred, the effect is temporary as most will attempt to discover new means to defeat security impediments (Gills et al. 1999). Since the chances of being detected and apprehended are relatively low and the possibility of stiff criminal sanctioning is equally low, shoplifters associate minimal risks with this type of crime and therefore are not easily deterred (Gills et al. 1999; Clarke 2003; Burrows 1988).

Overview

Crime relies, directly or indirectly, upon an array of factors, ranging from the levels of concentration of wealth to the physical organization of the urban center under consideration. Modeling the highly interconnected nature of this social system has recently attracted attention in computer science. As experiments in this domain cannot be performed without high risks, because they result on loss of human lives, simulation models have been chosen as supporting tools for this process. Multiagent systems (MAS) primarily study the behavior of autonomous and organized groups of software agents with the purpose of providing solutions to complex problems that could not be achieved by each individual agent alone. Multiagent-based simulation systems have been successfully adopted because the inherent characteristics of the agents (e.g., autonomy, sociability, and pro-activity) facilitate the construction of more dynamic models, thus contrasting with conventional computer simulation approaches.

Other different approaches, dubbed in general as bio-inspired approaches, have recently been investigated in conjunction with MAS for crime modeling. Collective intelligence as that demonstrated by swarms and the evolutionary approach are two of the most prominent concepts and have been used in the design of crime models. Here, an overview of these concepts from a decision support perspective is done in order to describe how they have been applied for the development of multiagent-based crime simulation (MACS). Two particularly relevant issues in the MACS context are discussed: model calibration and model evaluation.

Fundamentals

According to Russell and Norvig (1995), an *agent* is a physical or abstract entity that can be viewed as perceiving its environment through sensors and acting on the environment through actuators. Ferber (Ferber 1999) considers a multiagent system (MAS) as comprising (i) an environment; (ii) a set of passive and active objects (agents); (iii) an assembly of relations, which link objects to each other; and (iv) operations making it possible for the agents to perceive, produce, consume, transform, and manipulate objects. One can distinguish three levels of organization of agents (Rocher and Sherif 1972): micro-social, groups, and global societies. The micro-social level concerns the interactions between agents and the various forms they relate to one another. The level of groups and of societies refers to the dynamics of intermediate structures like organization and cities, respectively. Multiagent systems have been successfully adopted in conjunction with simulation models, which are generally referred to as multiagent-based simulation (MABS) systems. According to Gilbert and Conte (1995), MABS are especially appropriate when one has to deal with interdisciplinary problem domains. Such an approach, which is bottom-up in nature, is also appropriate for the study of social and urban problems, since social or urban environments are dynamic, nonlinear, and composed of a great number of variables and entities. The main objectives behind the construction of MABS systems are the following:

- To test hypotheses related to the emergence of macro-level behavior from interactions occurring at micro-social levels
- To build theories that can contribute to a better understanding of sociological, psychological, and ethological phenomena
- To integrate partial theories coming from different disciplines (e.g., sociology, cognitive psychology, and ethology) in a common theoretical framework

A particular kind of simulation, called geosimulation, addresses an urban phenomena simulation model with a multiagent micro-social approach to simulate discrete, dynamic, and event-oriented systems (Benenson and Torrens 2004). In geosimulated models, simulated urban phenomena are considered a result of the collective dynamic interaction among animate and inanimate entities that compose the map representation. The Geographic Information System (GIS) is responsible for providing the "data ware" in geosimulations.

The study of agent self-organization and related concepts, such as emergence, is another important concept within micro-social MAS. The basic idea is that societies of agents demonstrate intelligent behavior at the collective level out of simple rules at the individual level. Moreover, these individual rules often do not explain the behavior that is attained at the collective level. Swarm intelligence is characterized (i) by strictly local communication, (ii) by the formation of emergent spatial–temporal structures, and (iii) by the agent's making stochastic decisions based on the local information available. One of the branches of swarm intelligence is ant-colony optimization (ACO), proposed by Bonabeau et al. (1999). ACO is a meta-heuristic model for solving combinatorial problems that can typically be represented as graphs. ACO gets inspiration from other areas of science, in this case, biological sciences having the special feature of adapting well to dynamic settings.

In a nutshell, ACO works by allowing agents (ants) to explore a search space, but it requires these ants to leave feedback information about locations with good solutions on the space itself. Agents are then attracted by the feedback left in the environment – the larger the amount of information (pheromone), the more attractive the agents find the position in the environment. In order to avoid early convergence to local optima, the approach assumes that the information left is volatile and impermanent; if no other activity occurs, a piece of information left in the environment "expires" or disappears over a certain period of time. Although never explored as a model for criminal behavior, ACO's characteristics appeared from the start to be an ideal fit to this purpose, as we will discuss later. Briefly, it allows for investigating variations of a learning process with or without a social factor.

Genetic algorithms (GAs) (Holland 1975) are general-purpose search and optimization algorithms that comply with the Darwinian natural selection principle and with some principles of population genetics to efficiently design (quasi-) optimal solutions to complicated computational and engineering problems. Such meta-heuristics maintain a population of chromosomes, which represent plausible solutions to the target problem and evolve over time through a process of competition and controlled variation. The more adapted an individual is to its environment (i.e., the solution is to the problem), the more likely such individual will be exploited for generating novel individuals. In order to distinguish between adapted and non-adapted individuals, a score function (known as fitness function) should be properly specified beforehand in a manner as to reflect the main restrictions imposed by the problem.

Micro-Social Level for Crime Simulation

Despite the existence of several works on MABS that investigate aggregated features of crime by means of macro-simulation, tools for police planning have essentially focused on the micro-social level. These latter follow a conceptual framework defined upon the following features: the environment into which the agent is inserted, the agents (their perceptions, productions, transformations, and objects manipulation), and the interaction between them.

The environment is a space, which generally has a volume (Ferber 1999). The agents are situated in the environment or interact with objects inserted into it. In MACS, the environment can be real or artificial. Typically, when the designer wants to reproduce the real environment, Geographic Information Systems (GIS) using digitalized maps of a geographic area for representing, for instance, streets (Groff 2008), are used. Artificial environments reproduce the main features of a geographic area via abstractions such as grids (Brantingham and Tita 2008) or graphs. Despite the claim of Elffers and Van Baal (2008) that the use of real representation in MACS is not so relevant as the quality of the model, there is a trend in this direction mainly because it facilitates evaluation by visual comparisons. Another way to model the environment is by means of cellular automata (CA) typically to represent static objects. CA is a discrete model of regular grids in which the state of a cell at time t is a function of the status of a finite number of neighborhood cells at time t-1. Examples of environments modeled as a CA can be found in Liu et al. (2005).

The related work on MACS has typically been based on the routine activity theory (RAT) (Cohen and Felson 1979), which states that in order for a criminal act to take place, three elements must coexist: a motivated offender; a suitable target, either an object or a person that can be attacked; and the absence of capable guardians in charge of preventive actions. Therefore, most of the micro-social crime models are based on these three kinds of agents: criminals, guardians, and targets.

On a micro-social level, the criminal agent tries to commit crimes or to move. Each criminal is endowed with a limited view of the environment, measured in terms of a radius following a predefined unit of measure. Criminals have one or more points of departure that we are going to call “gateways.” Such points of departure represent places where criminals are likely to start out, e.g., their residences, metro stations, and bus stops, before committing crimes (Wright and Decker 1994). Target selection is typically probabilistic, based on factors such as target vulnerability, distance between the criminal and the target, and the criminal’s experience. The decision whether to commit a crime or not is made based on the existence of guardians within the radius of the criminal’s sight.

The criminal behavior can be modeled with a learning component that exploits the agent’s experience as well as with information coming from other criminal agents. The success rate of individual agents can be computed as the ratio of the number of successful crimes to the overall number of crimes attempted in their lifetime, as in Furtado et al. (2008), or based on preferences of criminals computed from data mining and based on discrete choice theory (Xue and Brown 2006). Criminals form communities wherein hints are shared. Due to the interconnection of the communities, such hints could be relayed to other criminals in other communities, and the rate at which this happens depends directly on the topology of the network of communities.

Usually there is a set of guardians (police or not) available, each one associated with a target area. A guardian can have a route of length *n*, which is defined as a set, and each component of which is a triple composed by the target area, the interval of time the guardian remains at the target, and the daily period (patrol shift) the routes refer to. Guardians can demonstrate deterministic or stochastic behavior. A deterministic guardian will always move to the same target area and at the same pace predefined as an input parameter. Police guardians are modeled following real data, since these data are available and known by police institutions. However, finding good routes can be an important goal in order to understand the impact of police patrol on crime prevention or reduction. In Reis et al. (2006), a genetic algorithm system called GAPatrol is devoted to the specification of effective police patrol route strategies for coping with criminal activities happening in a given artificial urban environment, which, in turn, mimics a real demographic region of interest. The approach underlying GAPatrol allows for the automatic uncovering of hot spots and routes of surveillance, which, in real life, are usually discovered by hand with the help of statistical and/or specialized mapping techniques.

Notice that, while many simulation studies are aiming at understanding and analyzing the role of various assumptions about the behavior of the respective agents as a function of the ever-changing constellation of other agents and, hence, have a theoretical emphasis (cf. Birks & Elffers, Gerritsen & Klein, this volume), we like to stress here the use of simulations as a means to study the resulting pattern of offender agents and victim agents as a function of various strategies that guardian agents, especially police agents, could have. This use of simulation modeling exploits the method for investigating various possible police strategies on the simulated offence pattern and, hence, has a more applied character.

The locations to be chosen by criminals are referred to as targets, which can be differentiated with respect to their mobility. Commercial/entertainment establishment such as drugstores, banks, gas stations, lottery houses, and malls are fixed, while mobile targets are, e.g., citizens in movement. In Brantingham and Tita (2008), citizen movement is modeled according to the Levy probability distribution, while Furtado et al. (2008) and Liang et al. (2001) have concentrated their study on crimes against property, hence modeling only fixed target.

Targets have a state of vulnerability that can be either active or inactive. A vulnerable target means that it is perceivable by a criminal. Otherwise, it would not take part in the set of high-priority choices of that criminal. In this case, each target must have a probability of being vulnerable, which can follow a distribution based on past real crime data for the associated target type or based on the preference of criminals (Xue and Brown 2006). In Liu et al. (2005), a tension factor was introduced in the model by measuring the impact of crime events on human beings. After a crime in a region, the tension increases, while the vulnerability decreases. The attractiveness of a target can vary depending on cost and reward factors related to the selection of the target such as the location, income, and race composition of the area based on census data. In Furtado et al. (2008), an exponential temporal distribution is used and varies on a daytime basis. For each period and type of target, a value for a configurable parameter, λ, must be determined at the start of the simulation in order to define the pace of occurrence of crimes. For instance, in the evening, drugstore robberies may follow a distribution based on a given value for λ; whereas, in daylight periods, the crime temporal distribution might shift, achieving values four times higher for λ. At any simulation tick, at least one target is made vulnerable in accordance with the temporal distribution associated with its related type. The state of vulnerability is essential as a parameter to control the pace of crimes per type as happens in real life. However, one of the limitations of using values for input parameters from historical real-data analyses, e.g., the pace of crimes (the λ parameter), is that the simulation model will not be capable of identifying a change in the pace of crime occurrences if that change occurs during the simulation time. This problem becomes more significant as the simulation time increases.

Modeling the Interaction Between Agents

Direct interaction means that agents communicate with each other by means of message exchange and/or because they are part of a community or society. In order to be part of a society, it is imperative for an individual to establish social links with other peers. Different forms of interaction among the same individuals, even considering small groups, may take place simultaneously and may vary at different paces through time. One usual means to represent and analyze the (evolving) social structure underlying an organization of individuals is by resorting to the concept of social networks. Roughly speaking, a social network alludes to any formal, graph-based structure where individuals are represented by nodes and the social relationships that unite them are represented by links (ties) between those nodes. The topology of a social network is an important issue to be considered in the analysis thereof, as it helps to determine the network's usefulness (from the viewpoint of the individuals that participate in the network).

The social interaction and learning aspects that underlie criminal activities were investigated in Sutherland's seminal work (Sutherland 1974) in which the differential association theory was proposed. This theory advocates that interaction with others who are delinquent increases the likelihood of someone becoming and remaining a delinquent. That is, peers can play a crucial role in the development of values and beliefs favorable to law violation. In this theory, Sutherland elaborates nine postulates, out of which two are particularly relevant from a perspective of direct agent interaction:

- Criminal behavior is learnable and can be especially learned through the interactions one establishes with other persons, typically through a verbal communication process.
- The main part of the learning of criminal behavior occurs within intimate personal groups.

*A*nother important result coming from works investigating social network models within the context of criminology is that social networks are a natural way to explain the concentration of crimes per area. Crime data analyzed from different regions, and even countries, usually reflect the fact that there are huge spatial (but also temporal) variations in the crime rate between different cities and between different regions in a city. In this regard, Glaeser et al. (1996) show that less than 30 % of the spatial variation of crime (both inter- and intracity) can be explained by differences in local attributes. The remaining 70 % can be explained by social interactions, which means that the agents' decisions about crime are somewhat positively correlated. The authors also show that the impact of social relations is greater in thefts, burglaries, assaults, and robberies (i.e., crimes against property) than in homicides. It is worth mentioning the work of Bosse et al. (2007), which created a model to simulate social learning of adolescence-limited criminal behavior, and the work of Furtado et al. (2008), which designed a model in which social networks are used to model criminal communication. In the latter, the authors showed that the goal of the crime model of generating a power-law spatial distribution of crimes was correlated to the communication aspect modeled via the social network.

Indirect interaction is modeled by means of objects or variables sharing, typically represented in the environment. Other kinds of non-intentional forms of communication that are sent by diffusion or propagation into the environment, like signals, are also used. Ferber (1999) alerts to the limitation that the lack of semantics of signals can provoke. Since the signal is propagated in the environment, all the agents living there can perceive it. A cry of a citizen can be perceived by a guardian as a call for help as well as used by a criminal as a discovery of a potential prey. One important feature of these signals is that their intensity decreases with the distance from the source and with time. The concepts of tension (Liu et al. 2005) and conductivity (Dray et al. 2008) previously mentioned are examples of indirect interaction.

An example of a hybrid approach that uses direct and indirect communication is that of Furtado et al. (2008). Here, communication between the agents was proposed from the concepts of ant-based optimization augmented with a social network. In this model, criminals prefer to commit crime in locations known to be vulnerable, with high payoff, etc. In other words, their choice considers their preference and knowledge about the crime points. The link here to ACO is that, according to this approach, ants always choose their next location in the environment (the place they move toward) biased by a mechanism (the pheromone marks) of indirect interaction. Another indirect communication strategy that ACO offers is that it includes concepts intrinsically related to the notion of "collective." In ACO, ants perform their local search tasks without dictating the whole colony's behavior, which, in turn, is recognized as an emerging result coming from all these local activities. Each criminal has three possible actions: commit a crime, not commit a crime, and move to a certain location. In order to reach a decision whether to commit a crime or not, criminals make use of a probabilistic approach which is adapted from the context of ant-based swarm systems (Dorigo and Stützle 2004).

Key Issues

In MABS, the calibration of the model is a crucial step of the design process (Malleson, this volume). These models are typically characterized by the existence of a lot of parameters, which together determine the general behavior of the model. The development and the parameter setting of MABS models can be long and tedious if there is no accurate and systematic manner to explore the parameter space.

Genetic algorithm has been studied as an alternative for parameter calibration in MABS. The basic idea is to consider the tuning process as an optimization problem. The optimization function for the MABS would be the distance between the artificial model and the real system. In MACS, the calibration of certain parameters in which the complexity is high deserves special attention, e.g., the place from where each criminal starts out to commit crimes. Examples of these initial locations, here called gateways, are bus stops, metro stations, and slums. Usually there is no real data or theoretical model to help one configure those gateways in a crime simulation model. Moreover, it is a combinatorial optimization problem, i.e., the problem of assigning criminals to gateways. More formally, let $G = \{G_i, i = 1, \ldots, N_g\}$ be the set of gateways and $C = \{C_j, j =, \ldots, N_c\}$ be the set of criminals under consideration. The goal is to allocate each C_j to a G_i in a way that a quality measure F, somehow related to the aim of the simulation model, is maximized. In this allocation process, any gateway can be assigned to a criminal and all criminals must be allotted to one, and only one, gateway. Besides, more than one C_j can be assigned to a given G_i (i.e., we have not imposed any limit over the number of criminals assigned to a gateway). Since this assignment problem is combinatorial in nature, the number of feasible gateway configurations is an exponential function of the number of possible gateways.

As important as the calibration of guardians in gateways is the calibration of the number of criminals. There is no real data to help on that and even estimations are very tough to do. Also, this number can change during the simulation or remain constant. Typically in many models, the number of criminals is constant during a simulation. The absence of mechanisms that could implement variability in the number of criminals, such as arrests, can be justified when the ultimate goal is to find good police patrol routes. Considering constant the number of criminals means that crime reduction is only attained by preventing a potential criminal from acting. We could say that, by doing so, there is a preparation of the model to work in the worst of the scenarios, i.e., no way to reduce the number of potential criminals. Thus, the preventive police-planning goal is to define strategies to cover the urban space in a way that could prevent crimes from occurring; events that change the number of criminals are irrelevant.

Social sciences have struggled with this topic due to the difficulty to conduct experiments in controlled environments. MABS have emerged as a tool for social analysis in a way similar to natural controlled experiments. However, model evaluation is one of the biggest challenges of MABS and MACS in particular. A typology for validation must consider the following aspects. The first aspect regards constructing validity to account for the difference between the real world and the rendering of the simulated environment. The challenge here is to design a model representing an approximation that won't be too detailed or similar to the real world because, in this case, the model loses its pragmatic value, and rather than testing theories, it only enumerates what happens under a specific and limited set of conditions. On the other hand, the model must fit the purpose for which it has been created without variables that would bring excessive and unnecessary complexity. The second aspect refers to the internal validity of the model, also called verification. Basically, it refers here to the reliability of the software in generating a determined result from the inputs and processing function for which it was designed. Minor bugs and ill-defined implementations can be responsible for results that falsify the experiments. The third aspect refers to the external validity, meaning how reliable generalizations of the model are for populations lager than the samples. Statistical conclusion validity is another important aspect to be considered in terms of MACS evaluation. Typically, MACS are stochastic and their variation and unpredictability pose problems in the establishment of statistical validation. The identification of regularity that deviates from chance is essential in that context. This must be done across simulation runs in order to be convincing. Finally, they describe the need for models to be evaluated as to their empirical validity via comparisons with real data. In geosimulation, for instance, visual comparisons between hot spots generated from simulations are plotted on maps for comparison with real-data hot spots. Several studies conducted in different countries and different contexts have shown that crime is not uniformly distributed in space and that some victims or targets have a much greater risk of victimization than others (Pease 1998). The temporal dimension also presents a nonuniform distribution with different types of crime having different rhythms (their periodicity) as well as time (their rate of occurrence). In Johnson et al. (2007), an analysis showing how crime clusters in space and time was provided. Following victimization at one's home, those nearby experience an elevated risk of victimization, which decays as time elapses. Another strategy for validating simulation models is to find patterns in real data that indicate crime distribution instead of only relating to the exact numerical values. Doing so, it is possible to compare the results of the simulation with expected distribution of events.

Notice that the use of simulation for investigating possible police strategies is, to some extent, less hampered by the type of problems we have discussed in the present section. In such applications we simply vary the parameters governing the guardian (police) agents, in a way that they represent the strategies to be tested. Actual parameters about the police process (e.g., number of officers available at particular times, priorities) may be available from the police force for whom the simulation is run, thus limiting the variability and hence the number of simulations to be run.

Future Directions

Simulation of criminal activities in urban environments is an asset to decision-makers seeking to find preventive measures. Law enforcement authorities need to understand the behavior of criminals and their response in order to establish safety measures and policies. A conceptual framework for micro-social multiagent-based crime simulation was described involving concepts from Computer Science and AI in particular. Special attention was given to calibration and evaluation aspects, since they constitute open issues demanding further investigations and techniques.

Future investigations in the calibration field are in fact advance in terms of decision support systems, since some parameters like a police patrol route and criminal–gateway composition can shed light on non-understood aspects of preventive policing. In this context, such investigations are expected to provide satisfactory answers to questions like: How far from the optimal patrol routing strategies are those that are actually adopted by human police managers? How complex do such optimal patrolling routes need to be in terms of their total lengths and urban area coverage?

Overview

This chapter introduces Situational Action Theory (SAT) and its key arguments:

Crimes are moral actions. There are many different types of actions that may constitute a crime, but what they all have in common is that they break a rule of conduct (stated in law) about what is the right or wrong thing to do (or not to do). What distinguish crime is thus not that they are a particular kind of action but that they are acts the breach rules of conduct (stated in law) and, therefore, need to be studied and explained as such.

People are the source of their actions, but the causes of their actions are situational. To explain the causes of acts of crime we need to understand the situational factors and processes that move people to break rules of conduct (stated in law). People are different and so are also the settings (environments) to which they are exposed. Acts of crime (particular acts of crime) occur when particular kinds of people (person propensities) encounter particular kinds of settings (environmental inducements) creating specific kinds of interactions that make people see certain action alternatives and make certain choices.

Social and developmental factors and processes are best studied and explained as causes of the causes. To explain the role of social and developmental factors and processes in crime causation, we need to understand how they (as causes of the causes) affect people's crime propensities and how they impact settings (environments) levels of criminogeneity and how they influence the spatiotemporal convergence of crime prone people and criminogenic settings (creating the interactions that may result in acts of crime or certain types of acts of crime).

Situational Action Theory: Background and Main Aims

Situational Action Theory (SAT) aims to explain *why* crime happens and the role of social and developmental factors and processes in crime causation (e.g., Wikström 2006, 2010; Wikström et al. 2012, pp. 3–43). It was specifically designed to overcome some recurrent problems in criminological theorizing such as the unclear definition of crime (i.e., the ambiguity about what a theory of crime aim to explain), the lack of a satisfactory action theory (i.e., the poor understanding of what it is that moves people to engage in acts of crime), and the poor integration of levels of explanation (e.g., Wikström 2010, pp. 212–216; Wikström et al. 2012, pp. 3–10). The argument is not that all criminological theories fail on all these points, but it is just that they generally fail on one or more of these points.

SAT seeks to integrate key insights from main person and environment-oriented criminological theories and research, and relevant social and behavioral science theories and research more generally, within the framework of an adequate action theory. SAT advocate an analytical criminology, a criminology that focuses on the identification and detailing of the key mechanisms involved in crime causation rather than the production of lists of statistically relevant correlates and predictors (often referred to as risk factors) of which most, at best, are likely to be only markers or symptoms and, therefore, lack any causal relevance (e.g., Wikström 2006, pp. 66–69, 2011, pp. 53–60).

Basic Assumptions About Human Nature and Social Order

Situational Action Theory is based on the key assumptions that humans are essentially *rule-guide actors* and that social order is fundamentally based on people's adherence to shared rules of conduct. People vary in their personal morals (personal rules of conduct) and settings vary in their moral norms (shared rules of conduct). A personal moral rule is held and enforced (through the process of self-control) by the actor, while a moral norm is held and enforced (through the process of deterrence) by (significant) others. Explaining human action (such as acts of crime) requires understanding how people's actions are influenced by the interplay between personal morals and perceived moral norms of the setting (environment), a problem that has been largely ignored in criminological theory.

SAT assert that humans have *agency* (powers to make things happen) but that they exercise agency (i.e., express their desires (needs) and their commitments and respond to frictions) within the constraints of rule-guided choice. The theory acknowledges that there are elements of predictability (habit) and “free will” (deliberation) in people’s choices. Explaining human action (such as acts of crime) requires an understanding of the role of agency (how it works) within rule-guided choice, a problem that has seldom (if at all) been treated in criminological theory.

Crime as Moral Actions

Criminological theories rarely specify or clearly analyze what it is they aim to explain. This is an important common omission since an explanation has to explain *something*. Without clearly defining what it is that is to be explained, it is difficult to unambiguously identify putative causes and suggest plausible causal processes that may produce the effect under study (e.g., acts of crime). A cause has to be a cause of something, and what that something is determines possible causes (and relevant causal processes).

Situational Action Theory argues that crime is best analyzed as moral actions. SAT defines morality as value-based rules of conduct about what is the right or wrong thing to do (or not to do) in a particular circumstance. *Crime* is an act that breaks a rule of conduct stated in law (rules that may be quite general or quite specific). What defines crime is thus not any particular type of action but the fact that carrying out a particular action (or refraining from carrying out an action) in a particular circumstance is regarded as breaching a rule of conduct (stated in the law).

Any particular action can, in principle, be defined as a crime, and there are variations over historic time and between places (e.g., countries) in what kinds of action are regarded as crime. Moreover, specific actions, like hitting or even shooting another person, may be considered crimes in some circumstances but not in others. The advantage of conceptualizing crime as breaches of rules of conduct (stated in law) is that it makes a general theory of crime possible by focusing on what all kinds of crime, in all places, at all times, have in common, namely, the rule-breaking. What is to be explained by a theory of crime causation is thus why people (follow and) breach rules of conduct stated in law. A theory of crime causation may be regarded as a sub-theory of a more general theory of moral action. The law is just one of many sets of rules of conduct that guide people’s action (e.g., Ehrlich [1936] 2008). The law is no different from other sets of rules of conduct; in fact, the law may be regarded as a special case of rules of conduct more generally. Explaining why people follow and break the rules of law is, in principle, no different from explaining why people follow and break rules of conduct more generally.

Analyzing crime as moral action does not imply a “moralistic” approach (no judgement whether existing laws are good or bad, just or unjust, needs to be made). However, SAT does not assume moral relativism (i.e., that all moral rules are equally likely to emerge). Common moral rules may be grounded in human nature and the problem of creating social order (see further Wikström et al. 2012, pp. 13–14). The explanation of why we have particular moral norms (and laws) and why people follow or breach moral norms (and laws) is different analytical problems. Importantly, people may breach a moral rule of conduct (stated in law) because they disagree with or care less about the rule (or their ability to exercise self-control is not strong enough to make them adhere to their own personal morals when faced with a temptation or provocation).

The Situational Model: Kinds of People in Kinds of Settings

People are different and so are the settings to which they are exposed. When a particular kind of person is exposed to a particular kind of setting, a particular situation (perception-choice process) arises that initiates and guide his or her actions in relation to the motivations he or she may experience. The elements of the situational model are the *person* (his or her relevant propensities), the *setting* (its relevant inducements), the *situation* (the perception-choice process that arises from the exposure of a particular person to a particular setting), and *action* (bodily movements such as speaking, walking, or hitting). A setting is defined as the part of the environment (objects, persons, events) that is directly accessible to the person through his or her senses (including any media present).

SAT proposes that variations between people in their *crime propensity* (i.e., the tendency to see, and choose, particular crimes as an action alternative) is essentially a question of their *law-relevant personal morality* (the extent to which their personal morality corresponds to the various rules of conduct stated in the law) and their ability to exercise self-control (which depends both on dispositional characteristics such as executive functions, and momentary influences such as intoxication and levels of stress – see Wikström and Trieber 2007).

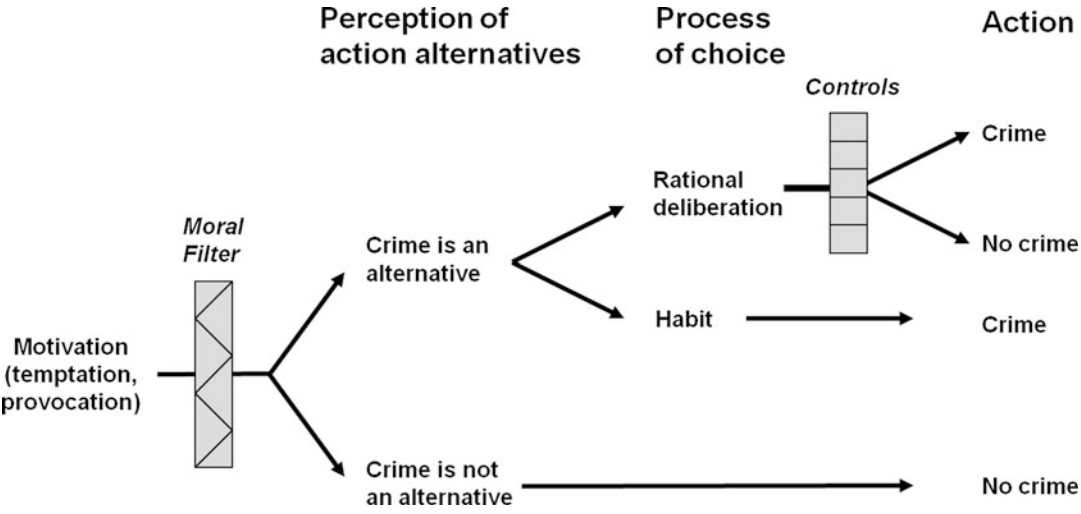
People will vary in their propensity to see a particular kind of crime as an action alternative not only depending on their personal moral rules but also depending on their moral emotions. *Moral emotions* (shame and guilt) attached to violating a particular rule of conduct may be regarded as a measure of the strength with which a person holds that particular rule of conduct. For example, while many people may think it is wrong to steal something from another person, some may feel very strongly about this while others may not. Those who feel less strongly about stealing from others may be regarded as having a higher propensity to perceive such action as an option.

People vary in their *ability to exercise self-control* (i.e., their ability to act in accordance with their personal morality when it conflicts with a perceived moral norm of a setting). The ability to exercise self-control exerts its influence through the process of choice and is only important in the explanation of crime when a person deliberate over several potent action alternatives, of which at least one involve an act of crime. The concept of self-control in SAT is different from that of self-control in Gottfredson and Hirschi's (1990) General Theory of crime (see further, e.g., Wikström 2010, pp. 228–234). Crucially SAT makes a clear distinction between self-control as situational process (the process by which a person manage conflicting rule guidance) and people's abilities to exercise self-control.

SAT further proposes that the *criminogeneity of a setting* depends on its (perceived) moral norms (the extent to which it encourage or discourage the breaking of particular laws in relation to the opportunities a setting provides and the frictions it creates) and their level of enforcement through the process of deterrence (note that if a moral norm encourages the breaking of a particular law, a high degree of its enforcement will be criminogenic). *Deterrence* is defined as "the process by which the (perceived) enforcement of a setting's (perceived) moral norms, by creating concern or fear of consequences, succeeds in making a person adhere to the moral norms of the setting even though they conflict with his or her personal moral rules."

Key Situational Factors and the Situational Process

The cornerstone of Situational Action Theory is that people's actions ultimately is a consequence of how they perceive their action alternatives and, on that basis, makes their choices when confronted with the peculiarities of a setting. The perception-choice process is crucial for understanding a person's actions. *Perception* (the selective information we get from our senses) is what links a person to his or her environment, and *choice* (the formation of an intention to act in one way or another) is what links a person to his or her actions (see further Wikström 2006, pp. 76–84). In contrast to most choice-based theories of action, which focus on how people choose among predetermined alternatives, Situational Action Theory stresses the importance of why people perceive certain action alternatives (and not others) in the first place. Perception of action alternatives thus



Situational Action Theory, Fig. 1 The situational process and key situational factors (applied to the explanation of crime) (Source: Wikström 2011)

plays a more fundamental role in explaining actions, such as acts of crime, than the process of choice (which is secondary to perception of action alternatives). The key stages of, and the key situational factors in, the perception-choice process, according to SAT, is illustrated in Fig. 1.

Motivation (defined as goal directed attention) is a situational factor that initiates the action process and is an outcome of the interaction between the person (preferences, commitments, sensitivities) and the setting (opportunities, frictions). According to SAT there are two main kinds of motivators; (1) temptations, which are either the outcome of the interaction between (a) a person's desires (wants, needs) and opportunities to satisfy a desire (want, need) or (b) the outcome of the interaction between a person's commitments and opportunities to fulfill a commitment (opportunities to satisfy a desire or to fulfill a commitment may be legal or illegal), and (2) provocations, which occur when a friction (an unwanted external interference) causes anger or annoyance towards the perceived source of the friction or a substitute. People vary in their sensitivities to particular kinds of frictions (as a consequence of their cognitive-emotive functioning and life-history experiences).

Motivation is a necessary but not sufficient factor in the explanation of crime. What particular action alternatives a person perceives in relation to a particular motivation (and whether that includes an act of crime) is dependent on the moral filter. The *moral filter* is defined as "the moral rule-induced selective perception of action alternatives in relation to a particular motivation" and is an outcome of a person's moral engagement with the perceived moral norms of a setting in relation to a specific motivation. If crime is not among the action alternatives a person perceives, there will be no crime and the process of choice is irrelevant as an explanation of why he or she refrained from committing an act of crime; he or she simply did not see crime as an option.

If an act of crime is among the perceived action alternatives the process of choice will determine whether or not a person will commit (or attempt) an act of crime. SAT distinguishes between two main kinds of processes of choice: habitual (automated) or deliberative processes of choice (in prolonged action sequences the action guidance may drift between habitual and deliberative influences). The important difference between the two processes is that in case of actions (such as acts of crime) committed out of habit, the actor only sees *one* potent alternative in response to a motivation (temptation or provocation) and act accordingly, while in the case of deliberation there is no predetermined response so the actor has to weigh pros and cons of the different perceived alternatives (a process that may be more or less elaborate dependent on the importance of the choice). There is plenty of evidence for the existence of a dual process of human reasoning of this kind (see, e.g., Evans and Frankish 2009). The neuropsychological basis of SAT's framework for habitual and deliberate decision making, linking these processes to areas of the brain's prefrontal cortex which have been associated with separate intuitive and cognitive functions, with particular implications for the role of self-control and emotions in action decisions, has been specifically explored by Treiber (2011).

When people act out of *habit*, they essentially react (in a stimulus-response fashion) to environmental cues, automatically applying experienced based moral rules of conduct to the peculiarities of a setting, while *deliberation* involves taking moral rules of conduct into consideration when actively choosing between perceived action alternatives. Habitual action is oriented towards the past, while deliberate action is oriented towards the future. When people act habitually, they routinely apply past experiences to guide current action (i.e., they do what they normally do in the particular circumstance without giving it much thought); when they act deliberately, they try to anticipate future consequences of perceived action alternatives and choose the best course of action. When people act out of habit (only see one causally effective alternative; although they may be loosely aware "in the back of their minds" that there are other alternatives, no such alternative is actively considered), rationality does not come into play (since there is only one potent alternative and, therefore, no weighing of pros and cons of different options) and their actions may even be irrational, that is, people may act in ways they would not consider in their best interest had they deliberated. When people deliberate they aim to be rational (to choose the best option as they see it), but, importantly, this does not necessarily involve an aim to maximize personal advantage (whether maximizing personal advantage is seen as the best option is a question of the actor's moral judgement). Habitual responses are most likely when people operate in familiar circumstances with congruent rule guidance (i.e., when there is a high level of correspondence between personal morals and perceived moral norms of the setting), while deliberate responses are most likely when people are in unfamiliar circumstances and/or there is a conflicting rule-guidance.

Only in choice processes when people deliberate do they exercise "free will" (although it is a "free will" within the constraints of perceived action alternatives) and are they subject to the influence of their ability to exercise self-control (internal control) or respond to deterrence cues (external controls). If there is no conflicting rule guidance, there is nothing to control, and, hence, in these cases (inner and outer) controls lack relevance for the action taken. A person's ability to exercise self-control is a relevant factor in crime causation when his or her personal moral rules discourage and the moral norms of the setting encourage an act of crime in response to a motivation. In this case, the extent to which a person can act in accordance with his or her personal morals (i.e., refrain from crime) is dependent on the strength of his or her ability to exercise self-control. Deterrence is a relevant factor in crime causation when a person's personal morals encourage and the moral norms of a setting discourage an act of crime in response to a motivation. In this case, whether or not a person will carry out an act of crime is dependent on the (perceived) efficacy of the enforcement of the moral norms of the setting.

SAT offer a general explanation of key situational factors and processes involved in crime causation. What may differ in *the explanation of different kinds of acts of crime* is not the process (the perception-choice process) leading up to the action, but the input to the process, that is, the content of the moral context (the action-relevant moral norms) and a person's morality (the action-relevant moral values and emotions) which drive the process. For all kinds of crime to happen (e.g., shoplifting, insider trading, rape, or roadside

bombing), the actor has to perceive the particular action as a viable alternative and choose to carry out the act. However, the specific moral background (relevant personal morals and moral norms of the setting) which guide whether, for example, an act of shoplifting is perceived as an action alternative may differ from that which guides whether an act of rape is perceived as an action alternative.

The Social Model

Situational Action Theory insists that the causes of crime are situational and that social and developmental factors and processes in crime causation are best studied and analysed as the *causes of the causes* (of acts of crime). SAT advocates a mechanistic explanation of human action (such as acts of crime). The theory is based on four key propositions (of which the first two refer to the situational model and the subsequent two to the social model):

1. *Action is ultimately an outcome of a perception-choice process.*
2. *This perception-choice process is initiated and guided by relevant aspects of the person-environment interaction.*
3. *Processes of social and self-selection place kinds of people in kinds of settings (creating particular kinds of interactions).*
4. *What kinds of people and what kinds of environments (settings) are present in a jurisdiction is the result of historical processes of person and social emergence.*

Figure 2 illustrates how the social and situational models are integrated. The key content of the situational model has already been discussed, and the remaining part of this paper will be devoted to a brief outline of the role of processes of emergence and selection in crime causation.

The social model of SAT focuses on the role of historical processes of emergence in the creation of criminogenic environments (social emergence) and crime prone people (person emergence) and contemporaneous processes of self- and social selection that bring together crime prone people and criminogenic settings (creating the situations to which people may respond to motivators by committing acts of crime). The concept of *emergence* refers to how something becomes as it is (e.g., Bunge 2003). For example, how people acquire a certain crime propensity (personal emergence) or environments acquire a certain criminogeneity (social emergence) as an outcome of processes of social interactions. The concept of *selection* refers to the contemporaneous socio-ecological processes responsible for introducing particular kinds of people to particular kinds of settings (and thus creating the situations to which people's actions are a response).

SAT proposes that *psychosocial processes* of moral education and cognitive nurturing are of central interest in the explanation of why people develop specific and different crime propensities (i.e., tendencies to see and choose particular crimes as an action alternative) (see further Wikström et al. 2012, pp. 31–32). SAT further proposes that *socio-ecological processes* (e.g., processes of segregation and their social consequences) become of particular interest in the explanation of why particular kinds of moral contexts emerge in particular places at particular times (see further Wikström et al. 2012, pp. 2–37).

Why certain kinds of people end up in certain kinds of setting depends on processes of social and self-selection and their interaction. *Social selection* refers to the social forces (dependent on systems of formal and informal rules and differential distribution of personal and institutional resources in a particular jurisdiction) that encourage or compel, or discourage or bar, particular kinds of people from taking part in particular kinds of time and place-based activities. *Self-selection* refers to the preference-based choices people make to attend particular time and place-based activities within the constraints of the forces of social selection. What particular preferences people have developed may be seen as an outcome of their life-history experiences. Depending on the circumstances, social or self-selection can be more influential in explaining why a particular person takes part in a particular setting (see further Wikström et al. 2012, pp. 37–41).

Analyzing relevant processes of emergence and selection and how they relate help us understand (i) why people develop certain kinds of crime propensities (and why a population in a particular jurisdiction come to have a certain distribution of crime propensities and why some jurisdictions have more crime prone people than others), (ii) why certain places become criminogenic environments (and why there is a certain prevalence and kind of criminogenic environments in a jurisdiction and why some jurisdictions have more criminogenic environments than others), and (iii) why certain contemporaneous self- and social selection processes create particular kinds of crime hot spots (and why the prevalence and kind of crime hot spots vary between different jurisdictions).

Situational Approaches to Terrorism

Graeme R. Newman
School of Criminal Justice, University at Albany, State University of New York, Albany, NY, USA

Overview

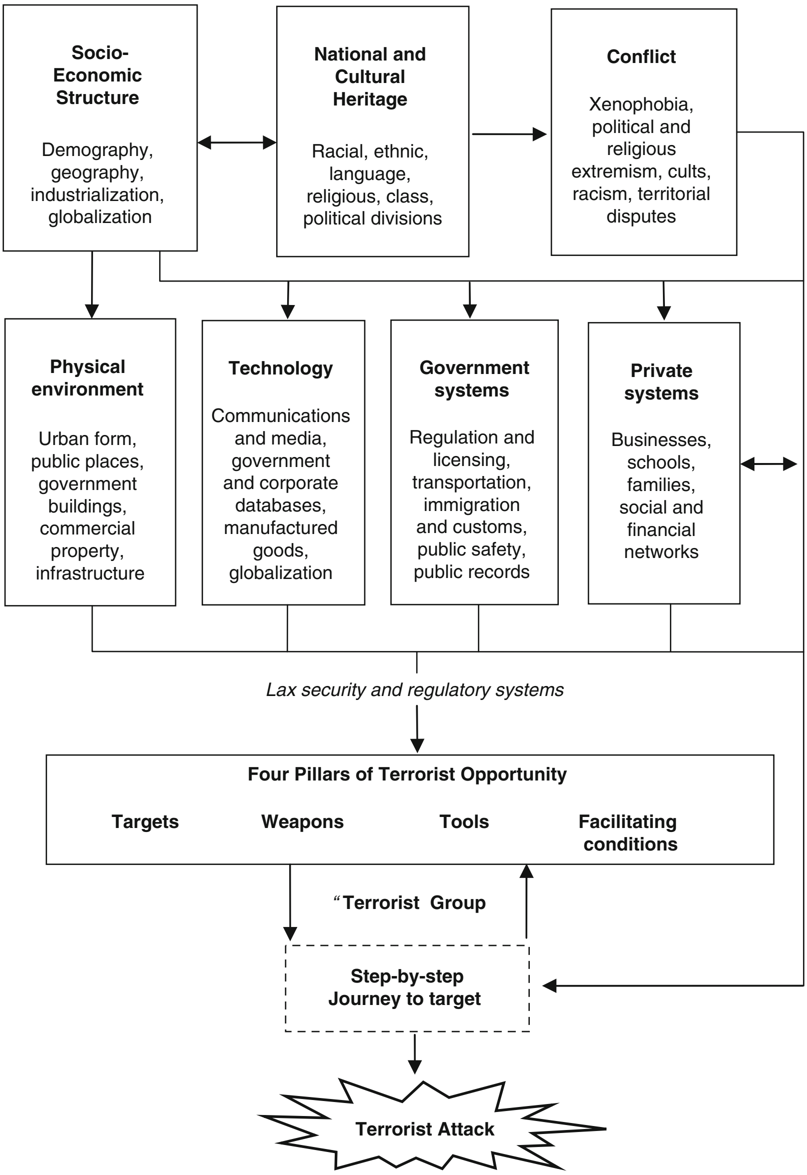
The situational approach to terrorism evolved from situational crime prevention, a well-established evidence-based approach to preventing and reducing crime. It argues that terrorists make choices that are limited by their perception of the opportunities afforded to them to carry out their mission. The situational approach explains *how* terrorists carry out their missions in contrast to *why* they do so. There are four pillars of terrorist opportunity: targets, weapons, availability of tools for doing attacks, and local conditions that facilitate terrorist operations. By manipulating these opportunities, interventions are directed at increasing the effort of mounting an attack, increasing the risk of carrying out an attack, reducing the rewards of attacks, reducing provocations to terrorists, and removing excuses terrorists use to justify their attacks. Because the situational approach focuses primarily on prevention, it places great emphasis on planning, which makes it a natural supplement to disaster response planning and to problem-oriented policing that seeks to solve crime and disorder problems. It is thus particularly useful to local police as a guide for developing local counterterrorism strategies.

Introduction

Situational approaches to terrorism derive from several decades of research, theory, and practice in the field of situational crime prevention. Pioneered by Ronald V. Clarke in 1988 in his seminal paper on coal gas suicides, situational crime prevention has evolved in many respects outside of mainstream criminology, which, since its inception in the nineteenth century, has been preoccupied with the root causes of crime, the search for the "born" or "made" criminal. Dominated by political science, the approach to terrorism has paralleled that of criminology: the search for the root causes of terrorism, with an overwhelming focus on its ideological, psychocultural, economic, and political causes. In contrast, the situational approach takes up where mainstream explanatory models leave off: it begins with a pinpoint focus on the specific situations in which terrorism occurs and, depending on the type of terrorism, works backwards to the causes. It does not completely eschew root causes; it views them as distant, background factors which for the most part are impermeable to counterterrorism interventions (see Fig. 1).

This conceptual distinction between situational crime prevention and other approaches in social science drives it to ask questions that others do not: how did the offender get to the point of being able to carry out his crime? What immediate factors in the social and physical environment produced a situation in which the crime was possible? Situational crime prevention asks not why but how an offender carries out his tasks. It is concerned with *motives* rather than *motivation*. It is concerned with *intervention* rather than *causation*. It takes seriously the old adage "prevention is better than cure."

Situational crime prevention is often attacked by those who hold to a contrasting view: "You can't cure an illness (disease, crime, terrorism) by treating its symptoms." The symptoms may disappear, but then reappear in some other form because the root causes have not been diagnosed. Counterterrorist experts complain, "If we protect this government building, they'll attack a shopping mall." This seems like a devastating blow to the situational crime prevention approach, but it is not as will be seen later in this entry. First, it is necessary to address the basic, intractable problem in the study of the causes and response to terrorism: its definition.



Socio-Economic Structure
Demography, geography, industrialization, globalization
National and Cultural Heritage
Racial, ethnic, language, religious, class, political divisions
Conflict
Xenophobia, political and religious extremism, cults, racism, territorial disputes
Physical environment

The Situational Definition of Terrorism

The definition of terrorism is famously elusive. The United Nations has tried for many years to agree on a definition and failed. The problem is political, legal, and conceptual. The political difficulty is reflected in the popular saying, “one man’s terrorist is another man’s freedom fighter.” The conceptual problem is tied up with the legal (which essentially binds the conceptual to the political). For example, serious political disagreements arose in the United States when the Obama administration chose to define the terrorist attacks on the World Trade Center as criminal acts and therefore subject to the regular due process of US criminal law. Opponents of that view argued that they were not criminal acts but acts of war against the USA, so that other legal procedures should follow. Others claimed that the attacks were not acts of war or criminal acts but something else – the position eventually favored by the Bush administration and resulted in setting up the prison in Guantanamo Bay, a kind of legal "nowhere land."

The situational approach finds these debates as mostly irrelevant to its enterprise. In fact, as noted earlier, situational crime prevention began with a study of suicide, an act arguably not always a crime, depending on the jurisdiction and circumstances of its commission. As it evolved, situational crime prevention developed more and more a focus on the specificity of the crime which often cuts across the traditional definitions of crime. This had important ramifications in respect to how crime was measured and recorded. Simply recording and reporting the number of burglaries, for example, in a police jurisdiction, were found to be useless for research or for prevention. It was necessary to collect very specific information about very specific types of burglaries: single-family residences or apartment blocks? Suburban or urban neighborhoods? Commercial or business districts? Adjacent to parks or woods? and so on. Generally speaking, it is the definition of the situation that is important for both research and prevention purposes, rather than the definition of the crime. So for the purposes of situational crime prevention, it does not really matter what one calls it, a crime, terrorist attack, or even an accident; it is the analysis of the situation in which these events occur that is of prime importance. As a result, Clarke and Newman in their book *Outsmarting the Terrorists* sidestep the issue by defining terrorism simply as "crime with a political motive."

The Situational Approach to Terrorism

Apart from the importance of specificity already discussed, there are three basic operating principles that play an important part in any analysis of terrorism from the situational perspective. These are opportunity, rational choice, and intervention.

1. *Opportunity*. This principle simply states that in order for a terrorist attack to be accomplished, the environmental and social conditions must be such that they offer advantage to the terrorist for carrying out the attack. For example, before there were cars, car theft was not possible. Before there were computers, software piracy was not possible. It is true that "theft" and "piracy" in the generic sense have always been possible, but it is clear that to speak of preventing or even analyzing such crimes, it makes little sense without examining their specific attributes. Furthermore, the social and physical environment may be structured in such a way that easy access to the targets of crime or terrorism is available. For example, early computers or cars were never designed in anticipation of software piracy or car theft. The mosaic of factors that make various crimes or terrorist attacks possible is called the opportunity structure as shown in Fig. 1.
2. *Rational choice*. Depending on what the terrorist wants to achieve by his attack (i.e., his motives), the terrorist will carry out his enterprise according to a rational choice from available options (i.e., part of the opportunity structure). The observer may consider what the terrorist is doing to be "irrational" such as the terrorist who kills himself in order to successfully complete an attack. This is called "limited" rationality as expounded by Cornish and Clarke in their groundbreaking work *The Reasoning Criminal*. Failure to understand the way terrorists think contributed to the shortsighted US counterterrorist policy which assumed that terrorists would not hijack an airplane and willingly kill themselves in the process – the unanticipated methodology of the 9/11 attacks.
3. *Intervention*. Situational crime prevention always begins from the point of how to disrupt the sequence of events that result from the offender's decision making. This involves generally two procedures for revealing points of weakness in the offender's or terrorist's action sequence. First, a step-by-step analysis is conducted to find out exactly the sequence of choices made by the terrorist in his journey to the target. For example, in the case of a suicide bomber, we must follow his journey from induction into the pool of potential bombers, his training, the selection of the target, and finally his journey to the target (see Fig. 2).

Situational Approaches to Terrorism, Fig. 2 Suicide bombing step-by-step (Adapted from *Outsmarting the Terrorists*, Table 5.3)

1. *Preparation*: Find safe house(s) for operations → Obtain or manufacture bomb paraphernalia → Select target or targets → Recruit bomber candidates → Specify exact location for detonation → Specify route to target → Establish group commitment → Train bombers → Prepare propaganda → reinforce individual commitment →
2. *Operation*: Intelligence gives "all clear" to target → Dispatch bomber → Bomber journeys to target →
3. *Follow up*: Claim responsibility → Broadcast propaganda → Review operation → Plan new attack → Establish supply chain for weaponry → To step 1

The journey to crime has been studied for a wide range of crimes including burglary, car theft, sex offenses, and robbery. Recent work emphasizing the step-by-step approach has adopted the concept of "scripting" from cognitive psychology which examines in detail the decision-making process and techniques used by offenders to exploit opportunities and accomplish their task. This approach has been used in analyzing credit card and check fraud, suicide bombing, Internet child pornography, identity theft, and trafficking in endangered species. The second important aspect of intervention is to conduct a careful assessment of the opportunity structure to identify weak points of security that may be exploited by criminals or terrorists. For example, particular targets may be more vulnerable, exposed, or accessible than others. Once these have been identified, the appropriate security systems may be installed. This is an important feature of situational crime prevention because it implies that there is much that can be done to protect targets even without knowing who the terrorists are or what their motivation may be.

Guided by the three principles of opportunity, rational choice, and intervention, Professors Clarke and Newman have developed a comprehensive approach to explaining terrorism which also provides a structure for organizing responses to terrorism. This helps to connect the often disjointed study of terrorism that focuses either entirely on the terrorist's characteristics or entirely on law enforcement responses to those characteristics. Instead, Clarke and Newman advocate that we "think terrorist" in order to identify a modus operandi according the opportunities available. The terrorist is placed within the opportunity structure of terrorism which is primarily composed of what they call the four pillars of terrorist opportunity: targets, weapons, tools, and facilitating conditions.

The Four Pillars of Terrorist Opportunity

1. Targets

In theory, terrorists could attack any target, as many politicians and law enforcement individuals have worried ever since 9/11. In practice, they must choose their targets carefully. And this choice will be strongly conditioned by the inherent attractiveness of those targets to terrorists, summarized as EVIL DONE:

Exposed: The Twin Towers were sitting ducks.

Vital: Electricity grids, transportation systems, and communications are vital to all communities.

Iconic: Of symbolic value to the enemy, for example, Statue of Liberty, the Pentagon, and the Twin Towers.

Legitimate: Terrorists' sympathizers cheered when the Twin Towers collapsed.

Destructible: The Murrah building in Oklahoma City and Twin Towers on 9/11.

Occupied: Kill as many people as possible.

Near: Within reach of terrorist group and close to home base.

Easy: The Murrah building was an easy target to a car bomb placed within 8 feet of its perimeter.

Of the above characteristics, the proximity of the target to the base of operations (near) is probably the most important. Research has noted that terrorists will base their operations in regions and countries where the local population is sympathetic to their cause. As noted earlier, the importance of proximity to target and base of operations has been known for some time in situational crime prevention research on the offender's journey to the crime. The reason is that the closer to base of operations, the more detailed information can be collected concerning the accessibility of the target and the route to the intended attack. Street and traffic conditions, for example, may be significant in carrying out a suicide bombing. If a target is distant, it will be much more difficult to obtain the necessary operational information. This is why all Al-Qaeda attacks against the USA, except the attacks on the World Trade Center, have been conducted against US targets overseas (embassies and military bases). These targets were generally much closer to the bases of operations of Al-Qaeda. In the case of the Al-Qaeda attacks on the US World Trade Center in 1993 and 2001, it was necessary to set up satellite bases close to the targets. Subsequent successful and failed attempts in the UK and USA have revealed that attacks inspired by Al-Qaeda have been carried out by individuals who were born of immigrant parents within the home country, though in some cases received training from terrorist camps overseas. Thus, the traditional distinction between domestic and foreign terrorism no longer holds, but the necessity of proximity of the terrorist base of operations to the target remains supreme.

2. Weapons

As with targets, terrorists favor certain weapons over others. The majority of terrorist attacks are conducted using small arms and munitions. Attacks with weapons of so-called mass destruction (biological or nuclear) have been few, and where conducted, of limited effect. The characteristics of weapons that make them appealing to terrorists are MURDEROUS:

Multipurpose	A high-powered rifle has a specific use, while explosives have a much wider application
Undetectable	Semtex is small, lightweight, and largely undetectable, ideal for penetrating layers of security
Removable	The weapons of terrorism must be portable, so they must be relatively light and reasonably small, unless transportation is available (see tools below)
Destructive	Explosive devices have a greater kill rate than guns targeted at specific individuals
Enjoyable	Terrorists are clearly attracted to their weapons. In fact, it is not just terrorists who enjoy weapons. Many ordinary people do also
Reliable	If terrorists have used a weapon, or one like it, many times before, they are likely to favor that weapon over another
Obtainable	How easy is it to get the weapon? Can it be bought or stolen easily? Or can it even be manufactured in-house?
Uncomplicated	All weapons require practice and training. A weapon that demands considerable skill, such as a free-flight armor-piercing missile launcher, will rarely be used or if used miss the target
Safe	The use of bombs as weapons is inherently more dangerous than the use of other weapons, especially when made in-house. But they remain the terrorist weapon of choice because they are so destructive

There will almost always be a trade-off between the target of choice and the weapon. If a target is particularly desirable, or difficult to reach, there may be a search for an appropriate weapon. For example, the first attack on the US World Trade Center in 1993 used a truck bomb parked under one of the towers. Though it did much damage, it failed to destroy the target which at the time was considered indestructible. The second attack used a new weapon, a passenger jet as missile, which was successful. The planning required to use this new weapon was very extensive and took years to accomplish. It also required Al-Qaeda to locate a satellite base of operations in the USA close to the targets (the relevant airports and target itself). Finally, it ignored the one attractive characteristic of weapons listed above: it was not "safe." The users, as with suicide bombers, were willing to die in order to reach the target. However, we should note that in the case of "regular suicide bombers," the explosives used are well developed and “safe” for those managing the training of the suicide bombers. The explosive vest must be well constructed so that it is detonated only when the bomber reaches the target.

Weapons of mass destruction, including biological weapons, have been rarely used by terrorists. The reason is that such weapons generally do not fit the MURDEROUS requirements of weaponry to terrorists. However, using this approach, Hassan Naqvi reviewed the main biological and chemical weapons theoretically available to terrorists and concluded that ricin toxin would be the most attractive weapon because of its exceptionally MURDEROUS qualities:

Multipurpose	Ricin can poison individuals by means of ingestion, inhalation, and subcutaneous exposure
Undetectable	Ricin is tasteless and water soluble, making it extremely concealable. Laboratory setups designed to extract ricin toxin from castor beans range from very simple to as complex as a drug lab. Any of these labs can be set up in a garage
Removable	Ricin is extremely toxic to humans in low doses. Very small amounts of poorly purified ricin are enough to harm multiple individuals. A single terrorist will be able to carry vast quantities of ricin without help
Destructive	Ricin is a thousand times more deadly than cyanide. In addition, the dissemination of ricin by means of food, water, or ventilation vectors would cause considerable panic and economic turmoil
Enjoyable	The extraction of ricin from castor beans is a fairly simple science experiment, and its clandestine use may add to the enjoyment of its production. Admittedly, it may not be quite as spectacular in its effects as are violent explosions and guns
Reliable	Ricin is an extremely hardy protein. Because it is resistant to changes in temperature, acidity, and even ultraviolet light, it retains much of its poisonous properties in environments as extreme as the stomach
Obtainable	Castor beans are available for purchase on the Internet, and laboratory equipment can easily be stolen
Uncomplicated	The extraction and dissemination of ricin is the most basic of all bioweapons. The instructions for its weaponization are easily found on the Internet
Safe	Ricin, although extremely toxic, will not harm terrorists if fairly basic precautions are taken, such as the use of masks

(*continued*)

3. Tools

Terrorist attacks cannot be accomplished without the tools of everyday life. Without such tools, it is much harder for terrorists to reach a target or use their weapons. For many of the commonest attacks, such as car or truck bombings, drive-by shootings, and targeted assassinations, terrorists are likely to need most of the following:

- Cell phones or other means of communication
- Cars or trucks to transport themselves and weapons
- Cash or (false) credit cards, bank accounts, or other means of transferring money
- Documents (false or stolen) – for example, drivers’ licenses, passports or visas, and vehicle registration documents
- Maps (and increasingly GPS), building plans, and addresses so that the target location can be pinpointed
- Television sets and monitors
- Video and still cameras for surveillance
- Internet access to collect information on street closures, traffic patterns, weather conditions, local news, and disseminate propaganda worldwide

Depending on the availability of such tools, the weaponry employed and targets reached may vary.

It may seem obvious that terrorists would need these everyday tools, but it is not obvious how they can use them without divulging at some point who they are and what they are up to. These tools are certainly widely available, but their visibility is also considerable. Using cash instead of a credit card to rent a car, for example, draws unwanted attention to the terrorist. Using a credit card exposes one’s identity – unless it is stolen. For these reasons, terrorists steal many of the everyday tools that are widely available, which of course opens them up to risk of getting caught. This is why there is a considerable, and increasing, overlap between terrorism and "traditional crime" such as money laundering, drug trafficking, and even bank robbery – a favorite way of the IRA (Irish Republican Army) to raise money. Some terrorist groups have even created entire departments that specialized in forging documents. Others have made their own money.

Despite the generality of tools needed by terrorists, some attacks do, of course, require specific tools – for example, a belt or vest to carry the suicide bomber's explosives – and it will always be important to understand what these tools might be and the supply chain that produces them.

4. Facilitating Conditions

Targets, weapons, and tools exist within physical, economic, and social environments. These environments serve to enhance their use; otherwise, they would be useless. At particular points in time or in particular regions or places, conditions may arise that facilitate terrorist ability to exploit these opportunities. These conditions make it ESEER for terrorists:

Easy: When local officials are susceptible to corruption

Safe: When ID requirements for monetary or retail transactions are inadequate

Excusable: When family members have been killed by local antiterrorist action

Enticing: When local culture/religion endorses heroic acts of violence

Rewarding: When financial support for new immigrants is available from local or foreign charities

One can readily see that the characteristics of ESEER are more or less those of failed or failing states, which is why they are the preferred abode of terrorist bases. ESEER is also exacerbated by the conditions of globalization that include the worldwide marketing of small arms whether legal or illegal, porous borders between countries making movement of terrorist operatives easier, the proliferation of nuclear technology and other toxic materials creating opportunities for terrorists to obtain or manufacture WMDs, and lax international banking practices that facilitate money laundering. The global reporting of savage or violent terrorist attacks on mass media and the Internet has also probably facilitated terrorist recruitment into various terrorist organizations. It is to the organizational aspect of terrorism that we now turn.

The Situational Approach to Terrorist Groups

With some exceptions, terrorism is a group exercise, which brings with it both advantages and disadvantages to doing terrorism. The advantages include being able to (a) mount a more complex one-off mission (the Northern bank robbery by the IRA or the 9/11 attack) and (b) sustain a continued series of attacks over a long period of time (e.g., Hezbollah in the Palestinian territories). However, the majority of terrorist groups dissolve within 1 year or less. Whether they completely desist or morph into different terrorist groups is still an open question. But this important fact suggests that there are serious problems that affect the structure and dynamics of terrorist groups.

Terrorist Group Structure

There are a number of different types of organizational structure identified among terrorist groups. Much is made of their formal or informal structures, how they arose, and their similarity to other types of organizations such as business models, specialist groups for hostage taking, or cell formation to insulate members from the overall structure of the organization. The latter protects against penetration by external agents and minimizes internal group dissention and distrust.

It is also likely that developments in communication technology may mitigate the difficulties faced in organizational structure of criminal and terrorist groups. Mobile phones in particular, especially smart phones that provide cheap access to the Internet in third world countries, have made it much easier for groups to coalesce and to overcome some of the external and internal constraints of terrorist group operations. Indeed, as has occurred in the Arab spring uprisings of 2011, many of these have been fuelled by social networking technologies. Demonstrations, sometimes turning into violent uprisings, have occurred without any formal organization at all. Social networking technologies may overcome the need to maintain a lasting formal group structure. Groups can come together – almost spontaneously for a specific event – then melt away until the next occasion. However, if routine, that is, repeated, attacks are to be sustained, obviously an enduring organization is essential, made clear as the uprisings in Libya, Egypt, and Syria unfold.

Terrorist and Criminal Groups

The situational approach views terrorist attacks that are carried out by groups or at least more than one person in much the same way as any other crime. That is, it follows the commission of the crime step-by-step; it does not presume in advance that there is a particular organized hierarchical structure. For example, the 2010 book *Situational Prevention of Organized Crime* shows that drug trafficking, contraband cigarettes, sex trafficking, mortgage fraud, and timber theft are commonly carried out by small networks of friends or family groups who live on different sides of a national border and take advantage of marketing and trafficking opportunities that are thus available.

Groups are viewed as part of the situational environment in which decisions must be made. The extent to which decision making is facilitated or constrained when it is done by groups or in group situations rather than by individuals is a difficult question to answer, though classic research on group decision making has suggested that in groups that are not well established, there is a tendency for polarization in decision making and a shifting of decision making to converge with the views of an authoritarian leader. So the group setting is yet another factor that limits or conditions terrorists' rational choice.

It is also important to recognize that in many, if not all instances, groups organized to commit traditional crimes ("organized crime") such as drug trafficking and extortion, corruption of government officials already existed before terrorist groups came along. Therefore, the existence of such groups is simply another opportunity for terrorist groups to exploit, and it is logical that they would do so. There is mounting research that demonstrates the ways in which terrorist groups develop their organizational capacities as a result of the existence of organized crime and eventually collaborate, overlap with organized crime groups, or even morph in some instances into criminal groups that do organized crime. From the situational crime prevention point of view, however, it does not matter much whether what these groups accomplish is organized crime or terrorism. All we need to know is how they make their choices, what interventions will constrain them, and how working within a group organized in a particular way facilitates or constrains the choices made along the way to accomplishing the mission.

The Situational Dynamics of Terrorist Groups

There are many sources of conflict within terrorist groups. Newman and Clarke in *Outsmarting the Terrorists* have identified the internal dynamics of terrorist groups that may constrain them as:

(a) The conflict between charismatic leadership and strict discipline. Charismatic leadership is probably the most significant attribute of terrorist groups and is necessary in order to transform terrorist groups into terrorist movements. It is needed to maintain faith in violence as a means to an end. But at the same time, strict discipline is needed to maintain operational security and efficiency. If charisma wanes (which we know always does), faith and thus discipline are undermined.

(b) The conflict between morality and hypocrisy. The moral contradiction between killing people (by terrorists) as a protest against killing people (by whatever enemy) is inherently a shaky morality, needing to be constantly fed by self-serving propaganda.

(c) Rules of entrance and exit. Some groups have no other rules than being a friend or family member. Others have strict rules for entry (applicants must prove themselves) and of exit – those who leave are obviously a security risk.

(d) Operational security. Complex operations require well-trained individuals who know each other well. But the more they know of each other, the more security will be jeopardized if one of them is captured.

The Situational Approach to Counterterrorism

The situational approach to counterterrorism is of course focused on prevention of terrorist attacks. As in crime prevention, this is its prime objective. Over the years, situational crime prevention has accumulated a range of techniques for preventing many different types of crime. These techniques, known simply as the "Twenty Five Techniques" of crime prevention, are grounded on five psychological principles that are directed at further limiting the rational choice of the offender. Applied to preventing terrorism these are:

1. Increasing the effort of mounting an attack or mission, such as protecting targets
2. Increasing the risk of carrying out an attack, such as surveillance and checkpoints
3. Reducing the rewards of attacks such as swift mitigation by first responders to reduce the injury and damage of attacks
4. Reducing provocations of terrorists such as avoiding controversial weapons
5. Removing excuses such as adopting clear rules of interrogation

If we superimpose these principles on the four pillars of terrorist opportunity, a broad array of techniques that suggest points of intervention is revealed (Fig. 3). Each of these five principles must be tailored to a specific type of terrorist attack after a step-by-step analysis has identified points of weakness.

Policy Implications

The four pillars of terrorist opportunity and the five modes of intervention that form the bases of the 25 techniques provide a framework for a systematic policy that would assess the risks of attack against various targets in various locations. After 9/11, "risk assessment" was promoted by the US Department of Homeland Security as a way of protecting against terrorist attacks. Unfortunately, because it lacked a systematic structure of how to assess comparative risks, or even what might be at risk, the major portion of resources allocated to US states by the federal government was distributed according to political largesse rather than according to a systematic comparative assessment of what was at risk. This error was in part also produced by the widespread panic by both politicians and security professionals such as Richard Clarke the then White House counterterrorism czar and reflected in the cry, "we can't protect everything." But the situational approach demonstrates that not all targets are equally attractive to terrorists. We do not have to protect everything, at least not to the same degree. By developing a systematic procedure for identifying risk, adequate planning and countermeasures can be set up both to prevent attacks and to mitigate the fallout of attacks should they occur. The manual, *Policing Terrorism*: *An Executive*'*s Guide*, by professors Newman and Clarke and published by the Center for Problem-Oriented Policing, shows how this can be done by local police departments.

However, the complaint that "we can't protect everything" reflects not only panic but also a basic misunderstanding of the situational approach to terrorism, which is that if we protect one target, the terrorist will simply shift to another target that is more easily accessible. This is called in the research literature "displacement" or the "substitution effect". And it is the major criticism of the situational approach to crime and to terrorism.

Displacement

Echoed in *The Economist* on March 8, 2008, and in other trade media, the displacement criticism argues that terrorists are so committed to their violence; if they can't attack one target, they will keep on trying until they reach another. However, we have already seen that terrorist groups, although they may be composed of committed individuals, are very likely to dissolve within a year, so the idea of commitment at least by a group to carry out an attack against anything anywhere remains highly doubtful. Furthermore, recent research in situational crime prevention by Professors Guerette and Bowers

	Targets	Tools	Weapons	Facilitating Conditions
Increase the Effort	• Identify vulnerable targets • Prioritize targets for protection • Close streets, build walls and barriers • Security training for VIPs • Control dissemination of weapons technology	• Reduce supply of cash • Design electronic products to prevent use as detonators, timers. • High tech passports, visas, driving licenses etc. • National ID cards	• Restrict weapons sales • Hold contractors liable for stolen explosives • Reduce explosives shelf-life • Bomb recognition publicity • “User unfriendly” weapons • Restrict information on weapons use	• Tighten identity and credit authentication procedures • Tighten border controls • Destroy safe houses/training camps • Disrupt recruitment (e.g. Madrasas)
Increase the Risks	• Strengthen formal and informal surveillance through CCTV, citizen vigilance, hot lines	• Technology to identify and locate cars, trucks, cell phones • Internet surveillance • RFIDs for parts on vehicles and electronic products • GIS chips in terrorist tools	• RFIDs/GIS chips to track weapons • Screen incoming cargo for weapons • Outlaw technology to circumvent screening	• “Know your customer” bank policy. • Track all financial transactions • Monitor foreign student activity • Promote ties between local police and immigrant communities • Conduct sting operations to foster climate of risk
Reduce the Rewards	• Conceal or remove targets • Bomb proof buildings/Kevlar curtains • Design guidelines to minimize injury from explosions • Swift cleanup of attack site	• Anticipate terrorist innovation in use of tools	• Avoid overreaction to attacks	• Use publicity to isolate terrorist group from community • Use publicity to portray hypocrisy, cruelty of terrorist acts • Anti-money laundering regulations
Reduce Provocations	• Unobtrusive public buildings at home and abroad • Unobtrusive dress, living accommodations for personnel abroad	• Use unobtrusive vehicles in foreign locations	• Clear and consistent rules of engagement • Minimal weapons use at protest demonstrations	• Work closely with immigrant communities and host community abroad • Clear rules for public demonstrations • Avoid provocative announcements
Remove Excuses	• Train personnel abroad in local customs, culture		• Avoid use of controversial weapons (eg phosphorous bombs) • Don’t overestimate utility of bioweapons	• Avoid maltreatment of prisoners • Clear rules for interrogation • Counter terrorist propaganda • Win hearts and minds

Situational Approaches to Terrorism, Fig. 3 Situational prevention techniques applied to terrorism (Adapted from *Outsmarting the Terrorists*, pp. 193–194) has shown clearly that displacement does *not* occur in some 70 % of cases studied where interventions were introduced for a wide range of crimes, and the same has been found for terrorism in respect to the effectiveness of airport security. Finally, should displacement be shown to occur, this is actually a demonstration that the intervention *had an effec*t on the terrorists' behavior. It means that the terrorist in displacing to a less preferred target is taking additional risks, thereby increasing the chances of being caught or thwarted in the attempt. And having to attack a target of second choice, a successful attack will produce fewer rewards to the terrorist: it may be less vital and produce less injury and damage. This leads to the final important policy implication of the situational approach to terrorism.

Attack Mitigation

If it is acknowledged that displacement *may* occur (not *will* occur), then it is possible to develop a plan of security for protection of targets that rates them according to how attractive they are to terrorists (EVIL DONE) but also the expected loss should they be attacked. This may easily be incorporated into the standard disaster response planning that occurs in most communities. Then, if a target is attacked, the fallout of that attack can be mitigated by an effective disaster response, and thus the rewards of the attack to the terrorists reduced. The importance of this mitigation should not be underrated. Certainly Al-Qaeda terrorists have understood this from the beginning. It is why they commonly include in their attacks bombs designed to disrupt the mitigating actions of first responders. It is also why they try to commit a number of attacks simultaneously. This methodology has been copied by many other terrorist groups, especially the Taliban.

The situational approach to terrorism fits nicely into the established disaster response infrastructure already established. This not only involves training of first responders, but an extensive organizational infrastructure that ensures that confusion does not occur in dealing with an attack (which occurred in the 9/11 attack) but also ensures that local communities plan systematically to protect themselves according to a rational assessment of risks. Much of this planning for protection involves regular situational crime prevention activities, well known in the field of problem-oriented policing especially partnering with businesses and local community organizations to solve crime and disorder problems.

Conclusion

In sum, the situational approach to terrorism bridges the well-known gap between the academic study of the causes of terrorism and the practical challenges of preventing and responding to terrorist attacks that are faced by policymakers, police, and security professionals. While waiting for the rest of social and political science to eradicate the *root causes* of terrorism, the situational approach provides a conceptual, practical, and evidence-based guide for eliminating the *immediate causes* of terrorist attacks.

Situational Crime Prevention

Nick Tilley[1] and Aiden Sidebottom[2]

Overview

Situational crime prevention is concerned with reducing opportunities for crime. It comprises "opportunity-reducing measures that (1) are directed at highly specific forms of crime, (2) involve the management, design and manipulation of the immediate environment in as systematic and permanent a way as possible, (3) make crime more difficult and risky, or less rewarding and excusable as judged by a wide range of offenders (Clarke 1997: 4)."

Since its inception, situational crime prevention has undergone several refinements, incorporating developments in crime prevention research and practice. Opportunity reduction measures have taken numerous forms and have been found effective in reducing a wide range of crime types. It has also encountered staunch resistance, both on theoretical grounds and on the implications deemed to arise from the implementation of situational interventions.

This entry charts the development of situational crime prevention. It begins by describing its origins, method, and key principles. Next, it discusses evidence of its effectiveness. This is followed by a review of the major criticisms of situational crime prevention and associated rebuttals. It finishes by outlining future directions for the field.

The Origins of Situational Crime Prevention

Just as there was evolution before evolutionary theory, there was situational crime prevention before situational crime prevention theory. The core tenet of situational crime prevention is that unwanted actions by others can be averted by changing the immediate circumstances of their prospective behavior. It is not necessary (and indeed it may not be possible) to alter the dispositions inclining them to act in undesirable ways.

Hedgehogs practice situational prevention. In the interests of not being attacked, they have evolved sharp spikes that increase the risk and reduce the reward to those animals that might otherwise attack and kill them. Similarly, skunks have developed smells, butterflies the appearance of large eyes, and stick insects – well – the appearance of sticks, to make them less attractive to or less easily identified by potential predators. Situational prevention can even be seen in plants: think, for example, of stinging nettles, cacti, and bramble bushes.

Humans too invented situational measures long before late twentieth-century criminologists began to articulate the relevant theory. Most of us, for example, carry around with us milled coins. These became commonplace in the seventeenth century as a way of preventing coin clipping, which was then widespread: the face value of the coins was supposed merely to reflect the value of the precious metals of which they were minted, and profit could be made by clipping off and keeping some of the metal but preserving the purchasing power of the coin. Unclipped coins thus went out of circulation as clipped coins had the same exchange value. In terms of Sir Thomas Gresham's famous aphorism: bad money drove out good.

The same fundamental attribution error may underlie the surprisingly long time it took for both evolutionary theory and situational crime prevention theory to surface. The "fundamental attribution error" refers to the human tendency to explain good and bad by the actions of agents with corresponding good or bad intentions (Ross and Nisbett 1991). Crime is bad so its causes must lie in bad intentions: in particular we should blame bad agents and the source of their wickedness. Indeed, echoes of this are still found in much criminology, which looks for the causes of crime mainly in criminal dispositions borne of bad genes, bad upbringing, or bad social conditions. In response to this, situational crime prevention theory presents revolutionary challenges to much taken-for-granted thinking.

The stimulus to the first formulations of situational crime prevention came from a crisis of confidence in conventional wisdom in the 1970s. Improvements in welfare during the postwar period and the simultaneous increases in crime cast doubt on any notion that there might be a simple causal relationship between deprivation and crime, which would be prevented by improvements in social conditions. Moreover, evaluations of efforts at offender rehabilitation, reflecting the dominant criminological opinion at the time, were not encouraging. The slogan "Nothing Works" came to be believed. Situational crime prevention emerged in the British Home Office and promised an alternative approach that focused on preventing crime events rather than addressing offenders' dispositions to commit crime. The approach was a pragmatic one. Situational crime prevention seemed to work, and policies might usefully be directed at working out how and why situations could be modified to reduce opportunities for crime.

Theoretical and Methodological Underpinnings of Situational Crime Prevention

Crime as Opportunity was published by the British Home Office in 1976 (Mayhew et al. 1976). It was followed in 1980 by a paper in the *British Journal of Criminology* with the title "Situational Crime Prevention" (Clarke 1980). These two papers articulated a fresh agenda for understanding and preventing crime.

Mayhew et al. mainly focus on physical means of reducing crime opportunities. Their starting point, however, is "the extent to which deviance may be a temporal response to the provocations, attractions, and opportunities of the immediate situation" (1976: 1). They refer to Hartshorne and May's classic study, finding that honesty in children is not a stable attribute but instead that situational changes in opportunity can lead them sometimes to cheat, steal, and lie (Hartshorne and May 1928). Mayhew et al. refer also to research showing the importance of the immediate situation on the behavior of those placed in institutions, such as borstals. The language is of "stimulus conditions," including "opportunities for action," providing "inducements for criminality," which are "modified by the perceived risks involved in committing a criminal act and – in a complex, interrelated way – the individual's past experience of the stimulus conditions and the rewards and costs involved" (Mayhew et al. 1976: 2–3). Although opportunity had been referred to in passing in previous studies, Mayhew et al.'s argument was that it warranted closer, center-stage attention.

One of the most important grounds for arguing that situational factors are worthy of consideration in their own right was the discovery that changes in the toxicity of the domestic gas supply in the UK had a substantial effect on suicide rates. Mayhew et al. cite a study which found that the 45 % drop in Birmingham's suicide rate from 122 to 67 per million between 1963 and 1969 was almost entirely attributable to reduced toxicity of the gas supply in that city (there were 87 gas-related suicides in Birmingham in 1962 but only 12 in 1970). The drop in Birmingham's suicide rate was twice the national fall. A later study by Clarke and Mayhew (1988) corroborated these findings on a national scale. It might be expected that suicides are not committed lightly, but are provoked by deep feelings of despair and, therefore, can only be prevented by looking at the underlying psychological or social source of these sentiments. Finding that the gradual switch from toxic coal gas to nontoxic natural gas largely accounted for the overall drop in suicides challenged that assumption. Having an easily available method of committing suicide, in particular one that was painless and non-disfiguring, seemed to be associated with suicidal behavior. Removing that method had a substantial effect on suicide rates. Even in relation to this deeply caused behavior, there did not appear to be displacement to alternative methods (an issue we will return to shortly). There are many ways of taking one's own life. Changing the gas supply can have no influence on the cause of suicidal dispositions. It does not make suicide impossible. It nevertheless produced a substantial effect on total numbers of suicides. If deeply motivated behavior could be prevented by a simple change in the situation, how much more readily might criminal behavior, lacking such profound emotional sources, also be prevented?

Mayhew et al. see opportunities deriving from various sources: potential offenders' age, sex, and general lifestyle; victims' status; patterns of daily activity; properties of objects (such as their abundance); physical security; and levels of supervision and surveillance (Mayhew et al. 1976: 6–7). They also spell out variables that would be important in testing opportunity theories, for example, "the greater freedom of men to be away from their homes at night, the density of residential properties in rural as against urban areas, the security of these properties, or the extent to which routes of access to them are visible to neighbours and passers-by" (Mayhew et al. 1976: 7). The main emphasis, however, was on the modifiable features of opportunities, notably "the physical security and surveillance aspects of opportunity" (Mayhew et al. 1976).

The Home Office paper goes on to discuss some examples of opportunity reduction as a means of preventing crime: the use of steering wheel locks to prevent car theft and the effects of design (front or back entry) and staffing (presence or absence of a conductor) on bus vandalism. Both studies find that situational variables were important in generating the crime patterns of interest. The introduction of steering wheel locks to all new cars in the UK, from 1971, reduced their theft but with some displacement to older cars. Areas of buses that were not easily supervised experienced far higher levels of vandalism than those open to surveillance.

Clarke (1980) adopts a more critical stance towards the then prevailing criminology than that found in the Home Office paper. He refers to the widespread "dispositional bias" which sees crime as mainly the preserve of a small minority inclined to criminality and which also continued to inform crime prevention policy and practice. He highlights the practical difficulties in changing criminal disposition or in altering the social conditions deemed to foster criminality, as well as uncertainties over the causal processes at work. He stresses, instead, the potential benefits of looking at crimes as results of consciously made, situated choices, even though those involved may not fully appreciate why they are making their decisions.

Clarke refers to three distinctive concerns of situational crime prevention theory: crime events (rather than criminality), separate categories of crime (rather than all crime), and current conditions for criminal acts (rather than dispositions). Two major types of preventive mechanism are discussed: (a) reduction of physical opportunities and (b) increase in chances of being caught, although (c) housing policies that improve chances of parental supervision of children are also mentioned. Clarke distinguishes between opportunistic offenders, whose crimes are less likely to be displaced by situational crime prevention measures and those who make their living from crime, for whom displacement is more likely. A middle group, who supplement their income from crime, produces the main puzzle, where there are plentiful alternative targets. Clarke speculates that classes of target may be protected by situational measures, for example, when much stronger steel coin boxes replaced vulnerable aluminum ones in British telephone kiosks.

While Clarke's suggestions marked a wide departure from much criminological thinking at the time, noticeable similarities are observed between the situational approach and developments in several areas of psychology. For example, Clarke's concerns with criminology's "dispositional bias" spoke directly to the ongoing person-situation debate between personality psychologists and social psychologists. The then prevailing narrative was that human behavior is best explained by more or less stable traits that make up an individual's personality. This was challenged by the pioneering work of Mischel (1968), who claimed that personality traits were poor predictors of behavior and that greater attention be paid to situational influences. Later "situationalists" could point to a series of classic experiments, notably Zimbardo's Stanford Prison Experiment and Milgram's electric shock study that demonstrated the ease with which situational forces could be manipulated in ways that trumped dispositions, often to dramatic effect. There are also hints of behaviorism in Clarke's remark that "decisions are much influenced by past experience (as) people acquire a repertoire of different responses to meet particular situations and if the circumstances are right they are likely to repeat those responses that have previously been rewarding" (Clarke 1980: 138). Likewise, Clarke acknowledges explicitly that situational crime prevention "is, perhaps, closest to a social learning theory of behaviour" (p. 139). Clarke also notes, however, that situational prevention may owe "something to the sociological model of crime proposed by the 'new criminologists'" (Clarke 1980). Moreover, towards the end of his paper, he avers that opportunity reduction "is entirely compatible with a view of criminal behaviour as predominantly rational and autonomous" (Clarke 1980: 145).

The Home Office report of 1976 and Clarke's manifesto for situational crime prevention of 1980 laid the foundations for subsequent developments. These can be considered under the headings of methodology, models of the offender, and classification of preventive techniques.

Methodology

Action research has come to be the main method used in situational crime prevention. In accordance with this, Ekblom (1988) describes the "preventive process" as one involving (a) obtaining data on a crime problem, (b) analysis and interpretation of the data, (c) devising preventive strategies, (d) implementation, and (e) evaluation, with (f) feedback via continuous monitoring of crime.

Because situational measures are applied on the basis of the analysis of specific crime problems, evaluation methods that try to determine whether a specific type of measure, say lighting upgrades or CCTV, is effective are not normally deemed appropriate. Instead action-research-based case studies attuned to the problem context have become the preferred method.

Several tools and analytic techniques to inform situational crime prevention have been developed. In particular:

- Crime pattern analysis has advanced rapidly better to specify the problems to be addressed, as well as their spatial and temporal components.
- Repeat victimization patterns have been very widely found and victimization (by place, person, or target) identified as the best predictor for future risk and hence most deserving of preventive attention.
- The phenomenon of "near repeats" has also been identified: the elevated risks faced by those near to the victimized.
- The CRAVED mnemonic (concealable, removable, available, valuable, enjoyable, and disposable) has been devised to capture the attributes of products that are most likely to be stolen.
- "Crime scripts" are used to tease out the steps involved in committing more or less complex

crimes, which can then be drawn on to work out where the most promising points of preventive intervention can be found.
- The "problem analysis triangle" organizes the critical elements that give rise to crime events.

Models of the Offender: The Rational Choice Perspective

A rational choice model has been proposed for offenders (Cornish and Clarke 1986). The simplest way of understanding how situational measures work is to assume some level of rationality on the part of offenders. A change in the situation leads prospective offenders to reassess the expected costs and benefits from engaging in a particular criminal act. If the change in the situation suggests increased rewards or decreased costs, then more of those at the margins of participation in crime will be drawn in. Likewise, if the change suggests decreased rewards or increased costs, fewer will. Little of the formal apparatus of rational choice theory, as used by economists and game theorists, has been adopted. Rather, the assumption is simply that crime choices are open to influence by changing the expected balance of advantages and disadvantages. Indeed, even if there is a very strong disposition to commit a particular crime, the presence of a police officer at the scene, for example, may be sufficient to lead the individual to decide in the event not to proceed.

The rational choice model does not suggest that each individual carefully considers all the options that are available to determine which course of action will maximize utility. Lack of information, lack of ability, and the costs involved in arduous and prolonged decision-making make that untenable. Rather, potential offenders, like everyone else, operate with "bounded rationality." This conceives of them as decision-makers who are responsive to changes in situations, but it does not embrace the unrealistic assumption that they are capable, conscious, careful, conscientious, and comprehensive calculators of costs and benefits to estimate expected utility in advance of each choice made.

Classification of Preventive Techniques

Clarke's early references to reductions in physical opportunities and increases in the chances of being caught as two categories of situational measures have since been refined and expanded. These have been generalized, respectively, to "increasing effort" and "increasing risk" for the offender. "Reducing reward" was then added, followed by "reminding of rules" (now called "removing excuses") and "reducing provocation" (Wortley 2001; Clarke and Homel 1997; Cornish and Clarke 2003). Taken together, these form a classification system of situational techniques. Each of the five major headings has a variety of subtypes, as shown in Fig. 1.

The classification of situational techniques serves four purposes. First, it provides a catalogue of the ways in which proximal conditions may affect criminal behavior. Second, it provides a repertoire of possible situational measures that can be countenanced when trying to determine what might be done in relation to a specific crime problem. Third, it provides a user-friendly teaching aide when introducing researchers and practitioners to situational crime prevention. And fourth, it highlights evidence gaps where case studies are required.

In some versions of the typology of techniques, the importance of perception is stressed in relation to risk, reward, and effort. That is, it is recognized that it is not only, or perhaps always most importantly, a question of *real* increases in effort or risk or *real* decreases in reward. For the person who might contemplate crime, the issue is that of the risk, effort, and reward that they *perceive* in relation to the criminal acts of interest. Similarly, provocation and rule recognition are about the ways in which situations are understood.

The Effectiveness of Situational Crime Prevention

A very large number of studies demonstrating the effectiveness of situational crime prevention have now been undertaken (e.g., see Clarke 1997 for a collection of successful case studies

Increase the effort	Increase the risks	Reduce the rewards	Reduce provocations	Remove the excuses
1. Target Harden • immobilizers in cars • anti-robbery screens	*6. Extend guardianship* • Routine precautions: go out in groups at night • 'Cocoon' neighborhood watch	*11. Conceal targets* • gender-neutral phone directories • off-street parking	*16. Reduce frustrationsand stress* • efficient queuing • soothing lighting/music	*21. Set rules* • rental agreements • hotel registration
2. Control access • alley-gating • entry phones	*7. Assist natural surveillance* • improved street lighting • support whistleblowers	*12. Remove targets* • removable car radios • pre-paid public phone cards	*17. Avoid disputes* • fixed cab fares • reduce crowding in pubs	*22. Post instructions* • 'No parking' • 'Private property'
3. Screen exits • tickets needed for exit • electronic merchandise tags	*8. Reduce anonymity* • taxi driver ID's • school uniforms	*13. Identify property* • property marking • vehicle licensing	*18. Reduce emotional arousal* • controls on violent porn • prohibit paedophiles working with children	*23. Alert conscience* • roadside speed display signs • 'Shoplifting is stealing'
4. Deflect offenders • street closures • separate bathrooms for women	*9. Utilise place managers* • CCTV for double-decker buses • Two clerks in liquor stores	*14. Disrupt markets* • monitor pawn brokers • licensed street vendors	*19. Neutralise peer pressure* • 'idiots drink and drive' • 'it's OK to say NO'	*24. Assistcompliance* • litterbins • public lavatories
5. Control tools/weapons • toughened beer glasses • disabling stolen cell phones	*10. Strengthen formal surveillance* • security guards • CCTV in town centres	*15. Deny benefits* • ink merchandise tags • graffiti cleaning	*20. Discourage imitation* • rapid vandalism repair • V-chips in TV's	*25. Control drugs and alcohol* • breathalysers in pubs • alcohol-free events

Situational Crime Prevention, Fig. 1 Typology of situational crime prevention techniques. **Source**: Tilley, N. (2009). *Crime Prevention*. Willan, Cullompton, Devon

and for a fuller bibliography, with over 200 examples, go to http://www.popcenter.org/library/scp/pdf/bibliography.pdf.). These cover a range of crime types and different settings. For example, in one study on residential burglary in England, lockable gates were installed to alleyways that ran behind terraced properties. The gates restricted access only to those residents in the affected properties, thereby reducing the opportunities for burglars to enter such properties from the rear, as was evidently the norm. The scheme was found to reduce residential burglary by over a third relative to the control area. Moreover, the scheme was cost-effective, recouping £1.86 for every one pound spent (Bowers et al. 2004). In another study, La Vigne (1994) describes how the implementation of a computerized telephone system in the New York City jail system led to considerable reductions both in illicit phone use by inmates and phone-related violent disputes. In other examples, the effect was immediate, as with the near disappearance of bus robberies in the USA in the 1970s following the implementation of cash drop safes and the shift to an exact-fair payment system.

Such studies do not find some specific measure or type of measure that "works" invariably – specific crime prevention panaceas are not expected. Instead, what they show is that strategies making alterations in the balance of rewards, efforts, and risks or removing provocations or adding rule reminders at the point of crime commission can be devised, which speak to specific crime problems.

The true extent of the effectiveness of situational crime prevention is likely to be higher than that gleaned from the published literature. Retailers and private businesses routinely employ situational measures to protect their assets and prevent loss or theft. Fitting merchandise with electronic tags or placing items in protective displays is commonplace. Such efforts are, however, rarely formally evaluated and hence are typically absent from the scientific literature.

Criticisms of Situational Crime Prevention

Both the theory and practice of situational crime prevention have been subject to an array of criticisms. The most common are itemized below, followed by the associated rebuttals.

Theoretical Criticisms

Situational Crime Prevention Only Displaces Crime

Arguably, the most enduring criticism of situational crime prevention concerns displacement. It is argued that situational crime prevention simply shifts crime around because it fails to address the underlying "root causes" of crime. Displacement can take several forms: by place, time, method, crime type, or offender. There are enormous measurement problems that mean that it is, in effect, impossible to rule out all forms of displacement. The best that is possible is to assess whether there is displacement where, when, and in relation to which offenses it would be most expected. On that basis, it can be concluded with some confidence that displacement rarely matches the crimes prevented by the application of situational crime prevention (Bowers and Guerette 2009). This is because (a) offenders like to offend in areas with which they are familiar and (b) crime opportunities are not uniformly available. Contrariwise, there is growing evidence that "diffusions of benefits" often occur whereby preventive effects extend beyond the operational range of the measures applied. The possible types of diffusion of benefits match those of displacement. They have been found quite widely, for example, by time, where "anticipatory benefits" include reductions in crime before the preventive measures become operative (Smith et al. 2002), and place, where the geographical range of crime reductions extend beyond the area covered by the measures (Clarke and Weisburd 1994). Proposed explanations for these patterns are that offenders tend to be unaware of the exact boundaries (temporal and spatial) of prevention measures.

Situational Crime Prevention Is Superficial and Simplistic

Crime is complex with many causes. Its explanation calls for attention to a wide range of variables relating to genetics, childhood experience, social structure, and the workings of the criminal justice system. Even if situational variables have any role to play, it is a small one that needs to be considered in the context of a wide range of other causal influences. In placing less emphasis on them, the situational approach is criticized for speaking only to the descriptive components of crime – *where* and *when* crime happens – and not to *why* crime occurs. Situational crime prevention is therefore alleged to be overly simple: lacking the theoretical depth of mainstream criminological theories and merely extending common sense.

The criticism is a weak one. Situational crime prevention draws heavily on three well-established crime event theories: routine activity, rational choice, and crime pattern. It is also underpinned by the widely accepted principle that situations yield causative influences on human behavior, in combination with predisposition, nor can it accurately be considered simple. While the superficial logic is often consistent with day-to-day observations, why the interaction between certain individuals and certain situations under contrasting conditions does or does not generate crime is in no way less complex than the question of why certain individuals do or do not enter a life of crime.

Situational Crime Prevention Is Applicable Only to Instrumental Offenses

Although situational crime prevention may be relevant to instrumental crime where some calculation of returns in relation to effort and risk might reasonably be expected and where, therefore, situational changes that alter expected utility might change an offender's decisions, for other types of crime, it is much less relevant. Many crimes, especially those involving violence, are more expressive than instrumental or are undertaken under the influence of drugs or alcohol. In these cases, those involved are unlikely to notice or adjust their behavior in response to more or less subtle situational factors.

There are clearly more examples of situational crime prevention being applied to instrumental crimes than there are expressive crimes. But generalizing this pattern to reduce situational crime prevention to an instrumental-only form of crime control is misleading. That many early situational measures relate to acquisitive crimes reflects demand not discordance. Situational crime prevention was developed by researchers based in the British Home Office, which, at the time, was primarily concerned with the high levels of residential burglary and car crime experienced in England and Wales. More generally, there is a situational component to all behaviors. The association of changes in the supply of gas in the UK with dramatic changes in suicide patterns was described earlier. There is also strong evidence to show that situational changes can lead to dramatic reductions in the probability of and harm caused by violence. Bars are a prime example. The shift from glass pint pots to shatterproof receptacles and changes to the internal configuration of bars and nightclubs have all been found to produce positive reductions in alcohol-related assaults in such settings (see Graham and Homel 2008).

Ethical and Practical Criticisms

Situational Crime Prevention Blames Victims

Offenders commit crime and so should be held fully responsible for their criminal behavior. Situational crime prevention suggests that crime problems derive from the opportunities created by those who have not committed any criminal act. Moreover, it suggests that they should accept some responsibility (and in certain cases bear some of the costs) of reducing opportunities. For many critics this is an affront, leading to accusations that situational prevention "blames the victim." Offenders choose to commit their crimes. Fault lies entirely with them. Moreover, it is the duty of the state in general, and the criminal justice system in particular, to control their behavior.

One suspects that the understandable emotions associated with victim blaming, including most obviously the unwarranted notion that some rape victims may be blamed for wearing provocative outfits, have placed greater prominence on this criticism than is deserved. Situational crime prevention recognizes that targets (broadly defined) can play a causative role in crime events. This is true of people, places, and products. Evidence suggests that certain measures are associated with reduced vulnerability to victimization (as well as its opposite). Most individuals welcome such advice and use it to take recommended precautions against crime. Most individuals would also accept that this is a reasonable expectation and that government agencies are largely impotent to protect them from crime in every situation all of the time. Moreover, there are examples where victims are open to blame and where they may be held culpable for the criminogenic effect of their actions (or inactions). For example, a shop that repeatedly experiences theft because of the way it displays goods, but passes the costs of the crimes to the state, may rightly be blamed for failing to take adequate precautions. Likewise, bar managers who blatantly supply alcohol to already intoxicated patrons may be held responsible for the violent crimes they produce.

Situational Crime Prevention "Criminalizes" Policy, Planning, and Design

The notion that the physical and social architecture of everyday life shapes crime opportunities and that it should therefore be adjusted to reduce crime, risks "criminalizing" areas of policy and practice (shaping them by a situational crime prevention agenda) to the detriment of other ends they may have. Pursuing a situational crime prevention agenda, it is argued, undermines social welfare policy, and diverts resources away from welfare provision and social crime prevention. This also applies to schools, hospitals, retailers, product designers, planners, and architects. In particular it may suggest acceptance, in the name of crime prevention, of an ugly "fortress society."

Knepper (2009) argues that situational crime prevention contributes more to social policy than the literature suggests. Many situational crime prevention case studies take place in settings that support welfare, namely, housing, hospitals, public transport, and schools. This is most clearly seen in the work of Poyner and Webb on how the design and configuration of social housing influences rates of crime (Poyner and Webb 1991). Effective situational crime prevention can thus increase the likelihood of meeting social welfare objectives.

With respect to the criminalization of products and places, it is trite but worth emphasizing that situational crime prevention amounts to more than simply target hardening. Situational interventions exhibit huge diversity, from high-tech baggage detectors to low-tech bicycle parking stands designed to facilitate improvements in locking practice. Nor are such measures ugly. To situational advocates, particularly those in the tradition of design against crime, manipulating the immediate environment in ways that reduce opportunities for crime without compromising, say, aesthetics, costs, or function holds sovereign (see Ekblom 2008). Finally, while some might consider gated communities as emblematic of a "fortress society," there are many examples of situational interventions altering the physical environment in ways that promote community togetherness by facilitating neighborly interactions. Lighting upgrades and subsequent increases in pedestrian street usage after dark is a case in point (Painter 1996).

Future Directions for Situational Crime Prevention

There is scope for some theoretical development in situational crime prevention. It is not clear that the rational choice model of the offender is necessary for it. The rational choice model emerged only after the core ideas about situational crime prevention had been formulated, at which point, as indicated earlier, various possible models of the offender were mooted. Moreover, the incorporation of provocation reduction and rule reminders suggests that agents can be responsive to situational changes that operate at the level of feelings and morals as well as at the level of utility calculation.

Displacement is a further area deserving of research. Evidence on the presence of displacement is lopsided. The assessment of spatial displacement and to a lesser extent temporal displacement predominates, while other types of displacement have been little considered, in part because of the challenging measurement problems. The empirical research that is available is also limited in what it can capture, even when technically highly sophisticated. It has long been recognized that displacement is likely to be contingent on factors such as alternative available targets and types of offender motivation. There is scope for further theoretical development to devise propositions that predict what kinds of displacement can be expected in what conditions, again delivering on the suggestions of early papers on situational prevention. The same is true for diffusion of benefits. That theoretical work then needs to be followed by empirical tests.

There is also scope to advance the application of situational crime prevention. While the range of crime types that have been targeted by research and practice has expanded enormously over the past 30 years, there remain important gaps. Studies into "unconventional" crimes, for example, organized crimes of various types (Bullock et al. 2010), terrorism (Clarke and Newman 2006), wildlife crime (Pires and Clarke 2012), and cyber crime (Newman and Clarke 2003), are available but at present are largely programmatic. Case studies evaluating measures designed to activate provocation-reduction or excuse-removal mechanisms are limited (Guerette 2009). Moreover, situational interventions have rarely been formally evaluated when applied in industrial, office, and agricultural settings (Guerette 2009). More broadly, situational crime prevention has yet to be systematically trialed in developing resource-limited countries, although interest appears to be growing (Pires and Clarke 2012). A key question relates to the challenges of carrying out the preventive process in settings where data are often absent.

The final point concerns exposure and dissemination. Despite being widely advocated and implemented in both North America and much of Europe, it is fair to say that situational crime prevention is yet to capture the imagination of the public and wield widespread influence on policymakers. There is a banality to situational crime prevention that belies its sophistication. This often means it is not credited for providing valid explanations for shifting crime patterns where traditional criminology fails. Nor is it always recognized for its role in producing major crime reductions. Take the much-storied crime drop experienced in several industrialized nations from the early to mid-1990s. Numerous hypotheses have been put forward for such declines, many receiving widespread media coverage. Yet arguably the most convincing explanation of the observed trends relates to the prevalence and quality of in-car (situational) security measures (Farrell et al. 2011). Failure to bring the successes of situational crime prevention to the attention of the public may stymie its progression and confine it to the margins of crime prevention policy and practice.

Overview

Criminology now includes an increasing body of research and theory that subsumes crime prevention within a larger topic of protection and survival in nature. That body of work not only considers crime prevention as representative of a larger survival process but also takes into account human-animal interactions. Such interactions include human abuses of animals and animal populations and nature in general – including abuses that are against the law. But human-animal interactions also include humans protecting against animal incursions into their herds and home territories.

Background and Review of Literature

The situational prevention literature has recognized historical examples of human self-protection as a background topic but has increasingly brought the interactions with nature to the foreground. After reviewing a bit of that literature, the current entry shifts to a pictorial review of situational crime prevention in America's "Wild West." That term often applies to a historical period that has disappeared, but even today many Western states include sections with ranches, horses, cattle, and exposure to predatory incursions. Political struggles are found between metropolitan environmentalists who wish to reintroduce wolves to rural areas and ranchers who fear the loss of cattle and sheep to those same wolves. Migrants from city to suburban fringe and rural areas seek greater security than the areas from which they came; but they introduce new risks and fears to the areas that they enter. Thus, one person's protection becomes another person's threat. Survival from outside threats is a perennial problem in human history as in natural history.

The situational prevention of attacks also was found in the Old West. Consider this problem: ingots of silver bullion were carried by stagecoaches that were often victims of robbery by gangs of armed men on horseback. The problem was completely solved by instead producing 300 lb ingots that could not be carried on a single horse (Lingenfelter 1986). That was the end of stagecoach robbery. This example has been noted by several criminologists (Tilley and Laycock 2002; Clarke 1999; Farrell and Pease 2006).

Another example from the Old West came from pre-cowboy times. The ancient cliff-dwelling Indians in what is now Arizona and New Mexico entered their homes by climbing up ladders. At night they pulled up their ladders to prevent intrusions. This illustrates that situational prevention is far from new in behavioral terms. Moreover, Oscar Newman (1972) called our attention to territoriality and defensible space. Although situational crime prevention now includes many more ideas than that, it is still recognized that Oscar Newman placed defense of oneself, one's offspring, and one's dwelling area within a larger natural history perspective. That perspective was elaborated greatly in Felson's (2006) *Crime and Nature*, which included symbiotic and competitive ideas about offenders and the larger society.

Yet the breadth of "environmental criminology" is widened still further by new criminological papers on human-animal interactions. Recent research on parrot poaching strongly supports the idea that such crimes are highly structured in time and space and therefore subject to situational crime prevention (Pires 2012; Pires and Clarke 2011, 2012). Additional important research considers human attacks on elephants (Lemieux and Clarke 2009), and a more general review of wildlife crime is found in Pires and Moreto (2011), explaining why such offenses are subject to situational prevention. It is also clear from Eliason (2012) that wildlife crime is theoretically understood using the routine activity approach, a thread running through each of the articles reviewed in this paragraph.

Clarke (1999) offers us a framework for evaluating security by offering 25 techniques for situational crime prevention, along with many examples. His framework is widely employed to analyze crime situations and recommend solutions. These techniques are organized in five columns based on how they contribute to crime reduction. Included are (1) increasing the effort to carry out the crime; (2) increasing the risks to the offender; (3) reducing the rewards that the crime gives to the offender; (4) reducing provocations, especially for dispute-related crimes; and (5) removing excuses for carrying out the crime.

The current review considers how ranchers and others in today's Wild West use situational prevention techniques to protect against intrusions and attacks. The more important goal is to add examples and hence to widen the repertoire of ideas for studying the prevention-protection process and for understanding routine activities and situational prevention of crime. This entry shall demonstrate how the techniques of situational crime prevention have been and are currently being used in the American West, especially for nonhuman predators. Despite the urban image of rural life as idyllic, the reality is far from that. Ranchers, farmers, and other property owners often have a great deal of land and animals that must be controlled and protected from people, animals, and insects. A protective mentality is very important for their economic survival and is taken very seriously.

A Note About the Pictures

The pictures used within this entry were taken by the primary author. Many of the pictures were taken in rural Oklahoma; a few were taken at the

National Cowboy and Western Heritage Museum in Oklahoma City and the Woolaroc Museum in Bartlesville, Oklahoma.

Crime Prevention in the West

We begin (Fig. 1) with a bank teller window, more heavily barred than most modern banks in the United States. Although the design of the bars is attractive, their main purpose is to keep offenders out of the money area – an example of target hardening along with a kind of perimeter control. That did not prevent very aggressive robbery by multiple armed men, but it did narrow the span of vulnerability. Figure 2 shows a safe from the Cattlemen’s State Bank, designed to be too heavy for easy removal and too hard to break, given its heavy lock. Although we take these safe designs for granted today, they originated in an earlier era in response to the mobility offered by horses and a desire to respond.

One of the most important inventions in the American West was barbed wire. Without it, one can argue that the West would never have developed, since mass grazing of animals would have been impractical if they could easily wander off. The Biblical image of a shepherd watching a small herd of sheep or goats contrasts with the American process of maintaining very large herds with minimal supervision. Barbed wire fencing was developed in the late 1800s as a method of frugally enclosing animals and land while also preventing human theft. Barbed wire fence design styles range from legal and patented to illegal versions of patented designs to custom designs, resulting in thousands of versions (Liu 2009). In fact, the Cowboy and Western Heritage Museum in Oklahoma City displays 1,300 different types of barbed wire fencing. Figure 3 contains a few examples of different barbed wire styles from the late 1800s, each with its own patent. None of these styles is currently in use today, but the basic idea continues to the present in other forms. Figure 4 shows a rudimentary rural fence, while Fig. 5 shows a more professional version – each of which serves to contain cattle and signal other people; modern fencing in the West (not depicted) consists of wire woven in a small v-pattern that encloses cattle and horses without catching their hooves, is very difficult to climb, and keeps out large predators unless they can jump. Each of these fencing types applied defensible space long before Newman articulated it.

Situational Crime Prevention and the Wild West, Fig. 3 Examples of different styles of barbed wire

Not so well known outside the West is the old technique of hanging dead coyotes on a fence as a signal to live coyotes that their lives are endangered if they cross (Fig. 6).

It is important to consider in reading the current entry that predatory animals, from insects to coyotes, do more than just nibble. Attacks sometimes decimate crops or herds and other times remove the profit margin. Early ranchers worked on a much smaller scale, but today's West includes not only large-scale operations but also many small-scale ranchers who work part-time in

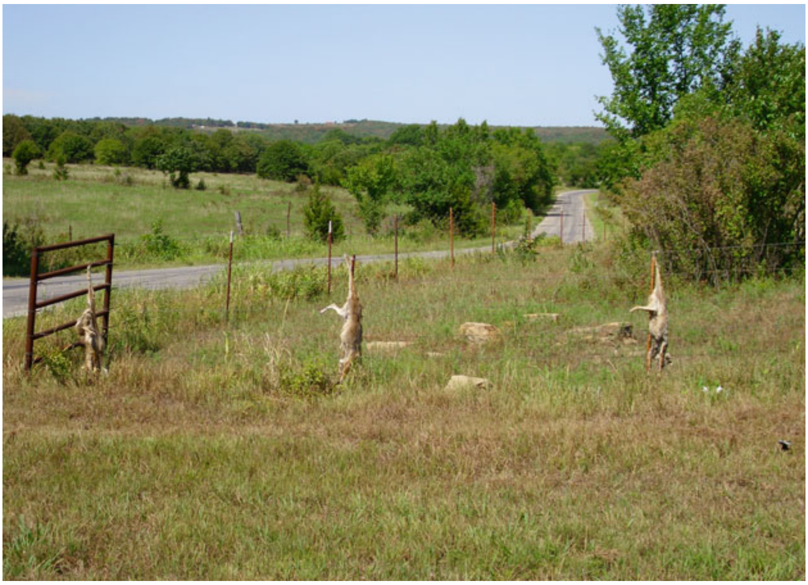
Situational Crime Prevention and the Wild West, Fig. 5 Well-constructed barb wire fence in rural Oklahoma

the city and are subject to considerable loss of income and way of life. Thus, protection of livelihood is a serious issue for them.

The use of predator against predator is an important part of their defense strategy. Owls are natural predators for farm pests, including small birds and rodents. Many rural people in the West place statues of owls in their barns to act as artificial place managers (Fig. 7). Plastic snakes and hawk statues are sometimes used for the same purpose. Scarecrows are designed to look like a farmer and are sometimes used as

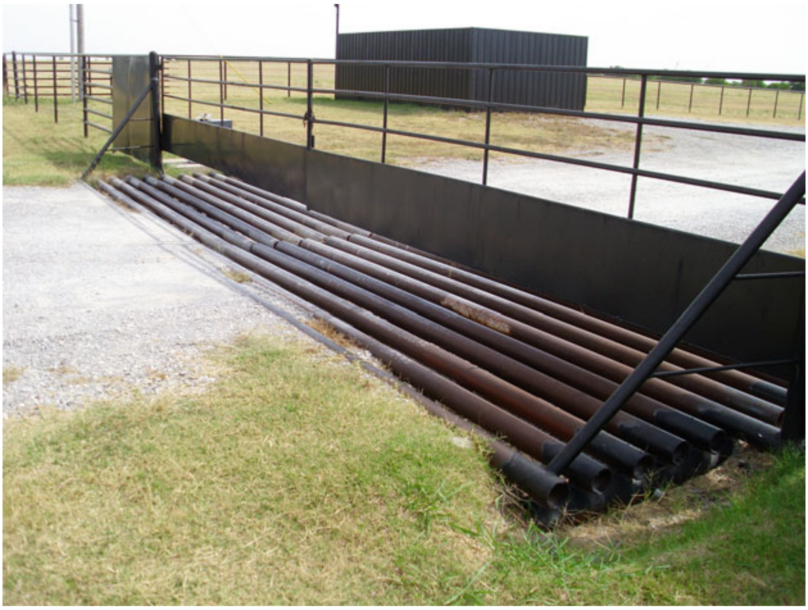


Situational Crime Prevention and the Wild West, Fig. 6 Dead coyotes hanging on fence as warning

Situational Crime Prevention and the Wild West, Fig. 7 Plastic owl serving as place manager in barn

artificial place managers to scare off birds and protect crops; many of the domestic pets in metropolitan areas become very important economically in the American West. The role of dogs was already mentioned above. Not so well known to urban people is the role of barn cats – commonly used as place managers at farms, ranches, and stables. These cats live in and around barns for the primary purpose of hunting and killing mice, rats, birds, moles, and small snakes.

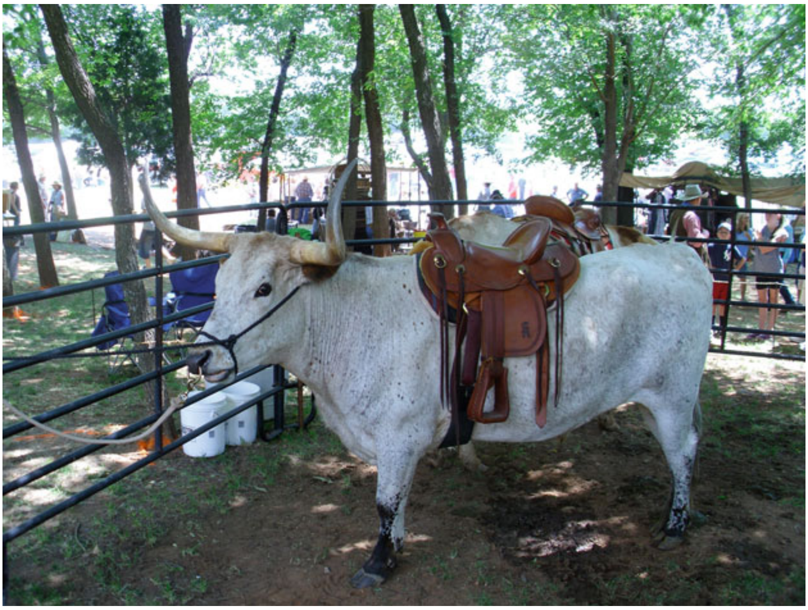
Animal containment is an important rural issue for many reasons, especially for large animals. Ranchers and farmers do not want to lose their cattle or find them injured and have to



Situational Crime Prevention and the Wild West, Fig. 8 Cattle guard

Situational Crime Prevention and the Wild West, Fig. 9 Guard donkey with longhorn cattle in rural Oklahoma

euthanize them, nor do drivers want to run into stray cattle. Figure 8 illustrates a cattle guard, designed to contain large animals in pastures while allowing gates between them to remain open. Cattle guards are formed by placing steel bars close together horizontally across a shallow ditch under a gate. The bars discourage hoofed animals from exiting through the gate as their hoofs slip on the bars and get caught between them. Cows and horses will generally avoid cattle guards, although they are not foolproof. Some horses may jump over them, and both cattle and horses have been known to catch their hoofs between the bars, breaking one or more legs, leading to certain euthanization.



Situational Crime Prevention and the Wild West, Fig. 10 Longhorn cow wearing branded saddle

Situational Crime Prevention and the Wild West, Fig. 11 Stall divider

One of the most interesting prevention techniques is to use guard donkeys near cattle to watch fences and prevent intrusions (Fig. 9). Donkeys are good place managers because they have a dangerous kick and tend to attack animal predators. Similarly, llamas or large dogs are sometimes used for the same purpose. This gives us a new way to look at "formal surveillance," with animals functioning as security guards, requiring relatively inexpensive maintenance, and demanding no pensions or benefits.

Figure 10 illustrates branding – burning unique marks into the flesh of cattle, horses, or saddles to identify them with a particular ranch.

This fits very closely with the situational prevention method of identifying property to discourage burglary (Laycock 1991). Sometimes a brand would be altered by the thief in order to allow sale. A more modern technique is less easily thwarted: Freeze branding leaves a white brand mark on an animal's hide and is more effective than burning. Thus, we see that Ekblom's (2001) "arms race" between offenders and crime prevention techniques applies as much in the West as in metropolitan areas around the world. Modern animals and property are also identified with brass nameplates (not illustrated) that offer some protection if offenders do not have time to remove them.

Because large-scale horse operations have been commonplace in the West, managing animal interaction is important. Because horses are herd animals, it is important for them to see and communicate with each other, but physical interaction can be problematical if they begin to fight. Horses within a single farm or ranch are usually separated from one another with a variety of walkways and stall dividers (see Fig. 11) allowing them to see, hear, and smell one another, without biting or kicking.

Conclusions

Numerous types of situational crime prevention apply to the American Wild West and today's remaining Western frontier. Target hardening includes bank teller windows and heavy bank safes. Barbed wire fencing and cattle guards serve to control access. Guard donkeys and barn cats serve as place managers. Branding cattle identifies property. Stall dividers and horse barn designs serve to avoid equine disputes. Dead coyotes on fences and owl statues in barns give instructions to intruders.

We can readily see that situational prevention depends on routine security built into the design and management of daily life. This applies in the metropolis and Wild West alike, but not always exactly alike. Much more needs to be known about human-animal interaction and predation and human protection of their own animals from others. Crime is part of a much larger ecological process which we are only beginning to understand.

So What Criminology?

Roger Matthews[1] and Jennifer Gibbs[2]
[1]University of Kent, Canterbury, Kent, UK
[2]West Chester University at Pennsylvania, West Chester, PA, USA

Synonyms

Administrative criminology; Critical criminology; Public criminology; Realism

Overview

Despite the continued expansion of academic criminology and the proliferation of publications, the policy relevance of criminology has noticeably decreased in recent years. Some commentators have suggested that academic criminology is becoming irrelevant socially and politically and that it has become increasingly marginalized from the process of policy making (Currie 2007). This has led to the identification of a growing body of what has become referred to as "So What?" criminology.

"So What?" criminology has a number of characteristics according to Elliott Currie (2007) including the use of impenetrable language; the adoption of highly technical research techniques which are often dauntingly quantitative, as well as a tendency to focus on trivial issues; and an orientation towards what C. Wright Mills (1959) called "abstracted empiricism." This makes research results difficult to read by anyone other than academic experts in the discipline, while the bulk of the literature remains inaccessible to both policy makers and the general public.

This body of work is produced in an academic context where there is an increased emphasis on publishing in peer-reviewed journals combined with a growing reluctance to engage in the challenging and time-consuming business of policy formation and development. Criminology is also becoming increasingly fragmented and organized into different theoretical and methodological silos, which has to some extent undermined the possibility of constructive debate in the subject producing a body of largely incompatible and partial knowledge. In contrast to these developments, realist criminology argues for the integration of theory, method, and practice and aims to move criminology in the direction of developing a more constructive and socially engaged approach to crime control. Thus, it is suggested that adopting a realist approach provides the possibility of developing an alternative to "So What?" criminology, which is both critical and useful.

Introduction

There is a growing paradox in criminology. Despite the increasing scale of the criminological enterprise involving an increasing number of students, courses, and publications, the policy relevance of criminological research has been decreasing. To make matters worse, this growing body of criminological endeavor suffers from a paucity of theory combined with the adoption of inadequate or inappropriate methodologies. This has provided the basis for the development of what has become known as "So What?" criminology.

This entry will outline some of the main features of "So What?" criminology, which include weak conceptualization, inadequate methodologies, and limited policy relevance. It will also examine some of the recent developments within criminology that have contributed to the growth of "So What?" criminology. Finally, we will offer some thoughts on the contribution that realist criminology can make to overcoming the limitations of "So What?" criminology.

The Main Features of "So What?" Criminology

The term "So What?" criminology refers to those forms of criminology that involve a low level of theorization and thin, inconsistent, or vague concepts and categories; embody a dubious or inappropriate methodology; or have little or no policy relevance (Matthews 2010). Currie (2007) has suggested that in order to overcome the deficiencies of "So What?" criminology, researchers should always aim to present their findings in a way that is easily accessible to policy makers, the general public, and practitioners. Thus:

> . . .some areas of criminological research have become so specialized, so technical and so driven by what has gone before that even many people within the discipline cannot really follow it without help. This means that the need for people who can do the work of synthesis and contextualization of research has become ever greater. (Currie 2007: 183)

Research findings and "criminological wisdoms," he suggests, should be disseminated wherever possible through public debate in order to foster a "public criminology." However, the problem with this approach is that there is little consensus in the field and that most "criminological wisdoms" are highly contested, and it is difficult to find much agreement among criminologists on any issues of significance.

Others have advocated a sort of division of labor within the subject dividing researchers into professional, policy, and critical criminologists, each developing their own forms of expertise and ideally contributing to each other's endeavors (Burawoy 2004). However, fostering such divisions within academic criminology is likely to increase the existing fragmentation of the subject and is more likely to exacerbate than resolve the growing irrelevancy of the ever-expanding criminological enterprise.

One of the most noticeable limitations of much contemporary criminology is poor conceptualization and lack of theoretical rigor. This is most evident in the way in which the central concepts like "crime" and "race" are used. Within the criminological community, there is little clarity or agreement how the concept of crime is to be conceptualized, and most criminologists are divided between those who think that it is an act and those that see it is a product of social reaction. Some use essentially legalistic definitions of crime, while others want to dispense with the concept of crime altogether and replace it with notions of "harm" or human rights (Muncie 1996; Hillyard et al. 2004). Realists have argued that "crime" is a process of action and reaction and have developed the sensitizing notion of the "square of crime" pointing out that the construction of "crime" is a *process* involving four basic elements – the offender, the victim, the state and public opinion, and the social norms (Young and Matthews 1992).

Similarly in relation to "race," rather than deconstructing this concept, all too often "race" is equated with skin color, and diverse ethnic groups are lumped together as if they formed a homogeneous group. Strangely in country like

America that has one of the most diverse ethnic populations in the world, much criminological investigation operates as if the American (criminal) population were divided into "blacks" and "whites," resulting in a form of "monochromatic criminology." In this bifurcated world, even Hispanics, which are soon to be the second largest ethnic group in America, are paid relatively little attention.

The theoretical and conceptual limitations of contemporary criminology, however, go far beyond these two examples. Administrative criminology, which emanates from governmental departments and which plays an increasingly major role in funding and conducting criminological research, is notoriously weak conceptually. Its theoretical weakness, often combined with dubious methodological approaches, tends to result in weak or equivocal conclusions and policy proposals. Often, using common sense or taken-for-granted categories of "crime," administrative and related criminologies veer towards a form of pragmatism which paradoxically is neither very practical nor makes much contribution to developing a cumulative knowledge about crime.

Administrative criminology also tends to gravitate towards empiricism or positivism and assumes that scientific investigation is based on what can be observed. Believing that the lack of theory can be compensated for by the use of "sophisticated" statistical methods, these criminologies tend to reduce the richness and complexities of crime and punishment to a "numbers game" (Young 2004). However, no amount of statistical manipulation can compensate for weak conceptualization.

The problem of method, however, goes far beyond debates about sample size, statistical techniques, and the problems of representation and generalization. Instead, criminological researchers must begin by asking a more fundamental question about how the social world can be best appropriated and understood. Criminologists operate in open systems, which are complex and messy. Social reality does not present itself in an obvious and unproblematic way. To paraphrase Marx: if the social world were intelligible at the level of appearances, there would be no need for social scientific investigation at all. Thus, the aim of investigation is to go beyond appearances and that which is directly observable and to uncover the complexity of a socially stratified and diverse reality. Thus, we need to move beyond simple description of the world and instead try to understand the causal processes involved. At the same time, we need to consider the relation between agency and structure and how the actions of particular individuals or groups are conditioned or shaped by the social structures in which they operate. The ultimate aim of criminological investigation is therefore not to produce descriptions or "facts," as if these speak for themselves, but *explanations*.

Empiricism comes in many forms. In criminology, there is a tendency to what we might call "functional empiricism" and "inverted empiricism." Functional empiricism refers to those approaches which see two observable phenomena that seem to change together and conclude that one must be influencing the other. Thus, Loic Wacquant (2009), for example, claims that there is a "functional equivalence" between the decline of black ghettos in America and the increased incarceration of African Americans and that this is a consequence of neoliberalism. However, why neoliberalism with its commitment to minimal statism would want to expand state provision in this way rather than leaving ethnic minorities to fend for themselves in the ghetto is not clear. It is also the case that in periods of neoliberalism, the number of people sent to prison has decreased as well as increased, suggesting that there is no necessary relation between neoliberalism and penal expansion (Matthews 2009b).

Inverted empiricism refers to those forms of investigation that claim, for example, that there is no causal relationship between crime rates and incarceration on the basis that these two rates do not always covary (see, e.g., Tonry 2001). However, comparing overall crime rates and imprisonment rates is problematic because measurement of these two variables changes over time and between different locations. This line of thinking by focusing on immediate observables tends to neglect a more detailed critical investigation into the attrition rates of different offenses particularly those offenses that are more likely to result in a prison sentence. Thus, naïve empiricists like Michael Tonry (2001) who claims that crime rates and imprisonment rates are unconnected because they do not correlate avoid examining the causal processes in play, and how changing patterns of crime over time as well as changes in the way in which different crimes are processed can influence the scale of imprisonment. An investigation of this type would reveal that the increase in incarceration rates in America is not so much a function of the police and judiciary getting tough on drug offenders, particularly those from ethnic minority groups, as Michael Tonry (1995) claims, but a significant increase in the number of violent offenders being processed (Bureau of Justice 2008).

The limited policy relevance of much criminology is associated with the theoretical and methodological weaknesses outlined above. In addition, many criminologists see themselves as professional academics in the way that Burawoy (2004) describes and largely divorced from policy and practice. Often, under increasing pressure to produce well-cited publications and manage increased teaching and administrative loads, a growing body of criminologists does not have the time or inclination to engage in public or political debate. Among those who are interested in engaging with policy and practice, it is often the case that because they present "facts" rather than credible explanations, their work often does not resonate with politicians or the public. In addition, findings are not presented in an accessible form.

All too often, criminologists dwell on the failures or limitations of different programs and fail to address the question of "what is to be done." Thus, in relation to major issues such as imprisonment and policing, we see endless publications listing the failures and the problems of these institutions and organizations, rather than engaging in a constructive discussion on how they might be improved or usefully reformed.

The Construction of "So What?" Criminology

There are a number of developments that have taken place within criminology over the last 20 or 30 years that have contributed to the development of "So What?" criminology in different ways. First, as mentioned above, there has been a considerable expansion in administrative criminology as a result of the increased dominance of government funding of criminological research. Reese Walters (2003) has questioned how "market-led criminology," which focuses on risk management, privatization, and cost-effectiveness, has influenced the production of criminological knowledge. Government-funded forms of administrative criminology, he suggests, are not interested in generating critical and reflexive research and have in recent years come to undermine and sideline critical criminological research. There can be little doubt that the changing nature of the academy coupled with the increasingly narrow focus of much government-sponsored research has produced a growing body of largely atheoretical research with a limited policy edge. Consequently, much "administrative criminology" often involves policy-driven evidence rather than evidence-driven policy.

Second, postmodernism has had a major influence on the social sciences in general and criminology in particular. Postmodernists have been critical of what they refer to as "grand narratives" and of the modernist belief that social progress can be achieved through the application of scientific knowledge to social problems. Postmodernists consequently present a form of relativism and generally express an anti-objectivism and antirealism. Although postmodernists often end up in producing their own meta-narratives and engage in debates which imply at least some degrees of objectivism and an independent reality about which we can debate, the advent of postmodernism has fuelled a relativism that was already present in criminology. This relativism suggests on one side that everybody's view is equally valid or that certain "standpoints" have privileged position in relation to truth.

Thus, Carol Smart (1992) in her well-referenced critique of "malestream criminology" in which she berates criminology for what she sees as its adoption of grand narratives argues instead for situated knowledge. Suspicious of what she sees as an essentially male-centered criminology, she argues that the truth claims of criminology have to be deconstructed and challenged from a feminist standpoint. Although rightly critiquing partial views of the world that claim to be universal, Smart wants to replace these one-sided views with another set of one-sided views. As John Lea (1998) has argued, replacing the views of the dominant group with those of the marginalized, victimized, and excluded women is to replace one form of fundamentalism with another. In the end, Smart muddies the waters rather than constructing a basis for the development of a feminist criminology. By advocating a form of standpoint feminism together with an antimodernism and antirealism, Smart gravitates towards relativism and foundationalism. From this perspective, it is difficult to see how she might develop a policy response that would reduce rape, domestic violence, and other crimes that victimize women. Thus, postmodernism tends towards defeatism and does little to move the field forward in developing meaningful and effective criminal justice policies.

Third, in conjunction with postmodern defeatism, there is a significant trend in academic criminology towards liberal pessimism. The implicit message of this stance as Stanley Cohen (1985) pointed out is to try to do less harm rather than more good. This brand of pessimism was popularized in the 1970s with the publication of Martinson's (1974) report on corrections – a report that was widely interpreted as claiming that "nothing works." Although Martinson in a subsequent article admitted that certain programs did work for some people under certain conditions, the pessimists embraced the "nothing works" mantra and applied it to different areas of criminology. Significantly, the claim that rehabilitation strategies were ineffective in reducing recidivism allowed a shift away from a commitment to try to rehabilitate prisoners to a policy of incapacitation and "just deserts." This in turn led to the warehousing of prisoners and the creation of what were described in the UK as "penal dustbins."

Liberals, in fact, have found it difficult to develop policies and interventions that are credible and which might resonate with the policy makers and the general public. This is partly because many are antistate or at least minimal statists, while most are anti-punishment. For the most part, their arguments are directed towards the reduction of state intervention and of limiting the use of punishment. Thus, there is a general policy of reductionism among liberal criminologists who argue for a decrease in the prison population and in many cases the use of community-based sanctions instead. However, because liberals often fail to address the issue of who should go to prison and for what purpose and for how long, the question of how far the prison population needs to be reduced can never be answered. The issue of imprisonment is, however, not just a question of numbers. Moreover, as some criminologists have pointed out, the greater use of community-based alternatives to incarceration can lead to "net widening" and the simultaneous expansion of both inclusive and exclusive strategies of control (Cohen 1985).

From the vantage point of liberal pessimists, there is a general wariness about proposing "solutions" or "alternatives." For some, there is little interest in improving prison conditions as this is only seen to relegitimize the use of incarceration. On the other hand, there is a growing skepticism about the use of community-based sanctions. At the same time, there is some suspicion concerning the use of the "welfare sanction" which is seen to deepen the level of state intervention into individual lives while extending the range of intervention to include the wider community (Cohen 1985; Garland 1981). Thus, liberal pessimists find it difficult to commit to any of these forms of regulation.

More recently, liberal pessimists have claimed that there has been a rise in "populist punitiveness" and that both politicians and the public are becoming increasingly punitive (Garland 2001;

Simon 2001; Wacquant 2009). Although these claims are based on thin theoretical and empirical foundations, there is a substantial consensus among liberal pessimists that we are witnessing a punitive turn (Matthews 2005). The main reference points for many of these liberal pessimists are the growing prison population on both sides of the Atlantic. The increase in the number of people in prison coupled with decreasing crime rates is seen as uncontroversial evidence of an increase in punitiveness. However, in relation to the American situation, the prison population leveled off at the end of the 1990s, while in a number of states, the prison population has actually decreased over the past decade. In the UK, we have seen a bifurcated response in recent years with the judiciary giving longer sentences for certain offenses like violence and murder, while giving reduced sentences for other offenses like theft and burglary (Matthews 2009a). This does not look much like the blanket surge in punitiveness that pessimistic liberals suggest. Also, in other countries such as Italy, Canada, and Germany, the incarceration rate has remained stable or declined in recent years (Meyer and O'Malley 2005). In short, these liberal pessimists add little that is useful or constructive to policy formation and in fact in relation to the debate around punitiveness have led us into a conceptual cul-de-sac. Unfortunately, doing nothing or trying to find reasons why proposed interventions are destined to fail creates a form of disengagement that allows policy makers and politicians a relatively free hand to orchestrate criminal justice policy. Criminal justice, however, is too important to allow politicians to make uniformed decisions.

Fourth, the demise of critical criminology in recent decades has contributed to the resurgence of conventional criminology with its natural scientific orientation. At its height of influence in the 1970s, critical criminology provided useful theories on crime and deviance including labeling and subcultural theories. Importantly, critical criminology encouraged critical discussions about the role of power and politics in relation to crime and justice, as well as raising questions regarding values and meanings. However, critical criminology was unable to offer a credible alternative to conventional criminology. In developing a skeptical view of convention attitudes towards crime, it tended towards a romantic and idealistic view of the criminal while downplaying the impact of crime on victims.

Eventually critical criminology was largely absorbed within the framework of mainstream criminology and became at best the "bad conscience" of conventional criminology. The demise of critical criminology was unfortunate, as it left the door open for positivism to gain ascendency within academic criminology. In recent years, however, we have witnessed the growth of cultural criminology that embodies an important critical impulse (Ferrell et al. 2008). Cultural criminology focuses on the experiences of marginalized groups, emphasizing questions of agency, motivation, emotions, and the generation of meaning. Cultural criminology, though, largely ignores the role of the state and wider issues of power. It has been criticized for acting as "zookeepers of deviance," while there is some confusion over what is meant by "culture" (O'Brien 2005). The problems are seen to limit its critical capacity, while from a realist perspective, cultural criminology like its critical criminological predecessors has a limited engagement with policy and social reform. Thus, while cultural criminology has no doubt reinvigorated critical interest among academic criminologists and in many respects breathed new life into the subject, its ability to provide a coherent alternative to mainstream criminology in its current form remains limited.

Countering "So What?" Criminology

By focusing on identifying causal connections between phenomena, realists seek to understand how and why change occurs. In contrast to postmodern defeatism and liberal pessimism, realist criminology involves a modernist perspective, promoting an evidence-based approach to social reform. Following its critical criminological predecessors, realist criminology aims to deconstruct key concepts like "crime" and "race" and to provide explanations rather than present a series of facts or decontextualized descriptions. Also drawing on the work of cultural criminologists, it aims to incorporate an appreciation of the cultural dimensions of crime control recognizing that policy formation will always be subject to cultural variations. In this way, realist criminology aims to develop a joined-up approach that incorporates sophisticated conceptualization and a robust methodology while making a contribution to policy formation.

Realists on Theory. First and foremost, realists recognize that "crime" is not simply a given nor is it an "act" or simply a product of "social reaction." Rather it is a process which involves a complex and changeable relation between offenders, victims, the state, and the public. It aims to avoid the relativism of postmodernists and the idealism of some forms of critical criminology. The aim is neither to romanticize nor demonize the offender but rather to understand the motivational and structural dynamics that create crime and victimization on one hand and which shape formal and informal responses on the other. Understanding the "square of crime" is important in order to remind ourselves that "crime" is neither a "top-down" construction imposed by the criminal justice system nor a "bottom-up" process involving certain "acts" or "behavior" or changing levels of tolerance but a complex relation between these different determinants. For realists, the development of theory is important but is not seen as an end in itself. Theory must be useful and usable.

Realists on Method. Although realists are critical of empiricism and positivism, they are also critical of those qualitative approaches that are purely descriptive. Consequently, from a realist perspective, purely descriptive ethnographies are of no greater value than the most dense and impenetrable forms of inferential statistics. Realists also reject those forms of "cookbook criminology" that claim that there is one methodological approach that is intrinsically superior to all others and should be followed on all occasions. In many respects, realists are methodological pluralists and argue that the selection of methods will be dependent on the nature of the object under study and the type of research questions that are developed (Sayer 2010).

Rather than rely on statistical correlations, the aim of realist investigation is to identify causal connections. The objective is to find out not only what works but how and why it works. It is also recognized that "what works" will vary according to context and also according to the subjects that interventions are directed towards. As Pawson and Tilley (1997) point out, it is not so much that certain programs "work" but that they are effective to the extent that they connect with the capacities of the subjects to whom they are directed.

Realists on Practice. The move away from "nothing works" (Martinson 1974) to "what works" (Sherman et al. 1997) has been a welcome break from the pessimism and impossibilism that permeate contemporary criminology. While the field today focuses on using evidence to form policy, the evidence for "what works" has been disappointing, largely due to a low level of theory and poor conceptualization combined with inadequate and inappropriate methodologies. A great deal of administrative criminology adopts an instrumentalist view of "what works" and pays scant regard for differences in contexts and in the capacities and propensities of the subjects at whom interventions are aimed. Given the complex and ever-changing contexts of social life, the difficulty is to find situations in which successful interventions can be replicated. Indeed, nothing works for everyone all the time. Thus, instead of claiming that a program or policy "works," perhaps it is more appropriate to claim that some programs work for some people under certain circumstances.

Critical realists also have a distinctive view of the nature and meaning of interventions. Interventions are not just practices but theories or hypotheses that postulate the possibility of bringing about an improved outcome. Consequently, interventions are potentially fallible particularly because they deal with complex social realities, as well as dealing with different groups of subjects and will invariably be implemented differently in different contexts.

Intervention provides tests for theories and hypotheses and potentially offers a basis for developing cumulative knowledge about what works in different contexts and for different populations.

Conclusion

Realist criminology, it has been suggested, offers an alternative to “So What?” criminology and aims to provide a coherent and constructive alternative that is able to provide an evidence-based approach to social reform. The task facing criminology is to develop a coherent and integrated approach that emphasizes the role of a theory and which is critical but grounded. Realist criminology argues for the deployment of methods of investigation that are responsive to the object under study and are designed to identify how and why measures work and ultimately to fashion interventions that are aimed at making tangible improvements in the world. In short, realist criminology is theoretical but not theoreticist, critical but not negative or impossibilist, Utopian but grounded in lived experience, methodologically flexible but rigorous, practical but not pragmatic, and policy relevant rather than policy driven.

Social Capital and Collective Efficacy

Kevin M. Drakulich
School of Criminology and Criminal Justice,
Northeastern University, Boston, MA, USA

Overview

Criminologists have long theorized that some neighborhoods have a greater capacity than others to recognize common problems and act collectively to solve them. Though this basic notion is derived directly from social disorganization theory, collective efficacy – a recent reformulation – has brought substantial new attention to the idea. Collective efficacy borrows from the idea of social capital to rethink the ways that this capacity is rooted in the local connections among neighbors. Specifically, *social capital* refers to a resource potential facilitated by the structure of local networks, while *collective efficacy* is the ability of a group to draw on this resource to recognize common interests and achieve specific tasks related to local social control. This reformulation has also garnered attention for innovations in the operationalization and measurement of the concept. Recent research has established that collective efficacy is an important predictor of differences in the level of crime between neighborhoods and may be significant to our understanding of the disproportionate prevalence of crime in neighborhoods characterized by economic disadvantage and residential instability (Sampson et al. 1997; Morenoff et al. 2001). However, important questions remain about the way residents perceive collective efficacy, the different ways they can choose to intervene when they become aware of a crime problem, and the connections between collective efficacy and other neighborhood phenomena including cultural forces and more formal crime control efforts.

Introduction

In 1942, a now-classic volume was published which made a radical suggestion: the high crime rates found in immigrant and African-American neighborhoods were not the product of the inherent criminality of individual members of these groups – a popular explanation at the time. Instead, Shaw and McKay revealed that delinquency rates were related to the social-structural organization of the city and were highest in the "transitional zone," an area characterized by low home ownership, socioeconomic disadvantage, and other social-structural disadvantages. The enduring power of their work is derived from the carefully collected and presented evidence of this link between neighborhood structure and crime rates.

Shaw and McKay (1942) also pose an explanation for this link, suggesting that, in simple terms, there is something about some neighborhoods that allows them to organize in ways that prevent crime problems or respond to them as they occur. Notably, however, this is somewhat of an amorphous concept, and both Shaw and McKay (1942) as well as a number of subsequent researchers have struggled with two important issues. The first is how to *theoretically* conceptualize exactly what is important about the social organization of a neighborhood. The second is how to *measure* this theoretical concept systematically such that its role as a mechanism can be tested.

After more than 50 years of incremental and mixed progress on these issues, a 1997 study purported to address both issues. *Collective efficacy* attempts to capture "the differential ability of neighborhoods to realize the common values of residents and maintain effective social controls" (Sampson et al. 1997, p. 918). While earlier work relied on either administratively collected data or aggregations of individual reports of personal behaviors, collective efficacy employed individuals as reporters of neighborhood conditions. Any one of these respondents, on their own, may be biased or simply in error in their assessments. Collectively, however, and when controlling for potential individual-level sources of bias, such respondents may produce a reliable and valid measure of a collective phenomenon – or, as Warner and Rountree characterize it, a Durkheimian *social fact*: "a thing distinct from its individual manifestations" (1997, p. 520).

By situating this collective capacity for control in the resource potential of specific forms of personal and organizational networks (Sampson et al. 1999, p. 635), collective efficacy potentially represents significant progress in our understanding of the group social processes relevant to the spatial distribution of crime. This entry begins by providing background on collective efficacy as a theoretical mechanism, tracing its development through several previous propositions. Collective efficacy, however, departs from previous propositions through several theoretical and measurement innovations. The following section details these innovations and surveys research on its importance to a variety of neighborhood phenomenon. The final section raises a number of potential controversies and open questions facing future work on collective efficacy.

Background

Simply stated, social disorganization theory suggests that the structural conditions of a neighborhood, especially the level of poverty and residential instability, disrupt local social organization and thereby increase crime. The direct association between the structural conditions and the crime rate is relatively easy to observe using administrative data, such as the US Census and the Uniform Crime Reports. More difficult to observe is the social mechanism by which this structure affects crime rates. Over time, research on social disorganization has frequently revised the theoretical operationalization of what it is about the organization of the neighborhood that matters, while simultaneously experimenting with a variety of different more or less successful means of measuring these theoretical mechanisms.

Shaw and McKay (1942), in their initial proposal of the theory, suggest several theoretical mechanisms. Some components of their explanation – including value heterogeneity and the cultural transmission of delinquent traditions between generations of boys within neighborhoods – have been largely ignored or dropped in subsequent revisions to social disorganization, including in the notion of collective efficacy. One component of their explanation, however, is the direct intellectual antecedent of collective efficacy. Drawing on a classic account of Polish communities in Chicago by W.I. Thomas, Shaw and McKay (1942) suggest that an "organized" community is characterized by "the presence of social opinion with regard to problems of common interest, identical or at least consistent attitudes with reference to these problems, the ability to reach approximate unanimity on the question of how a problem should be dealt with, and the ability to carry this solution into action through harmonious co-operation" (p. 184).

In subsequent years, Kornhauser's (1978) critique of the theory led to an increasing focus on the mechanism of social control to the exclusion of the subcultural and learning mechanisms – those explanations interested in value heterogeneity or the transmission of delinquent skills and values. Simultaneously, an emphasis on social ties among neighbors rose to prominence following Kasarda and Janowitz (1974) argument for a systemic model of social organization in which the local community is "a complex system of friendship networks and formal and informal associational ties" which are in part a product of local structural conditions (p. 329). Out of these trends came a new operationalization of the mechanism at the heart of social disorganization: a disruption of the social networks among neighbors which damages the neighborhood's capacity to self-regulate (e.g., see Bursik and Grasmick 1993).

While research inspired by these ideas represented both theoretical and methodological progress, it was still hindered by basic measurement issues. In perhaps the best example of this work, Sampson and Groves (1989) operationalize the mechanism of social disorganization as a combination of sparse local friendship networks, the presence of unsupervised teenage peer groups creating a nuisance, and low levels of organizational participation. In the measure of nuisance-causing unsupervised teenage groups, Sampson and Groves are attempting to directly measure a neighborhood's capacity for informal social control. Unfortunately, by operationalizing social disorganization via an outcome (the presence of rabble-rousing teenagers) rather than the social mechanism itself (the capacity for informal social control), Sampson and Groves open themselves up to the classic criticism of social disorganization research as using delinquency "both as an example of disorganization and something caused by disorganization" (Pfohl 1985, p. 167).

Sampson and Groves (1989) find a strong relationship between their measure of the presence of trouble-causing unsupervised youth groups and a variety of measures of local crime, but their measure of local friendship networks has somewhat less success. Warner and Rountree (1997) find similarly mixed effects for the role of local social ties in relation to local crime rates: they find that measures of the prevalence of interactions between neighbors (borrowing tools, having lunch or dinner, helping neighbors with problems) are negatively related to the crime rate only in largely white neighborhoods and appear unrelated to crime in neighborhoods with larger numbers of racial or ethnic minorities. Critics of the idea of social disorganization pointed out that some high-crime communities in fact had strong *criminal* organization (recent example in Venkatesh 1997; see discussion in Sampson 2002). Critics of the systemic model of social disorganization pointed out that many poor communities had dense social networks (Gans 1962) and that in some communities, ties between neighborhoods prevented informal social control efforts when they bridged the gap between residents who were involved in crime and those who may otherwise have organized against it (Pattillo 1998).

As of the 1990s, then, research on social disorganization theory was faced with several key issues. First, the exact role of social networks in social organization remained ambiguous. Second, there appeared to be a need to distinguish organizational activities that suppress crime versus those that encourage crime. Third, research in the area continued struggling to identify direct measures of any of these theoretical concepts to test the core hypotheses.

Social Capital and Collective Efficacy

The concept "collective efficacy" attempts to resolve some of the issues in social disorganization theory by grounding it in new ideas about the dynamics of interpersonal connections within groups and the capacity these connections create for collective action. By asking residents to report on their perceptions of their neighbors' reactions to hypothetical local problems, collective efficacy attempts to capture a task-specific *potential* for collective action rooted in the social networks of a neighborhood. Collective efficacy, then, is the collective realization among neighbors that they have a common goal in the safety of their neighborhood and a collective willingness to act to achieve this goal (Sampson et al. 1997).

Collective efficacy has found success by making three key theoretical revisions to older versions of social disorganization theory and by using theses revisions to better operationalize and measure the presence or absence of this phenomenon within neighborhoods. Theoretically, Sampson et al. (1997); (see also Sampson 2002) define collective efficacy as rooted in social capital: "the resource potential of personal and organizational networks" (p. 635), as task specific, and in particular as oriented toward the universally shared goal of living in a safe neighborhood. They find empirical evidence for a role for collective efficacy by operationalizing it as potential rather than actualized organization and as an emergent property of neighborhoods best captured by using local residents as imperfect reporters of this group-level phenomenon. The following sections discuss each of these theoretical and measurement dimensions that distinguish collective efficacy from earlier versions of social disorganization.

Social Capital

Perhaps the most important theoretical development for the reformulation of social disorganization theory is Coleman's (1988) version of social capital. Coleman (1988) combines economic rational choice theory with sociological normative theory to create the notion of "social capital," with the premise that "rational or purposive action, in conjunction with particular social contexts, can account not only for the actions of individuals in particular contexts but also for the development of social organization" (p. S96).

In a simple sense, social capital suggests that certain kinds or qualities of connections among people can facilitate particular actions that may not otherwise have been possible. It can take a variety of forms which may be better or worse at facilitating different kinds of actions. One such form is a marketplace of obligations and expectations in which people do favors or help one another with the expectation of indirect reciprocation (Coleman 1988). This form of social capital provides a framework for understanding why a resident would undertake an action – for example, intervening when they see teens vandalizing public property or a neighbor's house – that has minimal direct benefits for themselves. The key is that when that resident lives in a community with an active marketplace of obligations and expectations, they can expect that their favor will be reciprocated by others at some other point when the resident currently performing the favor has a need of their own arise. Other forms of social capital include the transmission of potentially useful information through networks maintained for other purposes or the presence of norms and effective sanctions. Coleman (1988) describes, for example, a norm in which all local adults are responsible for the safety of all local children in public spaces.

These forms of social capital are facilitated by social structure. The trust required for a marketplace of obligations and expectations, for instance, is more likely to emerge in a community with relative residential stability – the presence of long-term residents who may be expected to remain in the neighborhood long enough to repay debts into the collective pool. Such a marketplace may also be more likely when residents have enough resources to be able to do favors for neighbors but not so many resources that they will never need to ask neighbors for favors (Coleman 1988). Coleman (1988) also identifies particular kinds of relational structures that produce social capital, one of which is relevant here. *Closure* in social networks refers to the presence of sufficient ties between network actors. One specific form of closure relevant to collective efficacy is intergenerational closure, in which parents know the parents of their children's friends, through which they can more effectively monitor and sanction their own children. In simpler terms, it is harder to do something without your parents' knowledge when they know all your friends as well as the parents of your friends. Thus, network closure is an aspect of social structure that facilitates certain kinds of actions within the structure.

Social capital, then, suggests that elements of local social organization provide neighborhoods with a social resource that can be drawn upon to address local problems. For instance, in highly residentially stable neighborhoods, there is more likely to be a high degree of interconnectedness among residents. Due to this interconnectedness, residents may feel a sense of trust that if they help a neighbor, another neighbor may be willing to help them when they need it. This, Coleman argues, provides a social resource potential that can be drawn upon to address local problems. Similarly, interconnections between local parents and local children may both increase the surveillance of and provide greater adult resources for local children. Thus, social capital describes a process by which structural characteristics of a neighborhood like residential stability assist in the development of particular forms of social organization, which in turn can facilitate specific kinds of local actions.

Collective Efficacy as Task-Specific Action

One key to social capital is that – like physical or human capital – it often exists as a value-neutral tool that could be appropriated to different kinds of actions. A person could use a biology degree to cure cancer or create a weapon; spray paint can be used for art or vandalism. Similarly, a neighborhood could use comparable kinds of social capital alternatively to address a rash of burglaries, to prevent African-Americans from moving into their neighborhood, or even to encourage residents to refrain from reporting crimes to or cooperating with the police.

One type of action that can result from this social resource potential is attempts to control local delinquency or crime. *Collective efficacy* is the collective realization among neighbors that they have a common goal in the safety of their neighborhood and a collective willingness and ability to act to achieve this goal (Sampson et al. 1997). Notably this conception of social organization has changed little since Shaw and McKay's (1942) description of "harmonic cooperation." The theoretical advancements since Shaw and McKay have largely come in two areas: conceptualizing this organization as task specific (organization specifically against crime will be more relevant to crime as an outcome than more general kinds of organization) and developing a better model of how such a capacity might develop, especially as a product of the structural characteristics of a community. In practice, the task-specific potential to address crime is so highly related to the presence of specific local forms of social capital that the most frequent measure of collective efficacy combines a direct measure of the capacity for informal social control with a measure of social cohesion and trust (Sampson et al. 1997; Morenoff et al. 2001).

This conceptualization helps resolve some of the questions about the role of social ties and networks from prior work. Specifically, Sampson et al. (1999) suggest that collective efficacy is a task-specific potential for action that is rooted in social capital: "the resource potential of personal and organizational networks" (p. 635). In this way, collective efficacy departs from some of the more recent versions of social disorganization by de-emphasizing the importance of close friendship networks and instead suggesting that a resource potential exists in particular forms of local social organization, including more utilitarian and less affective connections among persons. Thus, a place where neighbors trust one another enough to develop a marketplace of obligations and expectations may possess collective efficacy even when neighbors are not actively friendly with one another, while a different neighborhood with dense friendship ties may still lack it. In fact, Granovetter (1973) has described the ways in which the preponderance of dense and largely redundant ties will be less useful in exposing people to new ideas or information than ties that bridge the gaps between different groups of people.

Measurement as Potential for Action

The key to measuring this new concept is to capture the *potential* for collective action rather than measuring the presence or absence of potential outcomes of such actions, as Sampson and Groves (1989) did with their measure of perceived juvenile delinquency. The potential, in this case, is reflected in a norm: *shared expectations* for informal social control. The measurement of this kind of norm – something that exists between neighbors rather than within any one neighbor – requires the perspectives of those residents. Sampson et al. (1997) accomplish this by using questions which ask residents to speculate about how their neighbors would respond to a series of hypothetical situations involving delinquent acts by youths. Respondents are asked about the likelihood that their neighbors would take action if they encountered one of a number of instances of youth delinquency. These include children skipping school and hanging out on a street corner, children spray-painting graffiti on a local building, children disrespecting an adult, and circumstances in which a fight breaks out in front of their house. Additionally, some versions of collective efficacy have included an additional noncrime outcome: the likelihood of neighbors acting to save a local fire station threatened by budget cuts.

By asking respondents to report their perceptions of the level of collective efficacy in their neighborhood, they attempt to capture a *potential* for action which exists in the connections among persons in the neighborhood rather than within any one resident or in any simple aggregation of residents. In this sense, collective efficacy represents an emergent property of neighborhoods – shared expectations about the control of local delinquency – that theoretically would not be captured by the simple aggregation of reports of individuals' willingness to engage in such control.

Reflecting the theoretical relationship between social capital and collective efficacy, most measures of collective efficacy also include items capturing the degree of social cohesion and trust in the neighborhood. Though the two are distinct concepts theoretically and it appears plausible that collective efficacy is to some degree a product of local social capital elements such as cohesion and trust, in practice the two appear highly correlated and thus have frequently been combined to create a single scale.

In doing so, collective efficacy appears to be more successful than earlier measures of the social disorganization mechanism in predicting local levels of violent crime and even mediating some of the association between structural conditions and violence (Sampson et al. 1997; Morenoff et al. 2001). Research has also found collective efficacy to be predictive of fear of crime (Gibson et al. 2002), partner violence (Browning 2002; Wright and Benson 2011), as well as outcomes less directly related to crime including health and mental health and sexual behavior outcomes such as pro-social competency and problem behavior, birth weight, premature mortality, short-term sexual partnering, and age of sexual initiation. Collective efficacy is also suggested to be the source of a spurious disorder-crime relationship suggested by broken windows theory (Sampson and Raudenbush 1999).

Controversies, Unresolved Issues, and Open Questions

By situating the collective capacity for control in the resource potential of specific forms of personal and organizational networks, collective efficacy represents significant progress in our understanding of the group social processes relevant to the spatial distribution of crime. Operationalizing collective efficacy as an emergent task-specific potential for collective action against delinquency and crime is a noteworthy effort to resolve the difficult problem of measuring phenomena which are a property of groups, or a property of the connections among persons, rather than a property of the persons themselves. This concept represents substantial progress over earlier attempts to theorize and measure a neighborhood's capacity for social control. However, several unresolved issues remain which pose questions for future research.

Lack of Mediation and Measurement Issues

Despite evidence for an apparent role for collective efficacy in the distribution of crime over neighborhoods, the structure of a neighborhood continues to exert strong direct effects on the crime rate. Although Sampson et al. (1997) claim strong mediation effects, Morenoff et al. (2001) suggest this claim may have been overstated. Though collective efficacy appears to have a direct effect on crime, it may not be the long-sought mechanism explaining the link between social structure and crime – or it may only be one component of such a mechanism. Alternatively, this lack of mediation may be a product of measurement error related to ways in which collective efficacy has been operationalized – specifically the difficulty involved in speculating about the potential reactions of other people to hypothetical situations. This raises a key issue for both the measurement of the concept of collective efficacy and the theory itself: we still know too little about how residents make assessments of the local capacity for collective efficacy.

How Do People Intervene?

Another area for future research is to develop a better understanding of how residents choose to intervene when they become aware of crime problems. Residents may directly intervene by confronting troublemakers or they may indirectly intervene by mobilizing external resources including the police department. Residents may be fearful that intervening in local problems could result in retaliation or simply put them at greater risk for victimization. Recent work has suggested just this: that a fear of reprisals acts as an impediment to participation in traditional forms of informal social control (Carr 2003; St. Jean 2007). Instead, such residents may choose to work through the police department to exert control over local crime, actions which do not appear to require the cohesion necessary for informal efforts (Carr 2003; Warner 2007). On the other hand, neighborhoods which lack faith in the police may be wary of choosing to intervene through the police, and in some of these neighborhoods, residents may choose to attempt to address some specific crime problems through local criminal organizations like gangs (Venkatesh 1997; Pattillo 1998). Thus, while collective efficacy research has largely been interested in *whether* neighborhoods are willing to intervene, we may also want to consider *how* neighbors choose to intervene and the differential consequences for neighborhoods resulting from these choices.

Culture and Norms About Crime: Universality or Heterogeneity?

Collective efficacy assumes that communities share common values with respect to local public safety (Sampson 2002) and – following Kornhauser (1978) – has largely eschewed a role for culture in encouraging crime. Kubrin and Weitzer (2003) suggest, however, that culture may play several different roles that are relevant to the collective organization against crime; future work would do well to consider the potential links.

Early criminological work on culture emphasized the prevalence of pro-crime values in lower-class or minority communities. Often portrayed as a reaction to strain over status, respect, or access to legitimate or illegitimate economic opportunities (Cohen 1955; Cloward and Ohlin 1960), such communities were characterized as having pro-crime or crime-tolerant cultural norms. These norms emerge as a negativistic or oppositional reaction to societal norms (Cohen 1955; Anderson 1999), or as an appropriate or predictable reaction to economic circumstances (Miller 1958; Cloward and Ohlin 1960). Shaw and McKay's (1942) early work in social disorganization characterized disorganized neighborhoods as suffering from a kind of normative heterogeneity in which children will be exposed to examples of both criminal and conventional behavior. Sutherland (1947) suggests that both organization against crime and organization in favor of crime will be relevant to understanding the local crime context.

Alternatively, instead of pro-crime values mattering, it may be that communities simply differ in the strength with which they claim conventional norms (Kornhauser 1978; Warner 2003). It may be that these communities are simply more resigned or accustomed to the presence of crime – that crime has infiltrated their cognitive landscape. Finally, culture may matter in ways that have little to do with values about crime. Small (2002), for instance, suggests that cultural framing mechanisms have the ability to either incite or sustain collective organization, including organization toward the goal of addressing local crime problems. For instance, a framing of the neighborhood as in crisis or under threat may *incite* organization (Small 2002; Carr 2003), while a cultural frame defining a neighborhood as one's best opportunity for success is necessary to *sustain* continued organization (Small 2002).

Connections Between Formal and Informal Social Control

Collective efficacy is, in essence, the capacity for *informal* social control. Of course, the police also act as agents of more *formal* social control efforts, and prior work has suggested that neighborhoods differ in both the behavior of police and perceptions of the police. The capacity for informal social control, then, may also be related to local formal efforts. This idea has only just begun to receive serious attention (see Kubrin and Weitzer 2003). Recent work has found evidence for a link between perceptions of the police and informal social control efforts.

Conclusion

Collective efficacy draws on the notion of social capital to present a new theoretical and methodological conceptualization of differences between neighborhoods in their ability to recognize common problems and act collectively to solve them. Social capital is grounded in social networks – it "exists in the relations among persons" (Coleman 1988, p. S100) – and is facilitated by particular kinds of local structural conditions such as residential stability or the presence of formal organizations. In turn, collective efficacy is the ability of a community to draw on this resource to recognize a shared interest in the safety of the local area and to achieve specific tasks related to local informal social control. Recent research has provided evidence of a role for collective efficacy in explaining inter-neighborhood differences in crime rates. Important questions remain, however, about how respondents estimate their neighbor's capacity for informal social control, the different ways people choose to intervene, connections to cultural dimensions of a neighborhood, and the links between formal and informal social control efforts.

Overview

Social control refers to the mechanisms through which a society is able to regulate and direct the behaviors of its members. These mechanisms take many shapes and sizes and are often classified by type and/or level. For example, social control is often divided into two types: informal and formal. Informal sanctions encompass such things as not engaging in an action so as not to disappoint one’s parents or because one believes the act to be wrong. Formal social controls involve more direct action against a person such as suspension from school or arrest and incarceration in the criminal justice system. These mechanisms also traverse various levels or domains of control ranging from the private to the public realm. The private level refers to those modes of control that are the most intimate or close to the person such as the control exhibited by family and friends and is the level most likely to contain informal measures. The next level, often referred to as the parochial or institutional level, involves those controls invoked by social institutions such as churches and schools. The public domain represents manners of control that are the most removed from the individual. This includes broader social connections between individuals, institutions, and the greater society and is often realized through formal legal sanctions. The levels of control are often complementary, interactive, and interdependent as well.

The following essay provides the reader with an introduction to the study of social control, formal theories of social control, and modern extensions and analytical techniques that have evolved to account for its multifaceted and multilevel nature. This research is grounded in two complementary sociological perspectives: social disorganization and social control. Originating in studies of the break down, or “disorganization” of communities, research in the first tradition looked to structural characteristics of a neighborhood that were associated with high crime rates. Later theorists then drew clear connections between the concepts of “disorganization” and “social control” clearly noting that the two concepts are but distinct ends of a continuum between high and low levels of social solidarity (Kornhauser 1978). When high, the community is able to exert both levels of informal and formal social control upon its members to achieve desired social outcomes. When low, on the other hand, individuals are left to their own devices.

From a social control perspective, this is not a good thing. That is, social control theorists do not begin with the question of why individuals commit crime, but rather why they do not (see, Hirschi 1969). The assumption being that left to our own devices, humans will always pursue pleasure and will do so in the easiest way possible. Since crime often offers high excitement and pleasure with less effort than traditional mechanisms (e.g., hard work), social control is then necessary to inhibit individuals from taking this path.

The following section reviews early studies of the organization, or rather the breakdown of the organization, of communities and their elaboration into formal theories of crime and delinquency. Connections between social disorganization and social control theories are described. Later sections then detail modern extensions of these theories and advances in scientific research that have informed the current state of knowledge and set forth pathways for future research.

Early Studies of Community Structure and Social Control

The 1996 publication of Hilary Clinton's *It Takes a Village: And Other Lessons Children Teach Us* brought national attention to the notion that the socialization of our nation's children is not just a family affair but involves all members of the local community. While this heightened attention to the crucial function of the community in the control and socialization of our nation's youth may seem somewhat novel, it is in fact nothing new to those who study societies and the mechanisms by which societies control their citizenry. Indeed, philosophers as far back as Aristotle noted the importance of community governance in maintaining social order and raising children. Beyond mere philosophy, a rich tradition of research and theory exists that details the important and complex relationship between community structure, interpersonal social relationships, and the exertion of social control upon a community's residents, particularly its youth.

The formal study of social control in America can be traced back to studies of the growth of American cities such as Chicago around the turn of the twentieth century. This school of thought, often referred to as "The Chicago School," approached the question of social control from the opposite direction – that is, this research examined what happens when a community is not able to exert social control upon its members. W. I. Thomas and Florian Znaniecki provide some of the earliest empirical work in this area writing on the life experiences of immigrant families trying to "make it" in the new world (1927). Of the many struggles these families faced, one of the greatest was raising their children in a community setting that was unfamiliar to them. The traditions in which they were raised no longer existed, and new traditions had yet to be established in their place. Thus these immigrant parents were ill prepared to socialize their children to this new environment. As immigrant populations tended to settle together (e.g., Polish families with Polish families, Irish families with Irish families, etc.), these problems rose above the individual or family level to become a larger group and even community phenomenon.

With the breakdown in traditional parental socialization roles, this research also found peer networks to take on a heightened influence in the lives of children. This is further demonstrated in an influential writing by Thrasher, *The Gang* (1927), that presented a chronicle of the evolution of neighborhood childhood playgroups into more formal "gangs" – some of which were criminal, some of which were not. According to this study, one primary feature of delinquent gang formation was that it filled a space or crack in social solidarity. These cracks, referred to as interstitial areas, were seen as pockets in society in which the community could not exhibit social control. These were the areas in which gangs were then free to form. As described by Thrasher, the gang provided the essential human needs of belonging and camaraderie that the family and community had failed to provide.

In addition to these qualitative accounts of life in a growing city, researchers at the University of Chicago began the development and formal testing of theories of community growth and governance. The most prominent of these theories was social disorganization theory developed by Clifford Shaw and Henry McKay. Applying a model of community growth developed by colleagues Robert Park and Ernest Burgess, Shaw and McKay were able to document patterns of arrest in the city over a 30-year time period. During this time, Chicago was experiencing rapid population growth primarily due to large influxes of immigrants from Europe as well as southern states. The city, in turn, started to experience high levels of crime. While some tended to place blame on the latest group of immigrants – be they from Poland, Ireland, Italy, etc. – Shaw and McKay conducted a scientific study of the arrest of delinquent youths and found that the criminal activity was concentrated in a small area of the city encircling the central business district which became known as the "Transition Zone." This area was in flux as neighborhoods that were once homes were swallowed up by business as the central business district (referred to in Chicago as the Loop) expanded. Housing in this area became relatively cheap as landowners stopped investing in properties they knew would soon be demolished. Because the rents in this area were cheap (and the housing in poor condition) it was often that the newest group of immigrants would first live in this area until they found jobs and gained solid footing in the "New World."

By mapping out crime data for over 30 years, Shaw and McKay were able to show that the crime remained in this area of the city regardless of the population inhabiting the area. In addition, they found that when crime did "move" to a new area it was because that area was experiencing conditions similar to those neighborhoods where crime had previously been concentrated. Thus, this study found that "social disorganization" and the high crime rates that attend it are primarily characteristics of a place and not the people who inhabit that space.

The characteristics of the place most often associated with social disorganization were high poverty, high residential mobility (people moving in and out quickly), and high racial heterogeneity. The first, poverty, was influential because there was little money to invest in improving the area. Homes would become dilapidated and community institutions such as schools, churches, and social organizations would break down. Second, because the neighborhood was "deteriorating" rather than being maintained, this is not an area where people desired to put down roots. Rather it was a stepping stone, an area where they would live briefly only until they could afford something better. Thus, once an individual or family acquired some wealth, they did not invest it in this area but rather they would move away leading to high residential mobility. Thirdly, as people came and went, especially during this time of high immigration, the area became populated by people with very different cultures, values, and even languages. This racial and ethnic heterogeneity lead to conflict and mistrust between groups as well as the inability of inhabitants to form basic social networks that help to hold a community together. Social Disorganization theory therefore posited that it was a combination of these three elements – poverty, residential mobility, and racial/ethnic heterogeneity – that lead to high levels of crime and delinquency in a given community.

Social Disorganization and Social Control: Making the Connection

While Shaw and McKay offered these basic renditions explaining why these structural factors might be of importance, it wasn't until much later that this theory was formally recognized as a version of Social Control theories and further elaborated from a pure macro-level theory to an examination of the microlevel processes that occur within a community. In a classic 1978 writing, Ruth Kornhauser examined many existing theories of crime and delinquency detailing their primary assumptions and classifying them based upon these underlying assumptions. Through this process she was able to clearly demonstrate the inherent ties between social disorganization and social control theories. According to Kornhauser, the structural factors related to disorganization of a community were indeed important predecessors of crime and delinquency *because* they lead to the disruption of the various components of both informal and formal social control.

In addition to highlighting the connections between social disorganization and social control, Kornhauser's work brought renewed attention to the social disorganization perspective by pointing out that the primary overlooked components of Shaw and McKay's work were the processes through which social disorganization at the neighborhood level is linked to individual-level delinquency. Not only are community structural characteristics important for understanding neighborhood crime levels. These ecological and social causes set the stage for a variety of undesirable consequences including weak social bonds developed between the individual and society, the inability of institutions to enforce common standards and goals, the defective socialization of children, the lack of continuous social networks, and, even the lack of the ability to take action to fix these problems. During the 1970s, 1980s, and 1990s, the search for a better understanding of the social processes by which social disorganization leads to reductions in social control became a fruitful branch of research for criminologists. The following section outlines some of the key knowledge gained during this time.

Extensions of a Theory: Systems of Social Control

John Kasarda and Morris Janowitz (1974) introduced what they coined the "systemic model" of a community control which envisioned the local community as a complex system of friendship and kinship networks. These networks were rooted primarily in family life and were the basis for the ongoing processes of socializing youth in the family and community. This research then tied these friendship and kinship networks to the social structural characteristic of residential mobility proposed by Shaw and McKay. Specifically, the authors proposed that residential mobility is a temporal variable as the development of social bonds and networks takes time. The longer one lives in a community, the more people one knows and the more opportunity one has to become involved in community activities and institutions. When people are moving in and out of an area fairly rapidly, these basic mechanisms naturally break down. This then leads to a reduction in the social networks a person is able to develop. Fewer social networks in turn diminish the ability of the family to properly socialize children and to enforce social controls, informal and formal, upon youth.

Subsequent research has further documented the importance of social ties. For example, Coleman (1988) argued that it is the resources transmitted through social ties, not the ties per se that are key to facilitating neighborhood social control. Similar to the familiar notion of financial capital (e.g., one's financial resources), these social ties and networks became known as a person's "social capital." Research in this area has examined such things as the number of family members living close by, the number of neighbors one knows by sight and by name, family composition (e.g., single-parent families), and the number of moves a family makes as potential indicators of social capital.

Although research has evolved to measure and explain social capital in various ways, it is important to remember that its primary nature is that it is something not housed within an individual but rather within the structure of the community in which the individual lives. Research by Robert Sampson and colleagues has been highly influential in the development of this concept and has resulted in the development of several terms and measures that are now generally accepted as a standard in the social control literature. The first of these is Intergenerational Closure. Intergenerational Closure reaches beyond the immediate family to measure the extent to which children are linked to adults within the community. While this includes immediate family, it also includes the parents of friends, as well as other adult figures such as teachers, coaches, church officials, or even just other concerned resident.

A second concept, reciprocal exchange, moves beyond the mere existence of such relationships and places emphasis on the ability of community members to rely on each other to exchange items (e.g., borrow a tool), information (e.g., tryouts for a sport team or new community organization), and even advice such as turning to one another for advice on child rearing. This concept encompasses more than merely knowing other community members to incorporating levels of trust between community members.

A third concept that has been highly influential in research in this area is that of "collective efficacy." According to research social capital may be a necessary, but not sufficient, aspect of neighborhood relations in the exhibition of social control. In addition to forming ties and resources in one's community, collective efficacy then refers to the willingness and ability of community members to come together and take action on a specific task. One such important task is the socialization of youth. Collective efficacy could also be visualized as a community coming together to earn funds to build a park, start a youth soccer league or improve a library. A classic example often given is the creation of a neighborhood or block watch group in which community members take turns patrolling the neighborhood and reporting suspicious people or activity in a direct effort to reduce crime. Not surprisingly, empirical evidence shows strong relationships between high levels of collective efficacy in a community and low levels of crime. In addition, some research has suggested that factors such as friendship networks and participation in community associations matter *only* through their ability to promote collective efficacy among residents (Morenoff et al. 2001).

Another aspect of social relationships brought to light in this research was social cohesion. While this particular term has several various definitions in general it refers to the sharing of common goals and values. For example, it would be hard for a community to come together to achieve a common goal (e.g., collective efficacy), if members did not agree on the goal. Just as residential mobility was shown to influence crime through its impact on social ties and networks, another social structural characteristic – racial and ethnic heterogeneity – appears to exert its influence mainly through its impact on another social interactive process. In this case, the effect is upon levels of social cohesion and the sharing of common beliefs and goals. Logically, the more different people are in a community the less likely they may be to share common goals and/or to be willing to come together and take action to achieve such goals.

Scholars note, however, that social cohesion can indeed go both ways when it comes to influencing crime and delinquency. That is, a family with strong cohesion with criminal members might then promote criminality in other members. As such, a community that accepts drug dealing, prostitution, or other types of deviance as normal can exhibit social "cohesion" in a fashion that promotes high levels of crime.

As the body of research on systemic social control continues to accumulate knowledge is gained about additional mediating processes and the reasons why they are important for the imposition of social control. For example, in addition to the factors noted above, variables such as family disruption, percent of single-parent families, sparse local friendship networks, mixed land use, population density, and the presence of unsupervised teenage peer groups all have been found to be indicators of decreased social control and, in turn, to lead to increased levels of crime and delinquency. Thus, the systemic model of social control informs us that the social structural conditions identified by Shaw and McKay as indicators of social disorganization do not directly cause crime but rather are related to high levels of crime and delinquency *because* they disrupt the more microlevel social process of human interaction that are necessary for a community to exert social control upon its residents.

Levels of Social Control

At the same time as the systemic model of social control was being developed and elaborated, complementary research was being conducted that elaborated upon the various levels of social control. Research by Albert Hunter (1985), and later Robert Bursik and Harold Grasmick (1993), detailed three distinct levels of control: private, parochial, and public. While these levels have been hinted at by the previous research, this section will more specifically identify the levels and their relationships.

The first level, private social control, is primarily informal in nature and is evoked through personal relationships. This level thus relates closely to the measures of social ties, networks, and cohesion noted above while adding in aspects of emotional attachments as well. For example, according to Travis Hirschi's original Social Bond Theory (1969), what stops an individual from committing delinquent acts are his/her bonds to society. These bonds take the form of personal attachments to people, commitment to conventional goals, involvement in conventional activities and the adoption of pro-social beliefs. Thus, simply knowing that a behavior will bring a negative response by a friend or family member or may negatively impact the ability of one to reach a goal exhibits enough "control" to stop the individual from engaging in the behavior.

The parochial level then incorporates the role of local social institutions in a community such as schools, churches, and community groups. This level of social control relates closely to the institutional controls noted in previous research and the importance of these institutions for the socialization of children. As children age such institutions take on increased importance in their lives and therefore become primary sources of socialization. The parochial level of social control may reinforce that exhibited at the private level, or in some cases, may protect the youth from further problems if the private level is not sufficiently developed. For example, a youth who is not highly attached to a parent in the home may form a strong bond with a coach or a teacher. That youth would then be less likely to break the rules than one who had no social control at either the private or parochial level. Thus, when the informal controls traditionally exhibited at the private level break down, the parochial or institutional level of social control may then serve as a second line of defense to prevent antisocial behavior.

The third level, public social control, was described by Albert Hunter (1985) as the ability of the community to access public goods and services to maintain order. This included but was not limited to police services. At this level the focus is either on the development of programs to create order and prevent crime or to catch those who are breaking the law and invoke enough formal control upon them to discourage them from continuing to break the law. At this level community financial resources and ties to greater society and social resources are of central importance.

It is easy to see the interdependent nature of these levels. If private social controls are strong, there is less need for parochial and public controls. On the other hand when private and parochial levels of control are weak, a greater use of public social control would be warranted (Black 1976). For example, an increased use of police force in an area is actually seen as a breakdown in private and parochial levels of social control. If all three levels are lacking, however, an area will be ridden with high rates of crime and violence. Research also suggests the potential for these levels to interact with one another. That is, for the effect of low social control at one level to have varying effects upon individuals based on other levels of risk or social control.

Moreover, it is important to note that this multilevel model of social control is not distinct from the systemic model but rather a further elaboration of the dynamics of social processes used to invoke social control. For example, levels of private social control in a neighborhood are determined by the ties between individuals and the strength of families. At the parochial level the strength of institutions and their ability to socialize youth is dependent on community member support both in terms of finances and participation. Research has further suggested that the social processes leading to the determination of private and parochial social controls are inherently tied to the larger structural characteristics originally identified by Shaw and McKay.

Advances in Theory, Testing, and Techniques

As highlighted by the previous discussion, social control is exhibited not only at distinct levels but through intricate interpersonal processes that are linked to the larger social institutions and structural characteristics of a community. Thus, the study of social control has become more complex in nature as have the theories that explain it.

One particular direction of theory development has been the integration of theories to address the various causes of crime and levels of social control. One example is Terence Thornberry's Interactional Theory that connects elements of social control and social learning theories as well as incorporating elements of the social structure as the interactional setting in which delinquent behavior is learned and even reinforced (Thornberry 1987). This theory also holds that different factors command primary influence at different stages of life. For example, while the family is key in early childhood through early adolescence, by mid-adolescence the school and other institutions outside of the family become more prominent with peer groups and the broad community taking dominance by late adolescence. Thus, according to this theory, the level of social control (private, parochial, public) bearing the strongest relationships to delinquency would change over the lifecourse.

John Laub and Robert Sampson (1993) also look at social control over different points in the life course and offer some of the first theories to extend this examination into adulthood noting what they call "adult social bonds." The institutions and social bonds that they incorporate as mechanisms of social control include marriage and employment as these offer new mechanisms of informal control upon the adult individual. For example, in adulthood the introduction of a spouse adds a new type of private social control while employment would expand connections to both parochial and public levels of social control.

Another fruitful theoretical avenue has been the risk-protective factor approach which seeks to identify factors at the individual, institutional, and neighborhood level that increase or decrease the possibility of deviant outcomes. Research in this area has tended to emphasize those factors that increase deviance such as previously noted correlates of delinquency (e.g., broken families, low attachment to schools). Analyses at the neighborhood level have also expanded to include such new things as number of gangs, availability of weapons, and ease of access to drugs.

Research utilizing this approach has been highly informative in gaining a better understanding of the interdependent and interactive nature of the multiple levels of social control. For example, one study asks "Do disadvantaged neighborhoods cause well-adjusted children to become adolescent delinquents?" (see Wikstrom and Loeber 2000). The answer here generally appears to be "No." However, some neighborhood enticements were found to lead some well-adjusted youth into delinquency particularly in later adolescence when influences outside of the home gain dominance. Other studies approach the question from the opposite direction asking whether "good" communities can help "not so well-adjusted" youth avoid negative outcomes (see Sampson et al. 2002; Kurlychek et al. 2011). In sum the basic consensus of these studies appears to be yes, that is, at-risk children fair better when raised in communities with high levels of parochial social control (e.g., strong social institutions and connections/cohesions among residents).

As theories of social control and crime become more complex, so do the data sets and analytical techniques needed to test them. For example, if social control spans three levels, then so must the data collected to explore it. The compilation of such data sets is time consuming and expensive thereby prohibiting a great deal of research in this area. However, several recent data collection efforts have evolved that are specifically designed to advance our understanding of the multilevel nature of social control. One such effort, the Project on Human Development in Chicago Neighborhoods (PHDCN), was specifically designed to examine how families, schools, and neighborhoods combine to affect child and adolescent outcomes. As an example of just how complicated such a data collection process can be it should be noted that this project has been ongoing for since 1994 and has received funds from a variety of entities including the National institute of Justice, the John D. and Catherine T. MacArthur Foundation, the US Department of Health, the US Department of Education, the National Institute of Mental Health the Harris Foundation, and the Turner Foundation.

In addition to the collection of data, the analyses of the data has been plagued by complexities such as the identification of compositional versus contextual effects and the spatial dependence of data as individuals are nested within schools and communities. Fortunately, recent developments in statistical techniques and packages have allowed researchers to effectively tackle many of these issues.

Perhaps the most significant advance in this area has been the use of hierarchical linear modeling (HLM) techniques to enable researchers to further disentangle the impact of individual-, institutional-, and neighborhood-level effects as well as exploring how factors at the various levels interact with one another. In addition this technique allows the researcher to identify what are known as "contextual" effects, which are effects above and beyond the mere aggregation of individual factors. For example, if being from a single-parent family increases the risk of delinquency by 5 % and one community has 10 % single-parent homes and another 50 %, the neighborhood with 50 % single-parent homes would naturally be expected to have more delinquency because more youth exhibit the 5 % greater risk of delinquency. However, a contextual effect would emerge if being in a community with more single-parent homes actually increased the risk of each youth, for example, instead of a 5 % greater risk of delinquency, it might be a 10 % greater risk of delinquency. Existent literature suggests that a pattern such as this might emerge as the percent of single-parent homes impacts other things such as the presence of adult role models, the ability of adults to supervise their children, and even the ability of parents to participate in community institutions/associations.

Examples of findings using this technique are abundant in the criminological literature. For example, research has found that the concentration of social disadvantage in neighborhoods has an independent contextual effect on adolescents' serious offending behavior even after controlling for multiple measures of individual-level risk. Studies have also found that adolescents residing in more economically disadvantaged neighborhoods were more likely to be involved in a range of serious violent behaviors after controlling for levels of individual-level risk. On the other hand, research has begun to show that youth with high levels of personal risk actually have lower chances of becoming delinquent if they reside in neighborhoods with strong social institutions and high levels of collective efficacy.

Future Directions

Although much knowledge has been gained about the role of social control, its types and levels in the causation of crime and delinquency, much is left to learn about the interactive and interdependent nature of social control. In particular, as noted above, research has just begun to show that living in an area with high levels of parochial social control can actually reduce the risk of a delinquent outcome for even high-risk youth. Research further exploring these connections holds the potential to inform crime prevention and intervention policy. For example, we might know that a youth is at high personal risk for delinquency because of family turmoil or other issues, but there may be ways to still reduce the overall probability of a criminal outcome for this youth by increasing other social controls such as attachments to school, involvement in community groups, and improving overall community levels of cohesion and collective efficacy. Or, working in the opposite direction, for youths living in high-risk communities, this research informs what might be done at the private/informal level to improve outcomes.

To answer questions such as these, there is also a need for more systematic social observation which better captures both the notion of a neighborhood and the real "feel" of living in that community. According to experts there are simply too many features of a neighborhood that are not measured readily by available public data sets (e.g., census) or cannot be systematically captured in surveys. To gain this type of information more observational and qualitative research is needed. Key researchers in this area stress the importance of collecting this information at the smallest unit possible (e.g., a block face – one side of a street within a block) (Sampson et al. 2002). This allows the researcher to then study these small geographic units, as well as providing the capacity to aggregate these units into larger geographical constructs (e.g., block groups, neighborhoods).

In conducting future research it is also important to remember that no community is an island. That is, each geographic area may be impacted by those areas surrounding it as well. As one example, when studying an adolescent it may be important to consider not only his/her home neighborhood but also the neighborhoods through which he/she travels to attend school or to which he/she travels to spend time with friends. It may also be important to understand concentrated disadvantage by not only looking at one community, but to also incorporate the resources of those communities that border it. One of the few studies in this area suggests that the consequences of being poor are worse for African-Americans in our society because not only do these individuals live in poor neighborhoods but they are much more likely than poor white individuals to live in communities embedded in areas of sustained poverty and disadvantage (Pattillo-McCoy 1999).

In summary, while we know much about social control and its importance in preventing crime, there is still much more to learn about the complex and dynamic processes through which it impacts individuals and the communities in which they live. Future research in this area holds the promise to help build stronger families, safer communities, and provide better life outcomes for even the most at-risk youth.

Social Control and Self-control Through the Life Course

Michael L. Benson
School of Criminal Justice, University of Cincinnati, Cincinnati, OH, USA

Overview

The concept of social control has a complex and controversial history in the field of sociology. Originally, it was defined as the ability of a group to regulate itself, but the term was subsequently redefined to refer either to socialization or social repression (Janowitz 1975). Within criminology, social control typically is used in the more classical sense to refer to the mechanisms through which groups attempt to orchestrate behavior and control deviance. Self-control, on the other hand, is a relatively new concept in criminology that refers to the differential ability (or inability) of individuals to refrain from taking advantage of opportunities to satisfy their immediate desires by engaging in criminal or deviant behavior (Gottfredson and Hirschi 1990). Both social control and self-control have been proposed as important factors that influence individual involvement in crime throughout the life course (Gottfredson and Hirschi 1990; Sampson and Laub 1993). Empirical support for their importance in the etiology, longevity, and patterning of criminal behavior is substantial, but a number of issues remain to be resolved, including the origins and stability of self-control, the effects of social control on criminal trajectories at different stages of the life course, and the factors that influence a person's exposure to informal social control. This entry addresses these issues by focusing on how social control and self-control may change over the life course.

Crime and Informal Social Control

Within criminology, informal social controls are seen as emerging from "the role reciprocities and structure of interpersonal bonds linking members of a society to one another and to wider social institutions such as work, family, and school" (Sampson and Laub 1993, p. 18). For example, husbands and wives are bonded to one another through socially recognized obligations and expectations regarding proper normative behavior. These interpersonal bonds act as constraints on the participants in a role relationship, in the sense that there is pressure on participants to meet their role expectations if they wish for the relationship to continue and if they wish to be viewed favorably by others. Children may be bonded to their parents by emotional connections of love and caring, and children understand that their parents have expectations regarding how they should behave. To the extent that children care about their parents, these expectations can act as a constraining force on their behavior. Similarly, being employed requires that one meet the expectations of one's employer to show up at work, do one's job, and not bring disrepute on the work organization. Thus, informal social controls that arise out of social roles guide behavior by placing responsibilities and constraints on the individual and by directing individual action in some directions rather than others. Prosocial behavior is promoted by strong social controls, while deviancy and delinquency are promoted by the attenuation of social controls over individual conduct (Thornberry 1987).

At different stages in the life course, individuals are potentially subject to different forms of informal social control that arise of out different role relationships and participation in different social institutions (Sampson and Laub 1993; Thornberry 1987). For children, informal family and school bonds are important. Children who are strongly bonded to their parents and who care about school are less likely to be involved in delinquency than children who have difficult relations with their parents or who do not like school. As children move through the life course, the major sources of informal social control change. Parents and school are not as important for young adults as they are for children and teenagers. For young adults, employment and marriage are potential sources of informal control. Some scholars argue that variation in the strength of informal controls influences the likelihood and degree of involvement in crime and deviance at all stages of the life course (Sampson and Laub 1993; Thornberry 1987).

For young children, families and specifically parents are the most important source of informal social control. The fundamental processes that seem to be present in successful families and missing in unsuccessful ones are attachment and control. Attachment refers to an emotional connection between parent and child, in which the child has feelings of love, respect, and admiration toward the parent and the parent feels similarly toward the child. It is a reciprocal process, involving both parent and child, but it starts with the parent (Hirschi 1969). By giving love and expressive support early on, parents can foster a sense of attachment in their children. Children who develop strong attachments to their parents care about their parents' feelings and opinions. They are aware of and sensitive to the impact that their behavior can have on their parents. They understand that if they are caught doing something wrong, it will embarrass and disappoint their parents, and they do not want that to happen. Rather, they want their parents to be proud of them. This emotional connection functions as a sort of internal monitor of the child's behavior when parents are not present. Parents who work at developing a strong sense of attachment in their children when they are young are exercising informal social control and are likely to be rewarded for their efforts when their children enter adolescence in reduced levels of delinquency.

Showering children with love and affection when they are young in the hopes of developing a strong sense of attachment, however, is not enough in and of itself to prevent involvement in delinquency or deviance. Expressive support is crucial, but parents who want to keep their children out of trouble must also exercise more direct types of informal social control. Direct control involves monitoring the child's behavior, recognizing deviance when it occurs, and correcting misbehavior when it happens (Gottfredson and Hirschi 1990). Parents must pay attention to their children and be aware of what they are doing and recognize when they are doing something that is wrong or inappropriate. By monitoring their children, recognizing deviance, and correcting misbehavior, parents can foster the development of conformity in their children and help start them off on trajectories aimed away from serious delinquency (Gottfredson and Hirschi 1990; Patterson et al. 1992).

As children grow older and move into adolescence, the sources of informal social control change from families and parents to schools and peers. Children who are strongly attached to school are significantly less involved in deviance than those with weaker attachments. School attachment is a multidimensional concept that has both objective and subjective elements. Objective attachment can be seen in school performance (that it, how well one does in the classroom) and involvement in school-related activities, such as committees, sports teams, or school clubs. Subjective attachment refers to one's aspirations and expectations in regard to educational achievement and one's sense of satisfaction with and affection toward the people and activities that constitute the school system (Sampson and Laub 1993).

That people often behave differently when they are in a group as opposed to being by themselves is so well known that it is something of a sociological and psychological truism. This truism appears to apply with particular force to juveniles, as most delinquency is committed in groups (Warr 2002). Thus, peers have long been recognized as an important influence on juvenile delinquency and as a source of informal social control in adolescence in the form of peer pressure. Juveniles who have delinquent friends tend to be delinquent themselves, while their nondelinquent counterparts tend to have nondelinquent friends. Although the empirical correlation between delinquency and having delinquent friends is well established, its interpretation is a matter of dispute. One school of thought holds that delinquent friends cause or exacerbate an individual's own delinquency through modeling and social reinforcement for delinquent behavior (Akers 1998). In contrast, conforming friends model and reinforce prosocial behavior. The other school of thought holds that the correlation between delinquency and delinquent friends is spurious and results from a self-selection process in which teenagers with delinquent propensities tend to seek out other teenagers with similar propensities (Gottfredson and Hirschi 1990).

As teenagers move into young adulthood, they may become subject to new forms of informal social control. These new forms of control include employment and marriage. Individuals who are lucky enough to find good jobs or enter good marriages or both become subjugated to new sources of informal social control. One of the most important sources is marriage. Marriage entails new responsibilities and ideally a strong emotional commitment to another person (Laub et al. 1998). To the extent that a young man is emotionally attached to his wife and his children, he is likely to curb his criminal inclinations out of respect for his wife's wishes and a desire not to jeopardize his family life. Marriage may influence involvement in crime in another way by limiting a person's access to deviant peers and to opportunities to engage in deviant activities. The time that a man spends with his spouse or children at home is time that he cannot spend with criminal peers on the street. Time spent working to provide a living for one's spouse and children is also time taken away from the risky attractions of street life. Getting married reduces one's contact with friends in general and delinquent friends in particular. Reduced exposure to delinquent friends leads to reduced involvement in crime and deviance (Warr 1998).

Qualitative and quantitative evidence suggests that, for some men, becoming involved with a woman and getting married can be a route out of crime (Shover 1985). What appears to matter most is the development of high-quality marital bonds (Sampson and Laub 1993; Sampson et al. 2006). However, the effect of a good marriage on criminal offending does not occur all at once. Rather, it is a gradual process that cumulates over time. The longer time an offender invests in a good marriage, the more likely that marriage is to have a preventive effect on his criminal trajectory (Laub et al. 1998). Offenders who enter into good marriages gradually become committed to their spouses. This commitment appears to function as a source of informal social control that grows slowly over time and leads toward desistance.

Crime and Self-control

According to Gottfredson and Hirschi (1990), at the individual level, the most important causal factor in crime is a behavioral propensity called low self-control. Low self-control refers to the relative ability (or inability) of an individual to avoid taking advantage of an opportunity to satisfy his or her immediate wants and desires by engaging in some form of criminal or deviant behavior. Other monikers for this concept include self-regulation, effortful control, self-discipline, and will power. People with low self-control are thought to be impulsive, self-centered, not concerned with long-term consequences, physically active, and risk-loving. Self-control is conceived to be an individual trait that varies over individuals but remains stable for any given person over time (Gottfredson and Hirschi 1990). Thus, people who have low self-control relative to others early in life will also have low self-control relative to others later in life, while conversely people with high self-control at one point in time will tend to have high self-control at other times. People with low self-control can be distinguished from people with high self-control by their tendency to pursue "short-term gratification with little consideration for the long term consequences of their acts" and with little sympathy for the rights or feelings of others (Hirschi and Gottfredson 1987a, p. 959). Low self-control is not always manifested in criminal behavior. Depending on the situation, it may be expressed in other deviant, risky, or disreputable ways, such as reckless driving, alcohol and drug abuse, promiscuous sex, and job quitting (Hirschi and Gottfredson 1987a, b). In short, people with low self-control are impulsive, insensitive to others, and almost always interested in pursuing their own personal pleasures in the quickest way possible. They are attracted to crime, deviance, and analogous acts because they tend to provide quick rewards and easy gratification.

Where does low self-control come from? According to Gottfredson and Hirschi (1990), the answer to this question can be found in the homes and families of delinquents. The parents of delinquents are responsible for the development of low self-control. In their theory, self-control is something that parents have to instill in their children early on by engaging in specific parenting practices. If parents fail to engage in these practices, then their children will not develop a strong sense of self-control, or to put it the other way round, then the children will inevitably have low self-control. In other words, self-control is not something that people are born with or that develops naturally as they grow up. Rather, it is something that must be instilled in children by their parents. To instill self-control, parents must do four things in regard to their children. They must (1) care for their children, (2) monitor their behavior, (3) recognize their wrongdoing, and (4) discipline or correct their wrongdoing when they observe it. If parents fail to employ this suite of practices, then their children will naturally develop with low self-control, and they will do so very early in life, typically before ages 11 or 12. After that, a person's relative level of self-control is set and cannot be developed or augmented later in life.

Current Issues and Controversies

Informal Social Control and Desistance

The causal role of informal social controls in the desistance process is disputed. Some scholars who take a life course perspective believe that change is an ever present possibility and that even serious long-term offenders can and do desist at later stages in the life course (Maruna 2001; Maruna et al. 2009; Vesey et al. 2009). From this perspective, desistance is seen as a process that involves several mutually interacting factors, including turning points, informal controls, and the structuring effects of routine activities. In theory, the path to desistance begins when an individual experiences some sort of turning point, such as marriage, military service, moving to a new location, or finding a fulfilling job. Regardless what it is, this event sets in motion a series of changes in the offender's life that may over time lead to "desistance by default." Desistance by default expresses the idea that offenders do not necessarily make explicit and conscious decisions to change their lives and "go straight" as a result of some sort of epiphany or a single transformative event. Rather, their behavior and sense of identity change gradually and perhaps largely unconsciously as a result of experiencing a turning point that exposes them to new sources of informal social control and that also changes their routine activities.

Getting married, joining the military, or finding a job can serve to knife the offender off from his previous life style and expose him or her to greater informal social controls. Turning points also impose the structuring effects of conventional routine activities on offenders. Military service, marriage, and employment, all require time commitments. They require that one be at certain places at certain times. They impose duties to fulfill and obligations to keep. In short, individuals become caught up in a series of routine activities in which they spend time with conventional others doing conventional ordinary things. The time available to hang out with criminal peers and engage in deviant activities is gradually reduced until it reaches the point where an offender has for all intents and purposes desisted.

Another school of thought, however, holds that desistance is not caused by turning points and increased exposure to informal social controls. This school of thought, called the developmental perspective, holds that there are distinct developmental trajectories that people get locked into. Developmental trajectories are stable in the sense that once people enter a particular trajectory or developmental group, their future progress is more or less determined. For example, Gottfredson and Hirschi (1990) argue that criminal behavior results from an underlying behavioral propensity. At an early point in the life course, each individual's propensity toward crime and deviance is established when their level of self-control is developed. From that point on, one's level of self-control drives behavior independent of other factors and is largely resistant to change. Thus, the presence or absence of desistance in adolescence reflects only variation in this underlying propensity toward crime. Another developmental theorist, Moffitt (1993), argues that there are two distinct trajectories – life-course-persistent and adolescent limited. Individuals on the life-course-persistent trajectory are unlikely to experience turning points such as marriage, or to react badly if they do experience them, because of certain innate characteristics that are established early in life. These individuals never really desist from deviant or criminal behavior, even though the form in which their deviance is manifested may change as they age. For example, the teenage mugger becomes the adult wife-beater. Adolescent limited offenders engage in crime and delinquency for a few years during their teenage years and then desist largely for maturational reasons, not because they are exposed to new forms of informal social controls.

Developmental theorists do not deny that there is an association between exposure to informal social controls and reduced involvement in crime and deviance, but they believe that this association is spurious and not causal. Reduced involvement in crime and deviance may be associated with participation in social institutions such as marriage and work, but it is not caused by them. Rather, participation in these institutions is a matter of self-selection. It is, of course, possible and some research suggests that both social causation and self-selection are involved in the desistance process (Wright et al. 1999).

Origins of Self-control

Even though low self-control is an individual trait that would appear to bear strong similarities to other personality traits, such as impulsiveness, aggressiveness, and insensitivity, the originators of the term explicitly rejected the notion that it is biologically or genetically based (Gottfredson and Hirschi 1990). Rather, in their view, low self-control is caused solely by inadequate parenting early in a child's life. Recent advances in behavioral genetics suggest that this conclusion is either not correct or greatly oversimplified. Insofar as genetic researchers have been able to determine, it appears that all individual traits are influenced to some degree by heredity, that is, by the genes that parents pass on to their children (Rutter 2007). Height, weight, body type, eye color, hair color, and facial appearance are some of the more obvious physical traits for which it often is easy to see physical resemblances between parents and their offspring. However, in addition to these gross anatomical characteristics, children also inherit psychological characteristics and behavioral tendencies from their parents (Plomin et al. 1990). For example, aggressive parents are more likely to have aggressive children than nonaggressive parents (Huesmann et al. 1984). A growing body of evidence now suggests that genetic factors also are implicated in the development of low self-control (Beaver 2011; Wright et al. 2008a; Wright and Beaver 2005).

Genetic factors may influence the development of low self-control in several different ways. First, low self-control appears to be a heritable trait or characteristic that parents pass on to their children. Thus, parental genotype directly influences offspring genotype, including the genes related to low self-control. Second, parents with low self-control tend to create home environments that are not conducive to the development of high self-control (Moffitt 1997). Indeed, their parental management techniques may be so inadequate that they actually foster the development of low self-control (Beaver 2011). In this case, the genetic effect is indirect in that the parent's genotype is implicated in the creation of a particular home environment that then stimulates the development of low self-control in the child. Finally, children born with genetically influenced personality characteristics that make them difficult to deal with, such as lack of impulse control, aggressiveness, and resistance to parental authority, may provoke negative parenting practices that further exacerbate behavioral tendencies (O'Connor et al. 1998). This type of effect is an evocative gene environment interaction, meaning that the child's genotype in a sense creates an environment that fosters the expression of behavioral tendencies inherent in the genotype.

Stability of Self-Control

One of the most provocative and controversial aspects of low self-control theory concerns the stability of this characteristic over the life course. As noted above, the originators of the term contended that relative differences between people in self-control remain stable as people age. Note, this contention does not mean that people with low self-control never change the way they behave as they age. Rather the idea of relative stability means that even though persons with low self-control may exhibit more moderate behavior as older adults than they did as teenagers, they will still be more antisocial, self-centered, and short-sighted than their contemporaries who have adequate levels of self-control. Indeed, research does indicate that absolute levels of self-control increase with age for most people.

At this point in time, however, research on the relative stability hypothesis has produced mixed results. While it is clear that there is substantial continuity in antisocial behavior over the life course, it is also clear that the level of continuity is by no means perfect. Evidence for stability comes from a number of longitudinal studies. For example, in a study of 205 boys aged 10–16, researchers asked the mothers to recall how easy or difficult it had been to get along with their sons when they were 1–5 years old. Five years later, when the boys were 15–21 years old, those who had been characterized by their mothers as "difficult" were twice as likely to have an official record of delinquency as those rated "easy." The difficult boys also self-reported committing delinquent acts at a higher rate than the easy boys (Loeber et al. 1991). Similarly, kindergarten children who are rated by their teachers as having high levels of hyperactivity are more likely to engage in delinquency during the transition from childhood to adolescence (ages 10–13) than children who do not exhibit hyperactivity (Tremblay et al. 2003). Finally, in a study using the Dunedin, New Zealand, data, White et al. (1990) found considerable continuity in antisocial and delinquent behavior from age 3 through the early teen years. Children who scored high on measures of disobedient and aggressive behavior at age 3 were more likely to exhibit other conduct disorders later in childhood and to be arrested by the police in their early teen years than children who scored low in disobedience and aggression (White et al. 1990). The fact that some children begin to show signs of abnormal conduct so early in life suggests that some forms of antisocial behavior reflect a general temperament that may persist over time (White et al. 1990). This study provides impressive evidence for continuity in antisocial behavior because it is a prospective study of a normal population (Wright et al. 2008b).

Thus, evidence for continuity in antisocial behavior is plentiful, but nevertheless, it must be interpreted carefully (Thornberry and Krohn 2003). Conduct problems at a young age do predict delinquency in the teenage years, but the success rate of these predictions is sometimes not very good. Most antisocial preschoolers do not go on to become antisocial adults or even antisocial juveniles. In the Dunedin study, for example, there was a high false-positive rate when antisocial behavior at age 3 alone was used as a predictor of antisocial behavior at age 11. Indeed, the predictions were wrong almost 9 times out of 10. The researchers note: "Of the 209 children predicted to have antisocial outcomes at age 11, 84.7 % did not develop stable and pervasive antisocial behavior" (White et al. 1990, p. 521). Other studies have had better results in the sense that the prediction rates are better. For example, Campbell and colleagues studied children from age 3 to age 13 with assessments at ages 4, 6, and 9 in between. Of the children who were rated as hard to manage by their parents at age 3, fully 48 % met formal criteria for having externalizing disorders (attention deficit, conduct disorder, or oppositional disorder) by age 9. In contrast, only 16 % of the children in a control group displayed externalizing disorders at age 9 (Campbell 1995). In statistical terms, the difference between 48 % and 16 % is large and represents a strong effect. However, in practical terms, one could say that the study actually shows that discontinuity is more likely than continuity as less than half of the problem group exhibited problem behaviors at both times. At this point, the most accurate summary of the research would be that continuity in behavior is indeed a widespread feature of human development, but it is not a universal feature.

Although research on continuity in antisocial behavior suggests that traits such as low self-control may be stable over the life course, they do not directly assess that stability. To date, there are few studies that directly investigate stability in self-control itself over time. The few studies that are available, however, suggest that like antisocial behavior, relative levels of self-control can vary over the life course. That is, instability in individual rankings on self-control over time has been observed, suggesting that self-control may not be an immutable trait. The degree to which self-control is malleable, however, is still open to debate with some researchers finding more stability than others (Burt et al. 2006; Hay and Forrest 2006).

Future Directions

A large body of research now clearly indicates that both social control and self-control are important factors in the etiology of crime and behavior in general across the life course. Furthermore, it is becoming increasingly apparent that within the life course, self-control and social control have interactive effects on each other. For example, an individual's level of self-control may influence how he or she reacts when confronted with a turning point, such as marriage, which would in turn affect the individual's relative exposure to informal social controls. Likewise, it is possible that exposure to increased informal social controls may eventually lead to transformations in the individual that increase his or her level of self-control (Giordano et al. 2002; Laub and Sampson 2003; Sampson et al. 2006). Future research on self-control and selection effects is needed, as well as, research on the transformative power of informal social controls in regards to developing increased self-control in adulthood.

Research on the stability of self-control over the life course has largely ignored whether self-control is malleable in response to direct officially imposed rehabilitative or treatment interventions. This shortcoming is unfortunate, because, as Currie has noted, research showing continuity in antisocial behavior over time reveals only what happens when no effort is made to change how individuals develop (Currie 1998). Yet, a voluminous body of research suggests that a multitude of rehabilitative programs work in terms of reducing recidivism among offenders at all stages of the life course (MacKenzie 2006). If delinquent and criminal behaviors are an expression of low self-control, then it follows by implication that reductions in offending caused by treatment interventions may also be associated with changes, indeed increases, in self-control. Future research is needed that directly assesses whether and how measured levels of self-control can be changed in response to different forms of intervention and treatment.

Introduction

For decades, the study of offenders who commit sexually based offenses generally and who commit predatory sexual homicide specifically has come almost entirely from psychiatry, forensics, and applied criminal justice. Mainstream theoretical criminology has mostly abstained from studying predatory sexual homicide offenders for a variety of reasons that will be explored. A negative consequence of this omission is that criminological theories are often poorly suited to explain the most pathological forms of criminal violence and, by extension, poorly suited to realistically explain the most pathological offenders. This is a major limitation.

This current entry seeks to redress this by exploring the utility of self-control theory (Gottfredson and Hirschi 1990) as a conceptual vehicle to understand sexual homicide offending. Although these offenders evince lifestyles that are consistent with the theory, their instrumental, methodical approach to sexual homicide is also in many respects directly contrary to the tenets of the theory. In addition, the current authors suggest that forensic typologies that seek to characterize sexual homicide offenders as organized or disorganized (Ressler et al. 1988) can be fruitfully understood within a self-control theoretical framework.

Criminology and Sexual Homicide

Two overlapping reasons explain the presumed incompatibility of studying sexual homicide offenders within the parameters of mainstream criminological theory. The first relates to the infrequency of sexual homicide and the likelihood that offenders in traditional criminological datasets contain such offenders. If murder has a low base prevalence, then the base rate of an even more pathological crime is of course lower still. For instance, the prevalence of serial murder has been estimated to constitute less than 1 % of the total murders in society (McNamara and Morton 2004). This means that community samples and even epidemiological samples simply will not contain predatorily violent offenders such as sexual murderers. Prior studies have found that some of the most frequently used datasets in criminology have approximately zero homicide offenders in them (DeLisi 2001) and instead are comprised of less severe/violent offenders. Due in part to data accessibility issues, mainstream criminology simply declined to understand the most severe offenders in favor of explanations that are compatible with more common, normative offenders.

A second reason that criminological theory has ignored sexual homicide offenders is plain condescension toward a topic that some academics view as too sensationalistic to be taken seriously. Although this might seem like a harsh accusation, the literature is littered with examples of it. For instance, Edwin Sutherland (1950), the patriarch of American academic criminology, argued that sexual psychopath laws – which were designed to socially control instrumentally violent criminals such as sexual murderers – were based on false, questionable knowledge based in popular literature as opposed to science. The tenor of Sutherland’s differential association theory is to repudiate individual-level pathologies of the offender in favor of social learning processes. Thus, sexual homicide offenders and the nosology surrounding them (e.g., psychopathy, sexual sadism) were portrayed as antithetical to more appropriate criminological theorizing.

More recently, Ray Surette advanced that serial murderers are media icons, the purpose of which is to “generate fear, degrade social networks, increase reliance on the media, and foster social isolation and polarization” (1994, p. 147).

In a review of a book that was at best tangential to the topic of sexual homicide, Shadd Maruna (2006) opined:

> My only substantial complaint though is the embarrassing decision to include the dated, non-academic, non-theoretical chapter by Ressler, Burgess, and Douglas on serial killers in the collection. Talk about letting down the side. With one, cheap attempt to grab the attention of the 'I signed up for criminology because I like 'Silence of the Lambs' market of undergraduate readers. Cromwell almost completely undermines all of the remarkable achievements of the real criminologists pushing the boundaries of criminological research. (2006, p. 275)

Indeed, the indices of major criminological theoretical works and anthologies of criminology theory contain little to no references to sexual homicide offending suggesting that the topic is largely unrelated to mainstream criminological thought.

Fortunately, not all criminologists have been so dismissive of the most extreme and violent criminals (see, e.g., Vaughn et al. 2009). And not all criminologists have ignored potential linkages between criminological theory and homicide offending. For example, Castle and Hensley (2002) surmised that social learning theory could be a useful theoretical framework toward understanding serial murder by exploring experiences from military service and exposure to killing as potential precursors to multiple homicide offending. Social learning theory was also used to understand the prospective linkages between juvenile fire setting and subsequent serial murder (Singer and Hensley 2004). Within the literature, there is also increasing acknowledgement that criminology has for too long overlooked the study of the most violent offenders. To illustrate, DeLisi (2006) noted, "For some time, unfortunately, mainstream criminology tended to focus on more normative offenders and less extreme forms of antisocial behavior. As a result, the study of murder and other extreme forms of violent crime were important but demonstrably peripheral to the discipline. Since the general public is fascinated with more extreme forms of criminal violence, academic criminology clearly missed an opportunity to connect with public audiences, including practitioners and policy makers" (pp. 172–173). Unlike their criminologist peers, forensic psychologists, neuroscientists, historians, and journalists have focused considerable scholarly energy toward understanding the etiology of sexual homicide, and it is from these disciplines where the sexual homicide epistemology largely resides.

The current entry has an explicit aim: to explore Gottfredson and Hirschi's (1990) self-control theory – a dominant content area in criminological theory and research – and its relation to sexual homicide offending. Sexual homicide offending is defined as the predatory perpetration of murder in conjunction with some sexually oriented offense, such as rape, sodomy, or other type of sexual assault. In some ways, self-control theory provides a useful framework for understanding the lives of predatory sexual murderers particularly those who leave disorganized crime scenes. However, in other ways, the offending behavior of these offenders is characterized by extremely high level of self-control and self-regulation particularly those who leave organized crime scenes. Thus, a self-control paradox exists when studying the apex of violent criminals.

Self-Control and Violence

To date, no study has formally examined self-control theory vis-à-vis sexual homicide although a range of studies have explored the association between low self-control – characterized by Gottfredson and Hirschi as being self-centered, impulsive, poorly tempered, and action oriented as opposed to cognitively oriented, preferring simple tasks as opposed to ones requiring tenacity, and having poor gratification delay – and violence. DeLisi and Vaughn (2008) reported that self-control was a strong indicator of career criminality, a status that is disproportionately responsible for the most serious crimes in a society. Using data from a statewide sample of institutionalized delinquents, they found that those scoring 1 SD above the mean on a low self-control scale were over five times more likely to become a career criminal and disproportionately likely to commit violent crimes. The association between low self-control and violence is not limited to offender samples. Drawing on data from students, Bouffard (2010) found that self-control was inversely related to both sexual entitlement and self-reported perpetration of sexual aggression. Self-control is a potentially important moderator of criminal careers over time because persons with very low self-control are theorized to continue offending often in violent ways.

Given the nature of most violent disputes, it is unsurprising that the self-control construct would be associated with reactive violence, which frequently typifies intimate-partner violence and generalized assaults (e.g., bar fights). By definition, having a quick, volatile temper means that interpersonal conflicts are not handled internally and ignored; they are handled externally and instantaneously settled. Inherent in this statement, moreover, is the salience of impulsivity and low gratification delay to understanding violence. Consistent with Gottfredson and Hirschi's (1990) theory, violence is an easy option to quickly end the aggravating stimuli created by another person. According to the theory, those with low self-control do not handle frustration and the day-to-day adversities imposed by adult responsibilities and thus will use a quick, easy method to deal with that frustration.

To use a clearly unscientific yet accurate descriptor, it could be said that offenders characterized by self-control deficits are generally *sloppy*. They are sloppy in their school habits and attention to detail which contributes to adverse encounters with teachers and other students and generally negative academic performance outcomes (Houts et al. 2010). They are sloppy in their attention to the emotional and time commitments of interpersonal relationships, and those relationships suffer. Almost an extension of their school difficulties, they are sloppy in their dedication and commitment to work responsibilities and, predictably, experience frequent periods of unemployment. Given the syndromic nature of self-control (DeLisi 2011), it is probable that offender sloppiness is also gleaned from their murder scenes. This issue is explored within the framework of self-control theory next.

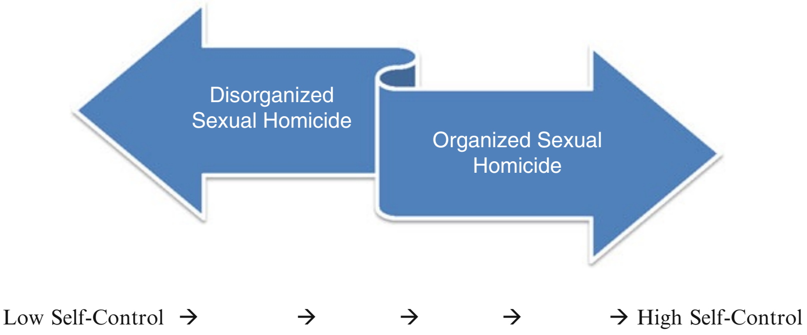
In an important work that sought to differentiate the murder scenes of sexual homicides and potentially draw inferences from the crime scenes to profile the offender, Ressler, Burgess, and Douglas (1988) advanced a typology of sexual homicide offending. On one hand was a disorganized sexual murderer whose offense was spontaneous, whose victim was known but depersonalized, and who engaged in minimal conservation during the attack. The disorganized killer's murder scene was random and sloppy, characterized by sudden violence with minimal use of restraints, and sexual acts after death. The victim's body was left in view at the death scene, and importantly, weapons and other forensic evidence were often present at the scene.

In contrast, the organized sexual murderer committed a planned killing of a targeted stranger who was personalized. There was controlled conservation during the killing, use of restraints, aggressive acts before death, and demand for submission. The entire crime scene of the organized killer reflected control. The victim's body was hidden, often transported, and there was an absence of weapons or other forensic physical evidence. Taken together, the Ressler et al. (1988) typology painted a picture of two very different perpetrators in terms of their functioning, their competence, their mastery over their murder victim, and (semantically most important) their *control* over their murder scene.

As shown in Fig. 1, the disorganized-organized sexual homicide offender typology can effectively be understood as a continuous distribution of self-control. In many respects, the disorganized offender's behavior contemporaneous to their homicide event is consistent with the conduct of the modal criminal offender. The murder is unplanned and hasty and represents a poorly contemplated, rash action to satisfy an underlying desire (recall that the victim is known to the offender). The crime scene of the disorganized sexual homicide offender is, simply, sloppy.

In contrast, the organized sexual homicide offender seemingly exudes self-control in certain respects. The crime scene evinces self-control: forensic evidence is cleaned up, and weapons

Social Control Theory of Sexual Homicide Offending,
Fig. 1 Self-control and sexual homicide organization



and other physical evidence are removed from the scene. The murder itself is premeditated and reflects considerable planning and control; it is a well-executed plan. Planning is not the strong suit of offenders with low self-control. All of these conditions of the organized sexual homicide offender intimate a paradoxical relationship between self-control and violence, one that could not be anticipated by self-control theory.

A sense of higher self-control has also been shown among other types of multiple homicide offenders. In their study of 34 subjects who perpetrated 27 mass murders between 1958 and 1999, Meloy et al. (2001) found that adolescent mass murderers are more often predatorily rather than affectively violent and often do not display sudden, highly emotional warning signs. In other words, their violence represents considerable control evidenced by their selection of victims.

Recasting the organized-disorganized typology as a continuous measure of self-control allows researchers to utilize a criminological theory to conceptually understand sexual murderers. Empirical research is needed to access the threshold where high levels of offender self-control are associated with extremely violent conduct. Additional research is also needed to access the linearity of this relationship. It is possible that the relationship between self-control and sexual homicide is curvilinear. It is also possible that high self-control evinced by sexual homicide offenders is comorbid with other important constructs, particularly sexual sadism and psychopathy. These correlates of sexual homicide offenders are examined next.

In his landmark *Psychopathia Sexualis*, Richard von Krafft-Ebing (1886) introduced the construct of sadism which involved a melding of sexual gratification of the offender with the infliction of pain and humiliation of the victim. In its original conceptualization, sadism was referred to as lust murder and correlated with an absence of guilty (today, known as psychopathy) and even the attempted consumption of the victim. A recent summary review of studies that examined the prevalence of sexual sadism among forensic populations produced a variety of important findings. Chief among them was the finding that the prevalence of sexual sadism was very high, about 30–40 % among offender samples. However, when the sample contained exclusively homicide offenders, the prevalence of sexual sadism was in the 70–80 % range (Krueger 2010; also see, Berner et al. 2003).

An important comparative study also shows the salience of sexual sadism to homicide offending. Yarvis (1995) interviewed and surveyed 78 murderers, 92 rapists, and ten rape-murderers to assess the prevalence of sexual sadism. None of the murderers and just 6.5 % of the rapists met the criteria for sexual sadism; meanwhile, the prevalence among rape-murderers (or, in the parlance of the current entry, sexual homicide offenders or sexual murderers) was 30 %. The criminal careers and life circumstances of sexual homicide offenders are typically severe and noteworthy for their psychopathology even compared to other serious criminals. For instance, Trojan and Salfati (2010) recently compared 137 single-victim homicide cases drawn from the Cincinnati, Ohio, Police

Department and 17 closed serial murder cases obtained from the FBI. Whereas the single homicide offenders averaged 13 arrests and eight convictions, serial murderers averaged five arrests and three convictions. Although this seems comparatively less severe, five or more arrests is a standard measure of habitual or chronic criminality (the most prolific serial killer had 25 prior arrests). The criminal histories of serial murderers also demonstrated more instrumental offenses suggesting a specific targeting of a victim that is consistent with the organized typology described earlier.

Hill et al. (2008) studied the forensic reports of 139 sexual homicide offenders in Germany who had served time in prison and 90 of whom had been released. The mean number of sexual homicide victims per offender was 3.7. Twenty years after their release, more than 23 % of offenders recommitted sexual offenses, and more than 18 % committed nonsexual violent offenses, such as armed robbery and aggravated assault. Three men or more than 3 % were subsequently convicted of attempted or completed murder. They found that the earlier that an offender committed his first sexual homicide, the more likely he was to be convicted of a sexual crime, which included extremely violent offenses such as sexual homicide, rape, sexual abuse of a child, and other sexual assault and any violent crime. Nearly one in five defendants convicted of sexual homicide has prior convictions for homicide, and more than half have other violent crimes in their criminal history (Häkkänen-Nyholm et al. 2009).

Langevin and his colleagues (Langevin 2003; Langevin et al. 1988) compared the antisocial histories of 33 sexual homicide offenders to 80 sexually aggressive offenders, 23 sexual sadists, and 611 general sex offenders. All these men had been seen for psychiatric assessments either for pretrial or as part of parole evaluation. Overall, the criminal careers and antisocial pasts of sexual homicide offenders were significantly worse than even these other severe risk groups. More than 27 % of the sexual homicide offenders had been committed to reform school, more than 21 % were gang members, over 15 % had been expelled from school for behavioral problems, and greater than 30 % had prior history of animal cruelty, vandalism, and/or fire setting.

Dietz et al. (1990) conducted a descriptive study of 30 sexually sadistic criminals. All of these men intentionally tortured their victims for sexual arousal. Their crimes often involved careful planning, the selection of strangers as victims, approaching the victim under a pretext, participation of a partner, beating victims, restraining victims and holding them captive, sexual bondage, anal rape, forced fellatio, vaginal rape, foreign object penetration, telling victims to speak particular words in a degrading manner, murder or serial killings (most often by strangulation), concealing victims' corpses, recording offenses, and keeping personal items belonging to victims. Beauregard and Proulx (2002) compared the offending process of two groups of non-serial sexual homicide offenders, 20 who were characterized or driven by anger and 16 who were motivated by sadistic pathology. Sadistic murderers were significantly more likely than non-sadistic killers to premeditate their crimes, humiliate their victims, mutilate their victims, and dismember the corpse of the victim. Sadistic murderers took longer to complete their offenses – nearly 90 % took longer than 30 min and were significantly more likely to be apprehended. They also experienced greater positive affect after the commission of their murder. Sadistic killers were also less likely to surrender to police after their crimes, less likely to admit to their crimes, less likely to admit all of the acts committed during their homicides, and less likely than other murderers to admit responsibility.

Research based on analyses of crime scene behaviors of sexual murder and rapes differentiates these forms of sexual violence. In cases of rape, offense behaviors include blindfolding and binding of victims, ripping the clothing of victims, possession and display of weapons, theft, and vaginal penetration. In cases of sexual homicide, there were more severe and depraved indicators of violence including forensic awareness on the part of the offender (e.g., cleaning up or destroying evidence at crime scene), multiple infliction of wounds, and multiple forms of penetration of the victim including objects (Salfati and Taylor 2006).

Across these studies, there is interesting evidence for considerable self-control on the part of sexual murderers. It is not known currently whether these offenders are demonstrating self-control in the Gottfredson and Hirschi (1990) sense or whether they are sadistic psychopaths whose proclivities for extreme violence are guiding their behavior. What is known, however, is that the violence of these offenders at least at the culmination of their murders does not comport with the sloppy profile of the modal criminal offender, one whose life is rife with self-control deficits.

Discussion

For the purposes of theory building, the extreme violence of sexual homicide offenders provides an opportunity to stretch the empirical veracity of constructs. At times, the behaviors of the most severe offenders cast well-known criminological constructs in a new light. For instance, cognitive functioning and intelligence are inversely associated with antisocial behavior, yet some sexual homicide offenders (most famously Ted Bundy) were highly intelligent. This does not impugn the intelligence-crime relationship but does offer opportunities to rethink theory and the putative associations between variables at different points on the offending distribution.

Gottfredson and Hirschi (1990) advanced a theoretical construct that was advertised to be *the cause* of crime, and empirically their theoretical ideas have fared well (see, DeLisi 2011). The current authors believe their theory also has utility for understanding sexual homicide offending and that the range of self-control can be superimposed on existing typologies of sexual homicide. But at another level, the pathology manifest by organized sexual murderers is contrary to the tenets of the theory. They are highly controlled. Based on prior studies of sexual homicide offenders, it is possible that what appears to be high self-control could be spurious and obscured by the effects of psychopathy and sexual sadism. Indeed, Meloy (1999) has previously characterized organized sexual murderers as compulsive (disorganized sexual murderers were referred to as catathymic in his model), which was characterized among other clinical features as having diagnoses for sexual sadism and psychopathy. Recent research has found that sadism and psychopathy are distinct factors in the psychopathology of sex offenders (Mokros et al. 2011); perhaps self-control is distinct as well.

Social Disorder and Physical Disorder at Places

Sue-Ming Yang
Department of Criminology, National Chung-Cheng University, Min-Hsiung, Chia-Yi, Taiwan

Overview

Urban disorder has now become a center of public policy. Sennett (1970) viewed so-called disorder as a manifestation of the social diversity of a place where people come from different racial, ethnic, social, and economic backgrounds. Thus, disorder is considered a byproduct that comes with the modernization of urban cities. Sennett argued that disorder is actually "useful" for urban dwellers, as a disorderly environment "forces" people to get to know one another and therefore, enhances familiarity among heterogeneous population and reinforces racial integration. On the contrary, disorders are often considered as social negativities by criminologists. For example, James Q. Wilson (1975) pointed out that daily hassles such as street people, panhandlers, rowdy youths, or 'hey honey' calls trouble urban residents as much as crime does, if not more. Garofalo and Laub (1978) also argued that these urban characteristics of the modern society (disorder is one of them) are the main sources of the "fear" of residents, rather than the true fear of "crime." Wilson and Kelling (1982) further suggested that disorder has criminogenic effects with untended disorder eventually leading to crime problems. These contrasting viewpoints illustrate the subjective nature of what disorder is and its corresponding social meanings. Browsing through the studies of disorder, it is difficult to identify one single definition that everyone agrees upon. Disorder from one person's view might represent the norm to another person. In this entry, various definitions about disorder will be reviewed. Two major types of disorder, social and physical disorder, and their association with crime will be reviewed and discussed.

A city isn't just a place to live, to shop, to go out and have kids play. It's a place that implicates how one derives one's ethics, how one develops a sense of justice, how one learns to talk with and learn from people who are unlike oneself, which is how a human being becomes human.

– "The Civitas of Seeing" Richard Sennett (1989)

The Sources of Disorder

In the view of the Chicago School researchers, a city is not merely an environmental setting but is rather an organism that grows, changes, and evolves over time (Wirth 1962). Urban areas are usually characterized with diversity in the demographic composition of people who live and work within them. From this perspective, a city looks like a "mosaic of segregated people," as referred to by Robert Park (1928). In cities, different people demonstrate their cultural heritage, live in different lifestyles, yet cohabitate in the same areas. The close contact of these "differences" naturally leads to tension and conflicts among different groups and the lack of cohesion results in social disorganization. Within the disorganized environment, each social or racial group competes for resources and actively seeks to preserve their peculiar cultural forms in order to sustain their own conception of life (Park 1928).

With the expansion of a city, the influx of population brings different cultures and values into a city. For urban inhabitants, therefore, the increase in exposure to different cultures and other value systems and lifestyles tend to create uneasy feelings for individuals. Due to the unfamiliarity of other cultures, an increased level of diversity might be seen as a sign of disorder by mainstream society (Sennett 1989).

However, disorder is by no means a clearly defined concept in either research or practice. The meaning of disorder, just like all other social norms, changes along with the development of a city. In other words, the definition of disorder might vary by society and represents the social norms separating between approval and disapproval behavior (see Durkheim's Moral Education, 1961).

The definitions of social norms are always the result of competition and the transaction of different cultures and value systems. This process is critical as the social meaning of a behavior often determines how people react to the behavior. In other words, when a society defines certain behaviors as unwanted or deviant, people will start viewing them as a menace or danger to society. Conflict criminologists have long argued that crime is socially constructed and is used by the powerful groups in the society to control the disadvantaged underclass. This ambiguous nature of the social norm is even more salient when dealing with less severe social phenomena such as disorder. Similarly, the defining process of disorder is not equally influenced by all groups in the society—the powerful groups often enjoy the privilege of determining the "*norms*" (Durkheim 1961; Sennett 1970).

The Definition of Disorder

Disorder is not crime, and usually represents minor violations of social norms that do not directly harm other people. Unlike crime, there is no commonly agreeable definition to classify disorder. Skogan referred to it as a "slippery concept" (Skogan 1990, p. 4). He argued that disorders are behaviors that are not prohibited by the criminal law; or disorders in isolation constitute relatively minor offences. The ambiguity nature of disorder leaves room for different ways defining disorder.

In prior literature, various occurrences and behaviors have been identified as disorder, ranging from deteriorated buildings to teenagers hanging out on the street corner. Even the term "disorder" is not always used to describe these minor violations. Past research has referred to this particular phenomenon as "signs of crime" (Skogan and Maxfield 1981), "early signs of danger" (Stinchcombe et al. 1980), "urban unease" (Wilson 1968), "broken windows" (Wilson and Kelling 1982), "soft crime" (Reiss 1985), "public moral offenses" (Weisburd and Mazerolle 2000), "cues to danger" (Warr 1984), "incivilities" (Taylor 1999), "sign of disrespect"

(Bannister et al. 2006), “warning signals” (Innes 2004), and “disorder” (Skogan 1990). Finally, most scholars have now settled on the term of either *disorder* or *incivilities* (LaGrange et al. 1992). While disorder has been discussed and theorized prior to 1990 (see Wilson and Kelling 1982), Skogan was the first to clearly articulate disorder and its impacts on neighborhoods (Skogan 1990). In his book *Disorder and Decline*, Skogan points out that the concept of disorder is ambiguous and can represent a variety of meanings. Thus, he notes that it is important to differentiate between the friendly “active uses of the environment” (not disorder) and disorderly behavior which bothers the residents of a neighborhood, as the former may suggest a very well-connected neighborhood while the latter may represent a disoriented neighborhood.

In addition to how research defines disorder, it is also important to know how law enforcement determines what phenomena are considered disorderly. In Kelling and Sousa’s evaluation of New York City’s Quality of Life Policing effort, they used misdemeanor arrests to represent police efforts without providing a clear list of targeted disorders. In the four scenarios illustrated in the report, the enforcement was mainly targeted at public urination or public drinking (open container). Sure enough, based on the broken window thesis drafted by Wilson and Kelling, the actual practice probably included more types of “minor offense” including things like panhandlers, drunks, addicts, rowdy teenagers, prostitutes, loiterers, and the mentally disturbed. On the other hand, Thacher (2004) summarized order maintenance police practices and noted four main categories of “disorders” that were the focus of police: (1) obstructing or lying down in the subway, (2) public urination, (3) panhandling, and (4) youth or student parties (page 396).

What kind of phenomenon is considered disorderly? After reviewing the various definitions and findings from studies, Kubrin (2008) concluded the following “Definitions of disorder used by researchers and officials studying and practicing broken widows policing are not necessarily consistent with residents’ perceptions in their own communities.” (page 206). From the previous literature review, it is apparent that disorder is indeed a “slippery concept” in both research and practice.

The Disorder and Crime Association

Recently, disorder has become a new center of attention for criminologists and criminal justice practitioners. From the Broken Windows Thesis proposed by Wilson and Kelling (1982), fear of crime research (see Garofalo and Laub 1978), to broken windows policing (or called the quality of life policing in New York City), disorder has been formulated as the core element in the equation of inquiry.

Despite the popularity of the broken windows based ideas among practitioners, the association between disorder and crime has been a much debatable topic (see Taylor 1999 and Sampson and Raudenbush 2004). Wilson and Kelling (1982) asserted that disorders are the root cause of crime. They suggest that signs of disorder lead to a sense of low social control perceived by those in the community, which triggers residents’ fear. Fearful residents may further withdraw from the community, and subsequently more serious types of crimes will occur. Therefore, targeting crime would not solve the fundamental problem, but focusing on disorder intervention will result in a greater crime prevention benefit.

Similarly, Skogan believes that incivilities will eventually result in neighborhood decline because they cause a range of psychological, social-psychological and behavioral outcomes in neighborhoods. Beginning with the appearance of incivilities, the decline of a neighborhood is a gradual process (Skogan 1990, p. 65). First, signs of incivilities cause social withdrawal of residents from participating community activities. It also discourages people from cooperating with their neighbors. Second, the existence of incivilities weakens neighborhood morale. Residents become concerned about their personal safety after a number of incidents happen in their neighborhood. As a result, residents lose trust in each other. Third, from a practical standpoint, incivilities undermine the housing market. It directly affects the willingness of people to invest in the area. Due to a lack of investment, the housing market is suppressed and neighborhood decline becomes an unavoidable outcome. To test his hypothesis, Skogan (1990) collected information from 40 neighborhoods in six different cities during 1977–1983. The simple association between disorder and robbery victimization in those neighborhoods was + .80. However, when other neighborhood factors were taken into account, the association dropped to + .54, though still fairly substantial. Based on these findings, Skogan concluded that with the small number of cases at hand, it is hard to tell "*whether they have either separate 'causes' or separate 'effects' at the area level*" (1990, 73).

Keizer et al. (2008) conducted a series of field experiments on physical disorder and found that the presence of disorder, such as graffiti, trash etc. increased the likelihoods of passersby to commit minor disorderly behavior. Though this study provides some direct support of the negative effects of disorder, the study did not examine the effects of disorder on crime. Moreover, their study focuses on physical disorder only, rather than both types of disorder. The association between disorder and crime was further confirmed by Weisburd et al. (2012) longitudinal study of crime trends in Seattle, WA. Controlling for opportunity variables as well as characteristics derived from social disorganization theory at street level, physical disorder was found to be one of the strongest indicators predicting crime trends. Specifically, streets with more physical disorder incidents were much more likely to be in the chronic crime pattern instead of crime-free pattern. Also, increases in physical disorder over time were related to increased crime trends. Though the findings lend confidence to the disorder-crime association, only physical disorder measure was included in the study.

While both Wilson and Kelling and Skogan believe disorder in the neighborhoods causes crime and other social negativities, other scholars hold different opinions on the nature of their association. In a study of drug hot spots in Jersey City, Weisburd and Mazerolle (2000) found that serious crime and disorder tend to cluster together in drug hot spots. In other words, disorder and crime are positively correlated at these drug hot spots. In contemporary social disorganization theory, both Bursik and Sampson treat disorder as a consequence of the lack of social control or as a product of structural variables. Thus, disorder is only related to crime through its associations with structural variables. That is, crime and disorder should be positively correlated but the relationship is not *causal*.

Corman and Mocan (2000) examined the association between disorder and crime rates in NYC over time. However, they did not collect directly measured disorder data; rather, they used misdemeanor arrests as the proxy of disorder. They found that misdemeanor arrests in NYC from 1974–1999 were significantly, negatively related to robbery, motor vehicle theft and grand larceny after controlling for economic conditions and deterrence, but were not significantly related to the other four index crimes. Despite the empirical disagreement, within all the theoretical arguments about disorder/incivilities, most of them assume a positive association between disorder and crime. Meaning, wherever there is disorder, there tends to also have crime problem. The issue is, whether the association is correlational or causal. Also focusing on New York City, Geller (2007) examined housing conditions and the relationship to crime rates in NYC. She tested whether deteriorated housing conditions leads to crime increases as expected by the broken windows thesis. The results of her study did not support such a hypothesis. However, in the study, only the effects of physical disorder were tested. This is an important distinction as some studies have suggested that social and physical disorder may have different relationships with crime.

St. Jean (2007) conducted an ethnographic study in a high crime neighborhood in Chicago and found that disorder and crime tended to coexist in the same areas. However, he pointed out the differential association of social and physical disorder with crime. Yang (2010) in a longitudinal study of City of Seattle, WA, also found a significant correlation between disorder and crime. The direction of causation, however, was opposed to what was suggested by the broken windows thesis. The results from Granger causality tests generally showed no causal relationship between disorder and violence, and in a few places the causality appeared to run from violent crime to disorder. Additionally, Yang shared St. Jean's findings and argued that research should make a distinction between social disorder and physical disorder. They are not only qualitatively different phenomena; moreover, these two types of disorder have different associations with crime.

Separating Social Disorder and Physical Disorder

Activities under the classification of disorders, or incivilities, are not all homogeneous. Under the big umbrella of disorder, there are two commonly used subcategories: physical disorder and social disorder (Skogan 1990; Hancock 2001; Sampson and Raudenbush 1999). Later, Taylor (1999) proposed very specific operational definitions of social and physical disorder (incivilities). Social incivilities include behaviors such as public drinking, drunkenness, rowdy and unsupervised teens, sexual harassment, arguing and fighting, open prostitution, and public drug sales. While physical incivilities include things like abandoned buildings, graffiti, litter, vacant and trash-filled lots, unkempt yards and housing exteriors, abandoned cars and the conversion of houses and apartments to drug-selling locations.

From a research standpoint, social disorder and physical disorder are qualitatively different. Sampson and Raudenbush (1999) clearly pointed this out in the beginning of their article: "*[s]ocial disorder, we refer to behaviors involving strangers and considered threatening... [p]hysical disorder, we refer to the deterioration of urban landscapes* (p. 603–604)." From this statement, it is obvious that social disorder requires the involvement of human behaviors, which impose threats to others in the neighborhood. Thus, the key element defining social disorder depends on the presence of actors who perform the offensive actions. St. Jean (2007) also believes that neighborhood disorder exists in two forms: physical and social disorder. He argues that physical disorder refers to "unpleasant neighborhood characteristics" created by messy environment such as litter, trash, abandoned tires, empty lots, and broken windows. On the contrary, social disorder is a result of the "unpleasant and perhaps intimidating social interactions among people in public space." As such, social disorder includes social behaviors like panhandling, public drinking, fighting, and loitering (St. Jean 2007, p. 196).

In addition, Hancock (2001) suggested another less general way of classifying disorder by looking at its duration. Based on its temporal length, he classified disorder into two groups: the episodic disorder which occurs at no fixed time, such as public drinking, and the on-going type of disorder like abandoned buildings which are always there, unless someone takes initiative to change the condition. Putting these ideas together, social disorder is usually an episodic behavior, which only lasts for a short duration. Conversely, physical disorder represents an objective condition that might last for a long period of time unless some actions are taken to change it. The focus of the latter is on the physical conditions rather than on individuals acting within the conditions.

Many of the past studies proposed clear definitions of social and physical disorder along with characteristics included within each category (Sampson and Raudenbush 1999; Skogan and Maxfield 1981; Skogan 1990; Taylor 1999; LaGrange et al. 1992). However, when doing analysis, people often combined these two categories together into one total disorder measure – assuming that they represent the same underlying construct. For instance, Skogan and Maxfield (1981) used a general term of "sign of disorder" to represent the violations of "people's expectations about fit and proper conditions and conducts." Within this "sign of disorder" they included a wide range of circumstances like unsupervised teens hanging out on the streets, abandoned buildings, illegal drug use, and vandalism. Sampson and Raudenbush (1999), though proposed clear definitions about social and physical disorder separate, did not examine their individual effects in their test of the broken window thesis. In their analysis stage, they made a statement that "*the results are so similar for physical and social disorder, and because the two scales are highly correlated (r = .71), we combine them into a summary index of disorde*r..." (p. 626). As such, the distinction between social and physical disorder and their associations to crime were not fully examined in the study.

In a separate study, Raudenbush and Sampson (1999) tested methodological properties of social and physical disorder measures using item response modeling with hierarchically constructed data. They found that social disorder measures were recorded less often and thus, less reliable compared to physical disorder measures, due to the rarity of the social disorder observations.

Steenbeek and Hipp (2011) also followed the item response modeling approach to explore the reciprocal effects of disorder on social structures and social control under the social disorganization framework. Using data collected in the Netherlands, they argued that the correlations between social disorder and physical disorder items were too strong. Thus, they constructed a disorder measure at the neighborhood level combing all social and physical disorder items rather than separating the two constructs.

In short, despite the fact that many prior studies have acknowledged the distinction between social and physical disorder, their separate effects to crime and other social problems are still understudied empirically.

Social Disorder, Physical Disorder, and Crime

Overall, the qualitative differences between social and physical disorder are rarely addressed. Mixing the concepts of social and physical disorder hinders us from disentangling the intertwined relationship between disorder and crime. From theoretical perspectives, social disorder and physical disorder are different in many ways. First, social disorder involves actors and current actions; thus, the presence of social disorder perhaps provides a pool of potential targets, motivated offenders or both for violent offenses to occur. Physical disorder, however, does not necessarily involve actors. Most of the time, we do not see/know the actors who dump trash or break glass in the next block. We recognize physical disorder when we see it, even without seeing the creator(s) of it. As such, physical disorder provides unmistakable visual cues to the users of the space. Therefore, residents' perception of physical disorder should be more consistent than their perceptions of social disorder as the latter involves an individual's value judgment.

Compared to social disorder, physical disorder is generally considered less criminogenic for crime. An abandoned place could attract would-be offenders to engage in criminal activities. However, physical disorder itself, without the presence of potential offender/victims, should be related to crime to a lesser extent than social disorder. It is possible that there exists a sequential relationship between social disorder and physical disorder. This possibility will be examined later using the Granger causality test to see if there is a directional relationship between the two types of disorder.

The distinction between social and physical disorder also carries importance on another equally important subject—fear of crime. In addition to crime, fear is another phenomenon that has long been connected to disorder (see Garofalo and Laub 1978; Kelling and Coles 1996). Kelling and Coles (1996) argued that fear mediates the effects of disorder on crime in a community. However, the differential effects of social and physical disorder were not discussed by Kelling and Coles. Based on Sampson and Raudenbush's phrases cited earlier, it is expected that social disorder and physical disorder should have different impacts on fear. Social disorder invokes a feeling of fear to residents, while physical disorder provides a more neutral image that might still be bothersome to some residents. As such, the emotional reactions related to social and physical disorder are not necessarily the same.

Empirical studies also support that social disorder and physical disorder are different and so are their associations to crime. The empirical evidence from Taylor's (1999) observations in

Baltimore provides a good example of how different those two types of incivilities can be. In the study, physical disorder is found to be correlated with changes in rates of aggravated assault, burglary, and motor vehicle theft while social disorder is correlated only with changes in the rate of rape (all of the correlations are significant at .10 level, Taylor 1999, p. 5). St. Jean (2007) analyzed crime data and interviewed residents in poor neighborhoods in Chicago to study disorder and crime. From cross-tabulation analyses, he found that places with high collective efficacy and low social disorder have fewer crime problems. Places with low social disorder tend to have low street drug dealing. However, high physical disorder had no significant association with drug dealing, robberies and batteries. While the finding seems to support the broken windows thesis, he argued that places with high levels of social disorder do not necessarily have more crime problems. The data at best could argue that in the absence of social disorder, it is also less likely for the places to have drug dealing problems.

Nonetheless, St. Jean sought for a more thorough understanding about the underlying mechanism linking disorder and crime by conducting in-depth interviews with street criminals and other individuals who live in the crime ridden areas to get their perspectives. The presence of physical disorder alone does not attract drug dealers to the area; rather, it is the location and the activities occurring within and nearby the area that determine whether it is going to become a drug hot spot. Though the dilapidation of buildings does show that the government did not invest in the area and perhaps there is a demand for drugs in the place from people who could not find any decent jobs. The association between robberies and physical disorder is even weaker. The robbers pick places to commit crime based on accessibility and anonymity, not because of the abandoned buildings or trash lying around in the areas. As for batteries, he found that places with high levels of physical disorder tend not to have battery problems. It is reasonable because places with physical disorder tend to be occupied by abandoned lots or buildings and therefore, are less likely to have domestic disputes due to fewer people living in the area.

From the qualitative interviews, St. Jean found that social disorder has strong and significant associations with narcotic violations, robberies, and batteries. But a closer examination of the mechanism behind the association revealed the complexity in the phenomena. Places with low social disorder tend not to have drug dealings; however, places with high social disorder may or may not attract drug dealers to the areas. Moreover, the association between social disorder and narcotic violations is sometimes reciprocal. That is, people who use drugs might be involved in social disorder while they are waiting for their needs to be met. As for robberies and social disorder, the relationship is positive and significant. But further inquiry shows that the locations and actors in the places matter more than whether the areas have social disorder. Sometimes, having more people hanging around a place provides a potential pool for robbery targets. However, when the people do not seem to be vulnerable or do not possess enough monetary goods, they would not be selected as targets. The tight coupling between social disorder and batteries shows that places with more disorderly people are also more likely to have domestic conflicts. Again, St. Jean found that the association is only supported in places occupied by high social disorder and disruptive families. In places that have high levels social disorder but are occupied mainly by non-disruptive families the association diminishes. Overall, the findings from the ethnographic portion of this study were consistent with what was found in the statistical analyses. That is, physical disorder does not matter in predicting crime places. Moreover, social disorder does not matter in offenders' decisions in choosing a place as their base; what really matters to them is where the place is located and who are hanging around the place. St. Jean's study provides a comprehensive picture illustrating the relationships among crime, social, and physical disorder. Nonetheless, the analyses in the study were all based on a short time period and limited the selected poor neighborhoods in one high-crime police beat in Chicago. Therefore, it is hard to know whether the relationships remain the same over time in other places.

Finally, in another study using 16 years of data collected at the census-block-group-level in Seattle, Yang (2010) studied the long-term associations between social disorder, physical disorder, and violent crime. The dual-trajectory analysis findings suggested that a block group with a low level of disorder (for both social and physical disorder) is less likely to experience violence problems. If a block group is assigned to the low rate social disorder trajectory, then there is an 88.1 % of chance that this block group will also be found in the no (or negligible) violent trajectory. Similarly, 82 % of block groups with negligible physical disorder problems are also relatively free of violence.

However, block groups that have high disorder problems are not necessarily also plagued by violence. For block groups within the high social disorder trajectory, there is only about a 30.6 % of chance of also being classified into the high rate violent trajectory group. Also, having been assigned to the high physical disorder trajectory only corresponds to a 30 % of chance of having a high level of violence.

This means that having no disorder can be seen as a powerful protective factor for block groups in preventing future violence – as there is less than 1 % of a chance that a block group will have a high level of violence if it has negligible disorder problems. Although having high disorder can be a risk factor to increase the chance that a block group experiences violence, only about 30 % of block groups that showed a high level of disorder also showed a high level of violence. This means that by using disorder as a risk factor, we will have a 70 % chance of making an incorrect prediction of where high violence places would be located. Perhaps lack of disorder and having high-disorder are not the two sides of the same coin. Or perhaps there is not a linear relationship between disorder and violence.

Furthermore, Yang also conducted geographic analysis on the selected block groups with high levels of social disorder, physical disorder, and violence (see Fig. 1). The visual illustrations on social disorder-physical disorder dyad and violence further confirm the previous findings. First, block groups with high violence trajectory are always located within the areas with a high level of social disorder. However, places having high social disorder do not necessarily have high violence rates. In other words, to locate a high violence block group, social disorder provides more accurate information than physical disorder. This finding echoes St. Jean's study results from Chicago. Second, places that are low in both social disorder and physical disorder are also free of violence problems. When a block group is free from disorder problems, it is also more likely to be free from violence problem. On the other hand, when a block group starts to show any signs of a disorder problem, it is very unlikely that it will exhibit a low rate of violence. High physical disorder block groups, though not informative of where the high violence block groups are located, are predictive of where the *low* violence block groups will *not* be. The spatial concordance between social disorder and violence points out a possibility that there may exist a connecting mechanism that governs both disorder and violence at places. The studies of St. Jean and Yang both show that having more broken windows does not necessarily predict what the level of crime will be at a given place.

The Next Step for Disorder Research

Overall, the empirical findings and theoretical arguments point to the need for studying these two types of disorder separately. Social disorder is found to be more relevant to crime than physical disorder. Perhaps it is because people involved in disorderly behaviors are also more likely involved in violence, regardless of the environmental factors. Or, perhaps it is also possible that these people might provide visible targets for motivated perpetrators or they might be the instigators of violent behavior.

Another possible source of variation is the type of measures used in the study. One of the major obstacles on studying the linkage between disorder and crime is whether residents could actually distinguish between disorder and crime (Gau and Pratt 2008). This is crucial as the mechanism outlined in the broken windows thesis to be effective; residents need to be aware of the

existence of disorder. As such, some scholars started to research the impacts of perceptual disorder and the factors that could lead to perceived disorder. Clearly, observed levels of disorder play a role in this process, but perceptions are more critical. Generally, it is found that the perceptions of crime and disorder are highly related and do not have discriminant validity (see Gau and Pratt 2008; Worrall 2006). In other word, disorder and crime might be manifestation of the same underlying construct with different level of intensity. Thus, police strategies targeting disorder, as opposed to crime, might not lead to either crime or fear reduction effects as intended.

Innes (2004) also proposed a potential mechanism about how disorder affects residents' perceptions about crime and disorder. What matters most is not the nature of disorder; rather, it is the interpretation of disorder that leads to fear and negative emotions. The signs of disorder provide a framing function that helps people to give meanings to the quality of places. As such, social disorder and physical disorder might send out different signals to people. Physical disorder might reveal the lack of investment of the places by both government and residents. On the other hand, social disorder can be indicative of the type of people who hangout in the areas and the strengths of social ties in the area.

Hinkle and Yang (in progress) further point out that it is important to evaluate whether residents' perceptions of disorder matches with the observed level of disorder measured by researchers through systematic social observations. They further argue that social disorder and physical disorder might have differential conditional effects on residents' perception about the disorder problem, fear of crime, and satisfaction of the residential environment. Thus, scholars who are interested in disorder-related research need to examine social disorder and physical disorder separately. Moreover, it is also important to control the methods of measurement used to gauge levels of disorder, be it the actual level or the perception of the problem.

Disorder, unlike crime, is a common phenomenon and exists in many people's daily lives. It has also become an important issue for research in many disciplines. Recent studies have shown the importance of evaluating social disorder and physical disorder separately. These two types of disorder are not only qualitatively different, but they also relate to crime in very different ways. Moreover, the presence of social disorder and physical disorder send very different signals to passersby, residents and potential offenders and possibly lead to different perceptions about places. Future research needs to pay closer attention to the distinction between the two types of disorder and their implications for social policy.

Overview

One would expect more terrorism incidents to originate in a socially disorganized environment, that is, an environment that has experienced a rapid social change that has destroyed the regular rules and bounds on human behavior. The notion that one's surroundings may influence behavior is not a new one. In particular, the idea that the organization of the social environment, such as neighborhoods, families, and communities, may stimulate violence has been around since the origins of the social sciences. Emile Durkheim was a pioneer in describing the anticipated effects of the social environment on violent behavior.

Anomic Behavior

To understand how a socially disorganized environment influences one's behavior according to Durkheim (1930 [1951]), it is important to understand how he viewed human nature. To Durkheim, humans lacked the ability to regulate their desires and wants. In fact, humans were like other animals in that they were controlled by their needs and desires, particularly food, shelter, and the sexual drive. Unlike animals, though, humans have the power of reflection, the ability to imagine more than they have, and it is because of this ability to imagine more that they require an external force to limit their desires and needs. In normal times, the social environment provides this external limiting force; that is, one's behavior is regulated by the social rules and norms that are ordinarily in force. For example, if an individual sees that another has a very nice and desired vehicle, under most circumstances, that individual will not simply go and take that vehicle by force. Under most circumstances, the individual will refrain from taking the vehicle, because the individual is kept in the bounds of legal and moral behavior by the traditional rules of society. The fear of arrest and the disappointment expected by one's family and community as well as other social consequences keep individuals from simply taking the object of their desires.

However, Durkheim (1930 [1951]) says that if the society is experiencing temporary but rapid social changes, normal circumstances do not apply. In fact, during these times, what are called anomic or socially disorganized times, it is as if the rules of society have been stripped off and individuals are left in a world with no normal ways of doing things and no rules about wrong and right. In addition, the power of reflection, the power to imagine more, better, and different will come into play. In this world, individuals may become so disoriented by the loss of rules and controls that they may start to want everything they see. In many cases, individuals will not be able to satisfy all of their wants and desires and will become unsettled. Because Durkheim studied what led people to commit suicide, he states that such persons are more likely to commit suicide. Compared to well-regulated societies, those which experience rapid social changes that create anomie are more likely to experience increases in suicides.

Durkheim's (1930 [1951]) writings on the effects of anomie on behavior can be and have been applied to crime and terrorism. An example of a rapid social change sufficient to bring on a state of anomie in the society might be a civil war between an insurgent force and the government. In such a society, where an insurgent force is violently attempting to overthrow the government and its rights to make and enforce rules about legal and illegal conduct, the rules that dictate right and wrong in everyday life will not be in place. This constitutes anomie, a state of deregulation of behavior.

An individual living in such a state will be unsure as to what the new rules and regulations are in this different, anomic world. When the old rules were forcefully removed by the outbreak of civil war and the new rules have not been made clear or taken root yet, individuals will either need to restrain their desires and needs themselves or they will find this new anomic world without rules intolerable. The inability to tolerate this anomic world may make it more likely for some people to do behavior that is against the rules and norms of behavior that used to be in force in the society. If such individuals are sufficiently motivated, perhaps by a grievance against the government (Gurr 1976), such individuals may become involved in extreme acts, including terrorism. Anomie, according to Durkheim, is not a permanent condition. Over time, a new set of rules to define what is normal in society will develop, and the society will regain its equilibrium. This new set of rules will make living more tolerable for individuals again, and this will decrease the rate at which individuals engage in problematic behavior.

It is important to remember that this theory of human behavior is probabilistic; it suggests that the presence of such rapid social change makes it *more likely* that *some* individuals will engage in actions that are problematic. It is not a theory that predicts that all individuals will engage in problematic behavior nor is it definite that any specific individuals will be so engaged.

How Much Rapid Social Change Is Needed?

To result in anomie, a rapid social change must involve a large-scale structural challenge to the ordering and functioning of societal institutions (Piven and Cloward 1977). In other words, the rapid social change has to be serious and broad. It is also important that the rapid social change be large enough to stimulate changes in the structure and routines of everyday life. If a rapid social change occurs that does not interrupt the structure and routine of everyday life for most people, it is unlikely to change the behavior of those individuals whose routines continue uninterrupted. For example, when individuals are released from the routine of going to work every day as well as the sustenance provided by work, this changes the pattern and rhythm of their lives. If the interruption continues for a period, it is likely sufficient to produce anomie.

How Do Anomic Conditions Affect Behavior?

A socially disorganized environment likely affects behavior through its effects on the structure and routine of everyday life (Snow et al. 1998). People are more likely to take action to preserve what they know and their current routines rather than to seek something new and better. The known routines they will act to save are the things they do every day (behaviors) and the way they think about these things (cognition). The behaviors involve habitualized patterns of action. The cognition involves attitudes individuals adopt when approaching their daily routines. These attitudes chiefly involve an unquestioning, unreflective routine way of getting through the day.

These behavioral and cognitive routines of everyday life are what constitutes the *quotidian*, which is derived from the French word for daily. For example, if a rapid social change occurs that does not affect the daily routine for most people, such as the actions as well as thoughts and ideas of getting up every day to go to work, come home from work, and taking care of children and home, then it is unlikely to stimulate people to do something about the rapid social change. It is when the behavioral and cognitive routines of the everyday are disrupted that individuals are likely to be moved to act. Action is particularly likely if the routine of work is disrupted. This is because work provides both monetary sustenance that is needed for survival and dominates the waking hours.

The Great Depression is one rapid social change that severely disrupted the quotidian (Piven and Cloward 1977). In particular, many individuals lost their jobs or livelihoods. As these individuals sought work and could not find it in their communities, many left their communities in search of it elsewhere. The Great Depression vastly affected the quotidian. The key connection between a socially disorganized environment and individuals taking action is whether the anomic conditions truly affect the individuals' lives by disrupting their everyday routines.

Once the quotidian is disrupted, the present world of individuals becomes a problem that begs to be fixed. This disruption makes everyday life unbearably uncertain until such time that the old routines can be reclaimed or new routines can be adopted and adjusted to. Inherently, individuals are spurred to action by the need to get back their old routines, thus reducing the uncertainty in their lives. It should be noted, though, that there may be a threshold for the loss of the quotidian, past which action may be unlikely. This threshold may lie at the complete destruction of the individual's way of life, such as for refugees from wars or victims surviving genocidal campaigns.

How Do Social Disorganization and the Quotidian Relate to One Another?

When Durkheim and the quotidian theorists were writing, they were not trying to explain the occurrence of terrorism. However, these works have been used to explain the occurrence of nonroutine collective action (Useem 1998). Nonroutine collective actions seriously contravene social norms, particularly those against violence. Terrorist attacks constitute nonroutine collective action. The acts themselves are born of the interaction and planning of a group of individuals and involve violence against people or property and, thus, are appropriately described as nonroutine collective action.

What, then, is the process of social disorganization influencing terrorism? First, the rapid social change must occur. It must occur rapidly, and it must have effects that broadly affect the lives of many people in society. An example would be the onset of a civil war. The society must not be able to absorb the negative effects of this change. Individuals will lose their integration into the rhythm and networks of life; they will feel cut off. In addition, they will only weakly be linked to the collective identity of those in their society. These individuals are set adrift.

Second, the social change must influence the everyday lives of people. In fact, it must have substantial effects on the behavioral and cognitive routines of the everyday lives of most people. For example, if a civil war breaks out, perhaps the fighting itself has made it too dangerous for citizens to travel to work every day or perhaps the factory in which they work has been shut down due to damage from nearby bombings. Losing the routine of waking up and going to work every day as well as the thought process that goes along with such a routine may be profoundly disorienting to individuals.

Further, along with the loss of everyday routines, individuals in such societies may not know how the rules and norms of life have changed. What is acceptable and normal may have changed. Both the loss of the routine and the previously known rules and norms have effects on people. With no routine and no norms, these individuals will be poorly integrated into society. They will be included in fewer networks and activities than before the loss of the quotidian; they should also have less identification with the collective identity. The severing of networks and the collective identity and the destruction of the previous norms and rules are what classically constitutes social disorganization. This social disorganization should make it more likely that individuals will do nonroutine collective actions. They may take to the streets to protest or riot, they may commit ordinary crime, and they may engage in political violence. This political violence may be what scholars consider terrorism.

How to Define Terrorism?

The next question must be what constitutes terrorism. Definitions of terrorism abound, and the debate continues on which definition is the best. Often, the definition of terrorism chosen will reflect the main interest of the definer. For example, the United States' Federal Bureau of Investigation, which often conducts domestic terrorism investigations, has a definition of terrorism some have called narrow and legalistic (Martin 2011). This definition is likely precise and legalistic, because it is used to investigate and enforce the law. On the other end of the spectrum, academics and researchers who perform studies of terrorism often use definitions that are broader or more detailed in order to facilitate the collection of data or analysis of data.

No specific definition of terrorism is adopted here, but some guidelines might be useful. These guidelines include non-state actors using unconventional force illegally against civilian or other noncombatant targets for political motives to influence an audience (Martin 2011). Noncombatant targets are often interpreted to include military personnel when off duty. Political motives are often interpreted rather broadly and may include acts of violence that are aimed at instigating social or religious change as well as strictly political motives. In addition, groups can have multiple or overlapping motives in that they may desire political autonomy for their social or ethnic group as well as religious change. An example of this would be the group Hamas, which seeks an independent Palestinian state that would be governed by Islamic law. Further, terrorist groups seek to influence a larger audience beyond the immediate victims of their attacks. For example, the Popular Front for the Liberation of Palestine (PFLP) undertook a campaign of dramatic aerial hijackings for the express purpose of publicizing the plight of the Palestinian people to the world. They chose aerial hijackings in order to grab the world's attention and to direct it to understanding Palestinian grievances. Similarly, the group Black September is thought to have undertaken the attack on the Israeli athletes during the 1972 Olympic Games in Munich, Germany, as a way of airing their grievances to a wider audience.

Is Breakdown a Reasonable Explanation of Terrorism?

In order for the Durkheimian model of societal breakdown to be a reasonable explanation of terrorism, three things should be evident. First, there should be a rapid social change of sufficient magnitude and scope that it cuts individuals off from the social ties and bonds they had to the community before the rapid social change. Second, this loss of ties (breakdown) should stimulate discontent in individuals in that society. This discontent may stem from being cut off from society in general or from the quotidian. Third, it is important to demonstrate whether this discontent must make nonroutine collective action more likely to occur. If all of these qualifications can be met, then breakdown theory has passed a crucial test with respect to whether terrorism is more likely to occur in an environment of social disorganization.

Alternate Hypotheses

It is entirely possible that breakdown theory does not explain terrorism particularly well. What then are the alternate explanations? The major competing explanation is known as resource mobilization and is best exemplified by the work of Charles Tilly and his colleagues. Where breakdown posits that individuals who are cut off from the rules and norms of society by the loss of the quotidian will be more likely to engage in nonroutine collective action, the resource mobilization scholars argue that there is no connection between breakdown and nonroutine collective action. In fact, resource mobilization (RM) scholars do not recognize a distinction between routine and nonroutine collective action; rather, they assert that both routine and nonroutine actions spring from the same mechanisms (Tilly et al. 1975). They also contend that crime and suicide are not collective actions, but instead, they constitute social pathologies and ought not to be considered for explanation by the RM perspective.

Next, RM theorists argue that collective action is explained by dense social networks and a robust collective identity. That is, individuals who are well integrated into the society through their primary and secondary social networks are more likely to engage in collective action. Primary networks are made up of family bonds and the informal social controls provided by this type of network. Secondary social networks are informal social bonds in work, school, and church. Individuals with strong primary and secondary social networks are more likely to engage in collective action according to this perspective. That is, individuals who are well connected to the people in their lives and who identify with the society's collective identity are more likely to be involved in collective action, such as social movements or protests.

More specifically, RM theorists suggest that rather than preexisting social isolation, weak social networks, and weak collective identification, collective action grows out of preexisting social organization. Social organization can include formal and informal social bonds and resources. Individuals who are well integrated into social networks, particularly secondary social networks, are a wellspring of resources, civic-minded attitude, and connections to other people. This type of connectedness makes it *easier* rather than harder to motivate collective action. In fact, individual connections to a whole group of individuals may make bloc mobilization possible, such as mobilizing church members to protest outside of abortion clinics (Useem 1998).

Taking Sides

How, then, to decide which perspective is most useful for explaining terrorism and other forms of crime? This question can be examined using several types of studies. The first type of study would be to interview individuals who have participated in collective action. This would involve collecting their personal information, such as whether they were members of secondary groups. It would also be helpful to ask whether they feel well connected to society or cut off. It would be important to examine those who engaged in routine collective action separately from those who engaged in nonroutine collective action. For example, one set of researchers examined the characteristics of African Americans in 15 cities during the 1960s, a period of great social unrest, including both nonviolent protests and violent race riots (Miller et al. 1976). They compared those who had engaged only in nonviolent protest (routine collective action) to those who expressed attitudes supportive of rioting (nonroutine collective action). They found that those who had engaged in nonviolent protesting were more likely to be older, married, and of higher occupational and educational levels and were less likely to have been raised in "broken" homes than those individuals who had attitudes supportive of rioting. Although many of these individuals may not have participated in the riots, this study may demonstrate that those who engage in routine collective action are more likely to be well integrated in society and less likely to be socially isolated than those who engage in nonroutine collective action. This study supports the breakdown position with respect to the role of social integration and organization.

In contrast, other researchers examined the social movement against drunk driving, known as Mothers Against Drunk Driving (MADD). The movement was founded by two married mothers who had lost daughters to drunk drivers with multiple prior offenses. Interestingly, the movement seemed to take off from the beginning, with MADD's first press conference being held months after its founding on Capitol Hill with three Congressional representatives present. MADD conducts routine collective actions, including tree plantings, gatherings at the US Capitol, and political lobbying, including lobbying US President Ronald Reagan to sign the federal legislation that would effectively raise the drinking age to 21 (madd.org 2011). One study found that on average, MADD participants were socially involved, married, middle aged, college educated, and held privileged jobs (Weed 1987). Further, another study found that MADD chapters were more likely to be founded in counties with wealthier and more educated residents (McCarthy et al. 1988). Given that MADD has only been involved in routine collective actions, this movement, the types of collective actions in which they engage, and the status characteristics of those who participate in it seem to indicate that routine collective actions may require some social organization and participants who are enmeshed in social networks.

The second way of studying the connection between social disorganization and collective action is to examine a particular movement which involved both routine and nonroutine collective actions for evidence that the presence of social disorganization increased the discontent of citizens, whether this discontent made it more likely that these individuals would participate in collective action and, finally, whether those individuals who were well bonded to their families and their communities and participated in community activities before the rapid social change were more likely to engage in collective action (Useem 1980). This case study examined the antibusing movement which grew out of the Supreme Court decision that mandated the racial desegregation of public schools by busing students to racially integrate previously segregated schools. The study involved interviewing individuals who lived in parts of Boston which were likely to be affected by the integration of schools. They were directly asked about whether they had engaged in any collective action, their levels of discontent, and their ties to family and community. This case study directly examined the key questions about breakdown and preexisting community engagement on collective action.

The rapid social change of the antibusing movement was represented by the order to desegregate public schools. The antibusing movement in Boston involved both violent and nonviolent forms of collective action, including boycotts, demonstrations which involved violence, the formation of private schools to circumvent the desegregation order, and the formation of community organizations to represent the antibusing interests. This case study found that those who were closely tied to their communities and those who were members of community organizations were more likely to be discontented with the desegregation decree. That is, socially isolated individuals were less likely to be discontented. This supports the RM position. Those who were discontented, in turn, were more likely to participate in collective action against busing. This supported the breakdown position. It seems possible that those who were more connected to their communities were better informed about the order to desegregate or were more likely to be affected by the order (e.g., had school-aged children) and, thus, had more of a stake in trying to protest or circumvent the desegregation order. This type of rapid social change did not affect all community members equally; those with school-aged children would be more likely to be discontented by it. Nevertheless, this study provided support for both breakdown theory and the resource mobilization theorists.

The third way of studying this question is to examine environments that have endured the effects of rapid social change that resulted in social disorganization. For example, we could also compare the levels of nonroutine collective action in states or countries that have experienced rapid social change and social disorganization to those countries or states that have not experienced rapid social change and social disorganization. This could allow researchers to examine many different countries around the world and over long periods of time. Or alternatively, we could examine the same environment over a long time period, including periods of rapid social change as well as relatively calm periods. In this way, we could examine the effects of rapid social change on collective action while holding the country environment constant.

One study examined patterns of crime and collective action in France between 1830 and 1931 (Lodhi and Tilly 1972). For collective actions, the authors included riots, strikes, and demonstrations. For the rapid social change, they examined the effects of urbanization (i.e., increases or decreases in the proportion of people in France living in cities with 10,000 or more people). Urbanization constitutes a classic rapid social change, because it generally involves the migration of rural residents to the cities. These rural residents often moved to the cities en masse in search of work, because they were unable to sustain a living in farming or because of an increase in the availability of jobs in the cities due to industrialization. The males and occasional whole families who migrated to the cities may be predisposed to difficulties in adjusting to the new urban environment. These adjustment difficulties may have resulted in social disorganization. From the breakdown perspective, these difficulties were likely to involve the isolation of these individuals from their family and community ties, leading them to be cut off from society. This would make them more likely to engage in nonroutine collective action. From the RM perspective, urbanization itself may have no actual effects on the individuals who migrated to the cities. Rather, it is the *experience* of living in a city that makes individuals more prone to collective action. This is called urbanity, which is the proportion of people who live in cities with 10,000 or more people relative to the population of the entire country.

Thus, this research set up a direct test between breakdown and RM. The main question was whether urbanization (breakdown) or urbanity (RM) would drive either crime, collective violence, or both. During the major period of urbanization in France, the number of property crimes declined, while crimes against the person did not appear to be driven by either urbanity or urbanization. These findings most clearly contradict the breakdown perspective, which suggests that urbanization should drive both person and property crimes upward. On the other hand, urbanity seemed to predict property crime and some of the forms of collective violence. That is, the experience of living in a city was more clearly responsible for increases in property crime and some forms of collective action than the social disorganization experienced by a society which has en masse migrations of its citizens to the cities.

Another way of testing which theory better explains how collective action is produced is to study one social environment over a long period of time to assess whether crime and collective action occur during the same periods of time. The RM theorists suggest that crime is not a collective action but rather a social pathology, and thus, it should have no relationship with routine collective action. In contrast, breakdown theorists say that crime and nonroutine collective action ought to occur at similar times, because they are driven by similar processes (social disorganization). However, routine collective action and crime should not occur alongside one another because they are not driven by similar processes.

LaFree and Drass (1997) looked at this question before, during, and after the civil rights movement in the United States. Unfortunately, the study did not separate routine and nonroutine collective actions. The authors compared homicide, robbery, and burglary arrest rates for blacks and whites to collective actions. These collective actions were primarily a result of the African American civil rights movement. Thus, they included such actions as sit-in rallies, marches, boycotts, protests, demonstrations, and civil-rights-related riots.

The idea is to examine whether crime and collective action follow similar patterns over time. If they do, it can be inferred that they are being caused by the same or similar processes, and this would support the breakdown perspective, because if they are predicted by the same processes, then, it is likely that collective action does not require preexisting community ties and membership in collective groups (Lodhi and Tilly 1972). If they do not follow the same pattern over time, increasing and decreasing at similar times, then, it is unlikely that they are driven by the same processes. This type of finding supports the RM model.

Upon examination, crime and collective action did follow a similar path, increasing and decreasing together from 1955 until the early 1970s for both blacks and whites. However, collective action decreased dramatically at this point as the civil rights movement, the rapid social change, came to its conclusion. However, arrest rates stayed high and continued to follow their own path from the early 1970s until 1991. These findings do not clearly support either breakdown or RM. It is possible that if nonroutine collective actions, such as riots, and routine collective actions had been examined separately and each compared to crime that the findings would have been more clearly supportive of one side or the other.

Overall, there is no clear winner in the debate between breakdown and RM. It is likely that both theoretical explanations work to explain different segments of collective action. For example, it is likely that preexisting social organization, such as membership in community groups and having personal ties to the community, makes routine collective action more likely, such as the MADD movement against drunk driving. Individuals who have a stake in the community are probably more likely to act to defend that community using legal and nonviolent methods when they perceive a change, like in the antibusing movement. However, nonroutine collective action likely does not require such organization. Individuals who are more likely to engage in nonroutine collective action, such as collective violence or riots, appear to be more socially isolated individuals who are freed to act in response to the socially disorganized environment which surrounds them. Thus, each of these theoretical explanations appears to explain different domains of collective action.

Is Social Disorganization Felt by Citizens?

It is likely that the social disorganization created by the rapid social change is felt by those who live in the society and are affected by the changing environment. This may be felt as a change of or removal of the norms, a feeling that the old rules no longer apply (Durkheim 1930 [1951]). This may also be felt from the loss of the everyday routine (Snow et al. 1998), which may be experienced as a feeling of restlessness or rootlessness. Further, this may also be felt as impending danger or a loss of a sense of safety (Useem 1998).

In an interesting but simple test of this notion of a feeling of impending danger, Useem (1998) examined the relationship between homicide rates, domestic handgun production, and rioting activity in the United States. The time period was 1964 until 1994, a time which included the African American civil rights movement as well as race-related riots in major cities. The thinking was that handgun production would increase as the handguns previously manufactured were purchased; handguns are not usually used for hunting, unlike long guns. Handgun production rates closely tracked the homicide rate over the time period, except for those years in which there were increases in riots. During these years, handgun production rates jumped up more than would be expected given the danger presented by the homicide rate. Thus, individuals appeared to be frightened by the occurrence of these riots and purchased handguns to protect themselves even if the riot did not occur geographically close to them. This research supports the notion that individuals can feel social disorganization as a sense of impending danger.

Does the Evidence Show a Relationship Between Social Disorganization and Terrorism?

The final question is whether terrorism is more likely to occur in socially disorganized environments. One interesting research study examined this question in the context of breakdown theory (Fahey 2010). In this study, the socially disorganized environment resulted from the occurrence of political instability within the country. The instabilities included the outbreak of war, genocide, adverse regime change, which was a move toward a more autocratic government, and a combination of these events occurring within a short time period. The occurrence of these instability types can be seen as measures of rapid social change. In addition, these types of events are also likely to affect the everyday lives of individuals. If the security situation in a particular country deteriorates rapidly, as in the case of war and genocide, or the political environment has suddenly become far less open, as in the case of adverse regime change, citizens will likely be less able to continue on with the rhythm and routine of their normal everyday life, such as work, leisure, and home time. In extreme cases, they may be forced out of their homes. In addition, the political instability may create a breakdown in the informal and formal social ties that bind individuals to society; the breakdown in the ties may make it more likely that individuals living in a society which has experienced this political instability will participate in nonroutine collective action. This will be due to the idea that the informal and formal ties can no longer function to restrain the actions of these individuals. Further, the loss of the everyday routine and the loss of the controlling power of social ties may work together to increase the likelihood of nonroutine collective action.

Fahey (2010) examined whether political instability was related to the occurrence of terrorism in 147 countries from 1970 to 2005. She found that when political instability occurred within a state, increases in terrorism incidents were more likely. One of the strengths of this study is that it examined the occurrence of instability worldwide over 35 years. This helps to ensure that the results are more stable, that they do not apply only to one country or situation, and that they do not apply to only one decade or time period. Political instability does seem to constitute a rapid social change in the Durkheimian model, and it likely affects the regulatory processes in society, that is, social disorganization, as well as the everyday routines of the citizens in that society.

Conclusions

The purpose of this entry was to discuss and explain the rapid social changes that may lead to social disorganization, the two dominant theoretical hypotheses to explain the association between social disorganization and collective action, and some of the evidence that has been used to support either or both of the theoretical expectations. More evidence is needed to come to a firm conclusion on the relationship between socially disorganized environments and terrorism. However, it is likely that both theoretical explanations have some utility. Specifically, it is likely that some individuals and groups are spurred to terrorism due to the loss of prevailing norms in a newly socially disorganized environment as well as the loss of identification with the collective identity. Further, it is also likely that those who had connections to others, particularly through community groups, before the onset of the social disorganization will be in a better situation to join, recruit, and mobilize for and engage in terrorism through a terrorist group. Bloc mobilization may be particularly important for terrorist groups. What seems to be clear is that social disorganization may be one possible explanation of terrorism incidents. For terrorism that occurs after a rapid social change that produces social disorganization, it is likely that the disorganization provides at least a partial explanation.

Social Factors and Third Party Policing

Daniel Brown-Kenyon
Institute for Social Science Research, Policing and Security, The University of Queensland, St. Lucia, QLD, Australia

Overview

The Third-Party Policing model of crime control advocates for the use of partnerships between the police and other key agents of social control – for example, government, business, and community sectors – however, to date, almost no research has examined the social factors that contribute to the success or failure of these partnerships. This entry utilizes a Social Identity approach to analyze some of the key factors that affect the efficacy of these partnerships. Specifically, partnerships are broken down into three distinct phases, and various social factors are considered at each of these phases. This entry also discusses some of the organizational level variables that will be affected if these partnerships are to succeed.

Introduction

Third-Party Policing (TPP) is an approach to dealing with crime problems where police form partnerships with other public service agencies, business, nongovernment organizations, and the community to deliver more effective crime control strategies (Mazerolle and Ransley 2006). The TPP approach requires identification of "legal" mechanisms that are the domain of other parties to assist police in managing public order. Mazerolle and Ransley (2006) identify a wide range of legal levers used in a variety of different settings, such as partnerships with local councils, business, health and safety authorities, and other law enforcement agencies. The primary aim of the TPP approach is to deliver a more effective police service through a twofold approach: recruiting suitable crime control partners and making use of legal levers otherwise unavailable to the police.

This contribution aims to advance the theoretical understanding of TPP by outlining current research and theory on intergroup relations and applying this to policing partnerships. TPP advocates that partnerships are vital for the success of modern policing practices. However, to date, little to no research has been conducted within the policing arena to examine these partnerships and what drives their success and failures. Drawing on the Social Identity literature (see Brown 2000; Haslam 2004), this entry examines some of the social and organizational factors that interact with the success or failure of these partnerships. This analysis is undertaken in five sections, which are comprised of two conceptually distinct areas, focusing on the social aspects of partnerships and then outlining the organizational factors that affected partnerships. The first section presents an overview of a Social Identity approach to intergroup process. The next section separates partnerships into three core stages, including partnership seeking, partnership development, and effective partnership functioning. Next, the role of information sharing in partnership development and functioning is addressed. Finally, some of the organizational constraints within police organizations that are likely to threaten the success of a partnership approach are addressed. At the end of each section, the arguments are summarized and important relationships between the key factors and likely outcomes are discussed.

A Social Identity Approach to Intergroup Process

Social Identity theory is the preeminent theory of intergroup relations. Social Identity theory explores the social motivations and consequences of group behavior. Specifically, Social Identity theory provides a context for examining individuals' behavior within groups (Haslam 2004). According to Social Identity theory, individuals possess social representations of themselves, which are comprised of the social networks they maintain, the groups to which they belong, and the organizations for which they work (Ellemers et al. 2002). Social Identity theory argues that social identity is a critical component of self-concept, and as such, individuals seek to view their group memberships in a positive frame. This is achieved through negative comparisons between their own group and other groups. Through these comparisons, individuals are able to boost their self-esteem (Brown 2000) and show preferential treatment to those of their own groups (Brown 2000). Social Identity theory provides a meta-level context to analyze and understand a range of phenomena involved in intergroup processes.

Since the conception of Social Identity theory, there has been substantial development with a range of subtheories having been developed to explain some of the more nuanced aspects of group behavior. This entry applies a Social Identity approach to understanding the three hypothesized stages of partnerships. The first stage, termed "partnership seeking," helps to understand the internal group structure of the police organization and how these social factors impact on partnership-seeking behavior. Here, key factors of cohesion, leadership, and the norms and values within the organization are all likely to affect the willingness of individuals to seek out partnerships. In the next phase, termed "partnership formation," the core factors of diversity, distinctiveness, and identification during the formation of a new partnership are considered. In the final stage, "partnership functioning," intragroup processes and their implication on cooperation are considered. Here, group identification, procedural justice, and leadership and the impact of these factors on cooperation within a newly formed partnership are discussed.

Partnership Seeking and the Role of Social Identity Theory

This section uses Social Identity theory to examine three internal social factors that police organizations face when seeking TPP partnerships. First, the way that norms and attitudes of a police organization are likely to dictate individual officers' intentions to seek out third-party partnerships is examined. Within this, the role of self-categorization and its impact on conformity with these norms are also outlined. Second, the role of leadership within a police organization in promoting partnership seeking and development of partnerships within the context of TPP is discussed. Finally, this section explores the effect of internal cohesion and how this poses a significant barrier for the police to effectively seek out partnership.

The development of self-categorization theory is an extension of Social Identity research and is particularly useful for understanding partnership-seeking behavior (Hogg and Terry 2000). Self-categorization theory stipulates that individuals categorize their social world by the groups to which they belong, through a process of depersonalization, in which people are reduced to a prototype of the group, thereby embodying the norms, values, and behaviors that personify the group (Hogg and Terry 2000). It is through this process of self-categorization that cognitive groups are formed. Depersonalization results in cognitive perceptions of similarity between individuals and their group. These effects are emphasized for individuals of out-groups, such that when they are perceived as a prototype of the group, the individual differences between group members are reduced and the similarities are enhanced. The outcome of this process is that individuals are no longer perceived as unique, rather, they are perceived to be a representative of their group (Hogg and Terry 2000).

Police are often faced with situations in which they categorize people into groups. This process allows the police to distinguish all members of a group – for example, a child protection agency – as being conceptually the same. Furthermore, the effect of self-categorization will be more salient. That is, the officer's identity as a police officer will be more powerful, when officers are faced with the possibility of sharing aspects of their work that makes them unique, such as crime control. Evidence suggests that a critical component of group discrimination is the dimensions that the groups are compared on (Ashforth and Mael 1989). As managing law and order is a key dimension distinguishing police from other professionals, contexts requiring police to share this role with others will likely result in increased categorization of those others. This effect is likely to result in the police taking steps to demonstrate the inability of their partners to fulfill the role that they have been assigned. Empirical research supports this position, with results consistently demonstrating that self-categorization effects are most pronounced in an intergroup context (Ashforth and Mael 1989; Doosje et al. 2002). An example for policing may include a collaborative taskforce where the police share the responsibilities with a partner, such as a child protective service, who has the same power to act and responsibilities as the police. Therefore, it is possible the police would attempt to exasperate the difference between the two organizations with an emphasis on the positive aspects of police and the negative aspects of the child protection agency. This would likely result in the police demonstrating reluctance to share their responsibilities with this other agency through a distrust of their ability to deliver the required services.

Research also indicates that the degree of identification felt toward an organization is a critical factor in conformity to group norms, attitudes, and behaviors (Tyler and Blader 2001). As individuals seek to enhance both their own status within the group as well as the overall standing of the group, they are highly motivated to perform in a manner that increases their standing in both domains. Conforming to norms and attitudes is one method to achieve this. In doing so, individuals represent the prototype of the group, while demonstrating active commitment to the group. Conversely, individuals face sanctions for failing to conform. Therefore, the degree of self-categorization and meaningful value that an officer places on their position within the organization will also be predictive of their willingness to conform to the organizational rules, norms, and behaviors.

This suggests that the organizational norms and attitudes of police organizations need to foster partnership-seeking behavior if a police agency is to be successful in institutionalizing TPP. Police organizations may need to undergo a cultural change, with a strong focus on the involvement of partnerships in crime control innovation. In these situations, the self-categorization process will continue to reinforce these norms and attitudes, thereby ensuring that new police officers will also engage in this behavior.

Self-categorization theory argues that group leaders are well positioned to change the culture and develop new attitudes. According to self-categorization theory, leaders are perceived to be members of a group that are *most* prototypical (Hogg 2001), the individual(s) that embody the values, norms, and attitudes of the group (Hogg 2001). Furthermore, self-categorization theory argues that leaders have the consent of their followers to change the cultural attitudes and norms of a group. Leaders within an organization hold the unique position to install change and create a culture of active partnership formation. They hold unique positions where it is legitimate for them to deviate from the accepted cultural norms to install change. Research has demonstrated this critical role of leaders in conveying of norms (Hogg et al. 2006). Likewise, research has also consistently demonstrated the importance of leaders in fostering innovation and supporting change. Therefore, the onus is on police leaderships to create and foster norms and attitudes that will promote active partnership seeking and development among the junior ranks.

An outcome of highly salient group identity and strong leadership can lead to high levels of cohesion within groups (Hogg 1993). Cohesion is defined as the social connections that tie individuals to their fellow group members, resulting in their desire to behave and act in a manner consistent with the group (Casey-Campbell and Martens 2009). Research has extensively examined cohesive groups, with an emphasis on the cohesion-performance relationship. There is mixed evidence supporting the cohesion-performance relationship. However, there is general support for the notion that highly cohesive groups perform better on tasks, particularly in project-based team environments (Chiocchio and Essiembre 2009).

The nature of police work lends itself to high levels of internal cohesion. The police are required to rely on each other for safety and to work together to effectively achieve outcomes. Often they are required to sacrifice their own safety and wellbeing for the benefit of society. Anecdotally, police organizations are akin to military organizations, where there is a cultural of solidarity and unity. However, when considering a TPP initiative, highly cohesive police organizations pose a significant constraint on the take-up of TPP partnerships. Research indicates that highly cohesive groups are more reluctant to engage with external groups in intergroup contexts (Hardy et al. 2005). Therefore, excessively cohesive police organizations are likely to prevent officers from seeking partnerships.

It is possible that highly cohesive organizations will attempt to develop internal solutions, instead of seeking partnerships. This results in a continued drain on resources, without commiserate efficiency gains. When advocating for TPP partnerships, the role of cohesion and its effects on the success of new initiatives may need to be considered. Evidence for consideration of these effects can be seen from previous investigations into policing practices. For example, one of the key recommendations from an inquiry into police corruption in Australia was that for new recruits to be educated to a minimum of a tertiary level in an attempt to reduce the insular nature of policing (Fitzgerald 1989). This recommendation was made in an attempt to prevent the effects of a highly cohesive organization perpetuating bad practice.

This section has highlighted some of the internal social factors that police organizations face when seeking TPP partnerships. From the research outlined, the following relationships are proposed. First, the norms and attitudes of a police organization are likely to affect officer's intentions to seek out third-party partnerships. Furthermore, it is possible that this relationship will be affected by the role of self-categorization, such that those who are highly identified may demonstrate greater conformity to these norms. Secondly, it is the role of the leaders within an organization to promote active search and development of partnerships. Finally, high levels of cohesion in police organizations are likely to impede effective partnership seeking.

Partnership Formation: Two Organizations Merging and the Role of Diversity and Distinctiveness

Organizational mergers have long been the topic of interest for a range of business and academic communities. This research has largely focused on the outcomes of a newly formed organization (Terry and O'Brien 2001); however, recent research has also considered the social factors that contribute to the success or failure of partnerships (Terry et al. 2001). Policing partnerships are akin to other types of organizational mergers. They require at least two different organizations to work toward a unified goal and deliver a product – in this case public safety. Research by Terry et al. (2001) has investigated the role of social identity during the formation of a new superordinate organization after a merger. This research indicates a range of social factors that should be considered when forming a TPP partnership. Primarily, during the initial merger, the higher-status group members react more negatively toward the merger than lower-status group members (Terry et al. 2001). The implication of this finding is critical to understanding the police motivations to form a partnership. It is arguable that the police will hold the higher-status position within most new partnerships; they will typically be the organization that initiates the partnership and the organization that has the most to gain.

The inverse of the status relationship is also true. There is evidence to suggest that individuals from lower-status organizations are more willing to join higher-status organizations (Terry et al. 2001). However, some results have found that the effect of status can be moderated by legitimacy, such that, if lower-status organizations perceive their status as illegitimate, they will be less likely to join the higher-status organization (Amiot et al. 2007). When considering these findings in the context of a TPP partnership, it is clear that steps need to be taken to mitigate these effects in order for these diverse organizations to work together. This indicates that the police need to ensure that they do not portray themselves as superior to their partner organization as well as approach their partners in a collaborative and transparent manner that avoids invoking perceptions of status differences between the two groups.

Research indicates that lower-status organizations have higher staff turnover rates after merger (Amiot et al. 2007). This research also suggests that lower-status group members have less identification with new organization (Amiot et al. 2007). Together, these two findings are vital to the understanding of how partnerships function. As highlighted in the first section, the key to ensuring that individuals perform for the group, and adhere to the group norms of behavior and attitudes, is increasing the identification that they feel toward the group. Therefore, if lower-status individuals feel less identification toward the partnership, they are less likely to remain in the partnership. If the police believe that they are a higher-status organization and their key partners – such as child protection agencies – are a lower-status organization, then this is likely to result in initial reluctance from the police to form a partnership. However, should this be overcome, issues of status legitimacy, identification with the partnership, and turnover rates are all likely to be significant challenges for both parties.

When a new partnership is formed, the police and their partners come together under the banner of a new group. This partnership is formed to provide a more efficient service and reduce the resource burden from one agency alone.

However, there is likely to be historical issues of status, prestige, and potentially conflict that need to be managed. Furthermore, issues of group diversity pose significant problems to the formation of these partnerships. Diversity within organizations has long been a topic of significant interest to the academic and business community (Brewer 1995). In the context of a TPP partnership, it is important to consider diversity within the context of police and the partner agencies. These partnerships involve individuals from different groups, with different experiences/skills and different organizational cultures. Furthermore, these individuals will come from organizations and skill backgrounds, which have different underlying philosophies and ideologies about how to manage complex crime problems. The research outlines the role of different approaches to problems and the impact of these cultural ideologies on the success of group performance.

Diverse partnerships have the potential to foster conformity to organizational norms and rules, as these become the superordinate guidelines to behavior within the given context (Rink and Ellemers 2007). To enable this, organizational identities need to be highly salient and provide significant emotional value to its members. In contrast, in partnerships where there is a history of conflict and highly charged emotions, the organizational identity will be weak, thereby making the subgroup identities highly salient (Tsui et al. 1992). This results in reduced compliance to the norms and rules of the partnership and a return to the norms and values of their originating organizations (Rink and Ellemers 2007). Forming a successful TPP partnership requires that all parties are aware of organizational diversity both within and across the partnering organizations. Historical conflict between partners poses a significant constraint on the success of these partnerships. Furthermore, by identifying common goals and objectives and reinforcing the mutual commitment of the organizations, it is possible to overcome these issues.

Research in the area of optimal distinctiveness theory helps to explain the conditions under which partnership identification is achieved. Optimal distinctiveness theory (Brewer 1991) argues that we have two competing drives in social groups – one for inclusion and one for distinctiveness – and that these two drives act in opposition to each other. In the context of a new partnership, individuals will want to be included in the partnership, to feel they are a valued member and that they are able to contribute to the development and direction of the partnership. However, individuals will simultaneously want to maintain connections with their original organization. Therefore, the successful formation of a new partnership is contingent on both of these needs being met at an optimal level (Brewer 1995).

For the police to form a partnership with key partners, a significant risk arises from these organizations being identified under the banner of a large and ambiguous group, typical of “whole of government approaches,” as these groups remove the unique contributions of the individual organizations that comprise the partnership. Likewise, the assimilation of groups under the higher-status group, in this situation the police, poses the same risks. These partnerships need to develop identities that are unbiased and do not represent just one group, yet attempt to encompass the root values and goals of the partnership. Research shows that group size and overly inclusive groups are both negatively related to performance (Badea et al. 2010). According to the optimal distinctiveness literature, this is likely to result in poor functioning and lack of identification at the superordinate level (Badea et al. 2010) and likely to result in high turnover or a quick end to the partnership. Therefore, these partnerships should avoid the use of group structures that inhibit the unique contribution of each member organization.

This section highlighted the role of several key factors that inform the process and the likelihood of police forming partnerships within the context of TPP. The role of group diversity, distinctiveness, and partnership identity have all been examined and discussed. Next several relationships between these variables are examined. First, partnerships where status difference between the police and a partner organization is highly salient are likely to result in poor intergroup cooperation and weak identification with the partnership. Secondly, diversity of organizational identities in the partnerships will impact on partnership functioning. Specifically, partnerships with historical conflict and competition for resources will not function effectively as a partnership; this effect may be exasperated by differences in cultural ideology about how to approach problems. Finally, the success of a new partnership developing is contingent on the ability for individuals to retain connection with their originating organization.

Promoting Cooperation Within a Partnership: The Role of Identification, Procedurally Fair Decision Making, and Leadership

TPP partnerships require the active and continued cooperation of its members. Significant research has explored the motivations that promote cooperation within groups, with a specific focus on information sharing, extra-role behavior, and ensuring that the long-term goals of the organization are met over the temptation of short-term individual gains. Recently, Tyler (2011) examined the relationship between instrumental factors such as material rewards and role titles, and social factors such as identification and procedurally fair decision making, in fostering cooperation of employees with the organization. The results consistently demonstrated that above and beyond instrumental factors, social motivation was found to be critical in adherence to organizational rules and norms, extra-role behavior, and intragroup cooperation (Tyler 2011). Extra-role behavior is defined as undertaking work and responsibilities that are outside the individual's job description for which they do not receive direct momentary reward.

In this section two critical aspects of cooperation within partnerships are highlighted: identification with the partnership and procedural fairness of decision making within the partnership. As discussed in the earlier sections, when an individual categorizes themselves as a member of an organization, this will lead to increased adherence to the norms and attitudes of the organization (Tyler and Blader 2001). Therefore, increasing the degree of social identification with the partnership will lead to an individual feeling greater emotional significance about their connection with the group, thereby increasing their drive to enhance the group relative status. TPP partnerships require a significant commitment from both the individuals and the groups connected to them. This commitment can range from undertaking activities that are beyond the typical duties of the role they fulfill to providing extra resources to ensure the success of the partnership. By increasing the degree of identification to the partnership, there is potentially an increase in the adherence toward the goals and aims of the partnership. Furthermore, this is also likely to result in the members undertaking extra-role behavior when faced with impediments to ensure the success of the partnership (Tyler 2011).

According to group engagement model (Tyler and Blader 2003), identification with the organization is enhanced by the decision-making processes that the organization uses. Specifically, the use of procedurally fair processes to arrive at decisions increases the strength of identification that individuals feel toward their organization. Research demonstrates a link between the procedural fairness of an organization and the behavior of its employees (Blader and Tyler 2009). Procedural fairness can be described as the processes and methods that an individual or group enacts to arrive at a decision as being fair (Blader and Tyler 2003). There is consistent evidence within a range of fields that demonstrate the link between procedural fairness and cooperation, acceptance of outcomes, and extra-role behavior (Tyler and Blader 2001). Furthermore, evidence suggests that people are more concerned with the procedural fairness of a decision rather than the outcome of a decision alone. The goal of a new partnership, therefore, is to behave in a procedurally fair manner, as perceived by all members of the group. This is achieved through unbiased decision making, offering all members a voice before a decision is made, making the decision on facts rather than opinions, and using clear and transparent processes. Therefore, the relationship between procedural justice and cooperation in the group is mediated through identification with the group (Tyler and Blader 2003).

For TPP partnerships, this finding implies that it is possible to increase the degree of identification that the individual members feel toward the partnership, by utilizing procedurally fair decision-making process.

The final aspect of effective partnership functioning relates to leadership. As discussed earlier, the role of a leader can be of critical importance in the conveying of norms, attitudes, and appropriate behavior (Hogg 2001). When a leader behaves in a manner that embodies the values of the group and is seen as the most representative member of the group, then it is likely that they will be able to gain the trust and confidence of their followers (De Cremer and Van Knippenberg 2002). Likewise, there is sufficient evidence to suggest that a leader that acts in a procedurally fair manner is also likely to enhance their subordinates' willingness to accept decisions (De Cremer and Van Knippenberg 2002). Extending this, research has indicated that leaders play a vital role in the development and fostering of innovative practices (Hogg et al. 2006). Therefore, it is vital that upon formation of the partnership, a leader who will drive the strategic direction, yet encompass the requirements outlined above, is identified. As outlined in earlier sections, leaders play a vital role in the success of any venture; they provide the strategic direction (Hogg et al. 2006) and can guide the subordinates through challenging times. The success of new partnerships hinges on the effectiveness of the leader.

Three critical aspects of a partnership define its functioning. First, individuals who are part of the partnership must demonstrate high levels of identification with the new partnership, as doing so will ensure compliance and cooperation with the partnership objectives. Second, in order to increase identification, the partnership must demonstrate procedurally fair processes in its decision making, with a particular emphasis on demonstrating collegial and collaborative approach and avoiding unilateral decision-making processes. Finally, the leadership of the partnership must represent all parties within the partnership and actively engage in procedurally fair process.

Organizational Constraints of Third-Party Policing

In their analysis of TPP approaches to policing complex problems, Mazerolle and Ransley (2005) outline that police organizations face organizations' constraints that are likely to impact on the ability of the police to form partnerships. When advocating for partnerships, these factors need to be considered in conjunction with the social factors outlined above. One of the most crucial factors that require consideration relates to the ability of organizations and government to effectively share information. This is vital, as without sharing of intelligence, methods, and policies, the ability of partner organizations to coordinate the delivery of their services becomes restricted. Furthermore, it may lead to redundancy and duplication of work or frustration for lack of action from partners.

The capacity to share information between partner organizations is one of the most complex factors to be overcome to facilitate a productive working partnership. When attempting to find innovative solutions to problems, one of the most important tools that can be employed is sharing information across organizational boundaries. However, when government agencies are involved in these partnerships, the transfer of information between partners can pose significant problems. Most Western governments have laws that restrict the transfer of information (Bellman et al. 2004). These restrictions typically impose conditions that prevent the transfer of information between government agencies. These laws are designed to protect the interests and privacy of individuals within the community. However, they can also prevent the effective coordination and cooperation of core agencies. Therefore, one of the most significant structural challenges that these partnerships face is the need to overcome information sharing hurdles (Lyons 2002). It is important to consider what information needs to be shared, how the information will be used, and who, under relevant laws, is able to hold that information. Addressing these considerations early in the formation of a partnership is critical to the success of a partnership.

Mazerolle and Ransley (2005) identify a number of organizational factors that either facilitate or constrain the adoption of Third-Party Policing. One of the most significant challenges that police agencies face in forming partnerships is the centralization of decision making. They argue that the concentration of decision-making power with the executive is not conducive to the formation of partnerships. The crux of their argument is that officers at all levels of the organization need to have the freedom to identify problems and innovate solutions, and doing so can only occur effectively when there has been a decentralization of decision making (Mazerolle and Ransley 2006). Furthermore, decentralization of decision making offers unique advantages to geographically dispersed police agencies. For example, issues that affect police forces in large metropolitan areas are likely to be significantly different from those that affect police officers in rural or remote areas. Therefore, officers need to be able to identify local solutions to local problems. This argument is not unique to TPP advocates. Problem-oriented policing, arguably one of the most influential developments in policing practice, has advocated for support from the senior executive for officers to implement localized strategies to complex crime problems (Goldstein 2003).

Finally, Mazerolle and Ransley (2006) outline that role specialization has a significant impact on the ability of officers to form partnerships, stating that more specialized roles are conducive to the formation of specific partnerships than roles that are more general. This argument follows the notion that officers and personnel that fulfill highly specialized roles within an organization will have greater insight into the needs from the partners and the ability of the partners to engage in a cooperative approach. Extending this argument, the seniority of officers will also have an impact on their ability to develop and formalize partnerships, with senior officers having the ability to implement formal cross-organizational partnerships and junior officers seeking ad hoc episodic partnerships. Therefore, identification of the right personnel within the police organization and gaining the support of the senior executive are factors that may well contribute to the success of potential partnerships.

Conclusion

In an era of social change in the way that the police conduct their duties, there is inherent value in a TPP approach to crime control. Through the use of effective partnerships, the police are able to provide a more efficient and effective service that has the potential to develop more holistic outcomes for the targets. This entry examines the partnership aspect of TPP using Social Identity theory to explore the intergroup processes that affect the ability of the police to seek out and develop crime control partnerships. Three critical phases comprise the process of partnership building within TPP: partnership seeking, partnership formation, and partnership effectiveness.

In the partnership-seeking phase, research outlined the role of the internal social structure of the police organization, with an emphasis on the norms and attitudes, to ensure that they are focusing on the ultimate goal of the organization. In conjunction with this, the role of internal cohesion within a police force was considered, with a particular emphasis focusing on what impact this has on the ability and desire of the organization to seek out partnerships. Research also examined the role of leadership in shaping the future direction of police agencies, with an eye toward fostering partnership-seeking behavior. In the formation phase of TPP partnerships, the research outlined indicates that through the consideration of the diversity of ideological backgrounds and organizational culture, it is possible to improve working relationships. Extending this, allowing individuals to join and have meaningful input into the future directions of a partnership while still allowing them to maintain a strong connection with the organization where they originated is another avenue to success. In the final stage, partnership functioning, the research outlined above argues that it is critical to help the individual form a sense of identity with the partnership in order to foster cooperation. It is possible to achieve this with procedurally fair decision-making process, with a strong emphasis on the use of unbiased, fair, and neutral process. Engaging and developing a strong and consistent leader is also important in fostering a strong sense of identity with the new partnership.

While this entry has largely focused on the importance of social factors in the formation and functioning of a partnership, there are also instrumental factors that contribute to the success and failure of partnerships. Information sharing is a significant challenge to the way that partnerships can function, with the inability of some information to be shared between partners potentially leading to duplication of work and frustration with partners. Likewise, the decision-making ability of individuals within an organization represents challenges for partnerships. In situations where all decisions need to be passed through the senior executive, this has the potential to limit the ability of officers to seek and contribute to partnerships. Finally, officer specialization is likely to impact on the quality and type of partnership, with more specialized officers having greater insight in the needs of their own organization in respect to specific issues but also insight into how partners function their ability to contribute to a coordinated effort.

The issue of partnership formation is not one that is solely the responsibility of the police. All key stakeholders, including government, policy makers, communities, and businesses have a role in overcoming the challenges faced in addressing complex crime. The police face many challenges in attempting to develop their practices in a new era of policing; therefore, drawing attention to these challenges provides opportunities for further research and input from policy makers and practitioners alike. If the police and society more generally are going to deliver a more effective service, then it is incumbent on the community to work collaboratively to develop solutions. As we learn more about how and why crime is committed, it is no longer feasible to assume that insular police organizations will be able to recruit and retain the knowledge, skills, and resources required to combat future criminal behavior.

Synonyms

Behavioral learning; Differential association-reinforcement theory; Learning theory

Overview

In their differential association-reinforcement theory, Burgess and Akers (1966) reformulated, and restated, Edwin Sutherland's principles of differential association (1947) to include the learning principles of modern behavioral learning. Sutherland's theory had been roundly criticized on two main grounds: (1) its failure to make explicit the precise mechanisms of learning and (2) difficulties operationalizing and empirically testing the main ideas of the theory leading some to assert that the theory was unfalsifiable (Nettler 1984). Akers (1973, 1998) subsequently revised differential association-reinforcement theory into a social learning theory of crime and deviance that included four key constructs: differential association, definitions, differential reinforcements, and imitation. In the most general terms, Akers' social learning theory asserts that both conforming and deviant behavior are learned in the same way, that one's likelihood of engaging in antisocial behavior is influenced by his/her prior and anticipated consequences of behavior, or that the probability of engaging in deviant behavior is contingent on the prior and anticipated future reinforcements and punishments one has experience regarding deviance.

Social learning theory remains a dominant perspective in criminology, and the empirical literature testing this theory is arguably one of the largest and most persuasive in the field (see Warr 2002). This entry provides a general overview of the assumptions, constructs, and propositions that are central to social learning theory, summarizes the empirical literature testing this perspective, addresses some of the key criticisms, and concludes with new directions for the theory.

Background

In 1965, C. Ray Jeffrey recommended that Sutherland's differential association theory be replaced with a single statement drawing on the principles of modern behavioral learning. Specifically, Jeffrey (1965, p. 295) noted that criminal behavior, like all other human behavior, is governed by the principles of differential reinforcement such that it "occurs in an environment in which in the past the actor has been reinforced behaving in this manner, and the aversive consequences attached to the behavior have been of such a nature that they do not control or prevent the response." The importance of Jeffrey's recommendation cannot be overstated, as he correctly pointed out that criminologists from the learning paradigm had neglected to incorporate the significant advancements in behavioral psychology into the understanding of crime since Sutherland's original contributions.

Around the same time, Burgess and Akers were in the process of integrating these modern learning principles into the differential association perspective. They believed that all of the explanatory variables and processes in differential association theory could be subsumed under a more general theory of human behavior that is based on behavioral learning principles. Burgess and Akers accomplished this by revising each of Sutherland's nine statements to form seven new propositions that invoke language from behavioral psychology and modern learning. For instance, the first and eighth propositions in Sutherland's differential association theory which read "Criminal behavior is learned" (p. 6) and "The process of learning criminal behavior by association with criminal and anti-criminal patterns involves all of the mechanisms that are involved in any other learning" (p. 7), respectively, were combined into a single proposition that read "Criminal behavior is learned according to the principles of operant conditioning" (Burgess and Akers 1966, p. 132). Further, the key proposition of Sutherland's theory which read "A person becomes delinquent because of an excess of definitions favorable to violation of law over definitions unfavorable to violations of law" was similarly revised in a manner consistent with behavioral learning, such that "Criminal behavior is a function of norms which are discriminative for criminal behavior, the learning of which takes place when such behavior is more highly reinforced than non-criminal behavior" (p. 143).

The initial formulation of social learning theory in criminology was heavily influenced by the behavioral learning paradigm developing in psychology (Bandura 1969). In this seminal work, Burgess and Akers discussed the importance of things like discriminative stimuli (signals that elicit a particular behavioral response), saturation (when the potency of a reinforcer is maximized and no longer affects behavior), and extinction (the reduction or loss of a behavioral response when reinforcement is withheld) when describing the learning process. The complexity inherent in this perspective, however, led many criminologists to question the utility and testability of this learning perspective. These concerns, along with the movement towards a variable-based criminology (Hirschi 1969), led Akers to revise social learning theory into a more tenable set of constructs and propositions.

Akers' Revised Social Learning Theory

Social learning theory is developed to explain not just the acquisition of criminal behavior but also the maintenance and modification of criminal behavior (Akers 1998). Put simply, the process of social learning offers not just explanations on the motivation to initially engage in criminal behavior but also explanations on how certain variables work to maintain criminal behavior throughout time and how these variables also can maintain and promote conformity over time. Akers (1998, p. 50) argues that "The basic assumption in social learning theory is that the same learning process. . . produces both conformity and deviant behavior. The differences lie in the direction. . .. [of] the balance of influences on behavior." Thus, individuals are at an increased likelihood of engaging in deviant behavior when they differentially associate with others who commit criminal behavior themselves, who define deviance as desirable, and who provide (or have provided) greater reinforcement than punishment for that deviance. Conversely, individuals are more likely to be prosocial to the extent that they differentially associate with individuals who engage in and espouse norms conducive to conformity.

When developing his revised social learning theory, Akers asserts that the social learning process can be principally captured by four distinct, yet interdependent, constructs: differential association, definitions, differential reinforcement, and imitation. The subsequent sections of this entry will elaborate on these four constructs and discuss how they influence the probability of engaging in criminal and deviant behavior.

Differential Association

Social learning theory begins with the assumption that all learning takes place in a context of structural interactions with others. The most important social context in which mechanisms of learning operate is through the differential associations individuals have. This construct draws heavily on Sutherland's theory, which emphasizes the importance of "intimate personal groups" in the learning process.

Akers asserts that differential association can influence delinquency both through behavioral/interactional dimensions and normative dimensions. The former refers simply to the direct association and interactions individuals have with others and whether the behavioral patterns that these associations expose to an individual are criminal or conforming. In other words, it refers to the behavioral nature of one's associates (e.g., deviant vs. non-deviant). The latter, however, are the different patterns of norms and values that an individual is exposed to through these associations. Sutherland's discussion of differential association was primarily concerned about the transmission of definitions that occurred in these differential interactions, but Akers essentially allows the differential association construct to incorporate a much broader range of deviant influences present when interacting with others, including the transmission of deviant definitions, providing reactions that are favorable to delinquent conduct that alters the perceived rewards/costs of crime and exposing individuals to deviant models from which to imitate.

Like Sutherland, Akers' social learning theory does not view all interactions as being equally influential in affecting human behavior. Instead, Akers retains the four modalities discussed by Sutherland, asserting that associations, and their subsequent influence on deviant behavior, vary in terms of frequency, duration, priority, and intensity. Frequency is how often an individual interacts with a group or individual. Duration concerns the length and relative amount of time spent in different associations. Priority refers to when in time the association began, in other words, which associations came earliest in time. Finally, intensity has to do with the "significance, saliency, or importance of the association to the individual" (Akers 1998, p. 64). Drawing on these four modalities, Akers (like Sutherland) argues that associations will have a greater impact on shaping an individual's behavior if they occur more frequently, if they have been interacting for longer periods of time, if they began earlier in the individuals life, and if they are more meaningful relationships to the individual.

This construct of differential association subsumes many of the major elements of Sutherland's differential association theory. Sutherland's recognition that the interactions that individuals have when associating with others is central to the learning process is acknowledged by Akers, and he continues to stress the importance that different modalities have on influencing how these associations shape behavior. In fact, given Akers' assertion that most learning is shaped by social reinforcement contingencies – rather than nonsocial ones (e.g., intrinsic rewards/ punishments) – differential association is a necessary condition in the social learning perspective.

Definitions

Sutherland's emphasis on the transmission and acquisition of definitions favorable to delinquency when explaining deviant behavior made it difficult to distinguish that construct from differential associations. However, Akers explicitly separates these two constructs in his social learning theory. Despite this, Akers' characterization of definitions is nearly identical to that described by Sutherland. Definitions can generally be thought of as the normative beliefs, attitudes, or meanings that individuals attach to any given behavior. These can include the motives, drives, rationalizations, justifications, and attitudes that define the circumstances in which the commission of an act is right or wrong, desirable or undesirable, justified or unjustified (Akers 1998, p. 77). In social learning theory, definitions can be both general and specific. General definitions refer to the broad religious and moral beliefs and norms one holds that favor either criminal or conforming behavior. Specific definitions refer to specific acts and situations in which behavior is, at minimum, justified. The distinction between general and specific definitions is of theoretical importance. Individuals may generally hold the belief that "breaking the law is wrong" but at the same time believe that "smoking marijuana is OK." Similarly, individuals may hold the general definition that "thou shall not steal" while simultaneous believing "it is morally justifiable to steal when hungry."

Definitions in Akers' theory do not *require* deviant behavior, as some scholars have wrongly interpreted in Sutherland's theory (Kornhauser 1978). Akers (1998) argues that *some* definitions favorable to delinquency can be so strongly held that they require delinquency. More common, however, is that individuals hold definitions that rationalize or justify delinquency in certain situations. In this way, definitions in Akers' theory are similar to the belief construct in Hirschi's (1969) social control theory, in that the definitions themselves do not directly provide motivation for delinquency but rather are conventional beliefs that are weakly held and can allow for other motivating factors (e.g., differential reinforcement) to have important and direct effects on antisocial behavior. That is to say, their moral reservations against delinquency are weak enough that it can be bypassed in some situations and thus allow for delinquent behavior when the right circumstances or reinforcement contingencies are present (Warr 2002).

Differential Reinforcement

Arguably the construct of greatest importance in Akers' social learning theory is differential reinforcement. Though Sutherland stated that criminal behavior is learned like all forms of human behavior, he spent little time discussing the learning process. Drawing on research in psychology, Akers argues that the process of learning antisocial behavior is best captured through the construct of differential reinforcement. "Differential reinforcement refers to the balance of anticipated or actual rewards and punishments that follow or are consequences of behavior" (Akers 1998, p. 67). If an individual believes that they are likely to be rewarded for engaging in deviance and/or punished for deciding upon conforming behavior, then that individual is likely to engage in deviance. Moreover, when faced with a similar situation in the future, that individual is likely to draw on their prior experiences and view that deviant behavioral choice as more reinforcing and the conforming option more punishing. This ultimately leads to what is arguably the most important proposition in Akers' theory: "Whether individuals will refrain from or initiate, continue committing, or desist from criminal and deviant acts depends on the relative frequency, amount, and probability of past, present, and anticipated rewards and punishments perceived to be attached to the behavior" (Akers 1998, p. 66).

From the social learning perspective, human behavior is governed by both reinforcements and punishments, whereby the former *increases* the probability that a behavior occurs and the latter *decreases* it. Both reinforcements and punishments can be either positive or negative, which references the fact that some consequences influence behavior by adding stimuli (positive) while others influence it by removing stimuli (negative). Accordingly, positive reinforcements increase the likelihood of engaging in or repeating deviance by providing a positive outcome or reaction to it (e.g., friends' approval, money, or intrinsic feelings of pleasure). Negative reinforcements increase the likelihood of deviance by removing an aversive or unpleasant feeling or event (e.g., eliminating the ridicule of classmates). Meanwhile, positive punishments decrease the likelihood of criminal behavior by providing a painful or unpleasant consequence associated with a behavior (e.g., an arrest), and negative punishments affect behavior by removing pleasant consequences or rewards (e.g., parental respect). These reinforcements and punishments influence the likelihood of engaging in deviance by altering an individual's perceived anticipated consequences when faced with similar situations in the future, which in turn affect one's decision-making calculus at the time of the offense (Akers 1990, 1998).

Just as with differential associations, reinforcement and punishment contingence are not all weighted equally but are influenced by the amount, frequency, and probability of their occurrence. The greater the amount or value placed on the reinforcement contingencies, the more frequently it is reinforced, and the greater the likelihood of experiencing the reinforcement all increase the likelihood of engaging in deviant behavior. Thus, for instance, if an individual places great value on the relationship she shares with her friend who frequently rewards deviant behavior, and she is certain that her friend will reward her for stealing, that individual will have a high probability of engaging in deviant behavior. However, the reinforcements and punishments that are provided by strangers for whom the individual has no personal relationship with will likely have little effect both on the present and on future perceptions of rewards and punishments.

Though the examples provided above have focused largely on social reinforcements and punishments (i.e., peers and parents), Wood et al. (1997) note that reinforcement contingencies can be nonsocial. For instance, the physiological effects of drugs and alcohol can be rewarding to some, which in turn increases the likelihood of repeated use. Moreover, some individuals may view deviant behavior itself as intrinsically rewarding. This would occur if the behavior itself, regardless of social reactions, is viewed as "fun" or "thrilling." Wood et al. provide support for this premise: positive intrinsic sensations from crime are significantly related to the maintenance of criminal behavior. Interestingly, Akers vests little in the idea that nonsocial factors are inherently reinforcing. For instance, he argues that individuals learn that the effects of drugs are enjoyable or unpleasant *through social reinforcement*. Similarly, Akers also argues that some individuals are prone to be risk-seeking but that they learn to become risk-seeking, and learn to see delinquency as "fun," through social interactions with others. In other words, individuals may experience physiological and intrinsic rewards from drug use and crime but primarily only do so if they are predisposed by a *social* learning history to do so.

Akers believes that the primary source of learning occurs through social reinforcements and punishments. When individuals value the relationships they share with others, the prior, anticipated, and actual reactions that they attach to deviant behavior are likely to be highly influential in affecting the likelihood that an individual offends. Importantly, this is not the same as having peers pressuring individuals to offend, but rather this process refers to the influence that these friends have by altering the perceived consequences of different behavioral choices. Social learning theory recognizes that humans are social beings who are concerned with the reactions and opinions of others and that our perceptions on what the anticipated consequences of behavior entail are necessarily a function of prior experiences in similar situations. Even tangible and material items, such as money and wealth, are valued by individuals because of the social rewards and prestige that they provide. Put simply, Akers argues that tangible and material rewards from crime derive their power of influence because they are symbolic of social rewards (i.e., prestige and status) and that their value (and thus their influence on behavior) is of little importance when the social rewards are disassociated from them.

In sum, the inclusion of differential reinforcement into the learning paradigm of criminology filled the important gap as to *how* criminal behavior is learned (i.e., a focus on the "reception" and not the "transmission" process). Though this contribution by Akers is arguably the most important aspect in social learning theory, it also remains one of the most misunderstood. The idea that individuals are affected by reinforcement contingencies does not mean that humans are passively conditioned by their environment, simply reacting to stimuli like Pavlovian dogs. On the contrary, social learning theory views that individuals are mostly actively engaged and attuned to the anticipated consequences of behavioral actions (Akers 1990), which presupposes that individuals employ some cognition before engaging in delinquency. If an individual determines that the relative balance of the consequences of deviance provides greater reinforcements than punishments, then that individual is at an increased likelihood of engaging in deviant behavior. Moreover, social learning theory argues that the actual consequence attached to the behavior will affect their future likelihood of offending: if an individual engages in antisocial behavior and they are rewarded for it, they are at an increased likelihood of repeating the action when faced with a similar situation in the future. Conversely, if individuals engage in deviance but experience a relatively greater level of negative consequences, they are likely to avoid deviant behavior in the future. Simply put, social learning theory argues that an individual's prior experiences influence how they interpret anticipated consequences in the future and that these anticipated consequences are influential when deciding on a behavioral action choice (Akers 1998).

Imitation

Imitation refers to the modeling of behavior after similar behavior is observed in others. The classic example of imitation derives from Bandura's (1961) Bobo doll experiments, where the behavior of children was observed after watching a model aggress on an inflatable doll. As is evident in these experiments, not all behavior that is observed is imitated by others. Of particular importance is the observed consequence of the behavior: if one observes an individual engage in a behavior and that individual is subsequently rewarded for the behavior, it is more likely that that behavior will be modeled. This is known as *vicarious reinforcement*. Conversely, if one observes behavior that is subsequently punished, it is less likely that the behavior will be modeled – what is known as *vicarious punishment*.

Another factor that influences whether an observed behavior is modeled is the characteristic of the model. In this way, imitation shares some of the modalities as the other constructs in social learning theory. The most salient models are those persons "with whom one is in direct contact in primary groups" (Akers 1998, pp. 76–77). This most obviously means that individuals are more likely to imitate the behavior of close, personal associates than that of strangers. But this statement also implies that individuals are more likely to model behavior observed in direct interaction than behavior observed through media forums. Akers (1998) has argued that technological and social changes have increased the relative importance of modeling behavior on television, movies, and video games. More specifically, given that the relative time spent watching television and movies and playing video games has increased over the last several decades, the modalities of learning have also increased (frequency, duration, priority, and intensity), making media models more salient.

Intuitively, the imitation of others' behavior is most influential in the acquisition and performance of novel behavior but plays little role in the maintenance of deviant behavior. The continuation of the behavior is more affected by direct reinforcements and punishments. For example, an individual may learn initially that violence is rewarded when one's status is challenged, but whether they continue to behave in that matter will be contingent on their own experiences with such behavior. However, imitation may still play a role in the acquisition of criminal skills that can make crime easier and less risky.

Though these constructs are treated and discussed independently, there is considerable interdependency among them. Indeed, social learning is itself a process that incorporates all of these constructs in a complex and recursive manner. Initial deviance is influenced by the balance of definitions one has been socialized to hold, by the modeling of others' behavior, and/or by the anticipated rewards and punishments that derive from a criminal event. Immediately after this event, the actual consequences of the action play an important role – if the individual experiences some reward, then he/she is likely to believe there will be positive consequences in the future. Further, if one does experience reinforcement, this will likely alter the definitions they hold and, in turn, could potentially alter the individual's criminal and non-criminal associates (i.e., self-selection). Indeed, social learning theory does not claim that associations are random but predicts that individuals do self-select into peer networks. However, social learning theory does predict that more often than not delinquent associations precede delinquency.

Research on Social Learning Theory

Few theories have been tested empirically to the extent that social learning theory has. These tests most often assess the relationship and direction between variables from the social learning perspective – differential association, definitions, differential reinforcement, and imitation – and some deviance outcome measure (i.e., general delinquency, drug use, violence). The overwhelming majority of these studies have found strong support for social learning predictions, with very few studies finding negative support for the theory.

One of the earliest and most seminal tests of the theory was conducted by Akers and his colleagues in 1979. Using substance use as an outcome, the results found that differential association (i.e., delinquent friends), definitions (how right/wrong substance use is), and differential reinforcement (how parents and friends would react to respondent drug use) were all strongly and statistically related to substance use, providing support for the social learning predictions. Imitation, however, was only weakly and inconsistently related to substance use, though Akers et al. (1979) note that this finding is not unexpected, as imitation is only predicted to have strong effects on the initiation of delinquent behavior. Though the research findings were strongly supportive of the theory, the clear operationalization of the theory into testable measures and predictions within the article is an equally important contribution. Since this work, many empirical studies have assessed the empirical validity of social learning, with most supportive of the perspective (Pratt et al. 2010).

Another common manner in which research has inferred the empirical validity of social learning theory is through an assessment of the relationship between delinquent peers and offending. As would be predicted by social learning theory, the relationship between peers and delinquency is one of the strongest and most consistent findings in all criminological research (Warr 2002). More frequent, longer-term, and closer associations with peers who engage in delinquent behavior is consistently related to the delinquency or respondents, while associating with prosocial peers is consistently related to conformity. This strong relationship has generally held using various samples and methodological specifications. Ultimately, these findings have led some scholars to conclude that delinquent peers are one of, if not, the most important causes of adolescent delinquency (Warr 2002) and provide considerable support for both the differential association and social learning perspectives.

Perhaps the most telling support for social learning theory comes in two forms: its relative superiority when faced with theoretical competition and its ability to explain known correlates of offending. Regarding the former, many empirical works in the field of criminology have sought to pit variables from one theoretical perspective against those from others. Most generally, this involves putting learning variables in statistical models and comparing the size of the effects against variables from control and strain theories. When this is done, the variables from learning theory tend to explain more of the variance in delinquency than variables from other perspectives (Warr 2002). Learning variables also do an impressive job explaining some of the well-known correlates of offending. For instance, Warr (1993, 1998) has demonstrated that associating with delinquent peers can explain both the age and marriage effect. Similarly, Mears et al. (1998) have shown that learning theory also explains a substantial portion of both race and gender differences in crime, respectively.

The empirical support for social learning theory has most recently been summarized in a meta-analysis conducted by Pratt and colleagues (2010). This study reviewed the published extant tests of the perspective to provide a synthesized estimate of the effect size of the social learning theory constructs. In reviewing these studies, Pratt et al. conclude that the empirical support for social learning theory is stronger than many other criminological perspectives and is at least as comparable as the most strongly supported theories (see Pratt and Cullen 2000). Interestingly, however, the different constructs of social learning theory appear to have varying levels of explanatory power. The constructs most strongly related to deviance are differential associations and definitions, the two constructs already captured in Sutherland's theory. Differential reinforcements and imitation are only modestly related to delinquency. If indeed differential reinforcement is the most important construct in the social learning perspective, these findings raise some questions about Akers' perspective and provide researchers with an important avenue to further assess the interdependence of the four constructs of social learning theory.

An extension of social learning occurred in 1998 when Akers (1998) suggested that an integrated theory (social structure and social learning) could explain structural variations in crime rates across communities. Although this premise has yet to receive much empirical attention, the basic argument is that social structure is linked to individual behavior – and in turn, crime rates – through its effects on social learning variables, namely, differential association, differential reinforcement, definitions, and imitation. Structural characteristics provide the contexts within which social learning variables operate: it causes individuals to differentially associate with delinquents and exposes individuals to a greater ratio of deviant reinforcement contingencies and to definitions favorable to delinquency, as well as a greater number of delinquent models to imitate.

Four dimensions make up the SSSL perspective. *Differential social organization* refers to the distribution of structural correlates of crime (age, race, gender, SES) in the community or society that affect rates of delinquency. *Differential location in the social structure* refers to one's own social and demographic location in the social structure that affects social learning variables (e.g., younger individuals are more likely to be exposed to other younger individuals who, in turn, are more crime prone). *Theoretically defined criminogenic aspects of social structure* draws on anomie, social disorganization, and conflict theories which, again, Akers argues affects one's exposure to criminal associates, definitions, models, and reinforcements that can promote deviant behavior. Finally, *differential social location in primary, secondary, and reference groups* refers to the more immediate personal networks that filter the larger social environment to either promote or discourage criminal behavior. In sum, the general premise of SSSL is that social learning variables fully mediate social structural characteristics correlated with high rates of crime. To date, however, this perspective has not fully been tested by researchers, and the ability of social learning theory to explain differences in crime rates remains in question.

Criticisms

Pratt and colleagues' (2010) finding that differential reinforcement and imitation had relatively smaller effects in predicting delinquency when compared to differential association and definitions can be seen as challenging to Akers' contributions to the learning paradigm, but several other criticisms also plague the theory. Most notable, several scholars have challenged the supposed causal relationship between peers and delinquency that is hypothesized by learning theorists. The argument is that the strong correlation between delinquent peers and delinquency is not evidence that differential associations cause delinquency but instead reflects the tendency for "birds of a feather to flock together" (Gottfredson and Hirschi 1990). This "selection" argument has more recently been championed most fervently by scholars from the control perspective who assert that both delinquency and the association with delinquent peers are both outcomes of similar causal factor (i.e., weak attachments to society or low self-control). The criticism is that delinquent associations are not random, but instead individuals self-select into friendship networks based on delinquent tendencies. Thus, proponents of the selection perspective argue that the relationship between peers and delinquency is spurious, as delinquent behavior is thought to actually precede delinquent peer associations.

Though often seen as one of the greatest challenges to social learning theory, this criticism falls short for both theoretical and empirical reasons. First, social learning theory does not predict that peer associations are randomly constructed but instead explicitly acknowledges that individuals self-select into peer groups based on their prior learning. Unlike control theories, however, social learning theory predicts that once this selection does occur, these associates are likely to have a continued influence on delinquent behavior through differential reinforcement and other learning mechanisms. The empirical research is supportive of the learning predictions: even when statistically controlling for competing variables that are thought to render the peer-delinquency relationship spurious (Gottfredson and Hirschi 1990), the association between peers and delinquency remains (Matsueda and Anderson 1998). Associations with delinquent peers most often precede delinquent behavior (Elliott and Menard 1996), which is supportive of the predictions of social learning theory. Still, this selection versus socialization debate is far from settled (see Weerman 2011). Future research using experimental and quasi-experimental designs will likely shed more light on this issue.

Another criticism of social learning theory concerns the types of deviant behaviors in which the theory is able to explain. Many tests of social learning theory have assessed whether Akers' theory can explain variation in substance use and other forms of minor delinquency. Much less research has examined how well social learning theory explains more serious forms of delinquent behavior, and the research that does finds that learning theory does a poorer job explaining these more serious forms of delinquency. The reason behind this remains relatively unexplored, but one possibility is that individuals who engage in more serious forms of violence have such high levels of criminal propensity (i.e., high in impulsivity) that they do not require learning mechanisms to engage in delinquent behavior. In any case, the finding that social learning has more trouble explaining more serious forms of delinquency is problematic for the theory, as Akers' perspective is designed to explain all forms of crime and deviance.

Finally, following Kornhauser's critique (1978, p. 34) of differential association/social learning theory assumptions that "man has no nature, socialization is perfectly successful, and cultural variability is unlimited," social learning theory has been interpreted by some as a theoretical perspective unable to explain individual differences and only applicable to group differences in crime where subcultural definitions adhere to deviance (Akers 1996, p. 230). A corollary is that the theory focuses entirely on the development of novel criminal behavior that, once learned, *requires* deviance. In essence, critics see little to differentiate differential association and social learning from cultural deviance theories. Akers (1996), in an exchange with Travis Hirschi on this subject (Hirschi 1996), suggests that these criticisms stem from ambiguities associate with and misrepresentations of Sutherland's statement of the differential association – problems that Akers (1996, p. 238) believes have been rectified in his specification of social learning principles by allowing for variations in both deviant definitions held by individuals and the social reinforcement they receive. "These deviations can develop within the same normative or cultural system. They do not require the existence or participation in an organized deviant subculture."

New Directions

Despite these criticisms, social learning theory remains one of the preeminent theories of crime, and the considerable empirical support for this perspective seems to justify this prominence. Nevertheless, there are some important questions deriving from social learning theory that have been left unexplored.

Saturation Effects and Discriminative Stimuli. In describing a social learning theory of crime and deviance, Akers (1998; see also Burgess and Akers 1966) invokes language from psychology that describes how learning differs across time and situations. Most notably are the concepts of saturation and discriminative stimuli. Saturation occurs when the potency of a reinforcer has been maximized, and that reinforcer no longer has an effect on behavior. This has clear implications for the structure of peer networks: some individuals may no longer be influenced by associating with delinquent associates, as their prior learning and already existing associates may have already hit a saturation point. Put simply, the relationship between delinquent associates and delinquency may be nonlinear, increasing at a decreasing rate. Zimmerman and Vasquez (2011) have assessed this saturation hypothesis at a neighborhood level. Their results provide support for the saturation effect: delinquent peers have a strong effect for individuals residing in non-disadvantaged neighborhoods but a diminishing effect in disadvantaged ones. Still, there is considerable research left unexplored on the saturation effect at the more proximal friendship network level and over the life course. How does the inclusion of a delinquent peer change the delinquency of an individual in a relatively nondelinquent network versus a relatively highly delinquent network? Further, do peers have the same effect over the life course? Or do individuals become saturated from delinquent peers leading to a declining peer effect as one ages?

The discriminative stimuli effect has been relatively neglected in criminological research (however, see McGloin et al. 2011), despite the direct implications it has for theory. Discriminant stimuli refer to stimuli that influence how an individual will act in a given situation. Discriminant stimuli are most important when they signal which situations and circumstances will yield reinforcement. To be clear, it is highly unlikely that individuals view that their friends will reward violence, theft, or other forms of deviance in all situations. Rather, it is more common that an individual's delinquent friends will reward it in some situations and under some circumstances. Discriminative stimuli serve as the cues as to when these situations and circumstances occur. The same logic applies in understanding one's definitions favorable/unfavorable to delinquency. As noted above, most delinquents do not hold the universal values that "deviance is right" but rather hold definitions that justify delinquency in some situations (Akers 1998). Unfortunately, most measures tapping into peer reactions and individual definitions use global statements on the rightness and wrongness of antisocial behavior. Considerable theoretical insight can be gained by beginning to incorporate this discriminative stimuli logic into learning measures and assessing what situations and circumstances allow individuals to justify deviant behavior. The overall point is that there remains important elements from the more general behavioral learning paradigm that have not been explored in criminological research that can shed some important light on the understanding of crime.

Differential Susceptibility: *How and When Learning Variables Matters*. Just as learning variables may not have ubiquitous effects across all situations, there may also be variability among individuals in this regard. For generations the primary question surrounding social learning theory has been the central question of causality: do peers and other associates (e.g., family) hold causal role in the facilitation of delinquency? As noted above, the overwhelming evidence supports the predictions from social learning theory. At this point, it seems worthwhile to move beyond simple assessments of *if* learning variables influence delinquency and begin to assess if they matter differently for different people.

Take, for instance, the relationship between delinquent peers and delinquency. Akers suggests that delinquent peers influence delinquent behavior by providing positive reactions to such behavior. He goes on to specifically acknowledge that the influence of such reactions is necessarily dependent on the ability of individuals to consider the longer-term consequences of behavior; in other words, it requires individuals to reflectively consider how their peers would react before deciding to offend (Akers 1990). If this is the case, then some individuals may not be susceptible to the risk of associating with delinquent peers. In particular, individuals high in impulsivity, who are characterized by their tendency to make decisions based almost entirely on situational stimuli, may not need or consider the reactions of their peers when deciding to offend. Instead, these individuals will be most susceptible to the situational risk of unstructured socializing with peers (Osgood et al. 1996). This hypothesis was supported by Thomas and McGloin (2013) using three different large-scale data sets: delinquent peers have their strongest effects on individuals low in impulsivity but only weak (and nonsignificant) effects on individuals high in impulsivity. Further, the situational risk of unstructured socializing with peers has its strongest effects on this high in impulsivity, but a weak (and nonsignificant) effect on this low in impulsivity. Thus, some individuals may be particularly susceptible to the reactions of their peers, while others may not need such reactions to motivate them to deviate. The larger point is that researchers should begin to think more critically about the mechanisms by which learning variables facilitate delinquency. These more nuanced considerations can shed light on important considerations as to how and when peers and other associates facilitate delinquent behavior. Do all individuals rely on delinquent associates to deviate? How and when do individuals consider their own definitions before deciding to offend? Indeed, the question as to if social learning variables are related to crime and deviance appears to have been answered, and researchers should begin to assess whether these variables matter differently for different people.

Objective versus Perceptual Measures. An area of growing interest among criminologists deals with the most appropriate way to measure variables of theoretical interest, and social learning theory has been particularly in the crosshairs of this discussion. Several scholars have expressed concerns regarding the adequacy of traditional perceptual measures of delinquent peers, whereby respondents are asked to report on the behavior of their friends. Most critically, critics have suggested that perceptual measures have had a tendency to overestimate the delinquent peer effect, because individuals are not accurately reporting the behavior of their friends, but instead are merely projecting their own behavior to them (Gottfredson and Hirschi 1990). The limited research that has been conducted is supportive of this claim: when objective measures of peer deviance are used, the relationship between peers and delinquency is reduced, though still substantively large. These findings have led many scholars of crime to encourage the use of objective measures over the use of perceptual ones while outright rejecting the utility of the latter measures because they reflect an individual's misperceptions of their friends' behavior and not the reality of it.

It is interesting that this movement has occurred during the same time period in which rational choice and deterrence theorists have advocated the use of perceptual measures over objective ones when assessing criminal decision making. After decades of empirical work challenged the core propositions of rational choice theory when using objective measures, scholars began to realize that sanction threats can only influence behavior if they are perceived by the individual. The crux of their argument was that these choice theories are perceptual in nature and, thus, require scholars to assess one's perceptions of their beliefs of risk rather than utilizing the objective reality of that risk. The positive research using these perceptual measures has led to some resurgence in the rational choice perspective (Nagin 1998). These positive findings has led Nagin (1998) to argue that scholars interested in the choice perspective should move beyond assessing if risk perceptions influence behavior and focus on how individuals actually formulate their perceptions of risk, in other words, what information (or "signals") go into the development of subjective risk perceptions.

Interestingly, social learning theory is also an inherently perceptual theory of crime. The core proposition of the theory is that the perceived reinforcements and punishments associated with behavior influence the present and future likelihood of offending. Given this strong emphasis on perceived reinforcements and punishments, and the robust relationship between these perceptions and offending, one future direction for social learning scholars is to heed Nagin's (1998) call and end the discussion on the superiority of objective measures over perceptual ones and begin to consider what factors go into one's perceptions of social reinforcements and punishments. To be clear, a recent study conducted by Young et al. (2011) found that individuals have a tendency to misperceive their own friends' delinquent behavior. Of course, this finding could be used as more ammunition for the objective-measure-superiority debate, but it also can be used to ask more interesting questions regarding individual perceptions of reinforcements: what causes individuals to misperceive their friends' behavior? Or more generally, how do individuals formulate their subjective perceptions of social reinforcements? The answer to these questions has considerably more theoretical utility and can shed important light on the learning process, in general.

Conclusion

Social learning theory begins with the assumption that criminal behavior, like all human behavior, is learned in the interaction with others. This theory went beyond Sutherland's perspective by more clearly specifying what this learning process entailed. Simply, social learning theory asserts that the probability an individual commits deviant acts depends on the relative frequency, amount, and probability of past, present, and anticipated rewards and punishments perceived to be attached to the behavior. The empirical literature supportive of the theory is one of the most impressive in the field of criminology. Nevertheless, considerable avenues of ongoing and future research can lead to more theoretical clarity.

Overview

Neighborhoods shape a variety of outcomes for children, families, and residents in general, influencing behavior, attitudes, and values as well. While some neighborhoods foster continuous patterns of criminal activity, others develop collective efficacy, the shared understanding that their constituent members have social capital resources which they are mutually able and willing to use to achieve collective outcomes. Neighborhoods cluster outcomes, some of which cannot be accounted for in terms of the characteristics of the individuals or households currently residing in them; they prove to be real communities with enduring characteristic patterns that survive the replacement of their constituent members. A useful neighborhood definition would be one that helped us better understand these neighborhood communities and their effects. These neighborhood communities are not only geographically meaningful but geographically identifiable as well because the networks of interactions among neighboring residents which produce them, which translate neighboring interactions into neighborhood communities and their effects, are constrained by predictable urban geographic substrates. New research has proposed behaviorally oriented definitions of neighborhoods, defining them in terms of their potential for interaction among residents. Defining neighborhoods in this way provides a lens to focus more closely on neighborhoods as effect-generating communities emerging from the networked interactions of their constituent residents.

Fundamentals/Key Issues

Why Neighborhoods Matter in the Twenty-First Century: The Continual Emergence of Neighborhood Effects

Neighborhoods: Social Capital, Collective Efficacy, and Crime There appears to be a continually increasing interest in the role of neighborhoods in shaping a variety of outcomes for children, families, and neighborhood residents in general (for an overview, see Brooks-Gunn et al. 1997a, b). These "effects" have included a vast array of phenomena ranging from child and adolescent development (e.g., abuse and maltreatment, school completion and achievement, drug use, deviant peer affiliation, delinquency and gangs, adolescent sexual activity and pregnancy and childbearing, parenting behaviors) to concentrated disadvantage and its many corollaries (economic attainment and labor market success, crime and violence, physical disorder, the perpetuation of racism, to name just a few). An overwhelming conclusion reached by all of these studies of neighborhood effects is that neighborhoods influence our behavior, attitudes, and values. They shape the types of people we will become and expose us to or shield us from early hazards that would seriously restrict the opportunities available to us later in life. After our homes, and in conjunction with them, they are where we first learn whether the world is safe and cooperative or inchoate and menacing.

Not all neighborhoods are alike, however. Some neighborhoods are characterized by high levels of effective community. They clearly offer social capital to their residents, a social organization which facilitates and coordinates cooperative action for mutual benefit, which allows residents to deal with daily life, seize opportunities, reduce uncertainties, and achieve ends that would not otherwise have been possible. This social organization is a resource which is not individually attainable because social capital is not a characteristic of individuals; it is a supra-individual property of social structure and it seems to be particularly well grounded in neighborhood communities. These sources of social capital tied to the neighborhood community context are analytically distinct from and as consequential as the more proximate family processes and relationships occurring in the home. Some neighborhoods develop a further layer, mutual trust and shared norms, values, and expectations, beyond the resource potential of neighbor networks, which allows them to utilize these networks to achieve desired outcomes. Collective efficacy occurs when members of a collectivity, with social capital resources, believe they are mutually able and willing to use these resources to achieve an intended outcome (Morenoff et al. 2001). The distinction is a subtle, but important, one. A neighborhood may have social capital resources available for its constituent members to utilize but they may not trust the willingness or ability of their fellow residents to use these networked resources for the collective good or they may not even be certain that they agree as to what the collective good might be.

From a less positive perspective, neighborhoods show remarkable continuities in patterns of criminal activity as well. For decades, criminological research in the ecological tradition has confirmed the concentration of interpersonal violence in certain neighborhoods, especially those characterized by poverty, the racial segregation of minority groups, and the concentration of single-parent families. Even in neighborhoods with less socioeconomic or racial isolation, crime rates persist despite the demographic replacement of neighborhood populations (Brantingham and Brantingham 1993). In addition, neighborhoods determine not only one's exposure to crime and violence but also a host of less tangible deleterious factors which contribute to the development of an urban underclass, signs of social disorder which lead residents to perceive their neighbors as threats rather than as sources of support or assistance (Massey and Denton 1993).

Neighborhoods: Geography and (Potential) Effects These neighborhood effects, both the community enhancing and the community degrading effects, necessarily involve a geographic context. Thus, to analyze and understand them, they necessarily require a geographic equivalent of a neighborhood and a geographic definition of one. Researchers have utilized a variety of such definitions. In fact, they have used so many that Galster (2001, p. 2111) argued that "urban social scientists have treated 'neighborhood' in much the same way as courts of law have treated pornography: a term that is hard to define precisely, but everyone knows it when they see it." Apparently, however, researchers often don't know it when they see it. The modifiable area unit problem (MAUP) is a statistical bias affecting areal unit summary values (e.g., totals, rates, proportions) when they prove "arbitrary, modifiable, and subject to the whims and fancies of whoever is doing, or did, the aggregating" (Openshaw 1984, p. 3). Miller's (1999) survey suggests that, when the spatial units used to study a phenomenon are not clearly defined by theory, any conclusions derived about the studied phenomenon may be hopelessly prejudiced by the arbitrary, at least from a theoretical perspective, choice of spatial unit.

While many statistical techniques and error modeling approaches have been used to try and counteract, reduce, or remove the effects of MAUP, Miller perceives that the ultimate solution has to involve a more behavioral-oriented definition of neighborhood. One needs better intuitions about the general nature of neighborhoods, not better statistical methods. The very existence of the modifiable areal unit problem (MAUP) evidences that theory has taken a back seat. Researchers who have developed methods for creating optimal analytic units with respect to predefined objective functions note correctly that MAUP would be irrelevant if neighborhood equivalents were chosen for theoretical reasons rather than administrative convenience (Alvanides et al. 2001).

Despite this, however, when a geographic definition of neighborhood is required for the purpose of quantitative analysis, "most social scientists and virtually all studies of neighborhoods . . . rely on geographic boundaries defined by the Census Bureau or other administrative agencies. . . [which] offer imperfect operational definitions of neighborhoods for research and policy" (Sampson et al. 2002, p.445). Administratively defined units such as census tracts and block groups do not directly measure, nor were they designed to measure, the potential for interaction among resident members, the primary process hypothesized to produce neighborhood communities and their effects. For example, the Census Bureau appears to theoretically focus on segregation type effects, defining tracts as "relatively homogeneous units with respect to population characteristics, economic status, and living conditions." In most cases, however, the sheer ubiquity of data gathered by the Census Bureau or other administrative agencies (e.g., school districts, police districts) proves to be an overwhelming temptation for most researchers. Theory succumbs to the preponderance of data. The very existence of the modifiable area unit problem (MAUP), however, evidences that census geography is not measuring what researchers are studying.

Undoubtedly, neighborhood effects involve a geographic context. Neighborhood effects, however, are not produced by neighborhood geography. Neither are neighborhood effects, at least not a lot of them, merely a by-product or spurious confound of the geographic co-location of residents with particular demographic characteristics or psychological profiles. Neighborhood effects hypothesize that there exists a thing, a social entity, a neighborhood community, which has effects. Neighborhood effects are the product of these neighborhood communities. Neighborhood communities and their effects emerge from neighboring interactions among their constituent members. Neighborhood communities are geographically constrained because the interactions which produce them are geographically constrained. Neighborhood communities are both geographically identifiable and have effects which persist through the replacement of their residents because the networks of interactions which produce them, which translate neighboring interactions into neighborhood communities, are constrained by predictable urban geographic substrates.

When we think about geography having an effect on community, it is because we believe that something about physical space affects something about how individuals interact within that space. Neighborhoods are more than colored boxes on a map or sets of geo-referenced variables for use in a geographic information system (GIS). A focus on maps, especially maps based on census or administrative geography, emphasizes those aspects of neighborhoods and their residents which can be effectively displayed or referenced to administratively defined polygons and ignores those which cannot. To understand the social-interactional aspect of neighborhoods, we may not necessarily have to think outside the box, but we do have to think about what's inside of it, residents potentially interacting with each other as neighbors.

Neighboring and Geographic Neighborhoods While it may seem obvious, it is worth highlighting that, at its most fundamental level, neighboring is a proximity-dependent relation. When we say that someone is our neighbor, we are making a statement about them being proximal to us. Neighbors must, by definition, live close to each other; but what constitutes the geographic proximity or availability that defines neighboring?

Many studies have called attention to the strong role of extremely short distances in neighborly contacts. At least from an individual household's perspective, the distances associated with neighboring are often effectively measured in feet and yards (Festinger et al. 1950). Residential propinquity's influence on social interaction is typically limited to those who live within a few households away. What is most important is who lives next door, not who lives in the same census tract; who lives a few houses away, not who lives a few blocks away. Neighbors have also been defined to be people who live within walking distance (Grannis 2009). Walking distance, of course, varies by person, being much greater for some than others due to their age and physical fitness and even changing seasonally in some areas. No matter how far walking distance is, however, for any particular person, the probability that someone will be identified as a neighbor declines rapidly with increased distance from one's home.

Because neighboring is so close at hand, it depends upon very subtle geographic features. Besides focusing on the number of houses or yards separating two households, a natural division, in both cognition and behavior, occurs at the face block. The face block includes all of the dwellings that front on the same street and are situated between only two cross streets (an exception would be cul-de-sacs which are face blocks delimited by only one cross street). The face block has been found to be an important sociospatial unit (Suttles 1972). At one level, the face block includes virtually all neighbors who live either next door to each other or directly across the street from each other and most of those who live within a few house lengths; therefore, it could be viewed as simply a reflection of the more general effects of proximity. However, studies have shown that residents have more interaction with those on the same face block than they do with residents beyond an intersection, even if they were spatially closer to the latter group (Greenbaum 1982).

Not all face blocks, however, are oriented towards the pedestrian nature of neighboring. Some front on large arterial streets devoted to providing access for travelers while others front on smaller streets more devoted to local living space. Studies of peoples' perceptions of street life reveal that residents clearly perceive the difference between heavy traffic face blocks continuously filled with strangers which are used solely as thoroughfares and corridors between the local neighborhood and the outside world on the one hand and light traffic face blocks which form the basis of lively, close-knit communities where everyone knows each other and residents consider the boundaries between house and street space to be quite permeable on the other hand (Appleyard and Lintell 1986). A tertiary face block has been specifically designed and maintained by governing authorities to promote local and pedestrian traffic. The tertiary face block is a more or less "natural" unit of face-to-face neighborly interaction (Suttles 1972). Tertiary face blocks are both oriented towards pedestrian travel and local residents, rather than outsiders who arrive by automobile or mass transit. Thus, tertiary face blocks are the types of face blocks most likely to give rise to social interactions (Rabin 1987). Tertiary face blocks provide a meeting place for neighbors (de Jong 1986). People use them for a host of activities including walking pets, riding bicycles, and chatting with neighbors. Shared tertiary face blocks provide a "permeable boundary" between households' private spaces. Tertiary face-block neighbors are "used for easy sociability and assistance when quick physical accessibility is an important consideration."

Face blocks terminate at intersections. An alternative way of thinking about this, of course, is that intersections connect face blocks with each other. The important question then becomes: Do they also connect neighbors and do neighbor networks terminate at intersections or do they bridge them to form larger structures? Intersections form a different metric than face blocks for measuring functional distance. Just as different types of streets differentially induce or fail to induce neighborly relations, different types of intersections may induce or inhibit neighborly relations from bridging them. Fortunately, the intersections of streets can also be operationally defined in a convenient and meaningful way. When streets of different classifications intersect, planners consider the intersection to be of the higher classification. For example, if a larger street intersects a tertiary street, planners would consider the intersection to be part of the larger street, but not part of the tertiary street. This makes intuitive sense because the inhibiting effects of the larger street will dominate. The nature of intersections either facilitates or impedes pedestrian-based neighborly interaction; therefore, an intersection is a tertiary intersection if all of the face blocks, however many, contiguous with it are tertiary face blocks. A non-tertiary intersection, in contrast, is an intersection such that at least one of the face blocks contiguous with it is a non-tertiary face block.

Studies have shown that tertiary intersections combined with tertiary face blocks can serve as a "pedestrian circulation system." Sidewalks provide access between residence and parks, churches, and neighborhood shops. Neighborly relations bridging face blocks occur "through the routes people take in meeting an average day's basic needs and desires. The newsstand where one buys the Sunday paper, the store one runs to for a quart of milk, and the streets one travels on to visit a friend" (Anderson 1992, p. 46). People come to envision their neighborhoods as networks of paths and channels along which they move (Lynch 1971). Tertiary intersections guide this "natural movement" (Hillier 1996) within a city.

Potential Neighbor Networks and Actual Neighbor Networks Individual neighbor networks evolve into neighborhood networks through the process of concatenation. Residents have relations with their neighbors who interact with other neighbors, and so on. These neighborly relations concatenate and consolidate neighbor-to-neighbor-to-neighbor. There are several important corollaries of this fact. First, the resultant network is as far reaching as its most extensive ramification. Relations concatenate to form a network typically larger, both relationally and geographically, than any individual's relations. Thus, relatively micro-level relations can result in a macro-level structure. Second, the resultant network is as fragile as its weakest link. Anything which can cause a relation to not form, no matter how trivial, breaks the network. In contrast to the first corollary, micro-level fragilities can destroy a macro-level structure. Third, the characteristics of the resultant network are not readily predictable from the characteristics of the local networks which concatenate to form it. Only as sets of individual networks concatenate do the characteristics of this aggregated network emerge. Finally, because a neighboring relation cannot exist unless residents are geographically available to each other, the network of potential neighbors cannot transcend the network of geographic availability; it is logically impossible. While individuals' lifestyles and habits may prevent them from having contacts and interactions with those who are geographically available to them, they cannot cause them to have contacts with those who are unavailable.

To study efficacious neighborhood communities emerging from neighbor networks, therefore, we need a definition of a neighborhood community whose importance is derived from the potential for neighbor networks to concatenate within it. Grannis (2009) defined this geographic availability in terms of shared walking arenas which mediate, guide, and constrain potential neighborly encounters. Building on this, the concatenated network of overlapping neighborly contacts can be no larger than the concatenated network of walking arenas; conversely, the network of potential neighborly relations, based on concatenated interactions, is a subset of the concatenation of these walking arenas. Grannis argued that tertiary block faces effectively proxy walking arenas in urban areas and thus the maximal concatenation of contiguous tertiary block faces, of walking arenas, represents the maximal consolidation of individual residents' potential to access each other.

Such a neighborhood equivalent would signify internal access. All residents within it would have a potential for neighborly relations using walking arenas. While it is unlikely that all, or even any, residents would traverse the entirety of this neighborhood equivalent, this internal contiguity would allow residents to interact with their neighbors down the street who interact with other neighbors further down the street, and so on throughout the network. Such a neighborhood equivalent would also signify constraint. To the extent to which the potential for neighboring relations depends upon walking arenas, it would constrain their concatenation. Based on these criteria, Grannis (2009) defined two types of neighborhood equivalents, t-communities and islands, one connecting tertiary block faces using only tertiary intersections and the other connecting tertiary block faces using all intersections. A t-community is a maximal contiguous network of tertiary block faces and tertiary intersections, while an island is a maximal contiguous network of tertiary face blocks and any intersections. The label "t-community" is short for "tertiary street communities" indicating that these neighborhood equivalents are connected by tertiary streets (Grannis 2009). A pair of neighborhoods would be geographically unreachable if they could only reach each other by crossing water; Grannis (2009) analogously label these discontinuous networks of tertiary block faces as "islands" since it is impossible for households in two different islands to access each other using tertiary block faces, even if they use non-tertiary intersections. Since islands are maximal networks of tertiary block faces and any intersections while t-communities are maximal networks of tertiary block faces and tertiary intersections, t-communities are necessarily subsets (although not necessarily proper subsets) of islands.

Selection vs. Influence These t-communities and islands, these walking arenas, interact with two different social forces to create neighborhood communities and their effects. First, neighborhoods are more than just neighbors residing nearby each other. They are vital entities, or at least they have the potential to be. Even when it appears static, neighborhood social life generally is not; it is a stable equilibrium reached amidst the strife of social flows. The vibrant, living part of neighborhoods consists of the flow and exchange, both spoken and silently modeled, of norms, values, identities, symbols, ideas, affect, sentiment, and other social and cultural goods and resources among neighbors along the conduits provided by neighbor networks. This flow pressures neighbors towards conformity.

This certainly happens verbally, through the exchange of personal information, life histories, and stories, as well as through establishing and enforcing rules for neighborhood children; however, it happens even more nonverbally. Community members model and enforce "appropriate behaviors" in their daily interactions with each other, especially with children (Coleman 1990). In addition to modeling appropriate behaviors, neighbors may use rewards to encourage normative behaviors or sanctions to discourage behaviors not compliant with social or personal norms. The degree of these sanctions or rewards varies greatly with the nature of the society; for example, in communities that emphasize social control and social cohesiveness, sanctions may be enforced by direct social pressure for conformity (Hogan and Kitagawa 1985). As norms, values, ideas, and other social goods and resources traverse and commingle along neighbor networks, they have the potential to engender a sense of community and identity, social capital, mutual trust, social control, collective efficacy, and many other important facets of neighborhood life social researchers interest themselves in. The collectively efficacious community network which emerges, or which fails to emerge, however, is embedded in the network of neighborly interactions which is embedded in the network of potential neighborly interactions which is embedded in the network of geographic availability.

Second, locational choice and homophily may certainly account for some of the effects of neighborhoods but numerous studies have shown that neighborhoods with similar population demographics, in terms of race, socioeconomic status, family structure, and a host of other characteristics, often yield different outcomes for their constituent members. Market explanations, while intuitively appealing, have failed to account for the richness and complexity of effects correlating to neighborhoods.

Locational-based neighborhood effects such as residential differentiation and segregation correspond to the influence-based neighborhood effects such as social capital and collective efficacy because in choosing to move away from dissimilar households, residents are implicitly choosing to segregate their networks of potential neighborly interactions as well. Since contact is a necessary prerequisite for interaction, if households settle in such a way that their immediate neighbors are similar to themselves, then they have settled in such a way as to not have neighborly interactions with those different from themselves. Neighborhood communities result from both the concatenation of homophilous locational choices and the flow and exchange of norms, values, and beliefs among neighbors. Their correspondence is not additive, as in a regression model, but rather sequential. Relocation, which is responsible for residential differentiation and segregation, determines geographic availability and the potential for neighborly interactions and thus, of necessity, the actualized neighborly interactions which influence works upon to create social capital, collective efficacy, and other important neighborhood effects.

Children and Their Families Neighborhoods are especially important for households with children because children are much less mobile, and thus more geographically dependent, than adults. Children and their playful interactions depend upon proximity much more than adults and their interactions do. Since children cannot drive and have little, if any, voice in relocation decisions, they are forced to share lives with neighboring children even more than are their parents. For children, the street in front of their home is "the mediator between the wider community and the private world of the family" (Appleyard 1981, p. 4). This is where children first learn about the world. They often play games in the middle of these streets, use them to walk pets and to ride bicycles, and the majority of their recreational activity occurs there (Brower 1977). Sidewalks provide access between residence and schools and parks. As a result, the relationships children form will primarily depend upon the opportunities to interact provided by walking arenas immediately surrounding them (Appleyard and Lintell 1986). Especially for young children, neighboring children are the most likely to become their playmates (Hillier 1996). Thus, the networks of relationships they form will be much more dependent upon the network of geographic availability. Unlike children, adults have many venues for social relationships beyond their neighborhood including work and voluntary activities. School-age children may have some of these to the extent their parents allow. Preschool children, however, have few, if any, of these alternative venues for social opportunities. Their lives are tightly bound by geography.

"The micro-ecology of pedestrian streets bears directly on patterns of interaction that involve children and families. Parents are generally concerned with demarcating territory outside of which their children should not wander unaccompanied by an adult, to ensure that their children stay in areas that are safe for play and conducive to adult monitoring. To the extent that these limited spaces of children's daily activities usually do not cross major thoroughfares, defining tertiary communities may provide a foundation for constructing neighborhood indicators of child well-being and social processes more generally " (Sampson et al. 2002).

Not only are your neighbors' children predisposed to become your children's friends, but they also determine the character of your children's playmates (Cochran 1994) and the kinds of role models they emulate (Massey and Mullen 1984). The flow of norms and values discussed above acts not only on children but their families as well. "For example, when parents know the parents of their children's friends, they have the potential to observe the child's actions in different circumstances, talk to each other about the child, compare notes, and establish norms. Such intergenerational closure of local networks provides the child with social capital of a collective nature" (Sampson 2001: 9). As a result, households with children are far more influenced by the norms and values of surrounding households with children than households in general are influenced by the norms and values of their surrounding neighbors.

Neighboring parents may become intimately involved in the socialization of each other's children. Neighbors rear children side by side and together have the potential to co-create a safe and value-laden environment. Parents monitor their own children as well as those of their neighbors (Sampson et al. 1999). Some neighborhoods expect that residents share values and are willing and able to intervene on the behalf of children. They expect that residents will actively engage themselves in the support and social control of children (Bandura 1997) and that the community will work together to successfully support and control children. Parents get to know the parents and families of their children's friends; they observe children's actions, both their own and their neighbors', in a variety of circumstances; they talk with other parents about their children; and they establish norms (Coleman 1990). Such structural and normative adult-child closure gives children social support, provides parents with information, and facilitates control (Sandefur and Laumann 1998). The choice to live in a neighborhood is to some extent a choice to rear children together with one's neighbors. Ultimately, a community of parents may develop around the community of children, mirroring it. People whose children play together form friendship relations based in part on that fact (Abu-Gazzeh 1999; Grannis 2009). While it is the children who are immobile and thus confined to neighborhoods that are most immediately impacted by neighborhoods, children's geographic dependence encumbers their parents as well.

The Menu of Neighborhood Equivalents Altogether, for both children and adults, through influence and selection, neighborhoods cluster outcomes which cannot be accounted for in terms of the characteristics of the individuals or households currently residing in them. It is as if neighborhoods have personalities, enduring characteristic patterns that survive the replacement of their constituent members. Neighborhood communities are geographically constrained because the interactions which produce them are geographically constrained. Neighborhood communities are both geographically identifiable and have effects which persist through the replacement of their residents because the networks of interactions which produce them, which translate neighboring interactions into neighborhood communities, are constrained by predictable urban geographic substrates. To study efficacious neighborhood communities emerging from neighbor networks, therefore, we need a definition of a neighborhood community whose importance is derived from the potential for neighbor networks to concatenate within it.

Grannis (2009) defined this geographic availability in terms of shared walking arenas which mediate, guide, and constrain encounters. What do neighborhoods such as t-communities and islands, defined and measured by their potential for interactions, offer us that traditional neighborhood equivalents do not? They provide us with a lens to focus more closely on neighborhoods as communities emerging from the interactions of their constituent residents. They use an entirely different metric than census geography, one based precisely on the potential for community generating neighborly relations. In contrast, administrative geography often focuses on neighborhoods as statistical abstractions, perhaps reflecting segregation but agnostic to any potential for community, for interaction, for neighboring. While both types of neighborhood equivalents have their uses, researchers need to use care as to which one they choose and perhaps use both to disentangle different mechanisms that are at work in neighborhood communities, one mechanism provided by the concatenation of neighboring relations into neighbor networks and another provided by service areas, such as those offered by schools or marketplaces or police which unite residents around similar needs and opportunities. T-communities precisely measure the first. Neighborhood equivalents, defined solely by their boundaries, measure the second to the extent their boundaries coincide with the service areas. A careful use of both t-communities and neighborhood equivalents defined by their boundaries could tease apart the different mechanisms at work (Grannis 2009).

Social Network Analysis of Organized Criminal Groups

Francesco Calderoni
Transcrime, Università Cattolica del Sacro Cuore, Milan, Italy

Overview

This entry discusses the state of the art in the application of network analysis methods to the study of organized criminal groups. It provides an overview of the development of the field from both the academic and law enforcement perspective and discusses the current approaches in the literature. Particular attention is given to methodological issues (data sources, type of network analysis) and to the discussion of the limitations of the application of social network analysis to criminal organizations. In the light of the current state of the art, the entry also discusses the recurrent claim that network analysis may help the law enforcement agencies to more efficiently disrupt criminal networks. Finally, it attempts to identify the future trends in the application of network methods in the study of organized crime, while suggesting some promising paths from both a research and policy perspective.

Introduction

The use of social network analysis (SNA) in criminology is a relatively recent trend compared to other social sciences. Among the multiple possible applications of SNA in criminology, it may be hard to identify trends and specific fields. Carrington (2011) has identified three main topic areas where network methods have found significant application in criminology: The first is the analysis of the influence of personal networks on delinquency and crime which, according to the author, is "the most common use of social network analysis in criminology" (Carrington 2011, 236). The second area is the influence of neighborhood networks on crime in the neighborhood. The third area is the organization of criminal groups and activities. In turn, the latter may be framed into three fields: The first concerns the application of SNA methods to terrorist networks; the second deals with street gangs, youth gangs, and delinquent groups (Carrington 2011, 244–246); and the last, discussed in this entry, concerns organized criminal groups.

The application of SNA methods to organized crime has a background which is based on the history of both research and law enforcement.

From the research side, the idea that organized crime may be better understood as a network rather than a hierarchical and structured organization is not new in criminological literature. The reaction against the alien conspiracy approach, which suggested to analyze organized crime as a bureaucratic organization, organized along a formal hierarchy and with detailed rules for its functioning, soon led to the alternative hermeneutic perspectives leaning towards more flexible and informal mechanisms. For example, Albini argued that organized crime is "a system of loosely structured relationships," mainly based on patron-client relations (1971, 288); the works of Ianni suggested that mafia-type organizations should be better understood as social systems based on shared social cultural and ethnical relations. He explicitly mentioned network analysis, as "an anthropological tool that is used to chart social interactions" (Ianni 1973, 4). Ianni analyzed a number of Puerto Rican and African-American criminal groups as networks, although the application was quite far from current use. Overall, although the concepts of network and network analysis were recurrently evoked to describe the functioning and structure of organized crime, there were very limited empirical applications using network analysis methods (Ianni 1973).

From the law enforcement side, since the mid-1970s there has been a growing attention on the processing and analysis of intelligence data in organized crime. In this context, link analysis (visual representation of the structure of a criminal group performed through manual or computer-assisted drawings) was increasingly applied by law enforcement agencies and a private industry quickly developed offering methodologies and training courses (Lupsha 1983, 63). Link analysis allowed to "establish the relationships that exist among individuals and organizations from bits and pieces of available evidence" (Harper and Harris 1975, 158). It became increasingly popular thanks to the development of intelligence software. The step from link analysis to SNA was relatively short.

Academic interests on organized crime networks gradually met with law enforcement network analysis attempts. Not surprisingly, Ianni and Reuss-Ianni, who had refuted the bureaucratic approach to organized crime for the social system approach, contributed to a volume on criminal intelligence analysis suggesting it be applied to organized crime (Ianni and Reuss-Ianni 1990). Indeed, from the very beginning, this idea was linked with its operational exploitation for law enforcement, at a time when the focus on strategic intelligence and analysis of organized crime was very strong.

Indeed, the first contributions in this field, dating back to the first half of the 1980s, already focused on the opportunities offered by network analysis in the strategic analysis and enforcement of criminal organizations (Davis 1981; Lupsha

1980, 1983). In his 1980 contribution Peter Lupsha suggested that effective enforcement of organized crime required a move towards strategic analysis of groups and operations. He suggested some “first steps that departments might engage in to move from a tactical to a strategic analysis perspective” (1980, 37). Among such steps, he included network analysis as an “essential and necessary step” (1980, 38). One year later, FBI Special Agent Roger Davis provided a first hypothetical example of the application of network methods to a criminal organization, using some basic network concepts, such as density and centrality, to a fictional criminal organization (Davis 1981, 18). One of the first empirical network analyses of a criminal organization was carried out by Lupsha (1983). The study focused on “The New Purple Gang,” a group trafficking in heroin and cocaine active in the New York City metropolitan area in the second half of the 1970s and composed of Italian-Americans with connections to La Cosa Nostra. The author maintained that his study was an application of network analysis and actually developed matrixes and graphs. Rather, the study merged broad concepts familiar to network analysis, such as reciprocity and ego network structure, with other approaches and data. Interestingly, some of the most common network analysis concepts, such as centrality, were barely mentioned. As a result, Lupsha’s study provided a first exploration of network analysis of organized crime, demonstrating how multiple methods could help to extract relevant information from police data.

In the following years, some scholarly contributions advocated the application of network methods to criminal organizations (among the first contributions Ianni and Reuss-Ianni 1990; Sparrow 1991). However, most of these nowadays “classic” contributions, albeit with some exceptions (e.g., Lupsha 1983), did not engage in empirical analysis of criminal groups, possibly due to the limited availability of datasets and software. Interestingly, Mastrobuoni and Patacchini (2010) and Papachristos and Smith (2011) have recently demonstrated that old law enforcement databases and archives may provide valuable opportunities for the application of SNA to organized crime. Not surprisingly, only 10 years ago, Coles still complained about the “failure by criminologist to adopt Social Network Analysis techniques and concepts in the investigation of criminal networks, particularly of organized crime”.

Only in the last decade the use of network analysis in the study of organized crime has seen significant developments. Since the beginning of the 2000s, interest in this specific field has significantly increased and contributed to opening new research directions in the study of criminal organizations. Indeed, the number of articles and papers on criminal, illicit, or, more generally, “dark” networks has grown only since the 2000s. Significantly, a special issue of a specialized academic journal was dedicated to SNA and organized crime (*Trends in Organized Crime*, Volume 12, Number 2/June 2009). Studies on criminal organizations are now an important sector in this increasing trend. The following sections of this entry attempt to review the current state of the art of the application of SNA to organized crime groups and to discuss present issues and future trends.

Criminal Organizations and Markets

In a very rough categorization, most current applications of SNA to organized crime have adopted either a “micro” or a “macro” approach.

Studies within the “micro” approach have normally focused on one organization or network with a relatively low number of nodes. One of the first examples was Natarajan’s study of a cocaine trafficking organization (2000). The study provided a detailed analysis of the structure and functioning of a criminal organization, through a mix of multiple methods (contact analysis, task analysis, status analysis, and network analysis). As to SNA, Natarajan applied some network concepts (centrality and density) and demonstrated that a systematic quantitative analysis of law enforcement and judicial sources could complement more traditional research methods in the study of higher-level drug trafficking.

In the following years, further empirical works have contributed to analyzing criminal organizations using network analysis. Most of them focused on drug trafficking (Morselli 2005, 2009; Calderoni 2012; Malm et al. 2011; Bright et al. 2012), but some studies analyzed car-rigging organizations (Morselli and Roy 2008), extortion/money-laundering activities (Varese 2006), or the structure or evolution of a prominent criminal within a New York mafia family (Morselli 2005).

As to drug trafficking, the application of SNA has provided unprecedented insight in the structure of trafficking organizations. In most drug-trafficking networks, a subset of nodes concentrated the majority of criminal contacts and communications. This emphasized that drug trafficking was mostly conducted by a subset of highly connected and active individuals who were able to bring different people and resources together. In general, these subjects were skilled criminal brokers tasked with the management of drug-smuggling operations. Conversely, the majority of nodes involved in drug-trafficking groups appeared to be marginal players, involved only in one specific operation or task. On the one side, the results revealed a specific organizational structure of drug trafficking. This was a rather horizontal structure, ideal for a flexible and fast-changing environment, where criminal activities and illicit partnerships depended more on criminal opportunities than on any internal organizational arrangement. On the other side, the mentioned structure did not correspond to an extremely elaborated hierarchy where different organizational layers/ranks could be observed and where bosses delegated to underbosses or capos who in turn command soldiers. Signals of structure and hierarchy did not emerge from the network analysis, but rather from complementary methods highlighting the informal division of tasks and differences in status among the participants. Overall, leaders/brokers were actually in contact with most of the other individuals in the criminal networks and maintained direct control over the criminal activities. Hardly any traces of delegation and rigid organizational layers were found, and this is probably due to the highest risks that may be faced due to information dispersion, lack of trust, and difficulties in controlling subordinates.

This picture was substantiated by evidence coming from different studies on drug networks from a variety of countries and typologies of criminal organizations, such as the United States, Canada, Spain, Australia, the UK, and Italy. These findings were consistent with, and provided further empirical evidence to, previous drug-trafficking research.

Studies within the “macro” approach have developed in very recent years, possibly because they were based on larger and more complex databases. They have generally analyzed larger networks, focusing on specific national or regional criminal markets or offender categories. This research has aimed at analyzing specific aspects of criminal networks and population. Malm and Bichler studied a network of 2,197 individuals derived from law enforcement intelligence data in Canadian Pacific Region (Malm et al. 2009; Malm and Bichler 2011; Malm et al. 2011). They used multiple networks (co-offending, kinship, formal organization, and legitimate association) and this allowed to focus on the interplay of different types of connections (e.g., family relation or partnership in legal business) within a large network of individuals involved in criminal organizations (Malm et al. 2009). In another study, they focused on a subset of 1,696 individuals involved in drug trafficking and analyzed the network characteristics of specific market niches (i.e., specific tasks within the drug-trafficking chain) (Malm and Bichler 2011). They have also explored the extent of co-offending patterns among criminal groups of different (ethnic or nonethnic) origin (Malm et al. 2011). Heber (2009) studied a sample of 127 serious drug offenders (principal offenders) in Sweden and further enlarged her network including the principal offenders’ co-offenders and eventually the co-offenders of the latter. As a result, her network included several thousands of offenders allowing an analysis of their distribution across the Swedish territory and of the structure of drug-trafficking activities. Some further contributions focused on American organized crime, namely, in Al Capone's Chicago (Papachristos and Smith 2011) and La Cosa Nostra in 1960 (Mastrobuoni and Patacchini 2010).

Overall, network studies have pointed out that the majority of drug-trafficking (and other criminal) groups are flexible and rapidly changing organizations, hardly fitting the typical pyramidal picture which is frequently suggested by the media and sometimes by law enforcement. Network analysis has contributed critically to the production of empirical evidence in this field.

Methodologies

Compared to the most advanced application of SNA in other social sciences, the methods currently applied in most criminological contributions may appear somewhat simpler. This may be due to the relatively recent development of network approaches in this specific field. In turn, this may imply a limited experience of most criminologists in the application of SNA but also, and more critically, a limited scientific acceptance of such methods within the discipline. Not surprisingly, in the past years most criminologists applying SNA have experienced difficulties in publishing in mainstream peer-reviewed journals. Another reason for the relative lag in the application of more complex network methods to organized crime may inherently relate to the this specific field. Indeed, available data on criminal organizations and criminal markets rarely allow to apply more complex analyses such as dynamic network analysis (DNA), multiplexity (multiple types of relations, e.g., co-offending, phone communications, and kinship), and exponential random graph models which would allow to study the evolution of organized crime networks in time and structure. Notwithstanding these difficulties, some studies have applied ERGMs and multiplex relations (Malm et al. 2009) and one recent paper announced further developments in the field of organized crime (Papachristos and Smith 2011).

Concerning data sources, the majority of studies relied on secondary data. Most micro studies used judicial documents, intelligence reports, or investigation files. Macro studies have used intelligence databases collected by law enforcement agencies (Malm and Bichler 2011; Malm et al. 2009; Heber 2009) or databases created through archival analyses (Mastrobuoni and Patacchini 2010; Papachristos and Smith 2011).

As for the types of SNA, most of the literature on organized crime groups has worked with complete (or whole or full) networks rather than the ego networks, differently from other main areas identified by Carrington (2011). Indeed, the complete network approach is naturally suited to the analysis of criminal organizations or criminal markets. Nevertheless, some studies used ego network approaches for studying the career of a prominent La Cosa Nostra member (Morselli 2005) or the impact of drug dealers' personal networks on their survival and success (Bouchard and Ouellet 2011) and the co-offending patterns among different typologies of criminal enterprises (Malm et al. 2011).

Within the full network perspective, the overwhelming majority of the reviewed contributions have focused on one-mode networks with individuals as nodes. Exceptionally, some contributions used two-mode networks with individuals and specific positions in the drug-trafficking chain (Bouchard et al. 2010), while another study, focusing on the world drug-trafficking market, elaborated a full network with world countries as nodes (Boivin 2011).

As already pointed out by Carrington (2011, 244), most network analyses of organized criminal groups are not particularly concerned with the testing of specific criminological theories. Nevertheless, most studies are concerned with the verification of hypothesis and concepts suggested by previous literature on organized crime (Natarajan 2000, 2006; Varese 2006; Morselli 2009; Malm et al. 2011). The existing literature shows a wide variety of approaches and different methods as to the network measurements and concepts. The most popular concepts are density and centralization, the analysis of subgroups (e.g., factions, cut-points, core-periphery), and the centrality of individuals (e.g., degree, betweenness, flow betweenness, eigenvector, closeness, clustering coefficient). Some contributions have merged network analysis with other methodologies such as script analysis (Morselli and Roy 2008), the content analysis of transcripts (Natarajan 2000; Varese 2006; Natarajan 2006; Calderoni 2012; Campana 2011), or spatial analysis (Malm et al. 2008).

Finally, a number of contributions discussed the theoretical, methodological, and practical repercussions of the application of SNA to organized crime groups (e.g., Morselli 2009). These works signal the ongoing meditation about the implications of network analysis in the study of organized crime.

Problems and Issues

One of the main problems encountered in studies applying social network analysis to organized crime is data validity and reliability. The different data sources used in the literature are all exposed to possible biases. Indeed, most of them are secondary sources originating from judicial cases, law enforcement, or intelligence databases. Inevitably, the analysis based on such sources will reflect the perception of law enforcement. Interestingly, however, most of the abovementioned problems seem to be inherent to organized crime research in general. The biases affecting network analysis are often likely to occur also when using alternative methodologies. Indeed, scholars using network methods frequently reported difficulties in controlling for law enforcement biases, and they discussed the possible limitations of their analyses in detail (Morselli 2009, 44–50; Bouchard and Ouellet 2011, 83–85; Varese 2006, 45–47; Calderoni 2012; Malm et al. 2009, 70–71). A recent contribution further explored how the selection of different judicial sources affects the extracted networks (Berlusconi 2013). In general, authors appeared aware of the limitations of their studies. This has not spared criticism and skepticism towards the uncritical use of network methods in the study of organized crime. Undeniably, some contributions have exploited the growing interest in network analysis and have inserted it in the titles, abstract, or keywords, but without actually using any network analysis concept. This may suggest that the increasing use of network analysis may have generated some side effects, not excluding the unnecessary abuse of network-related terminology and techniques, just because this has become "fashionable." Besides such collateral effects, critics have rarely pointed out what alternative methods could replace the advantages provided by SNA. In fact, an increasing number of scholars are using network methods and concepts and applying them to the study of criminal organizations in different countries. This general trend suggests that SNA may actually bring significant added value to this field.

Concerning the risk of biases related to the law enforcement perception of crime, this appears to be a major issue particularly for studies adopting a macro approach. When trying to analyze regional or national markets, these studies most often reflect law enforcement knowledge of markets and criminal networks. The validity and reliability of the sources relate to the effectiveness of law enforcement and to the quality of the databases. Inevitably, however, any law enforcement source is inherently incomplete. Individuals and activities not (yet) uncovered or investigated by law enforcement will be missing (Sparrow 1991, 268; Bouchard and Ouellet 2011, 84; Malm et al. 2009, 70–71).

Also studies adopting a micro approach, focusing on specific groups or networks, may be affected by the mentioned problems of validity and reliability. However, these problems may have a lower impact than in the case of macro studies. Focusing on particularly long and detailed investigations is likely to reduce the risk of missing data in a criminal network. When law enforcement has been intercepting and monitoring a criminal group for months, if not years, the chances for some skilled criminal to avoid detection are likely to be low (Morselli 2009; Calderoni 2012). Nevertheless, the risks that law enforcement may have misunderstood or misjudged the relevance of specific nodes remain and so also the possibility of a willing omission by the police (e.g., this may be the case of informants or undercover agents which have not yet been disclosed).

Interestingly, recent studies have demonstrated that network properties and measures are strong even if tested for missing data (Morselli 2009, 48; Malm et al. 2009, 70–71). Although these findings are encouraging as to the validity and reliability of network methods applied to organized crime, there is a need of further research in this direction.

Social Network Analysis as a Tool for the Enforcement of Criminal Organizations

As already discussed, one of the main drivers of the development of network studies on criminal organizations has always been its possible application in law enforcement. Scholars have claimed the operational benefits of network analysis for intelligence and investigations for years. Given the increasing interest in network analysis of organized crime, a number of law enforcement agencies have started to apply SNA in their criminal investigations, and some contributions from law enforcement analysts acknowledged the use of network methods in the enforcement of criminal organizations. However, operational results so far appeared quite weak and many law enforcement agencies showed some skepticism towards the application of network methods in organized crime cases. Although this may be related to some difficulties in cooperation between law enforcement and academics in general (an issue which is not limited to the application of network analysis and which goes largely beyond the scope of this entry), discussion with law enforcement analysts (from Germany, the United Kingdom, the Netherlands) who have actually experimented network analysis in their job provides more detailed information. According to their experience, the current applications of network analysis are not likely to provide critical advantages to law enforcement agencies in their everyday investigations. Indeed, in long-lasting investigations, the police normally acquires a detailed knowledge of the case. Each individual is monitored, her/his background scanned, and phone and e-mails are frequently intercepted. The application of SNA can hardly provide any additional knowledge to the officers and prosecutors working daily on the case. The idea that SNA can effectively identify the most important actors and show the police the most efficient way to disrupt a criminal network does not take into account that the police normally has a far better insight on the case than any researcher. More often than not, scholars identify the most important individuals, the best targets for network disruption, and the "usual suspects" that law enforcement had already identified.

This may explain the skepticism so far shown by some law enforcement professionals (some of which are increasingly being trained in SNA methods) when claims are made that SNA can help the police to identify the best targets. Network analysis can assist a researcher in reconstructing a network and in making sense of the structure and functioning of a criminal organization. While these analyses have provided unprecedented academic insight on the structure and functioning of criminal organizations, the risk is that current applications may have limited interest for law enforcers.

The above considerations should not lead to hasty conclusions about the futility of SNA and the enforcement of organized crime. Rather, they suggest that the exchange of experiences between academics and law enforcement should be improved. Notwithstanding the operational limits of current analyses, SNA concepts and methods have gained the interest of many law enforcement agencies around the world. As with most new techniques, it will take time to have it accepted and applied. The future trends discussed in the next section suggest that the use of SNA in the enforcement of criminal organizations may become a reality.

Future Issues and Trends

As already mentioned, the application of SNA to organized criminal group is a very recent phenomenon. Therefore, it is likely that further developments will come in the next years. Some trends may be reasonably anticipated.

The number of publications will increase. The rate of publications applying SNA to criminal organizations has been significantly growing, and this trend should continue, if not increase, in the coming years. Hopefully, this may improve the overall quality and standards in this specific field. It will also prevent and eventually remove the inappropriate exploitation of the word network analysis in contributions which do not actually make any use of SNA methods and concepts. Eventually, this may provide SNA applications wider academic acceptance in this specific field and reduce skepticism about the network methods.

Further, the increase in the number of published works will likely provide more empirical studies of specific organized crime groups (micro approach) and/or markets (macro approach). At the moment, the promising results produced by the first papers need further support or verification with other groups and countries. The replication of methodologies and analyses will play an important part until a critical mass of criminal networks and datasets will be analyzed and available.

The methodology will improve. As already mentioned above, so far most SNA studies on organized crime have applied relatively basic measures and concepts. Although this is not necessarily a problem, since also very basic analyses have provided valuable results, the forthcoming years will likely bring new, more complex network methods to be applied also in the study of organized crime groups. Inevitably, the main challenge in this direction will be data availability and, ultimately, the improvement of data collection procedures by law enforcement. The availability of new and better data sources will likely allow the application of advanced SNA techniques such as dynamic network analysis, multiplexity, and ERGMs. These will provide new avenues for analyzing the structure of complex networks and their evolution through time.

In addition to more complex network techniques, future studies will likely mix network methods with other methods, both quantitative and qualitative. Network analysis can be complemented with other quantitative techniques such as spatial analysis and hotspot analysis. Furthermore, the inherently quantitative approach implied in SNA may provide the best results when balanced by qualitative analyses. Studies within the micro approach may take advantage of a detailed analysis of the case studies, including interviews with law enforcement to verify possible biases, interviews with network participants, or content analysis of judicial sources and transcripts (Campana 2011). As anticipated by Morselli, "content analysis is indeed the next step toward enriching the various analyses conducted throughout this book" (Morselli 2009, 164).

SNA and the enforcement of organized crime groups. Notwithstanding the issues highlighted in the previous section, future improvements of network applications to organized crime groups may provide interesting developments for the operational/enforcement point of view. In particular, SNA may be applied not only within investigations, but across different investigations. This contribution may have a geographical and a chronological dimension.

From the geographical perspective, criminal organizations are frequently operating in different areas which may not always be within the jurisdiction of the same law enforcement agency. This is particularly true for large criminal organizations such as mafia-type associations which may commit crimes in different countries. Inevitably such extended criminal activity is likely to involve a number of different police forces and prosecutors' offices, with increasing problems in coordination and information sharing. Different cases and files are going to be opened. It may happen that a marginal subject in the investigation led by District A shows up to be a high-ranking criminal in the investigation conducted by District B. The application of SNA methods across investigations may provide critical information which would not otherwise be available to the single investigators/prosecutors. Through network analysis it may be possible to merge investigative data from a number of cases and provide an overall picture which may be otherwise too complex or difficult to achieve. The literature has already provided some examples of SNA studies merging data from different investigations (Morselli 2009, Chaps. 8 and 9). Results demonstrated that network structure and positioning may significantly change when different cases are merged.

From the chronological perspective, some criminal investigations are capable to survive prosecution and convictions. Frequently, family ties and kinship provide important connections among the members, and this allows such criminal groups to last over years. Mafia-type organizations (e.g., the five families in New York) may last for years, notwithstanding constant law enforcement monitoring and repeated prosecutions. In these cases, it may be important to achieve a very good knowledge of the history of a criminal group. Surely, prosecutors and policemen achieve excellent knowledge of the most dangerous groups in their jurisdictions, but in some cases this important knowledge asset may be dispersed due to reorganization, retirement, transfer, or resignation. The application of network analysis may provide important strategic information about the development and structure of a single criminal organization through time. Furthermore, SNA may allow to assess the changes and reactions of criminal organizations as a reaction to law enforcement. In this perspective, Morselli and Petit showed that systematic drug seizures by law enforcement had a significant impact on a criminal organization, although the group was to continue its operations for months (Morselli and Petit 2007). Further studies may analyze the impact of arrests (either random or targeted) on criminal organizations, applying dynamic network analysis techniques to organized crime groups. Ultimately, this may allow law enforcement agencies to estimate the impact of different strategies and investigations on the evolution of the structure of large and continuing criminal organizations. SNA methods may represent a valuable quantitative benchmark in this evaluation.

In conclusion, organized crime is one of the last criminological areas where SNA methods have been applied. If Carrington has argued that "the use of social network analysis in criminology is in its infancy," this is even more relevant for the use in the study of organized criminal groups. In the last 10 years, important steps have been made. The progress are encouraging and it is likely that, through the trial and error which is one of the basic methods of science, SNA will play an important part in the study of organized crime in the next years.

Overview

This entry synthesizes the current state of network-related research on street gangs around the themes of network structure, network action, and network location. At their core, street gangs are social networks created by the coming together, socializing, and interacting of individuals in particular times and in particular places. The employment of social network analysis has the potential to examine patterns of interaction among gang members and gangs, illuminate structural variation across gangs, and measure the influence of gang networks on individual action. This entry includes an overview of social network analysis, suggestions and directions for future gang network research, a discussion of limitations, and a vision for how a social network approach to gangs might inform theory, research, and practice.

Introduction

Over the past decade, the field of criminology has increasingly employed both the theoretical and methodological tools of social network analysis (McGloin and Kirk 2010; Papachristos 2011). Although criminology lags behind other disciplines in this network turn, criminologists have applied social network analysis to investigate organized crime syndicates, narcotics trafficking, terrorist organizations, white-collar conspiracies, and adolescent delinquency. But perhaps one of the areas of criminological inquiry most in need of a network-related approach is the study of street gangs.

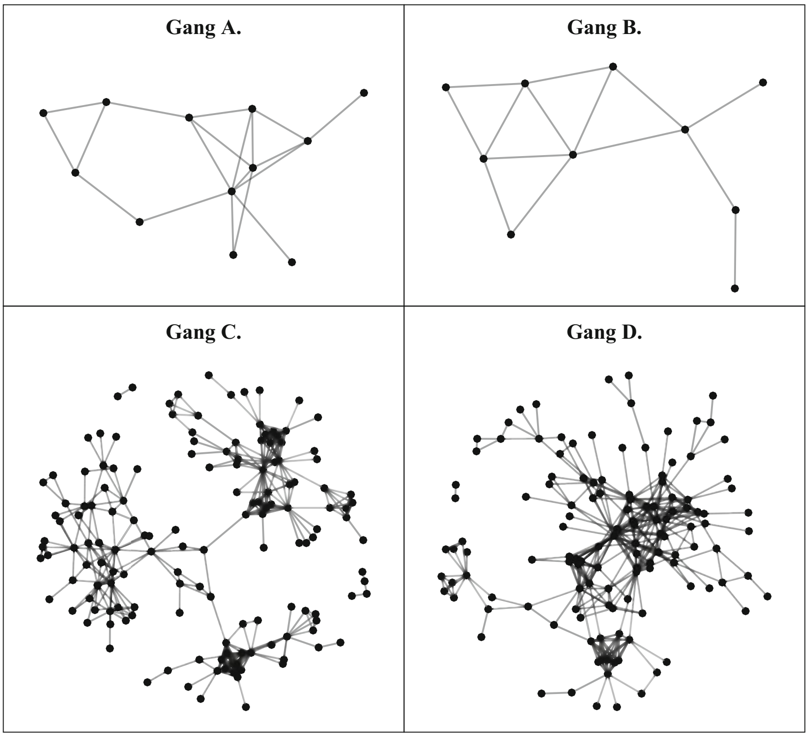
Street gangs are, if anything, social networks created by the coming together, socializing, and interacting of individuals in particular times and in particular places. Though scholars still heavily debate the definition of what constitutes a gang, virtually all gangs have some element of a group and it is this groupness that is at the heart of this entry. Street gangs are groups of individuals engaging in activities that are bolstered by group processes, culture, and structures. Social network analysis studies street gangs *empirically* to examine precise patterns of interaction among individuals and collectivities (see Papachristos 2006). *Theoretically* gangs operate as unique sociological entities with various structural and interactional manifestations. Research gathers, compares, and analyzes dozens of network properties at the individual, group, and system level, which brings fresh perspectives to old debates. Contemporary social network approaches have the potential to push past criminology's definitional bulwarks and typologies and reveal how real-life behavior of individuals and groups might inform theory, research, and practice.

This entry synthesizes the current state of network-related research on street gangs. Rather than simply plod forward in the standard literature review format of "this article says this" and "that article says that," the aim will be to review research in a way that provides a road map for future lines of inquiry. Specifically, the focus will be on measuring and theorizing street gangs from multiple levels of analysis in order to shed light on a broader range of empirical gang behaviors, structures, and processes. To wit, this entry is structured around three themes: (1) the structure of gang networks, (2) the actions of gang networks, and (3) the location of gang networks. In the following sections particular attention will be paid to the group nature of gangs as well as the locations and actions of individuals in gangs. This entry concludes with a brief discussion of the challenges to and limitations of social network analysis and gang research. To begin, the next section provides a brief discussion of social network analysis more generally and proposes its application to street gangs.

Social Network Analysis and Applications to Street Gangs

Social network analysis (SNA) refers to the study of social relationships among sets of actors and, more importantly, the analysis of how the patterns of relationships affect actors' behaviors (Wasserman and Faust 1994). Unlike traditional regression analyses in which effects are net of other variables (Emirbayer 1997), SNA assumes *interdependence* rather than *independence*. Indeed, it is such interdependence that is of analytic interest. Most network studies attempt to (a) analyze and describe the observed structure of relationships among a set of actors and/or (b) investigate how sets of relationships affect actors' behaviors, actions, opinions, and attitudes. Empirical research has demonstrated the importance of networks on a variety of phenomena such as getting a job, income attainment, political decision making, the diffusion of ideas, and even political revolutions.

Formally, social network analysis relies on graph theory: mathematical models that capture the pairwise relationships among a specific class of objects (Wasserman and Faust 1994). In graph theoretical terms, a network consists of a set of vertices (V) that represent a bounded set of actors or units and a set of edges (E) that define the relationship among the vertices. Relationships are commonly represented in a square matrix $X = x_{ij}$ where x_{ij} is the strength of relationship between unit i and unit j (Wasserman and Faust 1994). Edges can be binary indicating the presence of a relationship. Alternatively, edges can be valued measuring the intensity of a relationship, the



Social Network Analysis of Urban Street Gangs, Fig. 1 Four African American gang networks from Chicago's west side

level of interaction, or any other theoretically sound quantity of a relationship. Ties can also have direction, such that one node sends a tie and another receives it. Sociograms or graphs display networks visually in which nodes depict the vertices and lines depict the edges (see, e.g., Fig. 1).

Conceptually, gangs are clearly social networks. Gangs consist of actors who are tied to each other through group participation and identity, as well as neighborhood, familial, and peer relationships. Furthermore, gangs collectively act in particular moments and places, whether simply hanging out or engaging in gang warfare. Of particular interest for researchers is a gang's ability to activate ties in order to accomplish certain tasks and the ensuing consequences of those tasks. Figure 1 illustrates this point by mapping the network structures of four African American gangs in Chicago using police observational data. Each node represents a unique individual and each tie represents a non-arrest observation made by the police – sometimes called "field observations" or "field contacts" (see Papachristos et al. 2012a). Each tie is a police observation of two individuals hanging out on a street corner, which is perhaps one of the most fundamental gang activities. By aggregating such information over time and within multiple locations, a network structure emerges representing the patterns of direct and indirect associations among gang members as well as their non-gang companions.

All four of the gangs in Fig. 1 are from the west side of Chicago and are part of larger gang nations that date back to the 1960s. By virtually any survey or qualitative account, all four of these gangs should have the following: a hierarchical structure, formalized sets of rules and regulations, a division of labor, and intricate drug-dealing portfolios. Yet, the patterns of association shown in Fig. 1 reveal that some of the networks deviate from such accounts. Gangs A and B, for example, are smaller in size and less dense than gangs C and D. Moreover, the network structures of gangs A and B look more like ordinary friendship networks and are decidedly *not* hierarchical. In gang B, triangles of individuals overlap to make up the larger networks; this pattern suggests that the network is comprised of small cliques with overlapping membership as opposed to some formalized division of labor. In contrast, gangs C and D have a starburst type of structure with dense pockets of individuals linked together by one or two ties. These gangs are more centralized, a trait that is especially evident in gang C with a single individual joining three different parts of the graph.

The analysis of gang structures such as those in Fig. 1 can augment more traditional analyses of gangs by comparing structural traits of networks across time and space. A whole range of network measures and statistics – such as density, clustering, and degree distribution (Wasserman and Faust 1994) – can be compared and analyzed across samples of gangs to detect points of variation and similarity. Perhaps more importantly, SNA can examine the structural properties that distinguish a gang from other types of social groups.

A networked approach to gangs requires two related and nested units of analysis: (1) gangs as collectives and (2) gangs as a collection of individual gang members. The questions gang researchers ask rely on the unit of analysis. At the group level, researchers examine organizational structures, gang interactions within larger social spaces, and intragroup relations affecting larger social processes. Individual-level hypotheses center on relations between gang members and gang influence on individual behavior. Research agendas might include (1) how friendship networks within a gang mediate or facilitate violence, (2) the types of relationships from which gang leadership or influence derive, (3) patterns of social status and power among gang members, or (4) the ways in which gang members integrate into lager noncriminal networks (see Papachristos 2006). The remainder of this entry grapples with some of these hypotheses, which are organized around the themes of network structure, network action, and network location.

Network Structures of Street Gangs

Though not specified in formal network language, researchers' conceptualization of street gangs has relied on network concepts and ideas for decades. At the most basic level, gangs can be conceptualized as groups of delinquent individuals who socialize with each other. Rather than a random collection of strangers who happen to share social and geographic space, gangs have a collective identity, a culture, and sense of togetherness. As such, criminologists strive to understand group formation, cultural precepts, or collective processes. Prior research has provided tremendous insight into street gangs' culture, experiences, and understandings of their group, but has fared less well in explaining the structural variation and scope of street gangs. SNA, however, provides theoretical and methodological tools to evaluate gangs' organizational structure and participation in those structures.

Organizational Structure

Descriptions of the gangs as organizations range from informal friendships and associations (Fleisher 1999) to formalized corporate bureaucracies (Venkatesh and Levitt 2000). Multiple typologies have emerged attempting to classify gangs according to various organizational or group characteristics. For example, research has debated whether leadership and influence within a gang are vertical (bureaucratic) or horizontal (influence based) (Sanchez-Jankowski 1991). Other typologies differentiate gangs based on certain organizational characteristics such as membership size, meeting regularity, formalized rules and regulations, and gang activities (Bouchard and Spindler 2010; Pyrooz et al. 2012). Gangs are also frequently differentiated by the kinds of criminal behaviors in which they engage – i.e., violent gangs, income generating gangs, and delinquent gangs (Starbuck et al. 2001). Thus far, the majority of the research on gang structure has been largely descriptive and, therefore, limited from making topological comparisons.

SNA can advance this line of research by moving away from descriptive organizational characteristics to formal measures of group structures. This transition allows for testing organizational types, examining structural changes over time, as well as the ability to look at patterns of behavior, influence, and interaction. For example, network research on formal organizations suggests that informal relationships are often more significant in organizational behavior than formal hierarchical positions. Asking whether or not a gang has regular meetings overlooks the informal associations that may be at the heart of gang life. SNA has challenged conventional understandings of gang membership by showing how ties among individuals extend beyond the in-group and has also revealed more intricate relations within the larger gang structure (McGloin 2005). Frequently gang members are not friends, do not know one other, or have animosity toward one another. From a networked perspective, one builds the organizational structure from the ground up by tracing lines of influence and interaction among members.

A network approach to gangs has the potential to illuminate structural variation, model organizational changes over time, and examine organizational threat or stability. Figure 1, for example, presents structures representing actual lines of interaction among members, as opposed to a theoretical structure that may or may not fit the actual structure of the group. Formal analysis of networks sheds light on current typologies and develops new understandings of gang structures. One potential avenue of inquiry would compare the patterns of interaction within specified groups to group structures as reported by law enforcement or gang members. In many non-gang settings, often the informal networks of friendship have a stronger influence on behavior (see Haynie 2001). Another avenue of inquiry would compare structures at the group level in order to examine if particular network forms are more or less conducive to certain behaviors such as violence or drug dealing.

Structural Position

Not all gang members are alike. For decades, gang research has made important distinctions between the levels at which members participate in gang life and gang culture. Terms such as wannabes, hanger-ons, and associates typically refer to those individuals only causally involved in a gang, whereas terms such as hard core, down, or lifer are reserved for those more committed to gang life (Klein and Maxson 2006). Scholars often make the distinction between core and periphery gang members where the former refers to those who are active in the gang and the latter refers to members not central to the gang structure. The basic presupposition is that those who are more central to the gang structure are participating more fully in gang activities and those who are on the outskirts participate less.

Scholars also recognize the naïveté of such a core-periphery distinction. Gang participation is more amorphous than most typologies allow. Although popular media often depict gangs as secret societies with blood rituals and initiations, the reality is that gang membership is fluid (Fleisher 1999). Furthermore, membership is often unofficial; it is just as likely that membership is based on familial relations than a formal initiation. Some fully indoctrinated members may actually exert very little influence, while others who are not formal members may exert tremendous influence. Small cliques form within the group, which can at times divide the group into subdivisions, each with its own level of participation (Fleisher 1999; McGloin 2005; Papachristos 2006).

SNA can move research on gang participation forward by considering how positions within networks may or may not relate to levels of participation or vice versa. By empirically returning to basic gang networks (such as those in Fig. 1), analysts can use various network measures to find structural similarities or differences within and across groups. For example, one promising idea might be to analyze a sample of gang structures and test for structural equivalence in order to identify unique positions or roles in gangs. Another potential line of inquiry might locate sources of influence within gang structures – i.e., locating individuals, such as brokers or gatekeepers, who might be significant not because of formal titles or positions but because of their influence on member behavior.

Network Action of Street Gangs

Like other types of social groups, gangs can pursue collaborative goals, form alliances, and engage in collective action. Perhaps one of the most important areas of research on SNA and gangs investigates how gang network structures affect collective and individual action.

Gang Landscapes

SNA has the capacity to survey *gang landscapes*: the general patterns of relationships among a population or system of gangs (Kennedy et al. 1997). Social mapping of the collective relationships within a gang or across gangs offers insight into the organizational and territorial niches in which gangs exist. A gang landscape can map the alliances and rivalries between groups and individuals across a geographic space. Gang landscapes have the potential to situate specific gang activities and exchanges (such as violence and drug dealing) in the context of a total networked system. In other words a structural analysis illuminates gang actions and behaviors. For example, Descormiers and Morselli (2011) analyze how gang-level attributes (such as gang size, age of members, and ethnicity) and ecological factors (such as gang turf and underground economies) predict maps of gang alliances and conflicts in Montreal. In a slightly different approach, Papachristos (2009) maps the networks of violent exchanges between Chicago gangs over time and finds that prior relationships and the position of a gang in conflict networks are strong predictors of retaliation. This latter example demonstrates how patterns of the gang landscape provide insight into a social process of retaliation.

Group Processes

Gangs' group-level actions include protection, socializing members, and supplying resources. These behaviors imply a number of social processes that are negotiated within the gang. Prior research has revealed the potential mechanisms within gangs that contribute to their crime and delinquency – e.g., loyalty, status, and protection (e.g., Short and Strodtbeck 1963). Protection is of particular importance because survey research has consistently found that protection is one of the most commonly cited reasons for joining youth gangs (Klein and Maxson 2006). In the quest for mutual protection, gangs face a basic collective action problem: they must motivate members to actually come to each other's mutual aid in the face of a threat.

Network structures can facilitate or impede acts of mutual protection. In particular, the idea of *cohesion*, often measured as the density of ties within a network (Wasserman and Faust 1994), offers a fruitful direction for empirical analysis. A second approach to examining protection is by calculating the network density of gangs and correlating this with acts of violence – especially retaliation. For example, Papachristos (2009) found that gangs are more likely to reciprocate an act of violence when their actions are visible to other gangs. In other words, the collective processes involved in retaliation are more likely to occur when retaliation becomes a signal to other groups that a gang is capable of vengeance and protection. In addition to reinforcing the *esprit de corps* of the group, Papachristos (2009) finds such acts of retaliation can actually flame the spread of violence and create enduring networks of gang conflict that persist over time.

Research on gangs' group processes and the ensuing consequences has been virtually untouched. The launch pad for such inquiry should focus on how specific hypothesized processes might manifest themselves structurally or on how structures affect the hypothesized processes. Just as understanding the sociodemographic characteristics of neighborhoods allow one to understand how social processes ecologically unfold, understanding the networks of street gangs better unpacks the social context in which group processes unfold.

Group Influence on Individual Action

One of the fundamental questions in gang research is the extent to which gangs (as groups) actually facilitate individuals' delinquent or criminal behavior. This is in contrast to the selection effect perspective, which assumes like-minded and previously delinquent individuals come together to form a group (Bendixen et al. 2006; Thornberry et al. 2003). Mounting evidence from longitudinal studies supports a facilitation effect: individual delinquency is amplified in the gang context even when controlling for factors such as individual self-control, prior delinquency, and sociodemographic characteristics (Krohn et al. 2011; Thornberry et al. 2003). Individual delinquency, even among those with higher baseline delinquency, increases during periods of gang membership. However, what is still unclear is exactly how the gang facilitates crime and delinquency for the individual.

A growing body of network research shows that the structure of adolescent friendship networks is associated with self-reported delinquency, which can range from statutory crimes like underage drinking to more serious crimes like theft (Haynie 2001, 2002; McGloin 2009). In particular, this research finds considerable evidence for peer influence on delinquency: one's own delinquency is related to the attitudes, behaviors, and delinquency of one's peers. At the same time, only a handful of studies look at co-offending networks involved in serious crimes. Given the observed facilitation effect of gangs and the simple fact that gang associations appear more group-based than friendship networks, it is reasonable to hypothesize that the network effect of gangs on individual action should be larger than effects of friendship networks or co-offending networks. Furthermore, certain network configurations are more apt than others to facilitate imitation of behavior, to provide opportunities for deviance, and to exert stronger influence on its members. As such, we hypothesize that (a) the gang context amplifies group-level processes that foster delinquency and (b) gangs exhibit additional processes not found in delinquent peer groups.

Two recent studies by Papachristos and colleagues provide evidence for the group facilitation effect of gangs. In a study of gang members and their associates in Boston's Cape Verdean community, Papachristos et al. (2012a) examine a social network of more than 700 individuals, approximately 30 % of whom are gang members. Their study finds that individuals in the network are more likely to be gunshot victims when (a) they are gang members, (b) their immediate social network is saturated with gang members, and (c) their immediate social networks contain other gunshot victims. In other words, network exposure to gang members and gunshot victims increases one's own risk of being a victim. The second study surveys 150 active gun offenders in Chicago. Papachristos et al. (2012b) find that the network structure of individuals affects both their perceptions of the law and their subsequent law-violating behavior. In particular, individuals are more cynical of the law and subsequently more likely to engage in deviant behavior when their social networks are saturated with gang members. These two studies offer only a small glimpse into the ways network structure might influence individual actions and/or individual-level consequences. Future research should consider a wider range of group types (such as comparing gang members vs. non-gang members or members of other types of delinquent groups), different types of group processes (imitation, peer influence, and homophily), as well as various types of individual-level outcomes (beliefs, decisions, and behaviors).

Violence Prevention

From a social problem perspective, one of the most critical gang activities requiring attention is the incredibly high rate of lethal and nonlethal violence. A small but growing body of research has taken gang landscape mapping quite seriously as both a means of gang violence prevention and a research area. As part of a crime reduction initiative, Kennedy et al. (1997) mapped out gang rivalries and alliances in Boston. Violence intervention and prevention efforts relied on these network maps to direct attention toward gangs that were actively involved in shootings and target resources scarce to those gangs. This targeted group-based intervention strategy (of which gang network mapping was a key part) produced significant reductions in youth homicide and nonfatal shootings (Braga et al. 2001). Similar approaches evaluate the efficacy of group-based and outreach worker strategies in other US cities (Skogan et al. 2009; Tita et al. 2003).

Network Locations of Street Gangs

Gangs are decidedly local phenomena with strong connections to the character and culture of urban neighborhoods. In fact, part of sociology's continued fascination with gangs stems from their relationship to neighborhood social organization. Gangs are seen as de facto social institutions or collectivities that meet the basic needs of community and youth in otherwise disadvantaged communities. More than that, however, the neighborhood becomes a defining element of gang identity and group membership (Garot 2007; Grannis 2009). This association is so strong that many gang names incorporate their neighborhood of origins: the 35th Street Kings, Columbia Point Dogs, Westville Saints, and so on. Indeed, often the simple question "Where you from?" is a shorthand way for identifying gang members (Garot 2007). In a way, the gang itself becomes a reflection of many of the conflicts, cultures, and idiosyncrasies of the larger neighborhood.

Prior research has shown that space matters in shaping gang behaviors in at least two ways. First, and foremost, gang violence is commonly associated with the defense of gang turf or territory. Given the aforementioned attachment of gangs to urban space, threats to turf are considered threats to home, members' safety, and the identity of the group. Violence stemming from the protection of turf becomes as much a symbolic measure signaling the solidarity and reputation of the gang and community as well as an instrumental gesture in protecting a piece of land over which a gang claims ownership. Secondly and perhaps related to such matters, previous research also suggests that gang violence is spatially contagious; gang violence in a given neighborhood affects levels of violence in adjacent neighborhoods. In a sense, the group and dynamic nature of gang violence spills over into adjacent communities. Though such spatial effects are associated with crime and violence more generally, a recent study of gangs in Los Angeles suggests that the spatial effects of gang violence extend beyond immediately adjacent geographic areas to affect more geographically distant neighborhoods (Tita and Radil 2011; Tita et al. 2003).

To date, with few exceptions, such spatial analyses of gangs rely mainly on regression models of aggregate crime measures – i.e., the extent to which crime rates in a focal neighborhood are associated with rates in surrounding communities. Yet, crime rates themselves do not move across gang turf or other geopolitical boundaries: gangs and gang members do. Nearly all empirical studies on the spatial nature of crime theoretically acknowledge that the social networks of criminal activity – such as drug dealing, prostitution, and gangs – drive the observed contagion of crime across neighborhood boundaries (e.g., Cohen and Tita 1999; Morenoff et al. 2001). Yet only a handful of studies actually incorporate social networks and geographic space into the same analysis, and even fewer studies have applied both to the study of gangs.

The inherent networked nature of gangs and their strong links to urban space propose an excellent area of study for understanding the convergence of social and geographic space. This line of inquiry would be relevant not only to gang research but also to social science more broadly. In fact a recent issue of *Social Networks* (Adams et al. 2012) was dedicated entirely to the convergence between spatial and network thinking. Statistical models of geographic and network autocorrelation share many similarities and, in their most basic principles, have a similar functional form. The gang, both theoretically and empirically, affords an important instance in which to understand the convergence of both geographic and social space. For example, combining social networks of gang relationships with geographic models of diffusion could shed light on whether the clustering of gang violence in particular neighborhoods is related to ecological conditions, group processes (such as reciprocity), or some combination therein. Likewise, analyses such as these might advance our understanding of whether institutional memory captured in social networks might trump geographic barriers. Alternatively, spatial network research could also provide valuable insight into the ways that group processes and geography may impede or promote behavior – the relevance of such findings extends well beyond the world of the street gang.

Concluding Remarks

To review, SNA affords many unique opportunities to consider the group nature of contemporary street gangs. By considering gangs as networks of individuals or by mapping systems of gangs, researchers can more accurately measure structures and processes that make the gang a unique sociological entity. This entry has outlined some promising avenues for inquiry and, no doubt, many more exist. In advancing this network agenda for gang research, researchers should keep two things in mind. First, at the core of gang research is the inherent "groupness" of the gang. The application of SNA to gang research should proceed in a way that exploits new methodologies and data to understand this aspect of the gang. Second, the potential influence between SNA and gang research is bidirectional. This means that the application of SNA to gangs should not simply be a "cut-and-paste" of existing methodologies and ideas. Rather, the diligent application of SNA to gang research should provide insight into a range of small group behavior relevant to social science more generally.

Though enthusiastic about the direction of SNA and gang research, this entry recognizes that the methodology is not without challenges or limitations, two of which are mentioned here. First and foremost, boundary specification issues haunt all SNA research (Laumann et al. 1989) and pose even greater limitations for theoretical and empirical considerations of gangs. Boundary specification refers to the problem in SNA of identifying where the network begins and where it ends. Boundary specification can be driven by data considerations (who is in a dataset) or by theoretical considerations (who is part of the group). As discussed above, SNA research on gangs has already demonstrated that boundaries of gangs – defined by gang membership – are rather amorphous (Fleisher 1999; McGloin 2005). This suggests that finding the "true" group may prove elusive. More precisely, the shape of the network will be contingent upon where analysts draw the boundary of the group – whether, for instance, to include only "gang members" or to also include their associates. Figure 1, for instance, stopped at 2° of separation from known gang members (i.e., those individuals who were friends of friends of known gang members). In short, SNA provides a new way to discuss group membership and structure, but ultimately boundary specification becomes immensely important for theory and empirical research.

Second, future research should explore the limits of existing data as well as consider how to improve future data collection efforts. SNA requires relational data: a data source that contains some reference to the relationship among units. In some instances, this means revisiting old data sources with a new theoretical lens. For example, the study of co-offending networks (Schaefer 2012) and the study of gang homicide networks (Papachristos 2009) relied on official police data common in criminological research. But it required these authors to understand a relational aspect of the data not previously considered: how events link individuals and groups. The network literature refers to this as two-mode data (see Wasserman and Faust 1994). Similarly, ethnographic data often provides extremely rich information on the social relationships of its subjects. Fleisher (1999), for example, coded his field notes for specific instances of social ties to help uncover the patterns of the group – a time-tested anthropological technique for understanding group membership. Papachristos (2006) has even gone back and coded published ethnographies to a similar end. Moving forward, gang researchers should include network-related questions in future survey collection efforts. Indeed, much of the growth of SNA in criminology can be attributed to the network focus of a handful of surveys of school youth. Subsequent surveys of gang members or law enforcement could advance this area of research considerably by adding even a single network question to their survey instruments.

Spatial Models and Network Analysis

Steven M. Radil
Department of Geography, Ball State University,
Muncie, IN, USA

Overview

Several issues in criminology have led to the widespread use of spatial econometric statistical models. This entry outlines the principles and concepts behind the use of spatial models in criminology, including a description of the most commonly used models in spatial criminology. Next is a discussion of a critical but often overlooked element of spatial model specification, the construction of the spatial weights matrix, which should be theory dependent. The entry concludes with a discussion of the limitations of distance- or proximity-based approaches to constructing the spatial weights matrix, including the use of social network analysis to overcome these limitations.

Foundations of Spatial Modeling in Criminology

The recognition of geography as a factor in the explanation of a multitude of social phenomena has been an increasingly notable component of quantitative criminology. Research concerned with basic and applied questions pertaining to crime, criminal justice, and policy now typically incorporate geographic or spatial elements into analyses that utilize quantitative methodologies. An important reason for the adoption of spatial perspectives for quantitative criminology has been a growing recognition of the importance of context to human action. Incorporating context into quantitative models of human behavior is an ongoing focus of the subfield of spatial criminology.

The analysis of spatial phenomena in criminology has been made possible in recent years by the ongoing development of statistical techniques that attempt to deal with some of the unique problems of spatial data, especially spatial dependence. Dependence, or the tendency of characteristics of a given location to correlate with those of nearby locations, is a foundational issue in quantitative geographical analysis (e.g., Anselin 1988). When present in spatially organized data, spatial dependence can result in the spatial autocorrelation of regression residuals, which simply means that the values of variables sampled at nearby locations are not independent from each other (such values may be either positively or negatively correlated). The presence of spatial autocorrelation may lead to biased and inconsistent regression model parameter estimates and increase the risk of a type I error (falsely rejecting the null hypothesis). Accordingly, a critical step in statistical model specification when using spatial data is to assess the presence of spatial autocorrelation.

The statistical models developed to deal with spatial dependence, commonly called spatial econometric models, are now increasingly of interest to researchers from diverse disciplines investigating a wide range of issues, including crime and criminal justice. Many criminologists utilizing quantitative techniques now view spatial econometric regression models as an improvement non-spatial techniques as a result of the growing recognition that dependencies in the spatial structure of research data limit the reliability of inferences from conventional regression models (Anselin 1988). While there are now a variety of methods to address spatially auto correlated data in regression models, the standard workhorse in spatial regression is what are commonly referred to as simultaneous autoregressive (SAR) models.

SAR models can take three different basic forms (see Anselin 1988, 2002). The first SAR model assumes that the autoregressive process occurs only in the dependent, or response, variable. This is called the "spatial lag" model, and it introduces an additional covariate to the standard terms for the independent or predictor variables and the errors used in an ordinary least squares (OLS) regression (the additional variable is referred to as a "spatial lag" variable which is a weighted average of values for the dependent variable in areas defined as "neighbors"). Drawing on the form of the familiar OLS regression model and following Anselin (1988), the spatial lag model may be presented as

$$Y = pWy + X\beta + \varepsilon,$$

where Y is the dependent variable of interest, ρ is the auto regression parameter, W is the spatial weights matrix, X is the independent variable, and ε is the error term.

The second SAR model assumes that the autoregressive process occurs only in the error term. In this case, the usual OLS regression model is complemented by representing the spatial structure in the spatially dependent error term. The error model may be presented as

$$Y = X\beta + \varepsilon,\ \varepsilon = \lambda W\varepsilon + \mu,$$

where λ is the auto regression parameter and ε is the error term composed of a spatially auto correlated component ($W\,\varepsilon$) and a stochastic component (μ) with the rest as in the spatial lag model.

The third SAR model can contain both a spatial lag term for the response variable and a spatial error term, but is not commonly used. Other SAR model possibilities include lagging predictor variables instead of response variables. In this case, another term must also appear in the model for the auto regression parameters (γ) of the spatially lagged predictors (WX). This model takes the form

$$Y = X\beta + WX\lambda + \varepsilon.$$

Combining the response lag and predictor lag terms in a single model is also possible (sometimes referred to as a "mixed" model).

As Anselin (1988) observes, spatial dependence has much to do with notions of relative location between units in potentially different kinds of space, such as a conceptual social space. Accordingly, SAR models share a number of common features with network autocorrelation models. Substantively, spatial and network approaches have been used to explore similar questions pertaining to influence and contagion effects, albeit among different units of observations (see Marsden and Friedkin 1993 for examples). In such cases proximity or connectedness is assumed to facilitate the direct flow of information or influence across units. Individuals or organizations are also more likely to be influenced by the actions, behaviors, or beliefs of others that are proximate on different dimensions, including geographical and social space.

The Spatial Weights Matrix (W)

Spatial econometric regression models demand a careful consideration of both the theoretical and empirical spatial structure of the data in question (e.g., Florax and Rey 1995). However, the advent of new spatial econometric software packages has lowered the traditional technical barriers to the use of these techniques while simultaneously making it easy for users to choose among a few predefined spatial structures. New users may therefore be unfamiliar with the importance of the formal spatial structure to analytic outcomes and less likely to carefully consider their choice (Leenders 2002). The small literature new users may draw upon to understand this issue remains quite technical in nature, even when proclaiming the opposite intent (e.g., Griffith 1996). Taken as a whole, this state of affairs is less than ideal and unlikely to encourage careful thinking about space. However, the need to formalize the empirical spatial structure of the data for modeling is also an opportunity to reflect on the theoretical interaction of the geography and social processes being studied. In this manner, spatial analyses of human behavior and outcomes are at the core of an emerging "spatially integrated social science" identified by Goodchild et al. (2000), and an opening for the investigation of how human behavior and space is mutually constituted.

As typically argued in many geographic literatures and increasingly in quantitative criminology, spatial perspectives are important for both theoretical and practical reasons. Theoretically, spatial perspectives are of interest because of the long-standing interest in the social production of space in geography. Following Lefebvre's (1991) understanding of space as both social process and social product, the spatial structures of a given phenomenon are commonly investigated as underlying cause, constructed outcome, or both. For example, the perception of rivalries over territorial control between a set of gangs and the actual construction of bounded turf are simultaneously a social and a geographic phenomenon. The competitions are inseparable from the geography and vice versa. Hence modeling a social process such as gang rivalry requires a consideration of the modeling the social construction of space (Radil et al. 2010).

On the other hand, consideration of geography is a practical methodological matter. Data with a geographical component has important implications for statistical analyses; if processes that are affected by the underlying spatial structure in a study area are not accounted for, inferences will be inaccurate and estimates of the effects of independent variables may be biased (Anselin 1988). Perhaps the most important reason for the interest in quantitative spatial methods is the most straightforward: nearly all social science data is spatially organized, and ignoring this structural element is increasingly seen as untenable. To accommodate these issues, statistical models have been developed that attempt to deal with issues of spatial dependence. Conventionally, this is done through either introducing an additional covariate (the "spatial lag" variable discussed in the previous section) or by specifying a spatial stochastic process for the error term.

These models, now seen as both viable and important for social science research, have been discussed and exemplified in depth (see Anselin 2002 for an overview), but an essential element of these models remains largely ignored in the literature, despite the major theoretical and methodological implications. Both the lag and error models attempt to estimate regression parameters in the presence of presumably interdependent variables (Anselin 1988; Leenders 2002). This estimation process requires the analyst to define the form and limits of the interdependence and formalize the influence one location has on another. In practice, this is accomplished by identifying the connectivity between the units of the study area through a $n \times n$ matrix. The matrix is usually described in the literature as a "spatial weight" or "spatial connectivity" matrix and referred to in the preceding SAR models as "*W*."

This *W*, or matrix of locations, formalizes a priori assumptions about potential interactions between different locations, defining some locations as influential upon a given location and ruling others out. A simpler way of describing this is that *W* identifies, in some cases, who is a neighbor and who is not or with whom an actor interacts. However, the construction of *W* is more than just an empirical choice about neighbors. It is a theoretical decision regarding the spatiality of the social processes being discussed and one that has implications for the statistical estimates generated.

As *W* is supposed to represent a formal model of connections between geographic locations, how one translates theories about influence and its mechanisms across space into a formal mathematical construct is an important step. Put another way, at its core, *W* is really a theoretical geography of interaction. However, as a practical matter, the spatial analytic geography literature focuses on modeling interaction through a distance-based logic that typically takes one of two forms: contiguity or distance (Cliff and Ord 1981; Griffith 1996). Both of these spatial themes have been mobilized for constructing *W*s for various kinds of measures of spatial autocorrelation dating back to Cliff and Ord's seminal work (1981). Contiguity, or the physical connections between locations, is emphasized in issues that focus on areal spaces, especially ecological studies that use aggregated data and attempt to evaluate the relationships between neighborhood composition and crime outcomes. Distance between locations of interest also remains an important concept for criminology, in particular for journey-to-crime research.

Theorizing *W* with Social Network Analysis

Whether contiguity- or distance-based, the geography of influence is typically imagined and implemented in SAR models as a kind of gradient that uniformly diminishes with increasing distance, also known as the concept of distance decay (see Stephenson 1980). Classic examples of distance-decay thinking in social science are Boulding's (1962) "loss of strength gradient" which argued that military power has a direct inverse relationship with distance and Tobler's (1970) so-called "first law" of geography which states that everything is related to everything else, but near things are more related than are far things.

At a basic level, distance decay is the foundational concept behind the implementation of *W* in most spatial economic models, and the development and dissemination of spatial analytic software allow users to easily create *W*s from spatially organized data using the classic spatial forms of areal contiguity or point-to-point distance. While such software often guides researchers through the practical steps needed to create a matrix of spatial interaction or influence grounded in distance decay, there is no drop-down menu to offer guidance as to how best to capture the specific geography, or spatiality, of the social processes being analyzed. For any given research topic, are immediately contiguous areal neighbors enough, or should more distant neighbors also be included? If distance matters, at what distance does influence begin to diminish? Does influence diminish over distance in the same way for all social actors or behaviors? More to the point, why and in what way does distance "matter" in the operation of the social process under investigation? Addressing these sorts of questions remains the key challenges for a theoretically informed spatial analysis in criminology.

Somewhat surprisingly, theoretical discussions about the nature of *W* and practical discussions of how different specification choices may affect regression results have also been underemphasized in most spatial analytic literature. Despite these noteworthy efforts, Leenders (2002: 44) is correct in his assessment that "the effort devoted by researchers to the appropriate choice of *W* pales in comparison to the efforts devoted to the development of statistical and mathematical procedures." The net effect of this lack of attention is that theoretical conceptions about the role space plays in producing empirical patterns in a given dataset are often afterthoughts and little effort is given to understanding how sensitive model results may be to different specifications of *W*. Hence, the vision of a "spatially integrated social science" (Goodchild et al. 2000) remains unfulfilled, because when space is included in the analysis of social processes, it is often added in a default form without consideration of the geographic expression of the processes in question.

Criminologists have begun to explore such questions, often turning explicitly to the concept of social networks and the associated field of social network analysis. For example, social networks within neighborhoods are often implicated as being important mechanisms in the production and maintenance of safe, low-crime neighborhoods (e.g., Sampson et al. 1997). Such approaches argue that individual-level social bonds among local residents facilitate the formation of informal social control and the creation of shared goals and trust that regulate and censure local activities. A general acceptance of the importance of networks of local social relationships for understanding rates and patterns of neighborhood crime has prompted researchers to look into the kinds of social networks operating in communities in an effort to gather information regarding social ties among local residents as well as peer associations with delinquent others.

Beyond examining the degree to which individual-level ties influence crime patterns within a community, researchers are also beginning to explore the importance of institutional or organizational ties that can bridge communities. Sampson (2004: 158) argues for reconceptualizing neighborhoods "as nodes in a larger network of spatial relations" in order to account for the various ties that can link residents across space. Although Sampson (2004) does not specifically suggest what kinds of local institutions or organizations one should consider as important to explaining crime, in general terms he refutes the notion that neighborhoods are analytically independent and argues that ecological models of crime need to consider the different ways in which the observable outcomes in one neighborhood are partly the product of social actions and activities that can stretch beyond local communities (Morenoff et al. 2001; Sampson 2004).

Drawing on such arguments about the importance of both localized and no localized social networks, an emerging framework in quantitative criminology argues for a "deductive approach" to incorporating space built on the understanding that social networks are inherently geographic, existing both within and across localities and connecting communities separated by distance (e.g., Radil et al. 2010; Tita and Radil 2010). This analytic framework allows influence to take place not just between geographically proximate neighbors (as with conventional distance-decay-based spatial regression models) but also between locations that are connected directly by social networks. By carefully considering and allowing for processes that extend beyond (or perhaps preclude) spatially adjacent areas, one can ensure that the spatial weights matrix adequately captures the realities of the mechanisms of influence. Just as Morenoff (2003: 997) argues that spatial analysis "expands the neighborhood-effects paradigm by considering not only the local neighborhood but also the wider spatial context within which that neighborhood is embedded," a careful consideration of the spatial dimensions of social influence is under way as part of an attempt to facilitate the inclusion of the "wider *social* context of neighborhoods" into quantitative models of crime.

An early example of this emerging framework was found in the work of Mears and Bhati (2006), which links adjacent as well as nonadjacent areas to one another if the residents are economically and demographically similar by constructing *W* based on "similarity" that links socially similar areas together regardless of spatial proximity. Most recently, this framework has been advanced by research into the importance of both social and spatial linkages among gangs embedded within various types of local networks (Tita and Greenbaum 2009; Radil et al. 2010; Tita and Radil 2010). Rather than inferring connections through social similarity, the framework first demonstrated by Tita and Greenbaum (2009) accounts for influence by simultaneously considering linkages through geographic proximity between neighborhoods as well as through specific social ties that connect places. This approach carefully identifies direct social connections between neighborhoods based on rivalries between urban street gangs that are not geographically proximate, while also preserving the underlying spatial structure of the entire study area. Tita and Radil (2010) examined the utility of such an approach by comparing spatial regression model outcomes of gang violence using three differently constructed *W*s based on geographic adjacency, social connectivity, and a blend of both. Tita and Radil (2010) argued that violence committed by, and against, gang members in a socially and geographically distinct area of Los Angeles is largely a function of a *social* process that spans the local geography in such a way that violence in noncontiguous areas impacts levels of violence in a focal neighborhood and that blended *W* that incorporated both distance-based spatial effects and connections formed by specific social relations across neighborhoods offered the most meaningful results to the explanation of gang violence, both theoretically and statistically.

These studies reflect a growing interest and recognition in quantitative criminology of the need to not simply incorporate space and spatial effects in the study of crime but to do so in a way that moves beyond the uncritical notions of uniform distance decay that underpin SAR models. Specifications of the spatial weights matrix, or *W*, that rely solely on spatial contiguity or distance to define the spatial reach of the various social processes posited to be responsible for clustering force researchers to assume that all such processes decay rapidly and uniformly over geographic distance and therefore matter only among spatially adjacent neighbors. Furthermore, even when multiple social processes are considered, the conventional modeling approach has been to specify a single *W* rather than specify different kinds of connections between places for different social processes. In addition to making it impossible to parse the impact of one process from that of another, this is an a theoretical approach to understanding why and how space matters (Leenders 2002). By carefully considering the socio-spatial dimensions of the criminal phenomena of interest and of the actors behind them, the work of Mears and Bhati (2006) and (Tita and Radil 2010) demonstrate new possibilities by creating *W*s that explicitly capture the social and geographic dimensions of spatial influence through incorporating social networks. Further, such approaches allow theories of spatial influence to guide the construction of *W*, a meaningful advance given Leenders' (2002) concern with the lack of careful consideration of the underlying social processes of influence exhibited by researchers in their construction of weights matrices.

This is not to say that all the challenges of incorporating space into studies of crime have been met. For example, the developing arguments about the importance of microscale units of analysis in criminology (Hipp 2007) complicate the need to model interaction as the likelihood for spillover or other unmeasurable spatial effects increases as the areal scale of the unit of analysis decreases. Additional challenges include the need to incorporate dynamism and change over time in social networks and space and the need to consider overlapping networks (Ettlinger 2003) or multiple spatialities (Leitner et al. 2008) when theorizing the interactions between people and space. Nonetheless, the value of theoretically grounded notions of the geographic complexities of the mechanisms of influence in terms of positing various theories and mechanisms responsible for observable patterns of crime cannot be overstated. The current efforts underway in quantitative criminology have demonstrated the value of employing such an approach which should encourage future research into how social networks are involved in the social production of space and how the methods of social network analysis may be further utilized to understand if and how the structure of social networks have implications for material geographies of crime.

Spatial Perspectives on Illegal Drug Markets

Overview

Illegal drug markets have been the subject of considerable research in environmental criminology. Two main types of study have been conducted: evaluations of law enforcement strategies designed to police illegal drug markets and empirical studies which focus on the social and environmental context of places where drug distribution and consumption tends to occur. By addressing the dynamic relationship between drug trading, market procedures, environment, and police interventions, both approaches share the common aim of informing more effective crime prediction and control strategies. Since the main purposes of illicit drug markets are to both provide and secure the supply chain of illicit commodities, understanding *how* and *where* buyers and dealers position themselves to engage into transactions is critical to crime prevention.

This entry addresses what is normally the last and lowest stage in the illegal drug supply chain – the drug market. Here, the term *drug market* refers to urban location(s) where illicit commodities are illegally traded. This entry considers the extent to which illicit drug markets depend on the specific geography of places and on their amenities. The discussion will highlight how the areas surrounding these places affect their suitability as drug markets and what makes them attractive from an economic perspective. One proposition that will be discussed is that since the demand for drugs displays a nonrandom spatial pattern across the urban environment, crime prevention strategies might usefully focus on targeting and altering specific locations that are conducive to drug crime, rather than or as well as, focusing on particular individuals or groups of people.

This entry is organized as follows: first, the theoretical context and a dilemma regarding the location of drug markets will be discussed. Next, a marketing perspective will be discussed that has been proposed to explain the reasoning behind locational choices. The subsequent sections will explore the relational links between drug markets, drug-related crimes, and law enforcement actions. And, finally, further questions and potential research areas will be highlighted.

Theoretical Rationale

An urban-dweller’s routine consists of a number of activities distributed across the town or city, and the practice of committing crime is no exception. Environmental criminology identifies three factors which influence the probability of a crime event occurring: the “when,” the “where,” and the “how” (Brantingham and Brantingham 1995). The “where” refers to the spatial location of a crime. Researchers suggest (Cohen and Felson 1979) that patterns of criminal activity are influenced by both the physical environment and a criminal’s perception of what constitutes a good or bad opportunity for committing crime. Furthermore, it is proposed (Brantingham and Brantingham 1984; Cohen and Felson 1979) that the way in which a criminal moves around during their daily routine provides them with the knowledge about their surrounding environment and the opportunities it offers for criminal activity. Therefore, according to this perspective, crimes should be more highly concentrated within criminals’ awareness spaces, and these are likely to be defined by the constellation of places they move around within their noncriminal daily routines (Cohen and Felson 1979; Brantingham and Brantingham 1984).

This rationale has been applied by scholars (Eck 1995; Rengert et al. 2005) to try to explain how both drug buyers and dealers identify places that are potentially suitable for transactions of the kind they involve themselves in. Moreover, it is proposed that rational decision making on the part of both participants – buyer and dealer – in the transaction influences the geographical distribution of drug dealing locations (Eck 1995). Depending on the method of transaction, drug markets can be very large and dispersed, or small and more concentrated (Eck 1995). Scholars (Rengert et al. 2005; McCord and Ratcliffe 2007) have identified that profitable drug markets are often situated in or near socially disorganized neighborhoods, where there is a lack of social resistance to the market’s existence and from which there may be a ready supply of people willing to purchase drugs. However, the rationale for choosing these neighborhoods remains disputed: it is still unknown whether the locations are chosen initially due to their accessibility to a large number of drug users and their presence undermines the neighborhoods’ social organization (Eck 1994) or whether the initial lack of social resistance provides optimal grounds for establishing drug markets (McCord and Ratcliffe 2007).

Additionally, it has been noticed that the success of trading locations is associated with types of land uses that are conducive to, or generate, other types of crime. For example, drug dealing is likely to happen close to facilities which inherently and routinely generate a large flow of people. These are mainly open public spaces, retail, entertainment facilities, and transport interchanges that are associated with low levels of adequate guardianship or place management (Eck and Wartell 1996). In their analysis, Rengert and colleagues defined two types of built environment facilities that may be associated with the locations of drug markets. First, there are those which indirectly increase the profits from drug sales, because they facilitate nonresidents' access to an area. An example of this would be transport interchanges, which provide easy access to the drug markets (Brantingham and Brantingham 1995). Second, there are those which generate opportunities for drug transactions because they are used routinely by potential drug buyers, for example, areas near to homeless shelters or pawnshops, where potential buyers can readily convert stolen goods to cash (Anderson 1999).

The Main Dilemma

In the same way that legitimate businesses do not select their location at random, drug market placement may reflect rational decision making (Eck 1995; Rengert et al. 2005): the main aim of both activities is to attract customers and supply products to them in order to make a profit. From a strategic perspective, when deciding where to locate their stores, retailers focus on finding an accessible spatial location which will attract many potential customers. However, their locational choices are also constrained by different planning regulations and environmental impact assessments, which are required by authorities to allow the placement of the shop.

Rengert (1996) suggests that drug dealers may follow a similar logic and try to identify potential profitable sites. As Rengert states, "the quality of the sale's location is directly related to the quantity of profit for the illegal drug sales" (Rengert 1996). However, in contrast to legitimate trading, in the case of illegal markets, offenders have an additional goal: staying safe and unnoticed so as to avoid arrest (Reuter and MacCoun 1993). Thus, drug dealing locational choices are also constrained by the presence of legitimate and capable guardians who discourage criminal opportunities (Eck 1994). These include security guards, home and shop owners, and generally people who manage such places. In their study of drug and disorder problems, Mazerolle et al. (1998) found that at the level of street blocks, the place managers who engaged in crime prevention activities played an important role in guarding places from drug problems. Moreover, they found that place managers who engage their neighbors from the same street block in crime prevention efforts are more effective than individual efforts.

Eck (1995) has termed this specific aspect of drug markets the accessibility vs. security dilemma: "how to exchange illicit goods or service when the exchange process is very risky" (p. 71). Illicit drug markets typically face the conflict between needing to be accessible to many customers, including complete strangers, and avoiding the vulnerabilities associated with drug sales. Due to the illicit nature of the market, both customers and dealers are usually in a vulnerable position, since they run the risk of both legal intervention and being cheated or robbed by their counterpart during the course of a transaction. Of course, there is no means of securing the transaction through law enforcement or of resolving such conflict of interests through legal channels (Reuter and MacCoun 1993). Thus, violence is a very common means of regulating and resolving disagreements (Goldstein 1985), especially in street-based sales, where exchanges take place outdoors, often between anonymous participants. Both buyers and dealers will thus be motivated to limit their accessibility so as to reduce risk, seeking locations that they personally consider to be safest. Such places may be enclosed and familiar locations. For example, indoor sales may be made from fixed locations such as drug houses or deliveries made to indoor locations specified by the customers (Curtis and Wendel; 2000). However, in both of these scenarios, one of the participants will always be at a greater risk than the other, since they will not be familiar with the location. In some cases, unfamiliarity may lead to them avoiding a location altogether.

Eck proposes two models of drug markets which can overcome the access-security dilemma, given the constant risk of police presence. The first is the *social network-based transactions model*, in which security is provided through a network of trusted people. The second is the *routine activity model*, in which both participants use their legitimate daily activities to search for places which are potentially appropriate for engaging in drug deals. In the first model, there is no attachment to a specific location: through a social network both parties can arrange a mutually accessible location, potentially based on their routine. This type of market tends to be closed in nature, and the market itself may be dispersed over a large geographical area, leading to a low spatial concentration of drug dealing incidents (Eck 1995). Although a network-based exchange offers security, it also limits the number of participants in the transaction, which in turn reduces the potential for profit.

The second model proposed assumes that the spatial-temporal patterns of both participants' legitimate daily activities determine where their drug transactions occur. These markets tend to be spatially clustered and to focus on locations which are familiar to both participants, thereby reducing their perception of potential risks. These markets also need specific operating conditions: when surrounded, for instance, by a large number of legitimate activities and a constant flow of foot traffic, it is easier to blend into the crowd and search for potential customers. This type of market is often an open street market with a high frequency of transactions between anonymous participants. The market permits equal access to all participants and is located near places with mixed land uses and a high concentration of activities, such as shopping centers, high streets, and transport interchanges. Eck proposes that place managers from the legitimate sphere who control and manage these locations have a particularly important role in impeding this type of market.

It should be noted that not all locations which are next to shopping malls or transport facilities, for example, will form drug markets. According to this model, places which are more likely to have drug markets will be attractive from a retail perspective, offering a balance between the spatial distribution of those who demand the product and the distance they would be required to travel to the market. This concept will be discussed further in the following section.

State of the Art: Locational Choices and Spatial Economics

As with many crime types, open drug markets tend to concentrate geospatially: from all the available urban locations, there are very few which are well suited to illegal drug trading. Weisburd et al. (2004) found that a small number of street junctions in Jersey City (4.4 %) accounted for almost half of the drug sales arrests in the city. This demonstrates considerable spatial concentration of markets. According to Kleiman (1991 cited in Taniguchi et al. 2009) the reason for spatial clustering is that a large number of dealers operate in a single location, gaining security from arrest by spreading the risk of apprehension across all dealers. The same logic applies to customers who would prefer to be in a crowd than alone.

Rengert et al. (2005) propose that the exact location of open drug markets is likely to depend on the convergence of conditions that are most suitable for both participants involved in transactions and spatial patterns in demand. They suggest the model of "agglomeration economics" operates, as is the case with legal trade. That is, after a location becomes known as a site for specific goods, more customers will visit the area in the search of that good. At a certain point, the number of buyers that visit the area will be sufficient to support further suppliers of the product(s) and so more retailers locate there. In Wilmington, USA, researchers discovered that the likelihood of large drug markets being located near to each other is quite high. They say "there are best places to sell illegal drugs because these are places where demand is focused spatially" (Rengert 1996). That is, in order to stay profitable, a drug market's location should be attractive enough to a sufficient number of drug users. The attractiveness of the place is partially determined by the surrounding facilities, but above all by how far a buyer is prepared to travel to make a purchase (Pettiway 1995).

In legal trading, markets for goods which are highly valuable but purchased infrequently are usually found in very accessible urban locations, which may attract many potential customers from remote locations. In contrast, local markets tend to supply items, which consumers will wish to purchase frequently but will be prepared to travel only short distances to get them. In their study, Rengert and colleagues (et al. 2005) discuss concepts from the economics literature – *threshold population* and *range* – to frame a discussion on how the demand for drugs and the distance required to reach a market likely affect the location and stability of drug markets. Threshold is defined as a minimum number of customers required for a market to stay profitable. The concept of range concerns the distance that a buyer is prepared to travel to purchase a good. Pettiway (1995) suggests that the spatial range of a market that caters for vehicular movement will be larger than one that caters for pedestrian movement. Simply put, if the demand for a drug market is situated within the physical catchment area (an area to which they do or will travel) of many potential drug buyers, that market will remain stable or may even grow.

According to this rationale, dealers will try to establish markets at locations that reduce the total distance that customers will have to travel to reach them. In order to determine the demand for drug markets, US researchers have used methods of sociodemographic profiling to identify those types of neighborhoods with the characteristics that are associated with increased risk of drug use. They propose that if a drug dealer wants to sell drugs to a local community, he must first identify possible users. If the local demand is not enough to sustain a drug market, the dealer must consider factors that would attract potential customers into the neighborhood. For example, the market should be situated in close proximity to transport facilities, which are used routinely by many potential drug addicts, or it should be accessible to modes of private transport.

Furthermore, since drug markets are established along routes which are used on a daily basis by many potential drug buyers, the location and retail characteristics of these markets can vary considerably. Depending on where users and dealers live relative to the market, drug markets are classified as *neighborhood, open regional, semi-open regional, and closed regional markets* (Reuter and MacCoun 1993; Eck 1994). Neighborhood markets are described as places in which both customers and dealers are from the vicinity: they might be neighbors or know each other. Open regional markets are usually established close to places which are routinely used by a large number of nonresidents, such as shopping malls. These markets are large enough to support several competing drug dealers and can secure a high frequency of transactions. Semi-open regional markets are typically established when both participants aim to lessen the risks involved in open street markets. They do not live in the same area and they only interact if they know each other or have been referred by a third person. Closed regional markets' locations are determined by both participants of the transaction and are distributed over a wide area. The clientele of such markets are established through a network of friends and other trusted people. This type of market is the norm in wholesale drug dealing.

Alongside spatial clustering, drug markets are typically located in close vicinity to certain facilities: shopping centers (Eck 1995), high schools (Roncek and LoBosco 1983), bars (Roncek and Maier 1991), cash stores and pawnshops (Anderson 1999), transport links, train stations and highways (Eck 1994), and vacant homes (Rengert et al. 2005). Rengert and colleagues (2005) found that there are also facilities that discourage the establishment of drug markets in an area, such as police and fire stations or courts and federal buildings. Given that accessible drug dealing locations should offer good retail potential, drug marketplaces can be further classified according to the level of pedestrian and traffic accessibility, which may bring potential customers to the area. It can be suggested that, depending on a market's geographical positioning in the city, the level of accessibility will vary – from locally to regionally accessible markets. For example, Eck (1994) found that in San Diego, outdoor drug markets formed at locations about two blocks away from major transportation arteries, suggesting that they were regionally accessible markets. Importantly, this suggests that although offenders aim to sell drugs from accessible locations, they do not tend to do so on the major roads (presumably as a way of reducing risk). That is, for regionally accessible markets, operating in close proximity to major roads may offer an acceptable balance of custom and safety. In comparison, in Philadelphia, Rengert and colleagues (2005) found a high concentration of drug markets located in the suburbs, located away from major roads, suggesting that these marketplaces are oriented to local rather than regional demand.

State of the Art: Drug-Related Crime

The drug-crime relationship is usually examined through the theoretical perspective of a "tripartite framework" advanced by Goldstein (1985), which categorizes drug-related crime into three groups. First, there is "psychopharmacological" crime in which drug use affects aggression, thereby increasing the chance of criminal behavior. Second, there is "economic-compulsive" crime, in which crime is committed to finance drug use. Third, there is "systemic" crime, in which criminal behavior occurs in order to secure the drug supply chain, protect profits, control locations, compete for customers, or resolve conflicts of interests. A fourth category has also been proposed (Blumstein 1995 – cited in MacCoun et al. 2003; Curtis and Wendel 2000; Rengert 1996), which focuses on the negative impact of drug markets on local communities, mainly in terms of how drug dealers' behavioral codes and manners impact on community members who are not directly related to the market, for instance, by increasing gun carrying for the purpose of self-defense or conflict resolution.

Despite extensive research on the drug-crime nexus, little is known about how drug-related crime and drug markets relate to each other geographically. Based on crime pattern theory, it is suggested that drug markets can be both crime generators and crime attractors. The former may occur due to the inherent criminality of drug markets – with those who buy or sell drugs engaging in other types of crime while they are in an area, even though they may not have travel to such locations with the intention of so doing. Even though they do not travel to such locations to commit other forms of crime, this will nevertheless affect such crime rates in the area. Apart from potential drug buyers, drug markets can *attract* other offenders who purposely seek out criminal opportunities. In their research, Weisburd et al. (2004) found that drug-related crime clusters spatially around drug markets. Rengert and Wasilchick (1989) state that property offenses committed by drug users are spatially concentrated in close proximity to drug markets. Moreover, ethnographic research suggests that violence against dealers is not uncommon since they possess drugs and money.

Others (Eck 1994; Reuter and MacCoun 1993) suggest that depending on the retail nature of the market (street based, indoor from fixed locations, or delivery based), levels of violence and criminal behavior differ considerably. The indoor and delivery-based methods of transaction are safer than outdoor sales, since they enjoy an established and protected territorial boundary and/or security is provided by limiting sales to a network of trusted people.

The nature of a market – *local, export, public, and import* – is thought to affect levels of violence. According to Reuter and MacCoun (1993), local markets have the least violence, given that there is an established network of local social ties and all market participants interact on an ongoing basis within recognized territorial boundaries. Export markets also enjoy low levels of violence, since local dealers are interested in discouraging violence in order to attract more customers from outside the local neighborhood. Public markets feature a high level of anonymous participants operating in public places and hence lack clear territorial boundaries. Due to the resultant competition and weak social ties between participants, which in turn promote potential mistrust and disagreement both between dealers and buyers and among dealers, these markets have considerable potential for violence. Import markets may feature a similar risk of violence, since neither dealers nor customers belong to the given neighborhood and the process of establishing territorial boundaries may cause dissatisfaction among local residents and tensions between dealers. As a result, conflict may arise between dealers and locals as well as between competing dealers.

"Systemic" violence, which occurs in drug markets as a means of controlling a location and competing for customers, has been investigated in relation to drug dealing gangs, who usually operate from the so-called street corners (Taniguchi et al. 2009). These street corners are financially more beneficial than other street segments due to the possibility of targeting a greater volume of passersby (Eck 1994). Consequently, gangs compete to defend and control the corners as a matter of prestige and economic gain. Scholars (Taniguchi et al. 2010) have found that there is more violence when multiple gangs operate from a single corner than when a single gang controls it. In the former scenario, violence between gangs arises from their competing interests in finding clients and establishing territorial boundaries. In comparison, when a single gang occupies a strategically positioned corner, it has an economic interest in keeping the area safe from violence in order to attract more customers (Cohen and Tita 1999; Goldstein 1985; Levitt and Venkatesh 2000 – quoted in Taniguchi et al. 2010).

Several authors (Eck and Maguire 2000; MacCoun et al. 2003) have noticed that drug markets are highly responsive and adaptive to law enforcement. They have suggested that violent behavior linked to competition may be caused by intensive law enforcement actions. The link between police activities and drug markets will be discussed in detail in the following section.

State of the Art: Drug Markets and Law Enforcement

Apart from arresting drug dealers, one of the police's main goals in targeting drug markets is to understand how the operational structure of these markets can be disrupted. Since drug markets cluster in relatively few locations, which also feature specific land uses which support them, crime prevention researchers (Taniguchi et al. 2010) suggest targeting specific locations instead of drug dealers. By applying the categorization of drug markets according to where dealers and buyers live, as discussed above, scholars (Reuter and MacCoun 1993) have identified the markets which are expected to be the most and least vulnerable to law enforcement activity. Local markets are, for example, the most resilient to police activities, because both participants in the transaction are from the same neighborhood with strong social ties. Consequently, if the market's functioning is disrupted, the participants' shared knowledge of the neighborhood allows the easy reestablishment of the market elsewhere. In contrast, public drug markets can be easily disrupted, because there will be relatively fewer locations which are well known to both dealers and buyers and which are suitable for drug transactions. Targeting these locations may be sufficient to keep drug dealers and buyers apart.

However, it has been claimed that disrupting the operations of drug markets will not solve the problem, since they are highly adaptive to law enforcement and might reopen nearby or simply start trading at different times. This amounts to claims of spatial or temporal displacement (Repetto 1974). Although displacement is a common criticism of geographically focused crime prevention efforts, this concern has not been substantiated by empirical research. Furthermore, a number of studies (Clarke and Weisburd 1994; Weisburd et al. 2004) have found the reverse effect, namely, a diffusion of crime control benefits, whereby there is a reduction in the crime level in locations surrounding the area where police implemented crime prevention strategies. There are several explanations for this effect. From the perspective of agglomeration economics, "the immediate spatial diffusion is more likely than immediate spatial displacement" (Taniguchi et al. 2010). For example, it has been suggested that closing down the most profitable drug dealing location will make dealing in the neighboring locations less rather than more profitable. Dispersing the cluster of competing drug dealers will lead to a series of smaller marketplaces, each with fewer participants and drug transactions. According to this perspective, a forced change in spatial positioning can be sufficient in disrupting a drug market due to its detrimental effect on economic conditions.

Ethnographic research suggests (Weisburd et al. 2004) that after preventative interventions, drug dealers prefer to adapt their behavior and stay in the targeted area rather than move location. Both participants may implement less open modes of transaction, for instance, arranging the drug transaction time and place through mobile devices.

Weisburd and colleagues (2004) have studied the effects of geographically focused or hot-spot crime prevention strategies. Despite the widely held belief discussed above that hot-spot policing causes displacement, the researchers found no evidence on one of these. They strongly support the use of focused market targeting in police interventions since dealers resist moving away from a chosen area, as discussed above. They justify this support by emphasizing that dealers are part of the social and business community and when they relocate they may encounter violence caused by competition with established dealers in the new area. Moreover, existing networks of customers are not easily displaced to another location, since their limited geographical familiarity makes it harder to locate their dealer there. This can interrupt the supply-demand chain and hence affect the profitability of drug dealing at a particular place. This is one reason why focused hot-spot prevention may be beneficial to an area since one consequence is that reestablishing the market is likely to require effort on the part of the dealer.

Overall, researchers (Rengert 1996; Weisburd et al. 2004) are in favor of hot-spot policing, believing it to produce strong crime prevention results. Since the change in economic and physical conditions makes the location less attractive for a dealer, they have strongly suggested paying more attention to the surrounding conditions which affect the marketplace's economic attractiveness. However, caution should be taken in generalizing these results as several crackdown studies have found evidence that a diffusion of benefits to adjacent areas may be accompanied by partial displacement of the drug scene to indoor locations, other neighborhoods, or nearby metropolitan areas.

Future Research Directions

Overall, it can be noted that there is a particular environmental balance between physical and social characteristics which facilitate the optimal grounds for establishing a drug marketplace. As has been described above, the retail chain of drug supply operates differently depending on both the spatial structure of the area and the participants' profile. Moreover, drug markets are more likely to be located in areas with low levels of social organization. It is hard, however, to establish whether the choice of location is determined by the level of social organization or whether the social organization is undermined by the presence of a drug market. Whatever the case, the ensuing lack of legal guardianship provides, from the dealers' perspective, valuable protection from police enforcement.

For the future research directions, it may be worth looking at geography of separate crack or heroin markets alone and on crime concentration nearby. There is an opinion that crack markets tend to be more violent than markets for other drugs, but it is not supported with any empirical evidences. Additionally, it is useful to know whether markets that offer particular types of drug that is more expensive and difficult to source are harder to stamp out for good and are more liable to displacement.

Although many researchers recognize the relationship between legitimate movement and drug markets, it is still unknown how much and what type of movement is required for the establishment of drug markets. Locational choices may, for example, be influenced by whether the market is frequented by pedestrian or vehicular traffic. A drug market which, for example, relies on vehicular traffic may need to be located in close vicinity to main roads with easy and quick access *to* and *from* the marketplace. In the case of pedestrian traffic, the market will probably be located near places where there are a sufficient number of legitimate activities which can conceal the drug transaction process. Presumably, there should be multiple escape routes, lookout points, and workarounds (Eck 1995). Since street networks influence the way people navigate towns and cities (Brantingham and Brantingham 1995; Hillier and Hanson 1984), and the street networks vary from place to another, caution should be taken when generalizing findings from one location to another. This is particularly true when comparing findings from studies conducted in automobile-based societies with regular grid-like street networks, such as America, with those from pedestrian-based societies with street networks which have grown organically, such as the UK. To be more explicit, all drug markets are not equal, and those factors that influence one type of market may be different to those that influence others. Understanding the factors that affect different types of markets would be a useful next step, and consideration of how the morphology of the street network might shape or support opportunities for drug crime would seem to be a logical starting point.

Another priority research area is the drug-crime connection. Rengert and Wasilchick (1989) discovered that offender's search behavior is oriented towards the location of drug marketplace. They showed that drug-dependent property offenders search for potential houses to burgle on their way to purchase a drug. Despite the fact that many scholars have pointed to a significant relationship between drug use and crime, little is known about how drug-related crime patterns are associated geographically with drug markets: while those who use drugs may also commit crime, how are their spatial targeting decisions influenced by the location and type of drug markets? From a methodological perspective, it is necessary to apply appropriate crime data modeling techniques to examine the geography of criminal activities taking place in different locations and explore how potential drug users are positioned and move about within the city. Recent developments in the use of geographical information systems (GIS) allow the input, storage, merging, and analysis of geographical, statistical, and other types of datasets within a single file format. The high operational quality of these platforms enables the integration of many data formats and the construction of very large and detailed models. This means that it is possible, for example, to map drug dealing events in conjunction with sociodemographic statistics, data on land use, or crime statistics. This information can be aggregated according to different spatial units, such as the administrative boundary, ward unit, and building block. Remarkably, most of the research has focused on the patterns of drug dealing only at the area or grid-based unit of analysis. With few exceptions (e.g., Friedrich et al. 2009), drug markets have not been examined at the street segment level. Thus, in future work, it will be useful to conduct analyses using street segments as the unit of analysis. The advantage of detailing at such a fine scale of analysis allows more accurate data modeling – after all criminals do not navigate areas, they move along the streets. Moreover, from the detection and prevention perspective, it is quite useful to know the type of street segments that have a high probability of being or becoming drug dealing places and require more police attention.

Recent advances in computational methods allow very detailed modeling and analysis of data which should facilitate this sort of approach. For example, a group of researchers from Japan used a GIS platform to develop the Spatial Analysis along Networks (SANET) software. This provides a set of statistical tools that facilitate the analysis of point data with reference to the street network. The network statistics used represent a modification of numerous traditional spatial but also graph theoretical techniques. For instance, the software enables the analysis of the density of crime incidents across street segments, the shortest path between points, and the enumeration of the fraction of clustered crime incidents and so on.

The morphology of street network per se is another factor that can be informative in understanding and analyzing crime incidents within a city. Space Syntax theory (Hillier and Hanson 1984) and research discuss how the spatial properties of the street network influence the distribution of pedestrian movement patterns. Space Syntax has developed analytical tools, which using computer modeling (Depthmap software; Turner 2001) provide graphic (and quantitative) representations of the probabilities of pedestrian and traffic movement along the street segments. Namely, it estimates the accessibility levels for every street segment in relation both to its immediate surroundings (local scale) and to the whole city network (global scale). The quantifiable differences in the level of movement accessibility between different locations enable testing statistically why particular locations are prone to crime.

In conclusion, it should be emphasized that illegal drug markets are difficult and multidimensional problems involving many social and spatial factors. Mechanisms of illicit retail may vary from country to country, and so the theoretical frameworks described in this entry require further testing to determine the extent to which they do and do not apply in other cultural contexts. Methodological and computational advances offer the opportunity to do so and will likely provide new insight into patterns of drug crime.

Specialization and Sexual Offending

Danielle Arlanda Harris
Justice Studies, San Jose State University,
San Jose, CA, USA

Overview

The field of research into sexual aggression and offending is largely based upon the assumption that sexual offenders are inherently different from generic or nonsexual criminals. This position has permeated through more than just research and is now evident in the policies and practices that treat and manage sexual offenders and seek to prevent sexual abuse. This assumption of offense specialization proposes that sexual offenders commit sexual offenses persistently and exclusively (or at least predominantly) throughout their lives (Simon 1997; Zimring et al. 2007). It is often further implied that these offenders have a detectable degree of sexually deviant arousal and commit sexual offenses in a planned and repetitive way (Simon 2000; Zimring et al. 2007). Meanwhile, almost no other type of offender is viewed like this. Rather, they are considered to be criminally versatile, showing no apparent predilection for one crime over another.

This entry provides an overview of recent international literature regarding the nature and extent of offense specialization and versatility in the criminal careers of sexual offenders. A discussion of the many methodological considerations that arise from this research will be presented, followed by a brief overview of relevant theoretical perspectives. Finally, comments are provided regarding the implications for further research in criminology and criminal justice as well as prevention efforts aimed toward addressing sexual offenders.

Introduction

There are wide-reaching practical implications that stem from the view that sexual offenders are either specialist or versatile in their offending. The sexual offender "profile" has become increasingly visible in recent years. This has likely been encouraged by a small number of horrific incidents that received extraordinary attention by the international media. As a consequence, individuals who are identified as sexual offenders are now subjected to more discretionary decision making in the criminal justice system than almost any other type of offender (Simon 1997). This has led to more frequent and aggressive prosecution of sexual offenders as well as the passage of various special legislative initiatives aimed exclusively at sexual offenders (Simon 1997). Judgments about an individual's dangerousness and their perceived risk of reoffense are predicated upon the view that sexual offenders are "special cases" requiring or necessitating specific assessment, treatment, therapist certification, polygraphy protocols, probation models, protective custody, and so on.

If offenders do specialize in the types of crime they commit, then it makes sense for policy to be tailored toward specific individuals who have been determined likely to participate in a particular crime (Mazerolle et al. 2000). In this way, crime-specific incarceration policies would be influential in reducing the incidence of specific crime types. If knowledge of prior offenses could actually predict subsequent criminal events, then the identification of specialized offenders would certainly be useful in criminal justice decision making (Farrington et al. 1988).

If, on the other hand, offenders are predominantly versatile, crime-specific policies would have less impact. If versatility is the standard offending tendency, a reevaluation of many legislative initiatives and policies already in place might be necessary. One interpretation of this state of affairs would suggest that such initiatives, "fuelled by the assumption of specialization" (Simon 1997, p. 2), have evolved to cater to a sexual offender population that does not actually exist.

Competing Perspectives

The Specialist Perspective: Offense specialization is a central component of the criminal career paradigm and refers to an individual's tendency to engage in the same crime or type of crime on successive arrests or offending occasions (Blumstein et al. 1986). Specialist offenders are thought to become proficient at a certain crime, which they subsequently commit almost exclusively (Harris 2008). The consequence of this definition is that it is thought to be possible to predict any particular arrest in someone's criminal career based on their most recent prior arrest (Britt 1994).

Compelling evidence of versatility first emerged in the 1920s (Harris 2008) which left the notion of specialization largely marginalized for decades. Despite this, books continue to be written, research projects funded, and theories constructed, all with an assumption that offenders specialize in their offending (Gottfredson and Hirschi 1990). The strong belief in specialist offenders – shoplifters, drug offenders, and white-collar criminals – conveniently allows "us" to separate ourselves from "them." Nowhere is this trend more obvious than in cases of rapists or pedophiles.

The Versatile Perspective: The opposing position of offense versatility proposes a common construct of deviance that views all crimes as "acts of force or fraud undertaken in pursuit of self-interest" (Gottfredson and Hirschi 1990, p. 15). Gottfredson and Hirschi (1990) claim that all crimes are alike and argue that any distinction between them (such as trivial or serious, or victim or victimless) is irrelevant and misleading. It would follow then that distinguishing between sexual and nonsexual offending (or, e.g., between sexual offenses against adults and sexual offenses against children) is an equally futile endeavor.

Specialization and Versatility in Sexual Offending: Theoretical Context

Although offense specialization is probably best understood empirically, it is necessary to situate offending patterns within a meaningful theoretical context. Theory building in sexual offending research has largely occurred beyond the boundaries of traditional criminology (Simon 2000). Meanwhile, criminological theories tend not to consider sexual offenders on their own. Some have observed that these developments have created an almost philosophical apartheid between conventional criminology and sexual offending theory (Soothill et al. 2000). There are, however, appropriate explanations that attend to both of these observations. The following discussion will focus explicitly on those theories of sexual offending that speak to specialization or versatility.

Sexual offenses are usually understood within the context of deviant sexual arousal and paraphilia. But a more generic model would consider a sexual offense within the context of general criminality. Here, a sexual crime would be seen as an expression of general antisocial behavior that likely occurs rarely and in a haphazard fashion within an offender's criminal career. Some researchers have concluded that generic models provide sufficient explanation of sexual offending, while others hold that sexual offenders warrant more specific theoretical consideration.

The propensity to offend can certainly be understood by either general or specialist theories. In particular, sexual offending can be understood as either an example of general crime or as a special case requiring the presence of sexual deviance. The Integrated Theory of Sexual Offending (Marshall and Barbaree 1990) and the Conditioning Theory of Sexual Offending (Laws and Marshall 1990), respectively, are proposed as two such examples.

The Integrated Theory of Sexual Offending. Marshall and Barbaree's (1990) Integrated Theory of Sexual Offending focuses on opportunity and self-control and can be seen as a sexual offending-specific version of Gottfredson and Hirschi's (1990) General Theory published in the same year. Marshall and Barbaree (1990) combined developmental elements with situational and environmental factors to create an integrated explanation of sexual offending (Ward 2002). The authors proposed that men are biologically equipped to learn to express their sexuality aggressively. They contend that "the acquisition of attitudes and behaviors during childhood sets the stage for the developing male to respond to the sudden onset of strong desires characteristic of pubescence with a prosocial or an antisocial mental set" (Marshall and Barbaree 1990, p. 260). Similar to Gottfredson and Hirschi (1990), they illustrate the importance of parental attachment and argue that sexual offending is more likely in individuals whose childhoods are characterized by poor parenting or poor socialization (Ward 2002). Provided these preexisting variables are present, situational elements have the ultimate impact on sexual offending. Stress, intoxication, anger, presence of a potential victim, and the belief that detection can be avoided are the most important situational variables (Marshall and Barbaree 1990; Ward 2002).

Marshall and Barbaree's (1990) contribution does not address the issue of specialization versus versatility directly. For them, sexual offending remains independent of other behaviors and therefore warrants a unique explanation. They recognize that sexual offenders have the capacity to be criminally versatile and do engage in an array of antisocial behaviors. This represents a significant variation from other theories constructed to explain sexual offending which have essentially ignored this aspect of criminality. Ward et al. (2006) suggest that Marshall and Barbaree altered the theoretical landscape (within sexual abuse research) by simply acknowledging the component of nonsexual criminality.

Like the critics of Gottfredson and Hirschi (1990), researchers have also argued that the Integrated Theory is too general (Ward 2002). Their main criticism is that it does not account for important distinctions between types of sexual offenders (i.e., distinguishing, e.g., between rapists and child molesters) (Ward 2002). Drawing on typological traditions, Ward recommends that theorists should "develop more specific rather than general explanations" (p. 217). Evidently, influenced by the work of Gottfredson and Hirschi, the criminological tradition has moved in the opposite direction.

Conditioning Theory of Sexual Offending. Also published in 1990, Laws and Marshall's Conditioning Theory provides a coherent explanation of specialization in sexual offending by emphasizing learning experiences and motivation. Like other well-regarded theories of sexual abuse, Laws and Marshall (1990) do not preclude a sexual offender from being versatile. Instead, they simply do not make any reference to a sexual offender's nonsexual offending. In this way, they seek to explain only how an individual with certain experiences will come to offend sexually.

Conditioning Theory provides a theoretical basis for the deviant sexual preference hypothesis (Ward et al. 2006). Although it has a specific sexual offender focus, the theory argues that sexual deviations are learned responses to possibly accidental experiences with sexually deviant behavior (Ward et al. 2006). That is, they could evolve in anyone.

Deviant arousal patterns are said to develop through the process of classical conditioning and the "elaborated use of deviant fantasy in masturbation" (Laws and Marshall 1990, p. 226). This is likely a gradual process occurring during masturbation to a memory which need not have been sexually stimulating at the time of the initial experience (Ward et al. 2006). Classical conditioning describes the unconscious and "repetitious or traumatic pairing of sexuality and some negative experience [which] produces some type of intensive emotional response that distorts subsequent sexual gratification" (Schwartz and Cellini 1996, p. 14). This explains the unconscious compulsion to reenact one's own abuse to gain mastery over the experience. This has been supported empirically in samples of sexual offenders, particularly for juveniles.

A Theory of Specialization and *Versatility*. At this point, two compelling empirical realities must be considered and reconciled. First, it is known that not all sexual offenders present with deviant sexual preferences or deviant sexual arousal (Simon 2000; Weinrott and Saylor 1991). Second, it is known that many people who commit sexual offenses also engage in a considerable amount of nonsexual criminal behavior in addition to their sexual offending (Lussier 2005; Simon 2000; Weinrott and Saylor 1991). What is missing from these perspectives is a sensible explanation of two realities: sexual offending by men without deviant sexual interests and nonsexual offending committed by men who have explicitly been designated "sexual offenders."

Harris et al. (2009a) concluded that the components of Gottfredson and Hirschi's (1990) theory were appropriate for almost all (89 %) of the 506 sexual offenders in their sample. They indeed revealed the analogous behaviors that were predicted by the General Theory of Crime. At the same time, it still appeared that a small group of highly specialized offenders warranted the more sexually specific explanations such as those provided above (Marshall and Barbaree 1990; Laws and Marshall 1990). That is, for the remaining 11 % of the sample it was relevant to focus on such factors as sexual preoccupation; emotional congruence with children; and having a male, unrelated, or stranger victim. Essentially, the authors suggested that some aspects of sexual offending could be understood akin to the way Moffitt (1993) explained delinquency.

Borrowing Moffitt's (1993) framework amounts to a "Dual Taxonomy of Sexual Offending" where two distinct trajectories of offending are proposed. Thus, the observation of sexual offenses is understood to conceal two qualitatively distinct types of offending behavior: sexual offenses that are committed rarely or sporadically as part of the broader range of criminal activity in which an individual engages and sexual offenses that are committed by highly specialized offenders who seldom, if ever, engage in any other rule-breaking behavior.

The first category of offenders were referred to as "versatile" and made up the vast majority of offenders. They were characterized by general indicators of low self-control including substance abuse, adolescent antisocial behavior, elementary school problems, and unemployment (Harris et al. 2009a). They were more criminally versatile, engaged in a broader range of different criminal behaviors, and were more likely to offend upon release. This is in line with the results of a previous study (Meloy 2005) which concluded that the majority of sexual offenders could be described as situational or opportunistic, with versatile criminal histories.

The second category was "highly specialized" and represented 11 % of offenders, comparable in size to Moffitt's life-course-persistents or Wolfgang's chronic offenders. Contrary to their versatile counterparts, this group consisted mostly of child molesters and was characterized by sexual preoccupation, emotional congruence with children, and a greater likelihood of abusing known, related, and male victims (Harris et al. 2009a). Highly specialized sexual offenders were also statistically significantly more likely than versatile offenders to begin their offending in adulthood. This group best resembled the expectations of the theoretical perspectives that expect specialization (Laws and Marshall 1990; Marshall and Barbaree 1990).

It is definitely conceivable that more groups could be identified, particularly given the sample used in the study (Harris et al. 2009a) which is arguably biased toward sexual offenders in the direction of specialization. The group that is most notably absent in that study are offenders who have *not* been convicted of a sexual offense. Although the studies reviewed for this entry have demonstrated considerable similarities between convicted sexual offenders and the theoretical expectations of more generic nonsexual offenders identified in the literature, the opportunity certainly remains to assess this similarity empirically by including a control group of nonsexual offenders. This represents a worthwhile area of future inquiry.

Methodological Considerations in Specialization Research

Extant research on offense specialization is confounded by methodological inconsistencies which has an impact on current understanding of specialization. The most common concerns include the operational definitions of specialization and inconsistencies in the number and type of crime category classifications that are used (McGloin et al. 2007). Within the field of research on sexual offending, the added question of offender classification also impedes one's ability to compare results across studies..

Definition of Specialization. Many different techniques exist to define and measure specialization. Although each one has limitations when used alone, a combination of measures can be used together to paint a clearer picture of specialization. The simplest measure, the Specialization Threshold (ST), is a crude cutoff that detects specialization if an arbitrary proportion of one's arrests is for a particular offense or category of offenses (Cohen 1986; Harris et al. 2009b). Various thresholds have been used in prior research but Cohen's (1986) definition is used most often and declares specialization if 50 % of a person's arrests are for a particular type of crime. As the most simplistic measurement of specialization, the ST's main challenge is its inability to capture change or crime switching over time. The Forward Specialization Coefficient (FSC) (Farrington et al. 1988) and Diversity Index (DI) attend to that limitation by taking into account transitions between offenses (Sullivan et al. 2006). These models generate elegant coefficients that can be compared across studies. Although the FSC relies on consecutive transitions only, the DI can be calculated on nonadjacent transitions as well (McGloin et al. 2007). For some researchers, the DI has been preferred over the FSC for its more intuitive application and interpretation (Harris 2008).

Number of Crime Categories. It is difficult to compare results across studies because researchers seldom apply the same or similar crime classification schemes. Although there is no consensus on which to use (Sullivan et al. 2006), the convention in criminology has been three or four offending categories: personal/violence, property, drugs, and other (where "drugs" and "other" are sometimes combined) (Mazerolle et al. 2000). Mazerolle and colleagues showed that the outcomes of using three or four categories are substantively similar and opted for the parsimonious model of combining "drugs" and "other." So far, the emerging research on sexual offending has further integrated "personal" offenses into sexual violence and nonsexual violence.

Use of Official Data. The limitations of studying crime using official statistics have been discussed elsewhere (Farrington et al. 1988; Rice et al. 2006). In addition to the actual nature of their behavior and whether they got caught, an individual's criminal record can also be influenced by a victim's willingness to report an offense, local law enforcement practices, and sentencing policies (Harris 2008). Further, in the case of sexual offending, official statistics tend to underestimate the "severity of sexually motivated violent offenses" (Rice et al. 2006, p. 525). Procedures such as plea bargaining often mean that the actual charges brought against a person no longer represent the sexual nature of the crime (e.g., rape being pled down to assault). Despite these disadvantages, official statistics remain the most common source of data for studies of specialization, but their subsequent results should be considered with these limitations in mind. A combination of official records and self-reported data is recommended.

Number of Previous Criminal Events. The concept of specialization implies the presence of another important element of the criminal career paradigm: persistence. Because it is meaningless to discuss specialization in one or two offenses, specialization research is often restricted to frequent and persistent offenders or "career criminals." Of course, analyzing only those offenders with more than five arrests, for example, greatly reduces one's sample of offenders. In addition to reduced statistical power, this introduces a possible sample bias by including only sufficiently persistent offenders. Although some researchers have limited their analysis to participants with at least five offenses or nine offenses, the general convention is to include participants with two or more (Farrington et al. 1988; Harris 2008; Harris et al. 2009b; Sullivan et al. 2006) or three or more separate arrests or sentencing occasions.

Use of Arrest or Conviction. Specialization studies either use arrests, convictions, or sentencing occasions as the primary unit of analysis. Because each occasion might include multiple counts or charges, the convention is usually to record only the most serious charge at each event (Farrington et al. 1988). Using charges will hide arrests that failed to result in a charge and using sentencing occasions will hide convictions that failed to result in a sentence. The seriousness of most sexual offenses (compared with almost all other crime) means that recording only the most serious offense would conceal other co-occurring behaviors, thus inflating specialization. Although the opposite practice (of including every individual charge) has the complementary limitation of inflating versatility, given that the dark figure of sexual crime is so substantial, this method is considered the most appropriate for samples of sexual offenders (Harris 2008).

Classifying Sexual Offenders. Specialization is usually taken to mean the likelihood of committing the same offense on a subsequent occasion. Blumstein et al. (1986) notion of "offense clusters" broadened this definition so that rather than only detecting specialization in burglars who subsequently commit burglary, for example, (Britt 1994), an offense cluster of theft could be used to encompass such crimes as burglary, larceny, shoplifting, or fraud (Britt 1994). This approach is important for the present discussion because it is argued that some sexual offenders specialize *within* sexual offense categories (Soothill et al. 2000).

Consider a male child molester who is subsequently convicted for rape of a woman. Blumstein et al. (1986) would consider him a specialist sexual offender. A clinician, however, would consider the same individual quite differently from an exclusive child molester (who, e.g., might demonstrate the more typical characteristics of emotional congruence with children and difficulty in maintaining adult relationships). To Blumstein et al., he would be a "sexual offender," but to a clinician, although his offenses might all be sexual, he apparently shows no predilection for certain types of victims and might be considered a more challenging candidate for treatment. A mixed offending pattern (that includes both adult and child or male and female victims) might also indicate that he is potentially more likely to reoffend upon release, because his sexual crimes are unpredictable and his victim preferences are unclear. These characteristics are also those that would render an individual at higher risk of reoffending (according to many risk assessment tools) than his more specialized counterparts.

Empirical Evidence of Specialization and Versatility in Sexual Offenders

Almost a quarter century of research on offense specialization is summarized by the findings of one of the first articles on the topic: there is a "small but significant degree of specialization in offending superimposed on a great deal of versatility" (Farrington et al. 1988, p. 461). Regardless of method or sample, there is a clear indication of versatility among offenders within the criminological literature. A modest amount of specialization is detected in some samples, and this is most notably observed in persistent offenders who use drugs.

Despite clinical assumptions to the contrary, research that has focused specifically on sexual offenders over the last 10 years has drawn similar conclusions: many sexual offenders do not restrict their criminal activities to sexual offenses (Lussier 2005; Miethe et al. 2006; Simon 2000; Smallbone and Wortley 2004; Soothill et al. 2000; Weinrott and Saylor 1991; Zimring et al. 2007). Further, notwithstanding possible differences in reporting, arrest, and conviction rates for sexual and nonsexual offenses, adult sexual offenders are about twice as likely to be convicted for nonsexual offenses as they are for sexual offenses, both before and after being convicted of a sexual offense (Smallbone and Wortley 2004). The following section details the findings of a selection of specific studies in this area.

As early as 1991, Weinrott and Saylor (1991) concluded that specialization in sexual crimes was relatively rare. The 99 convicted sexual offenders in their study collectively self-reported nearly 20,000 nonsexual crimes in just the 12 months prior to their incarceration. The majority of these offenses were minor and mostly included public intoxication and petty theft.

Smallbone et al. (2003) found substantial offending versatility in the official histories of the 88 incarcerated adult male sexual offenders in their sample. The participants in their study included 33 rapists, 29 extrafamilial child molesters, and 26 incest offenders. Almost two thirds (60 %) of their total sample and 88 % of the offenders who recidivated reported having prior nonsexual criminal convictions.

Smallbone and Wortley (2004) later assessed the extent of persistence and versatility in the self-reported offending behaviors of 207 child molesters. Their sample was broken down further by victim relationship with 98 participants having committed incest exclusively, 72 having extrafamilial victims, and 37 having both intrafamilial and extrafamilial victims. Results from an extensive self-report questionnaire revealed considerable versatility with 69 % of the sample having been convicted of at least one nonsexual offense and 80 % having first been convicted for a nonsexual crime.

In an ambitious examination of almost 10,000 sexual offenders and some 24,000 nonsexual offenders released from prisons in 15 US states in 1994, Miethe et al. (2006) also found low levels of persistence and specialization among sexual offenders compared to nonsexual offenders. Sexual offenders had fewer arrests of all kinds than any other offender group except murderers. Although 70 % of the sexual offender sample had been arrested only once, some 95 % of those who had been arrested more than once had nonsexual offenses in their arrest histories.

Harris et al. (2009b) explored offense specialization in the officially recorded criminal histories of 506 sexual offenders referred for civil commitment in Massachusetts. They examined the sample by offense type (comparing rapists, child molesters, incest offenders, and offenders with mix-aged victims) and by referral status (comparing offenders who were observed and released with those who were observed and committed for treatment). Contrary to their hypotheses, their results indicated that treated participants were no more likely to specialize in sexual offenses than observed participants. When compared by offense type, as expected, child molesters were substantially more likely than rapists to specialize in sexual offenses. Child molesters were also more likely to specialize in sexual offenses against children (than rapists were to specialize in sexual offenses against adults). As a whole, the sample was also more likely to specialize in sexual offenses than in the other offending categories of nonsexual violence, property, and other offenses.

Later, Harris et al. (2011) examined the post-release offending records of the same sample of 506 observed and committed offenders for a period of up to 10 years. Again, they found that the tendency to be criminally versatile remained the most compelling offending pattern across the sample. Few differences were detected between treated and observed participants, and almost no differences were found between rapists and child molesters with respect to recidivism or to post-release specialization. Rapists were more likely than child molesters to reoffend at all and to reoffend violently. There were no differences between groups on their likelihood of committing sexual offenses after release.

Interestingly, specialization prior to incarceration was not indicative of specialization in sexual offending after release. Of the 53 participants who specialized after release, approximately half had specialized criminal histories (n = 27) and half did not (n = 26) (Harris et al. 2011). The authors concluded that the predictive power of a sexually specialized criminal history was limited.

Harris and Knight (forthcoming) elaborated upon the findings from the previous two studies by using an addition of almost 300 more cases and attempting to establish the existence of an identifiable group of highly specialized sexual offenders that may have been masked by the liberal definition of specialization (50 %) used in prior works. A small group of 166 highly specialized sexual offenders existed out of a larger group of 748 offenders and was made up mostly of child molesters. This was consistent with both existing empirical evidence and the findings from Harris et al. (2009b) which concluded that child molesters were the most likely offender type to specialize in sexual offending.

A deeper analysis of the sample's responses to various items from risk assessment tools demonstrated that the majority of the sample shared many of the general criminal attributes proposed by conventional criminology including the presence of analogous behaviors such as alcohol and drug use, problems in elementary school and adolescent behavior, and involvement in a range of different types of crimes. By comparison, the small group of highly specialized offenders was characterized instead by the variables identified by more specific theories of sexual offending. This study provided added empirical support for the Dual Taxonomy of Sexual Offending described earlier.

Specialization Within *Sexual Offenses.* As mentioned earlier, sexual abuse researchers distinguish between offenders who have sexually assaulted adults (rapists) and offenders who have sexually abused children (child molesters) (Meloy 2005; Simon 1997). Further distinctions are also made between familial and nonfamilial child molesters. A review of recent studies that have addressed the question of specialization *within* sexual offenses is provided here.

Rapists are repeatedly found to resemble violent nonsexual offenders most closely (Harris 2008). They are thought to be predominantly versatile in their offending and the commission of rape is seen to be part of a broader propensity to act in a generally antisocial manner (Lussier et al. 2005; Smallbone et al. 2003). Each of the 37 convicted rapists in Weinrott and Saylor's (1991) sample admitted to at least one nonsexual offense. Further, over half of the sample committed burglary and almost half committed robbery (Weinrott and Saylor 1991). The mean number of different offenses (out of a possible list of 22) that was self-reported by each rapist was 10.5 (Weinrott and Saylor 1991). Further, a third of convicted rapists admitted to having had sexual contact with a child (Weinrott and Saylor 1991).

Lussier et al. (2005) found that when compared with child molesters, rapists engaged in a larger variety of all crimes, had a higher frequency of property and violent crimes, and had also committed a "significantly greater variety of violent crimes than of sexual crimes" (p. 180). Addressing specialization using recidivism statistics, Langan and Levin (2002) found that 3 years after incarceration, drug offenders (41 %), larcenists (34 %), burglars (23 %), nonsexually violent offenders (23 %), defrauders (19 %), and robbers (13 %) were all much more likely than rapists (2 %) to be rearrested for the same type of crime for which they were originally convicted.

Child molesters, by comparison, are generally considered much less versatile than rapists (Harris 2008; Harris et al. 2009b). In fact, if a specialist, persistent offender exists, the stereotypical extrafamilial child molester is likely the most convincing example. Some evidence of crime switching has been detected in child molesters. For example, 12 % of the convicted child molesters in Weinrott and Saylor's (1991) sample admitted to attempting forced sex with an adult female and 34 % had abused children inside the family as well as outside the home. Lussier et al. (2005) also concluded that child molesters committed a variety of different sexual crimes. A quarter of Weinrott and Saylor's (1991) sample reported substance abuse and 20 % reported assault, theft, burglary, possession of stolen goods, and drug-related offenses in the year prior to incarceration.

Finally, incest offenders tend to most closely resemble non-offenders. When compared to rapists and child molesters, they display more social competence, having maintained steady employment and a stable marriage or marital-type relationship. Incest offenders are often thought to present with the lowest risk of reoffending, having engaged in a discrete and isolated event. But this idea has been challenged by evidence of versatility among samples of intrafamilial offenders (Harris 2008). Although a small sample, half of the 29 incest offenders in Smallbone et al. (2003) study "had at least one previous conviction for a nonsexual offense" (p. 57). All of Weinrott and Saylor's (1991) also small sample of 18 incest offenders self-reported at least one nonsexual offense. Other studies also find that incest offenders have reported committing nonsexual violent crimes and sexual crimes outside the home (Harris 2008). For example, half of Weinrott and Saylor's (1991) sample of incest offenders admitted to abusing extrafamilial children.

A Lingering Methodological Concern

In the methodological concerns raised above, the "offense cluster" of sexual offending was seen as irrelevant for sexual offenders. The research presented here, however, indicates that a substantial number of sexual offenders commit sexual offenses *outside* their assumed "specialty." The observation that identified rapists offended against children and identified child molesters against adults poses a unique problem for specialization studies that has not yet been evaluated properly. Much is made in the theoretical and treatment literature about the empirically significant and clinically valuable differences between rapists and child molesters.

The response to this conundrum is not a simple one because the distinctions between offender types are clearly valuable in practice. But, within the context of research, the considerable amount of crime switching results in the label of "rapist" becoming meaningless for a man who later admits to having child victims. Likewise, calling someone a "child molester" is similarly misleading if he has also offended against adults.

Policy Implications

Men convicted of sexual crimes (particularly against children) are now subject to specific, expansive, discretionary, and controversial legislation that has impacted almost every stage of the criminal justice system (Meloy 2005). Policies include community registration and notification, residency restrictions, mandatory specialized treatment, and civil commitment. Taken together, the studies reviewed above support existing criminological perspectives regarding versatility and challenge the assumption of specialization. By concluding that sexual offenders are largely indistinguishable from general criminals, these findings cast considerable doubt upon the value of these policies.

The focus of many sexual offender laws is to address the most chronic and persistent offenders. Evidently, specialized, persistent, and predatory sexual offenders do exist but they are an identifiable minority. So, the laws and regulations aimed specifically at them amount to a substantial financial commitment toward policies that addresses the rarest of circumstances. Further, it is now well established that children are much more likely to be abused by those who are known or related to them. Thus, a law that notifies a community of an offenders' name and address or that restricts offenders from living within a certain distance of a school or park is fundamentally flawed. These laws have the unfortunate consequence of increasing homelessness for an already disenfranchised population and reducing employment opportunities, thus elevating the likelihood of reoffending. The considerable burden that these laws place on police, parole, and probation officers should also be taken into account.

Concluding Remarks

Research now indicates that many sexual offenders neither restrict their criminal behavior to sexual offenses nor their sexual offending behavior to specific sexual offense subtypes (Soothill et al. 2000; Weinrott and Saylor 1991). Even accounting for the bias inherent in clinical samples of sexual offenders, or the difference between official statistics and self-reported data, the ultimate message is the same: a broad trend of versatility is maintained across the studies. When compared by offender classification, child molesters are consistently found to be more likely (and rapists less likely) to specialize in sexual offenses. Although incest is predominantly seen as a distinct behavior, existing studies of these men indicate that they also offend outside the home.

Various methodological considerations were examined. While it is clear that no approach is without limitations, researchers should manage these obstacles by using multiple measures of offending, multiple definitions of specialization, and mixed methods of analysis. The construct of offense specialization versus versatility should be considered in terms of the extent both to which sexual offenders commit nonsexual offenses and to which they commit sexual offenses outside their presumed sexual offense subtype.

Broader prevention efforts clearly need to do much more than rely on the selective policing and incapacitation of identified sexual offenders because there is now sufficient evidence to indicate that sexual offenders are generally criminally versatile. Individual offending tendencies are likely dynamic and could be influenced by a range of factors that remain underexplored. How these offending patterns emerge and perhaps change over time requires further examination. Such inquiries could in turn inform policy makers, criminal justice practitioners, and politicians alike with empirically valid evidence-based alternatives from which decisions regarding community safety could be made.

Specialization in Juvenile Offending

Crime repetition by youth; Patterns in youthful offending

Overview

Whether and to what extent juvenile offenders specialize in committing certain types of crimes during their delinquent careers has substantial implications for theory and policy. The question of offender specialization arguably first emerged with the advent of the positivist school in criminology in the late nineteenth century when Caesare Lombroso sought to identify criminal types. With the introduction of specialized juvenile justice in laws in the early twentieth century and their fundamental reforms in many countries in the second half of the twentieth century and into the initial decade of the twenty-first century, there have been considerable theorizing, research, and debate about specialization in youthful offending. Political debates in countries such as Australia, Canada, England-Wales, and the United States concerning the reform of youth justice laws have been influenced, in part, by the considerable research on specialization youthful offending. The main theoretical debate has been focused on the attempts to specify potential distinguishing characteristics of certain types of violent juvenile delinquents such as serious sexual offenders, murderers, and gang members, compared to less serious violent offenders, property offenders, and drug users/traffickers, for example. Many diverse labels have been applied to young offenders, such as serial fire-setter/rapist/murderer, career criminal, life-course-persistent/adolescence-limited offender, chronic/nonchronic offender, and adolescent psychopath/conduct disordered, that typically include attempts to specify types and patterns of crime. Oftentimes these labels or categories have been introduced into the media, political, and legislative circles, and debates emerge about whether to incarcerate, punish, and/or rehabilitate juvenile delinquents depending on what "type" of offender they are.

The essence of the theoretical debate is whether juvenile offenders can be classified into an "offender type" based on the qualitative nature, and/or quantity of their offending, versus whether there is more simply a single type of juvenile offender who engages in diverse and multiple antisocial and criminal behaviors. Not surprisingly, a considerable empirical research theme over the past half a century has focused on the nature and extent to which juvenile offenders demonstrate specialization in offending. The related theoretical debate has centered on considering that if specialization is not evident, then a single or general theory of juvenile delinquency could be sufficient to explain this phenomenon. In turn, criminal justice responses, therefore, could be directed toward a central set of causes or risk/protective factors to prevent juvenile delinquency from beginning as well as reoccurring. In contrast, if research demonstrates specialization or a diversity of types of juvenile delinquent offending patterns, then typologies require far more complex and unique theoretical explanations along with specialized juvenile justice responses, including treatment and intervention strategies, depending on the type of juvenile delinquent or young offender. To better understand how this debate on specialization has evolved over the years, it is necessary to describe the key theoretical controversies historically.

Key Issues and Controversies: Theoretical Debates

Typologies of adult and youth offenders gained popularity in the 1960s with the assertion that offenders could be classified into conceptually valid types based on fundamental differences in the crimes they committed. The most basic and obvious crime-centered typologies generally consisted of nominal categories of specialized criminal behavior consisting of property versus violent offender types. More types emerged as well including white-collar criminals, organized crime, street gangs, and political terrorists, for example. It was then theorized that these criminal types were explained by different sets of causal factors.

By the 1980s, there was a wide range of theories to explain ever-increasing types of offenders. In turn, typologies and related theories generated intense debates concerning basic definitions of deviance, delinquency, and criminality that are essential to assessing youthful offending specialization. For example, the assertion that delinquency was overwhelmingly associated with youth from low-income groups along with those belonging to certain ethnic/racial minorities was challenged by self-report studies of delinquency (e.g., Elliott and Ageton 1980). These studies demonstrated that minor delinquency was common for youth from all income and ethnic groups. A second criticism of initial crime-centered typologies was the reliance on offense records whereby the presence of a particular type of offense (e.g., sexual assault) determined a youth's "specialization" in offending. Critically, such a snapshot-based examination of offending patterns did not consider variations in offending over time. The longitudinal cohort studies of the 1970s and subsequent major cross-sectional studies provided a more valid basis for establishing typologies and specialization in youthful offending because they took into consideration changes in the frequency of offense types over the entire course of adolescence. Finally, a third key criticism involved arbitrary and income/ethnic group biases of juvenile justice laws regarding charges and convictions up to the 1970s. For example, juvenile justice laws from the early 1900s to the early 1970s virtually criminalized many childhood and adolescent antisocial and deviant behaviors. Typologies ranged from the enormous diversity of trivial antisocial behaviors such as status offenses (e.g., swearing and drinking alcohol) to the most violent crimes (e.g., rape and murder). However, because juvenile justice laws governed the ages between 8 and 21 depending on the country and within-country jurisdiction (e.g., state, province, region), it was abundantly clear that attempts to assess the nature and extent of specialization in juvenile offending had to be based on more sophisticated approaches.

What emerged from both longitudinal cohort and major cross-sectional research was that simple typologies based on the presence of certain offenses in a juvenile's history were inadequate for assessing specialization for several reasons. For example, status, property and violent crimes committed by juveniles varied substantially in not only degree of seriousness but frequency. To assess specialization, theoretically driven and complex equation-based indices often consisting of ratios of different types of crime such as property compared to violent crimes became central to investigating specialization in youthful offending. Seriousness of types of crimes, for example, based on the extent or amount of damage in dollars involved with property crimes, and the nature and extent of injuries for violent crimes also were incorporated into indices determining offender types. Another dimension was the variation in the extent of switching to different types of crime in certain developmental periods, such as childhood, adolescence, and adulthood. In other words, early crime-centered typologies were unable to address rapidly emerging evidence that delinquent careers were characterized by significant heterogeneity involving different patterns in the type, seriousness, and frequency of offenses committed over childhood and adolescence.

Several of the key concepts from the criminal career paradigm, particularly the concept of the career criminal, evoked intense theoretical and empirical debate. Klein (Klein and Malcolm 1979; Klein 1984) maintained that an abundance of empirical evidence demonstrated that juvenile offending was predominately unpatterned and reflected the notion of "cafeteria-style" offending. Subsequently, Gottfredson and Hirschi (1990) introduced their General Theory of Crime based on Hirschi's (1969) original research and his Bonding Theory of social control. This theory asserts that specialization does not exist and instead delinquents engage in a wide range of delinquent behaviors, stemming broken bonds to family and other societal institutions such as the church, school, and community. The absence of strong prosocial bonds further explains the time-stable personality trait of low self-control, which in turn is caused by lax and/or inconsistent parenting practices. Low self-control is established in childhood and remains stable throughout life. It is manifested by the pursuit of easy and instant gratifications inherent in deviant behaviors such as smoking, excessive drinking, short-term and multiple sexual conquests, recklessness, and crime, when opportunities are present. In effect, the General Theory of Crime predicts that juvenile offending is best understood as involving substantial offense versatility.

By the 1990s the developmental theoretical perspective of crime introduced more complex predictions about patterns in juvenile offending such as specialization and versatility. This perspective identified risk and protective factors for several forms of antisocial behavior throughout the life course beginning with early childhood and into early adulthood. Loeber (1990) asserted that children who exhibited recklessness, problems with authority, aggression, and coercive/manipulative behaviors were more likely to follow a more violent pattern in adolescence but also engage in diverse crimes. In contrast, children who were more withdrawn and antisocial were more likely to engage in covert patterns and drug use as adolescents.

The most prominent developmental theory relevant to specialization involved Moffitt's (1993) developmental taxonomy. She predicted that more sustained aggressive and violent life-course patterns were based on the age of onset of offending. Moffitt proposed two distinct types of offenders in the population: life-course-persistent' (LCP) offenders and "adolescence-limited" (AL) offenders. LCP offenders are characterized by the interaction, and accumulation, of individual deficits and environmental adversities that begin early in childhood and cascade over subsequent developmental periods. In effect, these individuals begin offending early in childhood/adolescence, engage in a wide range of deviant and criminal acts including bullying and other violent behavior, and persist into adulthood. In adolescence, therefore, this developmental group was predicted to exhibit frequent, versatile, and serious offending including violence. In contrast, AL offenders are predominately characterized by risk factors that emerge in adolescence. The primary risks involve status frustration driven by the expanding maturity gap between biological and social maturities (i.e., the observation that while adolescents experience physical or biological maturity at earlier ages when compared to the early twentieth century, their social maturity as evidenced by the age they assume adult social roles such as husband, breadwinner, father is delayed), as well as exposure to deviant or delinquent peers and role models. AL offending was predicted to be more specialized than LCP offending, in the context of offenses reflecting the effect of the maturity gap such as vandalism, public order, substance abuse, and status offenses.

As with all classic debates in criminology, measurement of key constructs are often central to resolving competing hypotheses, in this instance, about specialization versus versatility in youthful offending.

The Measurement of Specialization in Youthful Offending

Historically, methodological and measurement innovations have had to take into consideration the inherent limitations associated with data sources and especially official juvenile justice information recording. Most importantly, there is a consensus that official data significantly underrepresents the total amount of crimes committed, and even more for official juvenile offending data. During the past 30 years, measures based on informal and formal diversion programs have been introduced in many Western countries. Often, informal diversions from formal justice proceedings have not been recorded. In addition, there has been concern over the variations in the offense recording and charging process across jurisdictions even within countries. When only the most serious offense is proceeded with in terms of offense recording, trial, and/or sentencing, both the range and seriousness of actual offenses are under-recorded. This affects the accuracy of officially recorded crime records. Another limitation has been the concern with variations in the number of police charges that are recorded when police practices include deliberately over charging in order to enhance their ability to gain information about other crimes and to an advantage in plea bargaining to gain a confession of guilt. As well, police and prosecutors utilize their ability to increase or decrease the seriousness of the charges since criminal codes include wide discretion concerning the degree within a criminal offense category. For example, a violent assault resulting in death ranges from manslaughter to first-degree murder. All of these concerns raise questions over the validity of measures when using, for example, charges versus convictions in assessing specialization, especially across different juvenile justice jurisdictions included in comparative research designs. Similar validity concerns have been a source of debate with self-report methodologies utilized to assess specialization. Most importantly and especially when youth are involved, memory recall is often problematic in terms of overstating offenses, and the timelines in which they occurred in their past. Nonetheless, despite these limitations, most research on specialization in youthful offending has used a combination of methodologies to identify typologies based on a variety of specific measurement criteria. One advantage with official data is that a more complete delineation of potentially different offending trajectories over time is possible because this data can record patterns across childhood, adolescence, and adulthood. Similarly, complex cohort designs typically include multiple data recording approaches (e.g., including both official and self-report data) to measure the types, frequency, and temporal patterns of offending.

The seminal Philadelphia Birth Cohort Study (Wolfgang et al. 1972) was the most widely recognized initial methodological innovation in juvenile offender specialization research. Wolfgang and colleagues examined crime type patterns from offense to offense as a series of transitions using transition matrices. This method assessed the probability of juvenile offenders having received charges for similar crimes across adjacent offending events. Transition matrices identified whether specialization in certain crime types was evident by evaluating whether the probability of being charged with the same offense consecutively was greater in value than the probability of being charged with a different offense. Importantly, these techniques were also adopted to assess specialization using major cross-sectional research that included the complete court histories of charges and convictions for juvenile offenders (e.g., Farrington et al. 1988).

Related to the transition matrix methodology was the development of statistical tests in the 1980s to measure whether the probability of observed transitions to similar offense types was greater than could be expected on the basis of chance alone. Coefficients representing the level of specialization for specific types of offending in a sample became a standard measure. For example, Bursik (1980) introduced the Adjusted Standardized Residual (ASR) that determined whether the ratio between observed and expected transition values was statistically significant. Farrington et al. (1988) further introduced the Forward Specialization Coefficient (FSC) to control for the influence of infrequent cases that would distort the basic observed to expected ratio. The FSC represents a single value summary of specialization for different offense types based on the sequence of similar offenses in transition matrices. Fisher and Ross (2006) more recently asserted that the FSC is the most widely utilized measure of specialization to date because of its theoretical sophistication and predictive validity.

Despite widespread use, the transition matrix approach generally, and the FSC specifically, has several limitations (e.g., see Britt 1996; Fisher and Ross 2006; LeBlanc and Frechette 1989; Nieuwbeerta et al. 2011; Sullivan et al. 2009). Most importantly, the FSC describes specialization aggregately for a group of delinquents. This aggregate measure is theoretically appropriate for the explanation of the shifting from different types of crime within groups. However, it does not measure shifts in crime for specific individuals. In effect, the aggregate nature of the FSC does not produce information about the individual extent of specialization.

Within-individual change was central to the concept of criminal careers in the 1980s (Blumstein et al. 1986) and the individual-level examination of specialization in juvenile offenders. From this perspective, the measurement focus is on the proportions of similar offense types in individual criminal histories. Here, specialization was defined by the absence of diversity of different types of crime in an individual's offense history. Regarding a specific measurement, for example, Wikstrom (1987) calculated the total proportion of crimes belonging to a single category of offenses in the histories of offenders, which allowed for the utilization of different percentage thresholds for determining specialization. Wikstrom (1987) asserted that if, regardless of the type of offense, two-thirds or more were of one type, then the offender's criminal offending history is considered specialized. However, this measurement methodology is not applicable to occasional or limited offending. In a Swedish sample of delinquents, Wikstrom (1987) identified approximately one-third of juvenile offenders as specialists. Theoretically, different thresholds can be asserted as establishing specialization. In addition, this threshold measurement methodology raises validity concerns depending on the number of types of crimes available for analysis. For example, certain studies can and have calculated a threshold based on three categories of crime, such as property, violent, and status offenses. Others have used even more specific crime categories, making cross-study comparisons problematic because the two-thirds threshold used for three crime types does not appear an appropriate threshold for a larger number of categories. In short, determining specialization based on percentage threshold approaches is somewhat arbitrary and ultimately does not easily capture the nature of offense specialization.

More recently, the extent of specialization in an offender's history has been calculated using the diversity index which also focuses on the proportion of different offenses committed by individuals but also provides a measure of the probability that any two observed offenses drawn randomly from a criminal history belong to dissimilar offense types. In effect, by calculating the proportions of offenses across a specified number of crime categories, this approach provides an individual-level measure of specialization based on the complete offense patterns, rather than the sequence of offenses. This measure calculates the overall amount of similar/dissimilar offenses and allows for the comparison of specialization patterns for both individuals and groups. Again, however, when studies used different numbers of crime categories to calculate the amount of diversity, cross-study comparisons become problematic. In addition, some scholars have asserted that the diversity index does not provide precise information about the type of offense specialization, such as the frequency of different offense types (Sullivan et al. 2009).

Several recent studies have applied new and innovative approaches to measure specialization in juvenile offending (and more generally). These approaches typically involve complex multivariate techniques that have the ability to simultaneously capture the nature and extent of specialization, something that past techniques typically accomplished independently (i.e., the FSC compared to the diversity index). One such approach is Latent Class Analysis (LCA). While not designed specifically for the study of offense specialization, LCA is useful for identifying homogeneous subgroups of offenders that cluster around specific types of offenses within a sample. LCA has been used in the classification of offenders' criminal career trajectories that are based on the varying frequency of total offending over time (Francis et al. 2004). In effect, this technique has the potential to distinguish groups according to both the frequency and type of offenses committed.

Research Findings

The original empirical studies using transition matrices were characterized by mixed findings because of differences in sample composition, data sources, and several methodologies. Nonetheless, most of these studies identified considerable versatility in juvenile offending behavior, which therefore, provided initial support for the General Theory of Crime and the prediction of "cafeteria-style" offending patterns of juvenile offenders (e.g., Klein and Malcolm 1979; Klein 1984). However, several of the initial studies indicated some support for specialization for certain types of minor offending, such as theft (Wolfgang et al. 1972). Subsequent studies in the 1980s found evidence of specialization, again, for less serious crimes such as property and status offenses. For example, Farrington et al. (1988) demonstrated that the most specialized offenses involved status offenses (e.g., running away, liquor, incorrigibility, curfew, and truancy) and property offenses (e.g., burglary, vehicle theft) as well as drug use. As well, there was some indication of a modest tendency toward crime switching to more serious forms of offending, particularly from status to property and property to violent offenses (e.g., LeBlanc and Frechette 1989; Smith et al. 1984). The same pattern of mixed support for specialization was evident in other studies. For example, females were more likely to specialize in status offenses compared to males, who were comparatively more likely to specialize in serious offending (e.g., Kempf 1986, Farrington et al. 1988). Yet still, other studies did not report such differences. Even regarding ethnicity/racial groups, versatility was more prevalent than specialization despite some studies that indicated black youth were slightly more likely to specialize in more serious property offenses than white youth (e.g., Lattimore et al. 1994). Again, several studies did not report this pattern.

By the late 1990s, studies based on developmental theories' predictions concerning specialization in juvenile offending revealed even more complex findings. Mazerolle et al. (2000) examined Moffitt's typology and found AL offenders were more likely to specialize in nonserious offenses compared to LCP offenders. The latter also were more violent (see also Piquero et al. 1999). Subsequent developmental theory-based studies expanded into the adulthood stages revealing that offending trajectories over the life course confirmed the adolescence period had the least amount of specialization with specialization typically emerging later in adulthood. Most importantly, both onset and desistance occurred more often in the adulthood stages than originally predicted. In effect, as offenders aged into adulthood, their offending became more patterned but less frequent.

In sum, three main empirical themes regarding specialization in youthful offending were evident. First, adolescence generally involved the least amount of offense specialization compared to later periods. Second, a small but significant amount of specialization occurred during adolescence. This variation however, typically consisted of the less serious end of the offending spectrum, such as status offenses and theft. However, while this small but significant amount of specialization occurred, versatility was far more prevalent. Third, a small minority of juvenile offenders was responsible for much of the versatile offending committed in adolescence and, most importantly, for more serious violent offending.

Juvenile Justice Policy Implications Related to the Specialization Debate

The original juvenile justice laws reflected early crime-specific theories and crime-centered typologies that presupposed specialization in juvenile delinquency and, in particular, status offenses. Given the apparent extent of nonserious and more specialized offending, welfare/rehabilitation models of juvenile justice were dominant and focused on the family-based causes of delinquency through rehabilitation interventions in juvenile courts. In effect, status offenses were a key target for policy intervention with youth, and in many Western jurisdictions, formal status offender programs proliferated and were based on the hypothesis that youth status offenders would escalate to more serious forms of offending if formal intervention and treatment was not pursued. In other words, one rationale for these programs was that early and formal intervention/treatment was warranted if "status offenders" represented a distinct group of youth who specialized in nonserious misbehavior to prevent them from becoming involved in delinquency and more serious offending. Proponents of this view, therefore, subscribed to the belief that youthful offending was (a) characterized by some degree of specialization and (b) escalated to more serious forms of delinquency in the absence of intervention.

By the mid-1970s, however, the welfare model-based juvenile justice laws and assumptions about specialization in youthful offending were challenged theoretically, empirically, and politically. One reform theme was that diversion of youth outside of the formal juvenile justice system was necessary to avoid the hypothesized delinquent effects of labeling. In other words, the common view was that minor versatile offending such as status offenses and vandalism escalated into more diverse and serious offending types when juvenile justice systems labeled minor offending youth as delinquents. In effect, specialization was conceptualized more in qualitative terms such as status offenders versus serious criminal, property, and violent offenders. However, beyond the theoretical debates, research on specialization in juvenile offending in the 1970s and 1980s did not support the assertion that, in the absence of intervention, the majority of youth who specialized in status offenses escalated to more serious offending types.

The reform debates in several jurisdictions, especially Canada and the United States, focused on specialization themes involving the identification of certain types of offender categories including career criminals, chronic offenders, serious and violent offenders, and sexual offenders. In effect, the political and research debates did not just center on more contemporary themes and measures of specialization but rather on more broad conceptualizations focused on distinguishing types of minor offenders, types of property offenders, types of violent offenders, and combinations of offender types. Youth justice laws were and are still based on this conceptualization of juvenile delinquent or young offender specialization. In many jurisdictions, different sets of procedural processes are utilized depending on the above specialized categories as well as versatile types. For example, as stated above, minor property offenders and minor violent offenders in certain jurisdictions in Australia, New Zealand, Canada, the United Kingdom, and the United States are completely diverted away from juvenile justice court proceedings. In contrast, in Canada, the United States, and most other jurisdictions, the most serious violent juvenile offenders, such as murderers, are either processed in adult criminal courts or subject to adult length custodial sentences. In addition, patterns of offending, especially predominately minor violent offenses, automatically subject such offenders to more punitive sentences. The key assumption informing many of these sentencing options is that the minor violent offending specialization pattern typically indicates the potential for such youthful offenders to escalate into specialized violent and chronic offending.

The mixed results regarding the existence of specialization in youthful offending belie the above assumptions that there is a strong correlation between chronic minor juvenile offending and long-term chronic violent offending. While there is more support for the relationship between serious chronic violent juvenile offending and long-term violent offending trajectories, only an extremely small proportion of all juvenile offenders have been identified within this specialized type. The concern is that juvenile justice laws have become over focused on this rare offender category to the detriment of programming for the overwhelming number of less serious juvenile offenders. In other words, juvenile justice reforms have been influenced by the debate in research concerning specialization, arguably, in a progressive way in some countries (e.g., Australia, New Zealand, Canada, the United Kingdom) and in a regressive manner in several US states, for example, those with life sentences with no parole and formally capital punishment for the most serious juvenile offenders. Even more recently in Canada, a conservative federal government introduced punitive reforms to the national youth justice law based on the assertion that specialized violent and specialized property offenders require more punitive sentences.

Conclusion

There is a consensus that versatility typifies most juvenile delinquents or young offenders. There also is considerable evidence that for a small proportion of juvenile offenders, certain types of offenses distinguish them from other offense patterns. For example, sexual offenses, while not constituting the largest proportion of a young offender's offending profile, nonetheless, distinguishes such an offender from another young offender who has no sexual offenses in their offending profile. In effect, the conceptualization of offender specialization remains open to different operational definitions. The key to the different conceptualizations is the theory or policy rationales. Major theoretical insights, for example, have emerged from developmental theories of offending that have asserted certain types of specialization as discussed above. The related theoretical debates and empirical research has propelled further theorizing and research that has several benefits. First, multiple measures and indices involving increased methodological sophistication have emerged and enhanced the understanding of juvenile offending trajectories. Second, the specialization research has revealed far more complex and diverse patterns of offending than were originally hypothesized. Third, it is vitally important that sophisticated research designs continue to be employed in assessing specialization because the ongoing juvenile justice policy debates concerning how to react to different types of offenders are best informed by valid and empirically supported categories of offending as opposed to impressions and emotion regarding what constitutes serious youthful offending.

Overview

Stalking affects hundreds of thousands of people around the world every year, and criminal justice and mental health professionals are often required to manage or treat stalkers or their victims. This entry provides an overview of the phenomenon of stalking, its legal status, explanatory models, and victimology and impact. A detailed description of best-practice assessment procedures for perpetrators and victims and treatment/management considerations for both groups is also provided.

Fundamentals

What Is Stalking?

Stalking is a problem behavior characterized by repeated and unwanted intrusions inflicted by one person upon another in a manner that causes reasonable fear and/or distress. Intrusions typically come in the form of unwanted communications, such as those via telephone (including SMS), electronic media (e-mail, social networking websites), letters, or graffiti. In many stalking episodes, intrusions will also take the form of unwanted contacts, including loitering near the victim, following, maintaining surveillance, and making approaches. In addition to these core stalking behaviors, a range of other forms of harassment are often present, including property damage, theft, malicious use of the Internet (e.g., creating defamatory websites), sending or leaving unsolicited materials (ranging from gifts to items intended to frighten or implicitly threaten, such as dead animals), inveigling others to harass the victim, vexatious complaints, uttered threats, and assault.

The defining features of stalking behavior are that it is *repeated*, is *unwanted*, and *causes significant distress*. Even within this broad definition, stalking has been shown to occur in two basic patterns (Purcell et al. 2004). The first is a short-lived burst of self-limiting intrusions that occur over the course of a day or two and usually involve unwanted approaches by a stranger or distant acquaintance. The second involves both unwanted communications and contacts, and frequently other associated behaviors, tends to be perpetrated by an ex-intimate or acquaintance, and persists for weeks, if not months. The latter type tends to have a far greater psychological and social impact on the victim and is more frequently associated with threats and physical assault, so is more likely to attract criminal justice or mental health attention. In recent years, stalking behaviors have also been observed in a purely virtual environment, a phenomenon labelled "cyberstalking." Those who engage in cyberstalking use the mechanisms of the Internet to harass their target(s), but do not engage in the aforementioned behaviors commonly seen in "off-line" stalking. Studies of this behavior are few and bedevilled by problems with definition and methodology. The best investigation to date concluded that, while Internet-based harassment is common, pure cyberstalking is actually rare and most victims who experience stalking via the Internet are also targets of off-line stalking behavior (Sheridan and Grant 2007).

Legal Definitions

Stalking is a relatively new crime in most jurisdictions; the Californian law of 1990 was the first legislation specifically intended to prevent the behavior. By the end of the 1990s, stalking laws had been introduced in most English-language jurisdictions, with many countries in mainland Europe following suit throughout the first decade of the 2000s. The first wave of anti-stalking laws (1990–1999) usually conceptualized stalking as a precursor to assault, and so the purpose of the law was to prevent physical attack. More recently, stalking has been conceptualized as harmful in and of itself, and the introduction of the second wave of laws (those implemented since 2000) has tended to focus less on violence, although this is still a concern. Anti-stalking legislation is relatively uncommon outside of Australasia, Europe, and North America. Where present, it is usually included in domestic violence laws and so is typically poorly defined and largely restricted to female victims of ex-intimate partners.

Depending on jurisdiction, anti-stalking legislation typically requires three elements to prove the offence. The behavior or conduct element is usually defined as a "course of conduct," or conduct engaged in on more than one occasion (intentionally broad so as to allow for early intervention). There is no requirement that the individual instances of behavior be unlawful (e.g., repeated nonthreatening telephone calls would satisfy a course of conduct, although none would be illegal in isolation). Some jurisdictions leave the behavior element at this point without further defining the nature of the acts that constitute harassment or stalking, while others go on to define the types of conduct that are prohibited. The second necessary element is perpetrator intent. Most anti-stalking laws require either that the perpetrator intended to harass or cause harm to the victim or that they ought to have known that their behavior could have had that effect (akin to being reckless as to the effect of their behavior). The final element, which is present in many North American and European jurisdictions, although not in Australasia, is that the victim experiences the behavior as intimidating and feels fear or apprehension as a result. Two levels of proof are often required: a subjective standard (this victim felt fear) and an objective standard (a reasonable person would have felt fear). In many jurisdictions, stalking is divided into misdemeanor or felony offences, depending on the nature of the behavior engaged in. Furthermore, many anti-stalking laws provide for the civil option of a protection order for the victim, breaches of which are a criminal offence. Stalking laws have provoked considerable discussion, which is summarized by Kapley and Cooke (2007) and Mullen and colleagues (2009a).

Prevalence

Estimates of the prevalence of stalking vary according to the definition, sampling, method of enquiry, and willingness of participants to respond and answer candidly. Nonetheless, estimates are remarkably consistent across location and time, with lifetime victimization rates of 17–30 % reported for women and 4–12 % for men (Purcell et al. 2002; Smith et al. 2011; Stieger et al. 2008). Reported prevalence rates in the USA tend to be lower than other countries (7 % for women and 2 % for men) as the national survey included only those victims who experienced the stalking as dangerous or life-threatening (Basile et al. 2006). Victims are largely female (70–80 %) and stalkers are predominantly male (80–85 %), with 20–25 % involving same-gender stalking, usually male-male.

Explaining Stalking Behavior

Stalking, like any complex human behavior, is a product of a range of psychological, social, and cultural influences. People stalk out of anger, hope, lust, ignorance, or a combination of these factors. The influence of psychopathology, discussed later, is also relevant in many cases of stalking, either as a direct or indirect causal factor. To date there are no comprehensive theories to explain the variety of stalking behavior that is observed. Some single factor theories have been described, most commonly disrupted attachment (Meloy 2007). This theory posits that stalking is a consequence of insecure and, specifically, preoccupied attachment. Research has supported aspects of this theory, finding that stalkers do indeed often present with insecure adult attachment, although there is little evidence for a specifically preoccupied style. Proponents of stalking as an expression of disrupted attachment tend to focus on those seeking relationships and do not address other possible trajectories into stalking behavior. Moreover, the mechanisms by which insecure attachment produces stalking in some contexts but not in others, even within the same individual, have not been adequately explained. Nonetheless, there does seem to be some evidence for chronically disturbed attachment style in some stalkers.

Where attachment theory examines distal dispositional characteristics that may lead to increased proclivity to stalk, Spitzberg and Cupach’s (2007) application of relational goal pursuit theory to relationship-based stalking suggests more proximally relevant factors. In this theory, the goal of possessing a particular relationship becomes entwined with the perpetrator’s value system and is integral to their sense of self-worth and life happiness. In this context, pursuit of the goal (a relationship with the victim) takes on disproportionate significance. The failure to achieve the goal in spite of persistent attempts results in rumination and consequent negative emotional states, which the perpetrator attempts to escape by further efforts to achieve the desired goal. This is perhaps the most well-explicated theory of stalking behavior, although it also does not account for the variety of trajectories seen in stalking behavior, and to date it remains largely untested. A significant gap in the stalking literature remains, awaiting a truly comprehensive multifactor theory that adequately explains this complex behavior.

Classification Systems

In the absence of such a theory, many classification systems have been developed in an attempt to reduce the heterogeneity of stalkers into manageable categories that can assist decision-making. These taxonomies vary depending on the needs of the authors and audience. Those developed by clinicians emphasize the goal of treatment and management, while those for law enforcement tend to be used more as shorthand for management and referral options. In both realms, classification schemes tend to focus on three variables: mental disorder, prior relationship, and motivation. The earliest classification schemes focussed heavily on psychopathology, reflecting the fact that stalking behavior was seen as a manifestation of emotional and psychological disturbance. By the mid-1990s, prior relationship and affective state were also considered useful ways of differentiating stalkers. More recently, Mohandie and colleagues (2006) proposed a scheme based on the nature of the prior relationship and the context in which the stalking occurred. This scheme in particular may be useful for law enforcement personnel as it is relatively easy to apply based on minimal information. Many typologies have been proposed, and a useful review is provided by Pinals (2007).

A Multiaxial Classification Scheme

One of the most commonly used typologies, endorsed by the Group for the Advancement of Psychiatry Committee on Psychiatry and the Law, is that of Mullen et al. (2009). This typology, based originally on a sample of 145 Australian stalkers, took the unique step of proposing classification on multiple axes to determine type. The first axis is the nature of the prior relationship between stalker and victim; the second, the initial motivation for and context in which contact with the victim occurred; and the third, the presence and nature of any psychiatric diagnoses. Using these three axes, five stalker types were identified, which are described below. More lengthy descriptions can be found in Mullen et al. (2009).

The Rejected: These stalkers begin to stalk following the dissolution of an intimate relationship, however brief, in an attempt either to reclaim the relationship or to exact revenge against their former partner for leaving. In many cases, both of these motives are present at different times. Not typically affected by severe mental illness, these stalkers tend to present with antisocial, narcissistic, borderline, or paranoid personality traits, depression, and/or substance use disorders. In a minority of cases, dependent and obsessive-compulsive personality traits are evident.

The Resentful: These stalkers target an acquaintance or stranger, but invariably someone who they perceive has mistreated them, either in their own right or because they are representative of some organization that has provoked the stalker's ire. The stalking usually begins with the aim of righting the perceived wrong and over time becomes the only way to assuage feelings of resentment and regain their lost sense of power and control. These stalkers often suffer from paranoid or narcissistic personality disorders and occasionally present with paranoid delusions incorporating the stalking victim(s).

The Incompetent Suitor: These individuals target strangers or acquaintances with the initial intention to pursue a friendship or date. The stalking is an inept and often self-centered attempt to achieve that outcome. Over time it may take on an angry or aggressive tone as the stalker's wishes are thwarted, but this group typically does not stalk for an extended period, instead transferring their interest elsewhere. While many stalkers who fall into this category do not experience any form of mental disorder, this behavior does emerge in the context of impaired social skills and interpersonal deficits, and intellectual disability or developmental disorders are not infrequent. Also found in this group are narcissistic individuals who are assertive, overbearing, and simply can't imagine why any woman would refuse the opportunity to date them.

The Intimacy Seeker: These stalkers target acquaintances or strangers in an expression of their love and seeking love in return. Usually the stalker persists in an affectionate and amorous way, but very occasionally they can become angry and vengeful if they realize that the longed-for relationship is under threat. Often driven by a severe mental illness, these individuals may believe that they already have a mutually loving relationship with the victim, even in the absence of any true connection. Conversely, they may be intensely infatuated and believe that the idealized relationship is possible if they persist. Overvalued ideas of intimacy are almost ubiquitous in this group, arising either out of a severely disturbed borderline personality or at the more extreme end, a delusional disorder or schizophrenia with erotomanic delusions.

The Predatory: These men most often target strangers with the goal of achieving some form of sexual gratification, usually deviant. They use stalking as part of a wider repertoire of sexually inappropriate behaviors, and their stalking is usually characterized by surreptitious loitering, following, spying, and, in many cases, sexual violence. The predominant diagnoses in this group are paraphilias, depression, and substance misuse.

Psychopathology

Stalking is a set of behaviors, not a diagnosis, but studies suggest that at least 80 % of community referred stalkers have some form of psychiatric condition (McEwan et al. 2009). Personality disorders, schizophrenia, and major mood disorders are the primary presenting problems (McEwan et al. 2009; Rosenfeld 2003). In their retrospective file review of a forensically derived sample of stalkers, Mohandie and colleagues (2006) found 46 % had a probable diagnosis of mental disorder. Referral bias limits the generalizability of these findings, in that forensic samples are weighted towards more serious offending and severe mental illness.

There is a higher prevalence of major mental illness among those who stalk public figures (James et al. 2009). Over 80 % of individuals who made inappropriate communications or approaches to the British Royal Family were found to have a major mental disorder. In a study of individuals who pursued and ultimately physically attacked a Western European politician, over half were mentally disordered, most of whom were psychotic.

Suicidal ideation is also common among stalkers. Using retrospective file review, Mohandie and colleagues (2006) identified suicidality in 25 % of 763 North American stalkers, while McEwan and colleagues (2009) observed that one in ten of their Australian sample reported suicidal ideation. In a 3-year follow-up, McEwan and colleagues (2010) found that 3 of 138 stalkers (2.2 %) had committed suicide. Though small, these numbers represent substantially higher rates, indeed six times greater, than would be expected among psychiatric patients or community-based offenders. In all three cases, the stalker had a history of suicidal ideation or intent. This finding is of particular concern because suicidal stalkers pose an enhanced risk of violence towards their victim and third parties. Stalking risks will be discussed further in a later section.

Particular psychopathology is found more commonly in certain types of stalker, as noted in the multiaxial classification scheme presented earlier. For instance, personality disorders or traits predominate in Rejected stalkers though morbid jealousy of delusional intensity is also encountered in this group. Intimacy seekers are far more likely to have serious psychopathology, in the form of psychotic disorders, and female stalkers have higher rates of psychosis than their male counterparts (Meloy and Boyd 2003). As elaborated later, the risk of serious violence in the stalking situation is greater when the stalker has a nonpsychotic as opposed to a psychotic condition.

Earlier assumptions that stalkers have above average intellectual functioning have been called into question by a prospective study of stalkers referred to a clinic specializing in their assessment and treatment (MacKenzie et al. 2010). Intelligence testing found a mean intelligence quotient (IQ) in the average range (91.59 [SD 16.2]), with a verbal IQ significantly lower than performance IQ. These findings have important implications for psychological intervention programs for stalkers, which must reflect their cognitive abilities.

Victims and the Impact of Stalking

Stalking is an event that has a perpetrator and a victim. The victim is pivotal to stalking because stalking is, in effect, a victim-defined crime. Behaviors that are inappropriate and gauche are transformed into behaviors which are harmful and illegal by the apprehension that is evoked in the victim. While the line between the inappropriate and the fear inducing is in some respects influenced by the tolerance and sensitivities of the victim, most stalking that comes to the attention of the criminal justice system could be expected to provoke fear or disquiet in the majority of people.

Stalking has been viewed as a product of failed relationships and a form of domestic violence perpetrated by men against women. Earlier in the evolution of our understanding of stalking, the concept generalized from behavior directed at the famous to that of males who battered their partners. While lending attention to a long neglected issue, the concept of stalking is problematic when used to describe behaviors that occur in the context of an ongoing relationship. To begin with, the focus on stalking as a form of domestic violence has predominantly been on women as victims and men as abusers, while those who stalk former intimates can be female and victims can also be male. More importantly, while behaviors akin to stalking undoubtedly emerge among cohabiting partners, especially in relationships characterized by jealousy, this usually comprises behaviors that are aimed at information gathering (e.g., monitoring, surveillance) or coercive physical or verbal abuse and threats. A distinction should be made between such conduct and stalking. The aim of stalking is to make one’s presence felt *where it would not otherwise* *exist*. Where there is an ongoing relationship, however conflicted and potentially damaging, the behavior should be classified as a form of terrorizing and controlling intimate partner violence, not as stalking. Confusing the two is semantically and practically problematic as approaches to assessing and managing stalkers will be ineffective in situations where the stalker and victim continue to cohabitate.

A number of classifications have been proposed for stalking victims, all of them based upon the preexisting relationship, if any, between victim and stalker. The following is a relational classification of stalking victims, derived from the typology proposed by Mullen and colleagues (2009):

1. *Former sexual intimate*. The most common victim profile is a woman who previously shared an intimate relationship with the stalker, usually male, though women can be perpetrators and stalking can also arise in the context of same-gender relationships. This category includes only those cases in which the relationship has been explicitly terminated.

   Acquaintances, who can be:

2. *Family/friend*. Rejected stalking may follow the breakdown of a close friendship or estrangement from a family member. Occasionally, Resentful stalking can emerge in relation to some perceived injustice (e.g., dispute over a family estate).
3. *Professional relationship*. As below, those in the health, law enforcement, and teaching professions are especially at risk.
4. *Casual contact*. Intimacy seekers, Incompetent suitors, and Predatory stalkers may all target their victim in the context of a casual social encounter. Neighbor stalking usually falls into this category, most often involving a Resentful stalker incited by disputes over noise or a fence line.
5. *Workplace contact*. Where the victim meets their stalker in a workplace context. The stalker may be in a subordinate or superior position, or in some cases a client or customer.

   Those without any real connection to the victim:

6. *Stranger*. Some victims have no prior knowledge of their stalker. The stranger may identify themselves, but some remain anonymous.
7. *The famous*. As noted below, prominent figures such as politicians and media personalities attract a range of stalker types, particularly Intimacy seekers and Resentful stalkers. Some celebrities suffer the attentions of multiple stalkers.

To this can be added secondary victims, who are impacted by stalking as a consequence of their relationship to the primary victim (e.g., the victim's partner or other family members, co-workers, or neighbors). Stalking tends to have a "ripple effect" on the victim's social network. In some instances, stalkers pose a greater risk to secondary victims than their primary target.

It has long been observed that stalking can have damaging, if not devastating, consequences and it is the reason, ultimately, that stalkers have attracted the interest of mental health professionals. Stalking impacts upon the victim, the third parties, the stalker themselves, and the community as a whole. Such impacts have received systematic attention over the past decade. The initial studies were mainly descriptive and highlighted the psychological, occupational, and social impacts of these behaviors (Pathé and Mullen 1997). Subsequent large epidemiological studies (e.g., Purcell et al. 2002; Purcell et al. 2005) found that stalking was prevalent in Western nations and also confirmed the higher rates of psychiatric morbidity among victims of stalking.

Victims of stalking commonly report a profound sense of violation and loss of control over their lives. Many experience a pervasive mistrust of others that can persist long after the stalking has ceased. In their epidemiological study that compared matched controls, victims of brief harassment, and victims of protracted stalking (>2 weeks), Purcell and colleagues (2002, 2005) found that the rates of general psychiatric morbidity were significantly higher among those who reported a history of protracted stalking (36 % vs 19 % for controls and 22 % for brief harassment). Those subjected to severe stalking were also more likely to report recent suicidal ideation (10 %) and clinically significant levels of posttraumatic symptomatology (three times more likely than the briefly harassed group).

More recent studies of stalking victims have considered groups who are particularly vulnerable to stalkers. These include health professionals (Whyte et al. 2011) and public figures (Mullen et al. 2009), but there is also anecdotal evidence of higher rates of stalking victimization in other professions such as teaching and law enforcement. Studies to date suggest that the lifetime risk for a health professional being stalked by a client or patient is 20 % (Purcell et al. 2005), and those working in the mental health field, by virtue of the patients they encounter, may be more susceptible to such behaviors. One of the commonest motivations for stalking health practitioners is morbid infatuation, where a lonely, disordered patient misconstrues sympathy and attention as romantic love. These patients-turned-stalkers can be categorized as Intimacy seekers. Resentment is another common motivation, stemming from some supposed injury or dereliction. These stalkers fall into the Resentful category. A smaller group is pursuing reconciliation or revenge following the termination of a (usually long-term) therapeutic relationship (Rejected stalkers). The impact of stalking on health professionals can be significant, with over 70 % of affected psychologists in one study (Purcell et al. 2005) modifying aspects of their personal and professional lives, some of whom relocated their practice and/or their private address. Almost a third contemplated leaving their profession altogether, this figure rising to nearly 50 % among those whose stalker made malicious complaints to their professional registration board.

Assessment Guidelines

Assessments of stalkers or victims often take place in a stressful context. For the stalker, this may be as part of a presentence or parole report, or in a mandated treatment situation. For victims, help is often sought when the pressures of the stalking become overwhelming and they feel that they can no longer cope on their own. Stalkers tend to deny, minimize, rationalize, and justify their behavior. Victims often minimize the experience of stalking and overemphasize their responsibility for the harassment. In both scenarios, obtaining collateral information about the stalking episode is essential. Where available, police or court documents summarizing the behavior are invariably useful, as are accounts by those associated with the victim or stalker. When possible, it is usually best to avoid having contact with both the victim and stalker. Victims may experience attempts to obtain collateral information as simply another unwanted intrusion by someone acting on behalf of the stalker, while for stalkers, having a professional make contact with the victim can be understood as implicit support for an ongoing “relationship” or as an opportunity to obtain new information about the victim.

Assessing a Stalker

It is usually possible to form hypotheses about the motivation for stalking reasonably quickly. Information about the prior relationship between victim and stalker and about the apparent initial motivation can be gleaned from collateral sources or identified very early in an assessment. Often the best way of determining motivation is to simply ask the stalker what drove them to this behavior or what they originally wanted to achieve. A central aspect of the assessment is conducting a functional analysis of the stalking. This involves examining the common situational, emotional, and behavioral antecedents to and consequences of each intrusion. An analysis of this kind can provide useful information upon which to base hypotheses about the cognitive and emotional states associated with offending and the skill deficits that might lead them to stalk rather than use a more adaptive strategy to achieve their goals.

For mental health clinicians, particularly those with forensic expertise, the assessment will be like most others, with slightly more emphasis on the individual’s experience of other, similar interpersonal situations. For example, for a Rejected stalker, additional questions about prior relationships and breakups would be relevant, and for a Resentful stalker, enquiry into how they have handled previous injustices or disputes would be useful. Where sexually deviant behavior is present, a full sexual behavior assessment is appropriate, as for sex offenders. If the clinician is not trained in assessment and diagnosis of psychopathology, referral to an appropriately qualified expert is strongly recommended.

Assessing a Victim

Some stalking victims present for mental health intervention after the stalking has ceased. They are commonly seeking help to deal with post-trauma symptoms and reconstitute their life. An appraisal of the risk of recurrence of the stalking may also be appropriate. Many more stalking victims seek assistance when the stalking is ongoing, and the priority in these instances is to ensure all reasonable steps are taken to protect the victim's safety and privacy. Some may be engaging in behaviors which place them and other parties at risk (e.g., retaliating against their stalker), necessitating urgent guidance. Around 10 % will have suicidal ideation requiring assertive intervention.

As a consequence of their experiences, many stalking victims are distrustful, and some will have previously encountered negative attitudes from the "helping" professions. In engaging stalking victims, it is essential that the assessment is conducted by a professional familiar with stalking issues and the available interventions. It is important at the outset that stalking victims are reassured that the stalking is not their fault and that they are not alone in their ordeal.

Stalking victims require a comprehensive assessment, including a full psychosocial history that encompasses past victimization and a detailed account of the stalking. This includes the nature of the victim's prior relationship with the stalker, a description of the onset of the stalking, and the frequency and nature of the intrusions, as well as any strategies employed to end the stalking. How effective were these measures, and has anything exacerbated the behavior? Have they involved the police, and if not, why not? Are there any current protective injunctions, or is the stalker subject to any other legal directives? Is the stalker known or suspected to be mentally ill, and if so, are they known to the mental health system? Some victims, especially those stalked by strangers, may have limited information, but victims should be encouraged to bring as much documentation as possible to the assessment (including any evidence of the stalking in the form of letters, e-mail, phone records, photographs, court orders, or witness statements).

Stalking victims should be questioned about suicidal inclinations, any homicidal intent towards the stalker, and any measures they may have taken to defend themselves (e.g., keeping weapons in the house). One should endeavor to gauge the victim's current level of support, others affected by the stalking, the victim's employment situation, and mental health status. Are they suffering current anxiety or depressive symptoms, and how have these been managed? Maladaptive coping mechanisms such as substance abuse or gambling are not uncommon and may require specific interventions.

Risk Assessment

In any stalking situation, a primary concern for the victim is the likelihood of further damaging behavior. Often their worries focus on the likelihood of physical violence, the likelihood that the stalker will persist, or if they have stopped, that they will start again. Therefore, for those charged with managing stalking situations, risk assessment is a primary focus. For those working with stalkers, an additional concern is the potential for psychological and social harm to the perpetrator and what this means for other areas of risk.

While the stalking risk assessment literature continues to lack strong retrospective or prospective studies of representative samples, a sizeable body of published work now exists, and relevant information can also be gleaned from the much larger body of research into violence and offending risk assessment more generally. Two structured professional judgement tools for assessing stalking have been published and are undergoing validation trials – the *Stalking Risk Profile* (*SRP*) (MacKenzie et al. 2009) and the *Guidelines for Stalking Assessment and Management* (*SAM*) (Kropp et al. 2008). Where these tools are not available, clinicians and law enforcement personnel must rely on clinical experience and integrating the literature themselves.

Risk of Persistence or Recurrence Stalkers that persist for at least 2 weeks are at increased risk of continuing for months. Those with a prior relationship with the victim tend to stalk for longer, and as a rule, women tend to be more persistent than men. By far the strongest predictor of extreme persistence is psychosis, and these stalkers are unlikely to desist without mental health intervention. Recurrent stalking appears to be the domain of the personality disordered and those who share the victim's children, property, or locale, although a lack of research makes firm conclusions difficult (Rosenfeld 2003).

Risk of Violence As a group, ex-intimate partners present the greatest risk of violence, with up to half in this category using physical violence against their victim or a related third party (McEwan et al. 2007). Identified risk factors for violence for all stalkers include:

- *Demographic variables*. It has been repeatedly shown that the gender of the stalker or the victim has no impact on the prevalence of either threats or assault, and same-gender stalking victims are at equal risk of violence (Strand and McEwan 2011).
- *Stalking behaviors*. Stalkers who follow, loiter near, accost the victim, or enter the victim's home are at increased risk of violence. Escalations in the intrusiveness or intensity of the stalking have not been subject to research, but should be treated as periods of increased risk.
- *Threats*. Threats are common in stalking situations and have been shown to be a risk factor for violence, particularly for ex-intimate partner violence (McEwan et al. 2007).
- *Prior violence and criminal behavior*. The evidence is inconsistent; however, on balance, it seems that prior violence in particular is a predictor of stalking-related violence (McEwan et al. 2007).
- *Mental disorder*. Psychotic stalkers have consistently been found to be less violent than nonpsychotic stalkers; however, the presence of other risk factors should not be discounted because the stalker is psychotic (McEwan et al. 2009). The relationship between personality disorder and violence in stalkers is unclear, although findings from the wider risk assessment literature indicate that antisocial personality disorder in particular is related to violence.
- *Substance misuse*. Substance misuse is associated with stalking violence, likely having a compounding effect on other risk factors.

Formulation and Treatment Planning for Stalkers

Clinical formulation links assessment information with a systemic treatment and management plan. A good formulation will explain the mechanisms underlying the stalking and direct interventions to stop it. For the clinician assessing a stalker, the central focus of formulation is the *stalking behavior* itself rather than the presence of psychopathology or other matters. A detailed explanation of how to formulate stalking behavior is beyond the scope of this entry, but some guidelines are available in McEwan et al. (2011).

Treatment and Management

Stalkers

Management of stalkers often involves the use of the criminal justice system, which is described further below. Presented here are options for interventions designed to address the underlying causes of the behavior in conjunction with such environmental management strategies. The information provided in this section assumes the availability of an appropriately trained and supported mental health practitioner and a client that is willing and/or mandated to attend treatment. Whenever possible, treatment of stalkers should be undertaken by a clinician experienced in working with offenders, who has training in structured risk assessment, familiarity with the stalking research literature, and an understanding of local stalking laws. Those who work with stalkers (or their victims) should also be cognizant of the risks of such work and should take appropriate steps to ensure their own safety and security (Pathé 2002).

There is limited information available about the efficacy of offence-specific psychological interventions for stalkers, with Rosenfeld and colleagues' (2007) trial of dialectical behavior therapy the only published study. Treatment strategies described by these and other authors (e.g., MacKenzie and James 2011) take a cognitive-behavioral perspective and focus on helping the stalker to develop skills that they can apply in situations where they have previously used stalking (e.g., emotional regulation, problem solving, and communication skills are all targets of psychological intervention). Which particular skill deficits are most relevant to an individual stalker, and the prioritization of one skill over another, should be evident following a comprehensive formulation as outlined above. In addition to skill development, another central aspect of treatment is helping the stalker recognize potential triggers for stalking behavior, identify high-risk thinking and behavioral patterns, and implement alternative strategies.

As with any offender treatment, attention must also be paid to the client's readiness to desist from their behavior. Treatment readiness can be defined as having appropriate motivation, capacity, and ability to engage in treatment so as to maximize the likelihood of therapeutic change. Where motivation to engage is low, time should be spent helping the client identify personal goals that would be assisted by avoiding stalking in the future, encouraging the view that they are able to change their behavior, and reducing emotional distress that might be provoked by thinking or talking about their offence.

Maximizing treatment readiness may require other issues to be dealt with prior to beginning any offence-specific interventions. Perhaps the most common factors that interfere with a stalker's capacity and ability to engage in offence-related treatment are active symptoms of mental illness and substance misuse. As discussed previously, these may also be risk factors for further stalking behavior, and so appropriate treatment can both reduce risk and increase the client's opportunity to engage in other offence-related interventions. Mullen et al. (2009) provide a detailed description of the management of mental disorders in stalkers. In essence the appropriate treatments are no different to those offered to non-stalkers, although consideration of risk may lead to increased emphasis on the safety of the client and others and so greater impetus for involuntary treatment. Similarly, where substance misuse is present, interventions offered to individuals who do not stalk are usually appropriate, although with due consideration of the need to protect the stalking victim while treatment for substance misuse is undertaken.

Victims

Strategies to Combat Stalking These approaches need to take account of the individual circumstances, including the prior relationship between victim and stalker; the presence of shared children, property, or workplace; the methods of harassment; and the assessed risk to the victim and/or other parties. In most situations, the victim should be encouraged to inform relevant people of the stalking, so they are alert to the problem and better equipped to protect the victim and themselves. It is important to advise victims at the outset to avoid all contact with their stalker. Attempts to appease the stalker through "one last meeting," or to explain, yet again, why the relationship ended, are, in effect, perpetuating the "relationship" and reinforcing the stalker's efforts.

Using Anti-stalking Laws As stalking is a criminal offence in many jurisdictions, informing the police may not only offer a resolution but also open an official paper trail documenting the stalker's course of conduct. To maximize the likelihood of police action, victims should be encouraged to keep a clear chronological record of harassing intrusions and any tangible evidence of the stalking. While there are few surveys of police responses to stalking complaints, those that exist show that in the majority of cases, stalkers are charged with offences other than stalking (e.g., trespass), even where specific anti-stalking legislation exists. Anecdotal evidence suggests that police often recommend that the victim obtain a protective injunction, enabling them to prosecute a breach; however, this strategy may carry some risks (see below). Storey and Hart's (2011) investigation of 32 cases showed that legal intervention is one of the more effective tactics to stop stalking. This includes everything from a formal police warning to a conviction. Informal warnings from police were shown to be ineffective in this study.

Protective Injunctions Also termed restraining, non-molestation, apprehended violence, protection, no contact, or intervention orders, their use against stalkers remains a contentious issue. These orders should not be used indiscriminately with stalkers as they have the potential to inflame the situation, provide a false sense of security, and exacerbate the victim's distress. Protective injunctions are more likely to be effective if they are properly policed, and the perpetrator is an Incompetent suitor or a Rejected stalker who has less invested in the relationship (e.g., a brief relationship with no children) and with a nonviolent, law-abiding background. These orders are less likely to succeed with Intimacy Seekers, especially those with erotomanic delusions, and Rejected stalkers who have a strong investment in the relationship (long-standing, shared children and assets) and/or an antisocial personality disorder, morbid jealousy, or a history of domestic violence.

Privacy, Safety, and Security There are a range of measures that can enhance the victim's security. These are beyond the scope of this entry but are detailed in Pathé (2002). Victims and potential victims such as health practitioners should try to ensure that as far as possible all personal information is removed from the public domain. This includes delisting their telephone and fax numbers, obtaining a post office box address, and removing their name from the electoral roll and property titles. Stalking victims should be cautious in their use of social networking websites such as Facebook and Twitter and take appropriate steps to protect their privacy.

Clinical Management of Stalking Victims Cognitive-behavioral approaches have been recommended with stalking victims. As a consequence of their stalking experiences, a victim's previously held beliefs in their strength and resilience are replaced by feelings of extreme vulnerability, and their previous assumptions about the reasonable and predictable nature of the world are shattered. Cognitive-behavioral therapies aim to correct the unhelpful assumptions that underlie their anxiety and depression and the avoidance behaviors that frequently emerge in this context. Priority should always be given to the client's safety, and if the stalking is ongoing, some avoidance behaviors may be entirely appropriate. For stalking victims presenting with chronic or complex posttraumatic stress disorder, dialectical behavior therapy (DBT) may prove efficacious (Mullen et al. 2009b).

Although there is a dearth of randomized clinical trials for pharmacological agents in the treatment of stress-related syndromes, those most frequently used with victims of stalking, as an adjunct to psychological approaches, are the selective serotonin reuptake inhibitor (SSRI) antidepressants. These agents have demonstrated efficacy for stress-related symptoms, panic, and depression. Care should be exercised in prescribing benzodiazepines for anxiety, as the symptoms, and thus the need for treatment, may be protracted, increasing the risk of drug dependence. Furthermore, the benzodiazepine agents such as Valium may diminish alertness and self-control, which can exacerbate the victim's feelings of vulnerability.

Other Therapies Wherever possible, the victim's partner and other relevant family members and supports should be involved in their management and the development of a safety plan. They frequently share in the victim's distress and may have been more directly impacted than the primary victim. They often seek information to try to make sense of the stalking, and educating significant others can alleviate pressure on the victim, by stemming criticism and unhelpful advice. Some may require referral for separate counselling.

Group therapies and support organizations can provide some validation for stalking victims and assist in reducing the victim's sense of isolation and self-blame. They are a useful source of information, support, and advocacy. Stalking victim groups need to be mindful of security at the meeting venue and the confidentiality of their members.

Conclusions

Stalking is a complex and damaging behavior that has commanded the attention of behavioral scientists, mental health professionals, the legal system, and the general public. Stalkers vary according to their motivations and psychopathology, and this determines their level of risk in multiple domains, and their management. While theories of stalking are not well understood, this problem behavior is amenable to psychological and environmental interventions. The mental health and criminal justice systems have a key role to play in bringing stalking episodes and victim suffering to an end.

State Crime

Dawn L. Rothe
Department of Sociology and Criminal Justice,
Old Dominion University, Norfolk, VA, USA

Overview

State crimes have been one of the foremost social problems of the past 100 years, with wide-reaching costs and levels of victimization. During the course of the twentieth century, the state crimes of Turkey, Nazi Germany, Stalinist Russia, Pol Pot and the Khmer Rouge, and Maoist China were especially large-scale, dramatic examples. More current examples include the continued possession of nuclear weapons by some states in violation of the Nuclear Nonproliferation Treaty; the US wars of aggression in Iraq and Afghanistan; genocides and crimes against humanity that include the Serbian attack on Bosnian and Croatia, Rwanda, Yugoslavia, and Sudan's actions against Darfur; and the Democratic Republic of Uganda and the Democratic Republic of Congo's wars and stealing of natural resources by states and corporations alike. Other charges of state crime occurring around the world as of 2011 include the political, economic, and militarized oppression involving Egypt, Israel, the United States, China, Russia, Chechnya, and North Vietnam all of which have resulted in the victimization of tens of millions that lost their lives, were rendered homeless, imprisoned, and psychologically and physically damaged through the illegal or socially harmful actions of governments.

Despite the gravity, costs, and extensiveness of crimes committed by states, the field of state crime remains understudied relative to conventional street crimes in the field of criminology and criminal justice. Nonetheless, over the last two decades, considerable theoretical, conceptual, and empirical progress has been made by criminologists to better specify the nature, extent, distribution, causal variables, and issues associated with state violence. However, there remain two primary areas of debate within the field of state crime: the standard by which to define state crime and the issue of controlling state criminality for practitioners, politicians, citizens, as well scholars of state crime. This entry provides an overview of the history of state crime and subsequent costs, followed by a discussion of the contentious issues that remain within the field. The entry concludes with a potential philosophical change that could prove to be the most fruitful means in which to constrain and control state criminality.

The Fundamentals

History and Overview of the Field of State Crime

The criminological study of state crime can be traced back to Edwin Sutherland (1939), who called attention to a then-neglected form of crime, namely, the crimes of respectable people in the context of a legitimate occupation and of corporations. His extension of the concept of crime, beyond its conventional parameters, provided an important foundation built upon by several later scholars of white-collar crime. However, one can argue that William Chambliss'

1988 American Society of Criminology Presidential address on state-organized crime provided the more direct and immediate inspiration for more systematic attention to crimes of the state. Exploring crimes such as piracy and smuggling, Chambliss showed how states can be crucial in the organization and support of activities that violate their own laws and international laws when doing so fulfills their broader political and economic objectives. A number of criminologists, particularly critical criminologists, quickly adopted the concept, broadening and enriching the field. Their early work focused not only on crimes tacitly supported or organized by a sovereign polity but also on actions committed on behalf of states themselves. However, the early research on state criminality was plagued by definitional issues and generated much debate regarding whether the individual or the state (organization) was culpable for acts deemed state crime and what standards should be used to define state criminality. These two contested areas cut to the core of the field of criminology in general; thus, it was not surprising that this debate influenced the early development of the field of state crime and, in some cases, continues today and will be discussed further in the following sections.

Regardless of the remaining contentious issues associated with standards and definitions, since the onset of criminological inquiry concerning state criminality began the field has grown exponentially. For example, literature has been produced on state crime with topics ranging from the US invasion of Iraq, the illegal use of and threatened use of nuclear weapons, the ongoing genocide in Darfur, crimes against humanity in Uganda, the treatment of illegal aliens, the US role in and lack of response to Hurricane Katrina, to the many cases of state-corporate crime such as the Challenger, Imperial Foods, ValuJet cases, and more recently cases involving Halliburton, BP, and Abu Ghraib. Additionally, there are now two comprehensive texts on state crime, Penny Green and Tony Ward's (2004) *State Crime* and Dawn L. Rothe's (2009) *State Criminality: The Crime of all Crimes*, and six edited anthologies on state crime, including *Resistance to State Crime*, edited by Elizabeth Stanley and Jude McCulloch (2012); *State Crime in the Global Age* edited by William Chambliss, Raymond Michalowski, and Ronald Kramer (2010); *State Crime, Current Perspectives*, edited by Dawn L. Rothe and Christopher W. Mullins (2010); *State-Corporate Crime: Wrongdoing at the Intersection of Business and Government* edited by Raymond Michalowski and Ronald Kramer (2006); and *Varieties of State Crime and its Control*, edited Jeffrey Ian Ross (2000). Additionally, John Hagan's (2010) *Who Are the Criminals? The Politics of Crime Policy from the Age of Roosevelt to the Age of Reagan* examines both state policies towards street crime as well as acts of state crime within and beyond the borders of the United States. Other cognate areas of state crime include political crimes, political white-collar crimes, environmental crimes, finance crimes, and the recently added crimes of globalization (see entries in this volume).

Costs of State Crime

Committing the most harmful of crimes are entities and individuals acting on the behalf of, or in the name of, the state. The types of costs include physical costs such as death, dismemberment, torture, ill health, and other costs associated with interpersonal violence directly and indirectly; environmental costs that include natural resources; economic costs; and psychological costs that are associated with a host of victimization and perpetrator mental and emotional health issues. For example, crimes of the state also can lead to the destruction of infrastructures, resulting in additional devastating harms (e.g., the 2002 sinking of the Senegalese ferry Le Joola with a loss of more than 1,000 lives) and environmental destruction with lasting effects on generations of citizens (e.g., the 1986 disaster at Chernobyl). Perhaps most importantly, state-committed crimes rip asunder the social trust between a state and its citizenry as well as trust between states (e.g., invasion and occupation of sovereign states, including most recently Iraq). When states violate such trust, domestically or internationally, they threaten the security of the global order, peace, and their own legitimacy. Given the above, it is impossible to estimate an overall cost associated with state crime, yet, we do know it far outweighs that of street crime.

Key Issues and Controversies

History of Contention: Definitions and Standards

Dating back to Sutherland, the notion of an organization being criminally liable had consistently been met with resistance by criminologists until the late 1970s through the mid-1980. During this period some criminologists began to incorporate ideas from organizational sociologists' research as they argued that social scientists needed to move beyond focusing on the individuals who make up an organization and to recognize that the aggregate whole functions as an entity. As such, it was suggested that organizations, as social actors, can and should be the primary focus of analysis in state and corporate crime.

Others strongly objected to the notion of a state, as a social actor, in an analysis of state or corporate crime. Furthermore, within criminology, the idea of a state being criminally liable was met with significant resistance. There were those that denied state criminality was possible. However, within the international legal arena, the notion of a state as an actor that could be held accountable was already well underway as the concept of a state, as an entity possessing individual rights and subject to criminal liability, emerged back in the mid-1900s. Likewise, several legal scholars observed that there was a connection between individual criminal responsibility and state criminal responsibility under international law.

On the other hand, scholars who supported the idea of state criminality were divided upon the standards to be used to define such acts as criminal between those who favored a legalistic frame and others who favored a broader frame ranging from social harms to human rights. The tensions and debates over defining state crime, however, reflect a broader debate within criminology itself. Utilization of state-produced legal codes has long been the stated and unstated norm. Such a reliance on state-produced definitions has caused tensions within street crime and white-collar crime studies, with critically orientated criminologists rejecting state-produced definitions. The political nature of law production has long been the main rationale for this rejection given that one cannot separate the nature of the political process that guides legislatures (and legislators) from the legislation produced. Further, states have an inherent drive to fulfill their own self-interest and not define harmful and problematic behavior as criminal (especially their own). Consequentially, within the field of state crime in particular, alternative formulations have been advanced, including the standard of basic human rights precepts, socially analogous harms, and social harm framework, to the perceptions of the state's citizens, each not without their own criticisms, strengths, and weaknesses.

Standards

The substance of a debate about definitions goes beyond merely critiquing the source or the substance of a given definition as alternative formulations were put forth. For example, in 1970, Herman and Julia Schwendinger suggested using a humanistic approach that would draw from objectively identifiable harms to humans and violations of human rights as the core definition of crime. Others have advocated that crimes are any socially injurious actions, regardless of the actor in question. Still some scholars have advocated that state crime should be defined by a social audience that recognizes the act as deviant. More recently, some criminologists have called for the abandonment of the concept of crime entirely in favor of Zemiology, the study of harm, thus, a social harm standard. In general, two positions on standards to be used to classify state actions as criminal remain within the broader definitional debate among scholars of state crime: crime as a social harm definition and a legalist approach.

The legalist approach includes a state's own domestic law as well as the broader umbrella of international public law (customary law, treaties, charters, and the newly emerged criminal law). This framework includes other approaches and standards such as human rights and social and economic harms. Furthermore, international criminal law covers individuals as well as states, thus resolving any enduring reservations of the state as actors versus individuals. Additionally, the legalists' use of extant statute identifies an external reference point, while other approaches are said to use a more amorphous and relativistic definitional rubric. Those that accept the use of a legalistic standard suggest that it adds legitimacy to the field's definition. Legalists argue that if a critique of state crime studies is that they are not truly scientific but rather politically inspired diatribes, establishing the illegality of such actions under a legal code is a fitting response to such critiques. Nonetheless, this approach has been criticized as another example of continuing to use law as a "tool of the state" to control the very entities that create it.

The social harm approach begins with the realization that crime has no ontological reality and it is subjectively defined by states within the context of broader issues of power and political and economic interests. In the case of crimes of the powerful, harmful activities are rarely defined as criminal. Many acts and behaviors that cause serious harm are not part of the domestic or international criminal law, thus being omitted by those using a stricter rubric such as the legalist standard. Those advocating this framework suggest that harm be defined as physical, financial and economical, psychological and emotional, sexual, and cultural. This includes the observable forms of harm, but also those seemingly more "natural" including death and illness caused by starvation, untreated treatable illnesses due to lack of medical care, those who lose their traditions and communities due to economic displacement and relocation, and a host of other ways millions of humans suffer and experience harm as a result of state policies and actions. Most importantly, this approach focuses on the origins of the harm rather than merely the actors or states involved or the act itself. This is not to say the other approaches do not do this in their theoretical and analytical assessments; however, those working from a social harm perspective begin with this focus.

There are pros and cons to using either standard to determine what is to be considered a state crime. For example, the use of international law provides clarity and precision in the definitional processes. One need not negotiate the problematic aspects of defining "harm" per se. One of the major issues with using the legalist framework is that both state-produced law and international law are the result of a questionably legitimate political process. Additionally, given the objective nature of law as defined, there is the criticism that using it as a frame to define behavior as criminal serves to maintain particular power relations at both the state and international level. In fact, international law often fails to be created or is created in a nonjusticiable way, to express politicization of its construction. While states not only have the ability to define crime, they are more often than not powerful enough to resist definitions of crime that label their own behavior criminal. The above issues are also related to a separate but equally important problem: that of enforcement.

On the other hand, the social harm framework allows for various forms of negligence and actions that are harmful yet do not meet any extant legal definition of crime to be examined and decried. This perspective allows criminologists to develop their own determination of their subject matter rather than rely on predetermined laws and human rights to dictate the field of inquiry or make the claim that a particular state behavior is "wrong," thus removing the external political influences. The social harm perspective then avoids the formal institutionalized problematic way in which crime is defined and potential additional levels of harm that could be generated by controlling crime in general through a formal system of response. Nonetheless, using a social harm frame has its own weaknesses. While this framework might add a conceptual and ideological purity to definitional processes, it takes an already broad subject matter and casts the net wider to what could be perceived as nearly the entirety of individual and institutional behavior within contemporary societies. Additionally, as with any other standard, the question becomes who then defines what is or is not harm?

Given the strengths and weaknesses of the above standards, the field of state crime now incorporates both positions. For example, while a legalist may well stick to the standard of international public law, there are times when such a standard is not acceptable. Consider the research on state crime involving, explicitly and implicitly, international financial institutions (IFIs) or crimes of globalization. Here, the intersection of these institutions not only results in immense harm, but the harms are not covered through the application of international public law, save for human rights violations in some cases. Although the policies and implicit and explicit actions of these IFIs can result in or facilitate state criminality, they are not covered under international public law, thus requiring a broader standard for defining such actions as "criminal." On the other hand, the use of a social harm standard can be complementary to the legalist approach when such harms include human rights violations. In both of the examples noted, the intermixing of these standards provides researchers of state criminality with the objective foundation as argued by the legalists within the limitations of the legal perspective. The value of both positions should not be recognized as the field of state crime research continues to grow.

The Quagmire of Controlling State Criminality

Resisting or controlling state criminality is bound to some degree with the definitional quagmire. Those that draw from the legalist standard promote formal and informal accountability mechanisms from social condemnation to prosecution. On the other hand, scholars working within the social harm framework generally see resistance and controls not in terms of accountability but in terms of policy responses. There are additional forms of harm that result from relying on a crime control industry. According to those who embrace a social harm standard, it is far more important to address not just the harms committed but also the underlying structural conditions that facilitated them. Accordingly, they suggest that this requires debates about policy and resources rather than handing the problem over to another arm of the broader power structure that, more often than not, further facilitates social harms: a criminal justice system. It requires using something beyond "the masters' tools" to confront, constrain, and control state crime. This can include movements from below, including social movements as has been witnessed in 2011 in Egypt, Tunisia, Libya, Bahrain, Yemen, and other Middle Eastern countries and with the Occupy Wall Street Movement.

Other scholars of state crime view international law as fundamental to the potential control of crimes of the state and mechanisms of accountability. These mechanisms include an international court such as the International Criminal Court and other states' domestic criminal justice systems. Additionally, impunity for crimes of the elite has long been an issue. Granting them near immunity for their actions in favor of extensive definitional and policy-related debates would suggest a reinforcement of impunity. Further, controlling state crime and holding heads of state or other high-ranking government officials accountable have long been met with contradictions and controversy from the perspective of state crime scholars as well as juristic practitioners. Consider that current geopolitical and international legal structures offer no threat of consequences. International law can be violated without threat of prosecution simply because there is no empowered institution to do so, and when it does occur, it is riddled with issues of selectivity. This reality has led many criminologists to deduce that the legalist standard and subsequent domestic and international laws are meaningless and not a valid framework for identifying or controlling state criminality. Indeed, for the legalist standard, the greatest obstacle is to actually control state criminality in some meaningful way. This includes ending impunity in the face of *realpolitik* and power differentials at the international level.

Discussions of resistance to complex forms of state criminality range from the formal to the informal, from the individual to the local to the state level, and to the international level. At the individual level, there are cases of dissenters and whistleblowers, as examples. At the local, organizational, and state levels, there are NGOs, media outlets, social movements, and political and civil groups that attempt to change existing conditions and expose state criminality. At the international level, there are political pressures from other states and international intergovernmental organizations and international laws that serve as deterrents to state crimes or after-the-fact accountability. Within each of these categories, resistance fluctuates and occurs at various points of time in relation to specific state criminality and the resources of organizations. It is through all of these mechanisms that awareness of the harms produced and illegalities of states' actions can come to be recognized and generate appropriate responses.

Future Directions

The term *cosmopolitan* is an ideology expressing that all of humanity belongs to a single moral community: an ideology for "global citizenship." Such an ideology is not new. For centuries philosophers have speculated on the conditions for achieving enduring peace between nations, one of which includes the notion of cosmopolitism or universalism. Consider Kant's thoughts in his 1795 essay *Perpetual Peace*, where he suggests *ius cosmopoliticum* (cosmopolitan law/right) be a guiding principle to protect people from war – grounded in the belief of universal hospitality. In more contemporary times, the idea of cosmopolitism reemerged in both formal and informal political realms that included the development of a United Nations, the global citizen, and an international community. While there remains a distinct contradiction between this ideology and the current state of international affairs, one vision for the future would be a reality of the ideal type where global citizens become the primary consideration in foreign policy and state actions. There is no magic answer or quick policy fix for state crimes: the worst crimes. It is an ongoing problem that requires diligence, commitment, and a change in ideology, praxis, and relations.

State-Corporate Crime

Elizabeth A. Bradshaw[1] and Ronald C. Kramer[2]
[1]Department of Sociology, Anthropology and Social Work, Central Michigan University, Mt. Pleasant, MI, USA
[2]Department of Sociology, Western Michigan University, Kalamazoo, MI, USA

Overview

State-corporate crime has been defined as the illegal or socially injurious actions that occur when one or more institutions of political governance pursue a goal in direct cooperation with one or more institutions of economic production and distribution (Kramer et al. 2002). Originating from a series of papers and articles produced by Ronald Kramer and Raymond Michalowski in the early 1990s (see Michalowski and Kramer 2006), the concept of state-corporate crime unites two parallel streams of criminological literature to draw attention to the mutually dependent interorganizational relationships between governments and private corporations. Scholarship on state-corporate crime seeks to breach the conceptual wall between economic crimes and political crimes in order to create a new lens through which criminologists can examine the ways illegal acts and social harms often emerge from intersections of economic and political power. While the concept of state-corporate crime could be applied to illegal or other socially injurious actions in societies ranging from private production systems to centrally planned political economies, most of the early research focused on state-corporate crimes within the private production system of US capitalism. State-corporate crimes within a global capitalist economy involve the active participation of two or more organizations, at least one of which is in the civil sector and one of which is in the state sector.

Antecedents

The concept and theory of state-corporate crime evolved within the broader tradition of white-collar crime research in the field of criminology, and it introduces a third form of organizational crime to examine in addition to the separate focus on either corporate or state crime. The roots of the concept can be traced to Edwin Sutherland's analysis of corporate offenses in his classic work, *White-Collar Crime* (1949). Over time, two divergent approaches to white-collar crime research emerged. One approach embraced the occupational dimension of white-collar crime, while the other stressed the importance of focusing on organizational offenders. Occupational crimes consist of offenses committed by individuals for their own personal gain in an occupational setting, while corporate crimes are illegal or socially injurious acts committed by corporate officials acting on behalf of the corporation for the benefit of the corporation (Clinard and Quinney 1973). The organizational turn in white-collar crime research retained the importance Sutherland placed on studying crimes of the powerful and paved the way for an organizational analysis of corporate crime (Clinard and Yeager 1980; Kramer 1982).

Although the broader study of white-collar crime also includes offenses committed by government officials, the concept of state crime more explicitly draws attention to the illegal or harmful actions committed by the state as an organizational entity. Highlighting the important relationship between politics and the economy, state crime is often motivated by the need for capital accumulation by modern nation states. Defined as acts prohibited by criminal law and committed by state officials in the pursuit of their jobs as representatives of the state, "state-organized crime" includes acts such as piracy, smuggling, and illegal spying on citizens (Chambliss 1989). As with corporate offenses, deviant behavior by state actors can take the form of both crimes of commission and of omission (Kauzlarich et al. 2003).

To sum up, after the organizational turn in the field of white-collar crime, two nearly independent bodies of research had developed. Theory and research in the area of corporate crime had concentrated primarily on organizational deviance within private business corporations. Paralleling that work but seldom intersecting with it, others had examined crimes by governments. Despite its ubiquity, the structural relations between corporate and governmental organizations had been relatively peripheral to the study of organizational crime. Kramer and Michalowski suggested that many forms of organizational deviance are generated at the interstices of corporations and government and they introduced the term state-corporate crime to denote these particular forms of organizational deviance.

In addition, rather than limiting inquiry to acts in violation of criminal law, white-collar and organizational crime studies broadened the scope of criminological concern to include violations of other forms of law, such as regulatory law for the study of corporate crime and international law for the analysis of state crime. With regard to crimes of the state, since governments select which behaviors to criminalize, socially harmful actions committed by the state are often exempt from any legal scrutiny. For this reason, some criminologists argue that it is necessary to move beyond the confines of law in favor of approaches that focus on violations of human rights or other forms of social harm (Schwendinger and Schwendinger 1970; Hillyard et al. 2004). The study of state-corporate crime fully supports this expansion of criminological inquiry to encompass violations of regulatory and international law, as well as other legal, but socially injurious behavior, as legitimate phenomena for analysis.

Development

Initially, four case studies (Kramer 1992; Kauzlarich and Kramer 1993; Aulette and Michalowski 1993; Matthews and Kauzlarich 2000) established the foundation for understanding two distinct forms of deviant state-corporate interactions: state-initiated corporate crime and state-facilitated corporate crime. State-initiated corporate crime occurs when corporate entities undertake organizational deviance at the behest or direction of, or with the tacit approval of, government institutions. Illustrating this concept, the case studies of the *Challenger* explosion and the US production of nuclear weapons both draw attention to explicit role of the state in initiating deviant interorganizational actions. Alternatively, state-facilitated corporate crime occurs when government institutions of social control fail to restrain deviant business actions, either due to direct collusion between corporations and government or because they adhere to common goals that would be thwarted by forceful regulation. Both the investigation of the fire at the Imperial Food Products chicken processing plant and the crash of *ValuJet* 592 highlight the failure of the state to effectively constrain corporate criminality.

The original development of the concept of state-corporate crime stems from a case study of the deviant state and corporate intersections that resulted in 1986 *Challenger* space shuttle explosion. At first glance, the explosion of the *Challenger* appeared to simply be an accident. However, Kramer's (1992) examination demonstrated how the interactions between a government agency, the National Aeronautics Space Administration (NASA) and Morton Thiokol, Inc. (MTI), a private business corporation, led to risky decisions and unsafe actions that resulted in the death of six astronauts and one school teacher. While the technical cause of the disaster was the failure of the O-ring seal on the solid rocket booster, larger structural and organizational forces increased the likelihood that a dangerous outcome would occur. Budgetary compromises, political pressure to launch, and what (Vaughn 1996) later identified as the "normalization" of deviant practices within the organizational culture at NASA led to a catastrophic explosion.

Also focusing on the historical, political, and contextual factors contributing to deviant state and corporate interactions is Kauzlarich and Kramer's (1993) study of the environmental damage caused by the US nuclear weapons manufacturing industry. For more than 50 years, the Department of Energy (DOE) and the Atomic Energy Commission contracted with private multinational corporations such as Westinghouse, DuPont, General Electric, and Martin Marietta to produce nuclear weapons. While DOE owned the equipment and oversaw the production of nuclear weapons and materials around the country, the corporations were responsible for daily manufacturing operations. Producing nuclear weapons results in enormous amounts of radioactive and nonradioactive hazardous waste. This waste was improperly disposed of causing irreversible environmental damage. For example, two of the most environmentally harmful nuclear weapon facilities, the Hanford facility and the Savannah River plant which both produce plutonium and tritium, have released billions of gallons of liquid waste contaminating the local air, soil, groundwater, rivers, and watersheds. Encouraged by Cold War cultural beliefs and lacking interorganizational oversight, the nuclear weapons industry placed production of defense materials above the environmental consequences of warhead production (Kauzlarich and Kramer, 1993).

Another foundational case study of state-corporate crime by Aulette and Michalowski (1993) details the 1991 fire at the Imperial Food Products chicken processing plant in Hamlet, North Carolina, that resulted in the deaths of 25 workers and injured an additional 56. Although the technical cause of the fire was a rupture in the hydraulic line near the deep fryer that sent a wave of fire throughout the plant, it was discovered that Imperial had deliberately locked the fire doors to prevent employee theft, thereby denying them access to a safe exit. Beyond the actions of Imperial, a complex pattern of regulatory failure was revealed. Facilitated by a long history of privileging business interests over labor, North Carolina's neglect to fund the state's Occupational Safety and Health Program severely weakened regulatory oversight designed to protect workers. In contrast to the examinations of the *Challenger* explosion and the US manufacturing of nuclear weapons that demonstrate the direct role of the state in the commission of corporate wrongdoing, the Hamlet fire study identified a different type of relationship in which the state indirectly creates the conditions for corporate crime to occur (Aulette and Michalowski 1993).

Matthews and Kauzlarich's (2000) examination of the crash of *ValuJet* Flight 592 in the Florida Everglades on May 11, 1996, helps to further define the role of the state in facilitating corporate crime. While the explicit cause of the crash that killed all 105 passengers and five crewmembers was the explosion of oxygen generators in a cargo compartment that resulted in fire, government investigations also identified the failure of both ValuJet and SabreTech (an airline maintenance company) to comply with numerous regulations as important factors. Dually tasked with the conflicting mandates of regulating the safety of the airline industry while simultaneously promoting it, the Federal Aviation Administration (FAA) refused to implement safeguards and guidelines that could have protected passengers in favor of the economic interests of the airline industry. By ignoring two specific recommendations by the National Transportation Safety Board (NTSB) to place smoke detectors in cargo holds (the exact area the fire started in *ValuJet* 592), as well as to reclassify cargo holds to prevent the spreading of fire to the rest of the plane, the FAA indirectly sets the stage for the crash to occur (Matthews and Kauzlarich 2000).

A Theory of State-Corporate Crime

State-corporate crime has three useful characteristics as a sensitizing concept. First, it refutes the notion that organizational deviance is a discreet act by illuminating the relationships between social institutions. Second, by embracing the relational character of the state, the concept of state-corporate crime demonstrates how the horizontal interactions between political and economic institutions contain the potential for illegal and social injurious actions to occur (Wonders and Solop 1993). Finally, adopting a relational approach to the state not only allows for a consideration of horizontal interactions but of the vertical relationships between different levels of organizational action: political-economic, organizational, and interactional.

Corresponding to each level of social action are three theoretical approaches to the study of corporate crime: differential association theory, organizational theory, and political economy. Developed by Edwin Sutherland, differential association theory is a social psychological theory that seeks to establish the processes by which individuals learn deviant behavior. While differential association has been criticized for failing to consider the institutional context, the organizational perspective helps to link the external political-economic environment with the work-related thoughts and actions of individuals occupying structural positions in the social organization of work. Motivated by pressure to achieve organizational goals in a competitive setting, there exists an inherent inducement for the organization to participate in crime (Kramer 1982). The perspective of political economy demonstrates the implicit criminogenic potential of pressures for profit maximization within capitalist markets. By drawing attention to the structural relations between political and economic institutions, the political-economic perspective recognizes that many crimes of corporations and of governments are ultimately crimes of capital arising from the ownership or management of the accumulation process (Michalowski and Kramer 2006).

Independent of one another, each of these three theoretical approaches is inadequate to explain organizational deviance. In an effort to overcome these shortcomings, state-corporate crime scholars propose an integrated theoretical model of organizational crime that combines the three levels of analysis with three catalysts for action: motivation, opportunity, and control (Michalowski and Kramer 2006). The first catalyst for action concerns goal attainment. As the emphasis on goal attainment by political-economic institutions, organizations, and individuals increases, corporations and state agencies become more susceptible to engaging in organizational deviance. The second catalyst for action – opportunity – assumes that organizational deviance is more likely where legitimate means are scarce relative to goals. Finally, the third catalyst for action examines the presence or absence of social control at all three levels of analysis. Organizations subjected to a high operationality of social controls are more likely to cultivate organizational cultures that favor compliance with laws and regulations, and those organizations that are not subject to such controls are more likely to develop cultures of resistance. By investigating the linkages between levels of analysis and catalysts for action, a more nuanced understanding of state-corporate crime can potentially be developed.

Recent Research Trends

Beyond its early incarnations, the concept and theory of state-corporate crime has been increasingly used to understand diverse forms of organizational deviance engaged in by state and corporate actors. In addition to the early empirical and theoretical research on state-corporate crime, *State-Corporate Crime: Wrongdoing at the Intersection of Business and Government* (Michalowski and Kramer 2006) includes case studies on topics such as globalization, women and state-corporate crime, corporate facilitation during the Holocaust in Nazi Germany, the National Highway Transportation Safety Administration (NHTSA), Ford Motor Company and the Bridgestone-Firestone tread separation case, the Exxon Valdez oil spill, Enron era economics and economic democracy, violations of the treaty rights of indigenous peoples, the invasion of Iraq, as well as the role of Halliburton in Iraq. In addition to these early case studies, more recent research on state-corporate crime has emerged, particularly concerning international and environmental issues.

International Issues

A number of criminologists have paid increasing attention to the changing nature of state power in the global neoliberal economy and have begun to focus on the international arena. One theme among numerous recent case studies of state-corporate crime concerns the organizational deviance that has occurred due to the US invasion of Iraq. A second prominent theme is the relationship between private military firms and governments and the implications this has for state-corporate deviance. Moreover, other case studies on the state and corporate interactions surrounding international conflict over scarce natural resources, as well as the antecedents of the most recent global financial meltdown, have also been undertaken.

Kramer and Michalowski (2005) argue that the 2003 invasion and occupation of Iraq were illegal under international law and can therefore be classified as an instance of state crime. Laying the foundation for international relations is the United Nations (UN) charter, which at its core prohibits the use of aggressive force between nations with only two exceptions: self-defense and humanitarian interventions. Initially, the

Bush administration sought to implicate Iraq in the September 11th terrorist attacks in an effort justify war as self-defense. After being forced to concede that there was in fact no connection between Iraq and 9/11, the Bush administration argued for preemptory war due to allegations that Iraq possessed weapons of mass destruction, thereby constituting a direct threat requiring defensive military action. As a final strategy, the Bush administration attempted to convince the UN Security Council that it was necessary to go to war in order to protect Iraqi citizens from human rights abuses by Saddam Hussein. Despite all the efforts to legitimate war in Iraq, none met the legal requirements of international law and were unable to receive necessary approval from the UN Security Council. In the end, the March 2003 decision to go to war in Iraq was undertaken in clear violation of international law and paved the way for continued state-corporate crimes as a result (Kramer and Michalowski 2005).

Whyte (2007) explores how the overarching principle behind the US invasion and occupation of Iraq was the creation of a new rule of law based on the opening up of the economy to privatization by Western, and particularly US, corporations in breach of international law. Facilitating this transition, the Coalition Provisional Authority (CPA) was given the power to rebuild the Iraqi economy over a 14-month period. Guided by neoliberal economic principles, the CPA spent over $20 billion in Iraqi oil revenue to restructure the economy, much of which was disbursed to US corporations with scant oversight or documentation. Through 100 legally binding administrative orders and decrees, the CPA set the foundations of Iraq's new economy, justice system, and political structure based on the idea of "trickle down" economics. The Development Fund of Iraq (DFI) provided the CPA with immediate money from Iraqi oil revenues to be dispersed for the humanitarian needs of the people. Since the DFI funds were disbursed in bundles of cash, CPA transactions did not leave a paper trail and contracts frequently went undocumented entirely. Moreover, the Bush administration in conjunction with the CPA took steps to thwart audits and investigations into the dispersal of funds. A US government appointed auditor has since established that an unknown sum of the DFI funds have disappeared as a result of bribery, overcharging, embezzlement, product substitution, bid rigging, and false claims. These forms of state-corporate corruption under the CPA have been essential in achieving neocolonial dominance in occupied Iraq (Whyte 2007).

In the course of the occupation and invasion of Iraq, privatized security has been deployed on a scale never before seen. Rather than abdicating its authority to private military firms (PMFs), Welch (2009) contends that governments work in direct cooperation with them, creating a situation of fragmented power. Although it has enjoyed close ties with the Bush administration, even recruiting former officials from the CIA and the Pentagon, Blackwater has received criticism for its lethal actions in Iraq. For example, in May 2007, Blackwater employees opened fire on the streets of Baghdad twice in 2 days, including a standoff with Iraqi security forces. Another incident, labeled "Baghdad's Bloody Sunday," occurred on September 16, 2005, when Blackwater guards shot and killed between 8 and 20 innocent civilians and wounded dozens of others in Nisour Square. A documented repeat offender, Blackwater has also been investigated for at least six other episodes of excessive force. Despite this pattern of criminality, the US government has not only neglected to prosecute Blackwater employees and other contractors but has extended immunity from wrongdoing altogether with respect to the reconstruction of the Iraqi economy. In this manner, the decoupling of police and government forces enables private contractors to escape accountability for war crimes and human right abuses (Welch 2009).

Part of a broader trend of privatizing military functions, private military companies (PMCs) today have become a legitimate industry involved in a wide range of activities including protecting governmental and nongovernmental organizations during humanitarian missions, in addition to protecting corporate interests such as the extraction of oil and mining. Whyte (2003) argues that the unfolding of the PMC market can be understood as transference of law from international prohibition treaties and national criminal law to civil contracts as the principal means of legal regulation. Far from a reduction of state sovereignty in the era of neoliberal globalization, private military markets are dependent on the consent and support of governments for their livelihood. Moreover, governments have also come to recognize the benefits to be gained by forging a state-corporate alliance in the private military market. Accepting the proliferation of PMCs as not only inevitable but also desirable, the United Kingdom has embraced a "soft-touch" regulatory mix that strengthens state-corporate military relations in a number of ways. First, such an approach enhances British industrial competitiveness in weapons manufacturing and other industries. Second, encouraging the growth of PMCs also allows governments to monitor and influence remote territories while remaining ostensibly neutral, thereby conducting foreign policy by proxy. Finally, the difficulty of prosecuting PMCs under international law and the reluctance of the UK government to support the UN convention on mercenaries create a law-accountability gap. By expanding the PMC market, the opportunity structure for state-corporate crime is increased as states and corporations are able to engage in high risk or politically sensitive conflicts while evading accountability for their actions. Absent any new criminal legal controls, state-corporate crime in the PMC market is only likely to accelerate (Whyte 2003).

Providing a revised theoretical framework of state-corporate criminality, Rothe and Ross (2010) analyze how anomie and social disorganization, resulting in a lack of regulation, are significant factors in explaining the criminal propensity of private military companies (PMCs). Private forces (such as Bechtel, Blackwater, CACI International, DynCorp, Halliburton and subsidiary Kellogg, Brown, and Root, Logo Logistics, and Titan) provide a wide range of services including direct tactical military assistance, military consulting (strategic advisory and training), and logistic, intelligence, and maintenance services to armed forces. Within each of these sectors, however, there are variations in the types of crimes committed including murder, fraud, and war profiteering. PMCs are not held to the same rules of engagement as the military and have an unclear legal status that is undefined by international law. Lacking internal and external constraints at every level, PMCs operate in anomic (lawless or normless) conditions that cultivate criminogenic behavior. Social disorganization occurs when communities are no longer able to create and enforce informal mechanisms of social control. As they operate in war ravaged areas, PMCs function in disorganized environments with uncertain mandates, high rates of employee turnover, and little social support. These factors converge to produce an environment in which regulation and social control breaks down and PMCs are free to engage in deviant behavior without consequence (Rothe and Ross 2010).

In the face of recent US actions that violate international law such as the war on terror, the war in Afghanistan, and the war in Iraq, a large segment of the citizenry nevertheless shows support for these policies. Part of the ideology of military aggression, Klein and Lavery (2011) argue, is perceived in-group victimization. A corporately owned political and cultural institution, the mainstream media functions as a tool by which politicians emphasize and validate the national experience of collective victimization. In an attempt to legitimate their illegal actions, elites and organizations use the media to amplify their claims of victimization and thereby neutralize criticism. At least in part, fear of being a terror victim seems to be related to the content of news media. Moreover, there also seems to be support for the notion that terrorism victimization in the media can contribute to public acceptance of state-corporate criminality (Klein and Lavery 2011).

Confronted with widespread political and economic violence for much of the past century, the experience of the Democratic Republic of Congo (DRC) cannot solely be explained by internal factors experienced in the transition from colonial to postcolonial rule. Rather, Mullins and Rothe (2008) argue that neighboring states, transnational corporations, and international organizations all play a significant role in the continuing violence within the DRC. Seeking control of large concentrations of valuable mineral fields including gold, diamonds, silver, copper, and coltan, transnational corporations have been more than willing to negotiate access with warlords and militias controlling the hinterlands despite widespread human rights abuses. While demand from European markets is an important factor spurring participation by transnational corporations and their Western trading partners, states and international organizations also play a crucial role in facilitating the sale of illegally misappropriated resources. Capitalizing on the chaos surrounding the Second Congolese War in 1995 by enacting patterns of illegal resource appropriations particularly for gold and diamonds, Uganda acknowledged to the World Bank (WB) that production levels might reflect exports usurped from the DRC. The WB and the International Monetary Fund praised Uganda and Rwanda for their increases in production, despite the illegal means by which it was achieved. While it is largely recognized that there is no indigenous production of gold in Uganda, Metalor Technologies, a Swiss refinery, has been responsible for purchasing the Congolese gold from Ugandan sources. Although it had been demonstrated that over 100 companies from over a dozen countries are benefiting from illegal mineral exploitation, there has been reluctance on behalf of governments to intervene. The institutional structure of the larger international community therefore plays an important role in perpetuating the political and economic violence in countries engulfed by genocidal civil war such as the DRC (Mullins and Rothe 2008).

As an investigator for a 2002 Royal Commission examining fraud within the Dutch construction industry, Van Den Heuvel (2005) helped reveal that rather than an isolated incident of collusion, the entire sector had engaged in illegal practices including fraud, undercutting the market, unjustified subsidies, monopolization resulting in higher prices, and bribery of politicians and public servants. At the core, the Commission identified the industry-wide pandemic to be due to multiple forms of collusion or a secret agreement for a fraudulent purpose. One form of collusion occurred between contractors themselves, such as illegal price fixing. A second type involved collusion between authorities and contractors, such as favoring particular contractors over others. Finally, a third type of collusion identified by the Commission occurred at the individual level in the bribing of public servants, for example, providing generous gifts and favors. The Commission concluded that these forms of collusion within the Dutch construction industry were so interconnected that they constituted a culture that placed contactors above the law and in control of authorities. Because of the pervasive collusion between contractors and authorities, it seems necessary to enact stricter rules governing state-corporate interorganizational relationships (Van Den Heuvel 2005).

Liederbach (2010) contends that while the state established the framework for the 2008 mortgage default crisis, corporate malfeasance was at its core. From the 1930s through the 1970s, there were stringent government regulations on mortgages which restricted lending practices such as issuing variable rate loans, capped interest rates, and prohibited partial monthly payments (known as negatively amortized mortgages). However, statutory changes and deregulation by Congress during the early 1980s removed these restrictions. Coasting on the economic success of the 1990s, an effort to increase national homeownership led by the US Department of Housing forced the government-sponsored entities, Fannie Mae and Freddie Mac, to engage in riskier subprime mortgage markets since the targeted borrowers could not qualify for prime loans. Setting the conditions for the crisis to thrive, during the early 2000s, the Federal Reserve expanded the availability of credit by setting and maintaining surprisingly low interest rates and decreasing the amount of money banks were required to keep in reserve. All of these factors culminated in an economic meltdown that resulted in millions of home foreclosures and an unprecedented $750 billion taxpayer-funded bailout to rescue distressed financial institutions (Liederbach 2010).

Environmental Issues

Another emerging trend within the research on state-corporate crime is case studies examining the environmental harm resulting from organizational deviance. Of increasing significance are the state and corporate interactions contributing to the critical problem of global warming and climate change.

Smandych and Kueneman (2010) contend that Canadian officials and oil corporations are guilty of manipulating environmental regulations as well as the practice of "greenwashing:" disinformation provided by an organization attempting to present an environmentally friendly public image, in this case surrounding the Alberta tar sands project. Criticized for its concentrations of toxic waste and a major source of greenhouse gas emissions, the aggressive state-corporate development of the Alberta tar sands project began in 1990s. Effectively surrendering sovereignty over the nation's resources, the 1989 Canada-USA Free Trade agreement obliges Canada to share its oil and gas resources with the USA. The two means of extracting the oil from a mixture primarily comprised of sand are strip mining and underground "in situ" mining, both of which are environmentally disastrous leading to the devastation of pristine boreal forests, contamination of the Athabasca watershed, and depletion of natural resources. In this regard, the USA accrues the benefits while Canada suffers pollution of its land, air, and water. Working hand in hand with the oil industry, specifically US-based multinational oil corporations, the conservative governments of the Province of Alberta and the federal government of Canada have suppressed attempts to define the harm caused by the tar sands as criminal activity (Samandych and Kueneman 2010).

Lynch et al. (2011) applied the concept of state-corporate crime to global warming by examining the politicization of global warming under the G.W. Bush administration. Although industry leaders are often selected for governmental positions, appointing corporate leaders from the oil and mining industries to crucial environmental policy positions was a dominant trend in the Bush administration that strengthened state-corporate ties and deterred action on climate change. Despite the overwhelming consensus of climate change scientists, the Bush administration colluded with corporations in the fossil fuel industries in an effort to discredit and suppress science on the human causes of global warming. White House officials deliberately sought to undermine science on global warming in a number of ways including blocking publications, editing government reports, altering federal policy, and pressuring climate change scientists to delete references to global warming and climate change in government-sponsored research. Furthermore, the corporate strategy for undermining information on global warming was to fund and create front organizations to disseminate misinformation about climate change to the public. In this manner, the policies of the Bush administration privileged the interests of the fossil fuel industry over the interests of the public (Lynch et al. 2011).

Four forms of state-corporate crime shape the social and environmental harms caused by global warming. Kramer and Michalowski (2012) argue that state and corporate actors produce these harms by (1) denying that global warming is caused by the actions of humans (anthropogenic), (2) thwarting attempts to reduce greenhouse emissions, (3) excluding from the political arena ecologically just adaptations to climate change, and (4) responding to the social conflicts that arise as a result of climate change with militarism and violence. While anthropogenic global warming is the result of over 200 years of industrialization and fossil fuel consumption, it is possible to identify state-corporate relationships that caused knowable and predictable harm and that could have been avoided. Therefore, the failure of state institutions to mitigate or reduce carbon emissions in the private and public sectors should be understood as a state-corporate crime of omission. More than just a failure to act, however, the orchestrated denial of climate change despite overwhelming scientific evidence to the contrary constitutes a state-corporate crime of commission. Designed to cast doubt on the evidence for anthropogenic global warming, the global warming denial counter-movement has been directed, organized, and funded by corporations and conservative think tanks. States and corporations have also refused to seriously consider socially just adaptation policies despite the increasing number of social conflicts resulting from climate change. This too, it is argued, constitutes a state-corporate crime of omission (Kramer and Michalowski 2012).

Conclusion

The study of political economy has been around for a long time, and the idea that corporations and states often act together in ways that have serious social consequences is not new. However, the concept and theory of state-corporate crime filled a gap in the evolving study of organizational crime within criminology. By examining social harms that result from the interaction of political and economic organizations, scholarship on state-corporate crime has made an important contribution to the field. The concept has generated a substantial body of research, and some argue, "the approach developed by state-corporate crime scholars is a significant advance toward developing a powerful integrated theoretical model" (Green and Ward 2004, p. 51). Judged by the growing number of criminologists who find the concept state-corporate crime useful in their work, research and theory in this area have the potential to make additional contributions to the study of organizational offending, particularly with regard to international and environmental crimes.

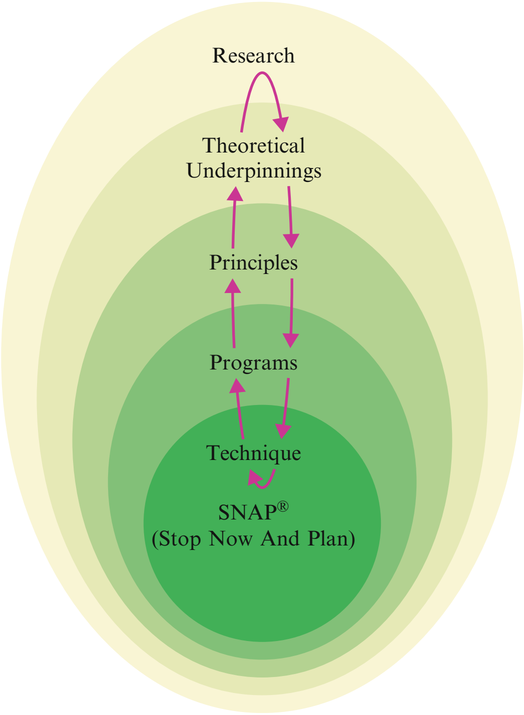
Overview

This entry presents a comprehensive summary of the SNAP® (Stop Now and Plan) model including its related programs which are part of a crime prevention strategy for at-risk children under the age of 12. At Child Development Institute (CDI), a multiservice, not-for-profit children's mental health organization, the mandate for two key evidence-based clinical programs, SNAP® Boys and SNAP® Girls, and the Centre for Children Committing Offences (CCCO) promotes effective services for these "forgotten" children who have or are at-risk of having police and/or child welfare contact for their disruptive behavior. The comprehensive strategy includes (1) police-community referral protocols; (2) gender-specific risk assessment using Early Assessment Risk Lists (EARLs); and (3) gender-specific interventions, the evidenced-based SNAP® programs (for further details, see Koegl et al. 2008). The overarching goal of SNAP® is to keep high-risk children in school and out of trouble. SNAP® has been found to reduce aggression, delinquency, and antisocial behavior; increase social competency; prevent further and future delinquency; improve academic success by decreasing behavioral issues at school; engage high-risk children and their families in service; increase effective parent management skills; and connect children and parents to community-based resources. Authors discuss key aspects of the SNAP® model including SNAP® principles, theoretical foundation, model framework, and research summary of findings to date.

Fundamentals of SNAP®

Over 27 years, CDI has developed its expertise in responding to children with disruptive behavior problems and their families. In 1985, with the decriminalization of children under the age of 12 in Canada, CDI (with support from the provincial Ministry of Children and Youth Services in Ontario, Canada) developed SNAP® programs in response to the need of mental health services for this age group of high-risk children and families. The SNAP® model is based on a comprehensive framework (Fig. 1, SNAP® Model Framework) for effectively teaching children with serious behavior problems emotion regulation, self-control, and problem-solving skills. Parents also learn SNAP® skills as well as researched cognitive-behavioral parenting techniques. Children and families learn how to stop and think in order to find solutions that "make their problems smaller, not bigger." The



Stop Now and Plan (SNAP®) Model, Fig. 1 SNAP® model framework

SNAP® Model Framework depicts the interconnectedness and relationship of the theoretical underpinnings, principles, programs, and technique and how research plays a role in each of these key areas. The SNAP® programs have been developed with the *technique* as the cornerstone of the program components, have been continuously informed by theory and research, and are delivered through adherence to the SNAP® principles. This dynamic model provides feedback loops which allow for fluidity between the elements to influence and inform ongoing development. The evidence-based SNAP® programs have been adapted to different populations and settings: SNAP® Boys, SNAP® Girls, SNAP® Schools, SNAP® for Children with Asperger Syndrome, SNAP® for Aboriginal Communities, SNAP® Youth Leadership, and SNAP® for Youth in Custody.

Technique

There is robust evidence that early childhood interventions focused on enhancing self-control are likely to bring greater return on investments (Moffitt et al. 2011). Further support for this approach is identified in other investigations which highlight that children tend to be good candidates for learning self-control strategies, especially before the age of 10 (Piquero et al. 2010). The SNAP® technique is a cognitive-behavioral emotion regulation, self-control, and problem-solving strategy intended to help children *stop and think before they act* and come up with socially appropriate plans to address their problems – helping to control impulsivity, challenge cognitive distortions, and think about the consequences of their behavior. A key aspect of the SNAP® technique is to help children identify their bodies' physiological responses (*body cues*), thoughts, feelings, and triggers (things that make them feel angry/sad/worried) and help them to make the connection between their body cues, feelings, thoughts, and what they can do to effectively regulate arousal levels and help their bodies calm down (*Stop*), so that they can come up with an effective *Plan*. As discussed in the article, *Rolling Out SNAP® – An Evidence-Based Intervention: A Summary Of Implementation, Evaluation, and Research* (Augimeri et al. 2011a), SNAP® was first developed in the former Earlscourt Child and Family Centre's day treatment classroom for children with behavioral problems in the late 1970s, and the technique underlies the entire foundation of the SNAP® Model Framework (see Fig. 1). This was then formalized with the creation and publication of program manuals (Earlscourt Child and Family Centre 1990a, b, 2001a, b, 2002; Levene 1998) and trademarked in 1998.

As noted in the SNAP® program manuals, there are a number of steps to the SNAP® technique that have been mapped onto the image of a stoplight – red light (*Stop*), yellow light (*Now and*), and green light (*Plan*). These steps are used to teach children to regulate their emotions by helping them to calm down (e.g., by taking deep breaths and/or counting to ten) (*Stop*); replace "hard thoughts with cool thoughts" (coping statements, cognitive restructuring) to help them remain calm (e.g., "this is hard but I can do this") (*Now and*); and generate effective solutions which meet these three criteria: 1. make their problems smaller instead of bigger; 2. make them feel like a winner; and 3. not hurt anyone, anything or themselves (*Plan*).

Programs

The introduction of the first SNAP® program (SNAP® Under 12 Outreach Project, now known as SNAP® Boys) in Toronto in 1985 was designed specifically to address the gap in services when the age of criminal responsibility in Canada was raised from seven to 12 under the *Young Offenders Act* (YOA) in 1984. Prior to the YOA, the *Juvenile Delinquents Act* (JDA) enacted in 1908 prosecuted children as young as 7 years of age. The YOA placed these children under the responsibility of child welfare legislation versus criminal justice; this remained when Canada replaced the YOA with the Youth Criminal Justice Act (YCJA) in 2003.

SNAP® Boys was launched in partnership with Toronto Police Service through provincial funding from the former Ministry of Community and Social Services (today, Ministry of Children and Youth Services). The mandate of SNAP® Boys is to serve children under the age of 12 who are engaging in antisocial behaviors who do not legally fall under the purview of the YCJA. SNAP® Boys is noted as the most fully developed, longest sustained, empirically based multicomponent intervention specifically for "pre-offender" youth under the age of 12 (Howell 2001, 2003). Its sister program, the SNAP® Girls Connection (now known as SNAP® Girls), began in 1996 and is the first reported *gender-specific* intervention for girls under the age of 12 with disruptive behavior problems. Both programs are fully manualized and are in various stages of replication worldwide.

Presenting issues of the children admitted into the SNAP® programs typically include stealing, lying, mischief, vandalism, aggression, assault, bullying, and truancy. A significant number of these children also experience academic difficulties and comorbid mental health symptomology, such as depressive and anxious behaviors or ADHD (Pepler et al. 2004; Walsh et al. 2002).

Children admitted into the SNAP® clinical programs (SNAP® Boys and SNAP® Girls) have had police contact for their own misbehavior and/or have a score within the clinical range on standardized measures assessing externalizing behavioral issues (aggression, conduct, rule breaking). Primary referral sources include schools, police, child welfare, parents, and other mental health and medical professionals (see Fig. 2).

As noted in the SNAP® Logic Model (Fig. 2), assessment is informed by an ecosystemic approach (also a SNAP® *principle*, see Table 1) that takes into account interventions targeting the child, the family, the school, and the community. The Early Assessment Risk List (EARL-20B for boys or EARL-21G for girls), a structured clinical risk/need assessment device for use with aggressive and delinquent children, is also completed to provide a comprehensive framework for evaluating risk factors known to influence a child's propensity to engage in future antisocial behavior. Informed by the ecosystemic assessment, the risk assessment takes into account multi-informant perspectives (child, parent, teacher, and clinician), identifies the unique treatment needs of children and their families, and assists clinicians with treatment planning in order to mitigate these risks.

The SNAP® clinical programs (SNAP® Boys and SNAP® Girls) offer multifaceted services including core and adjunct components which are available to children and families based on their level of risk and need. In the SNAP® programs, components are goal oriented, skill focused, and developmentally responsive. Integrated into each component are key skill acquisition training techniques (i.e., role-play, modeling, self-talk) and generalization activities (home practice assignments) to transfer learning of the SNAP® technique and SNAP® parenting skills from the clinical environment to real-life settings. Following the ecosystemic and EARL assessments, a treatment plan is tailored to the child and family's strengths, risks, and needs. Children and families typically begin with completing the core components. Core components include:

SNAP® Children's Group – a gender-specific manualized core component that focuses on teaching children emotion regulation, self-control, and problem-solving skills with a special emphasis on challenging cognitive distortions/thinking errors. Examples of topics covered include introduction to SNAP®, peer pressure, dealing with anger, and bullying. Children participate in a 13-week SNAP® group, occurring once a week for 1.5 h.

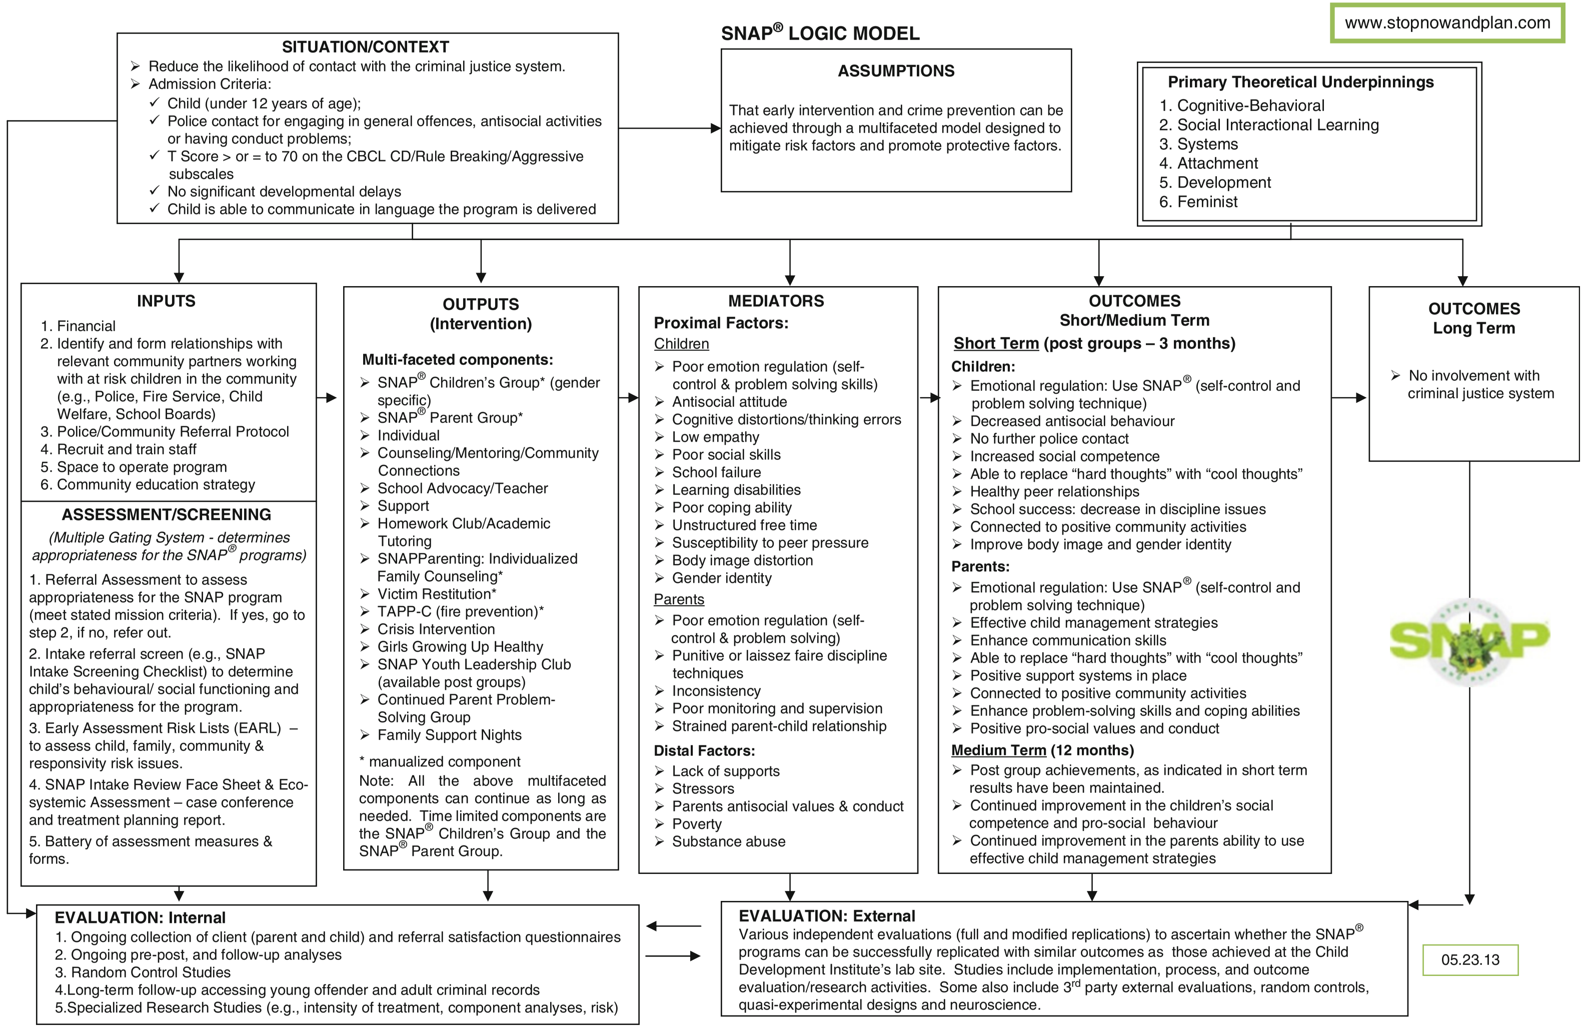
SNAP® Parent Group – a manualized core component that runs concurrent with the SNAP® children's groups. Parents learn emotion regulation, self-control, and problem-solving skills and effective child management strategies with a special emphasis on challenging cognitive distortions/thinking errors, reducing isolation, and enhancing parent-child relationships. Examples of topics covered include effective communication, positive reinforcement, limit setting and consequences, and family problem solving. Three of the group sessions are joint parent-child sessions where parents and children practice skills together.

Girls Growing Up Healthy (GGUH) – a manualized core component unique to SNAP® Girls, this mother-daughter group focuses on enhancing relationship capacity, healthy relationships, and physical and sexual health. Topics covered include preparing for puberty, deconstructing stereotypes, and planning for the future. Caregivers and daughters meet for 8 weeks, once a week for 2 h.

The following adjunct components are offered based on the child's and family's identified goals, strengths, risks, and continued treatment needs:

Individual Counseling/Mentoring/Community Connections – provides children with individualized support with a SNAP® worker to reinforce and enhance skills learned in the SNAP® children's group and address treatment targets (i.e., social skills, coping ability, cognitive restructuring) and goal attainment. Children can also be matched with volunteers who connect them with structured recreational activities in their community.

Stop Now and Plan Parenting (SNAPP): individualized family counseling – based on our SNAPP Manual, is offered to families who are



www.stopnowandplan.com

SNAP® LOGIC MODEL

SITUATION/CONTEXT

- Reduce the likelihood of contact with the criminal justice system.
- Admission Criteria:
  - ✓ Child (under 12 years of age);
  - ✓ Police contact for engaging in general offences, antisocial activities or having conduct problems;
  - ✓ T Score > or = to 70 on the CBCL CD/Rule Breaking/Aggressive subscales
  - ✓ No significant developmental delays
  - ✓ Child is able to communicate in language the program is delivered

ASSUMPTIONS

That early intervention and crime prevention can be achieved through a multifaceted model designed to mitigate risk factors and promote protective factors.

Primary Theoretical Underpinnings

1. Cognitive-Behavioral
2. Social Interactional Learning
3. Systems
4. Attachment
5. Development
6. Feminist

INPUTS

1. Financial
2. Identify and form relationships with relevant community partners working with at risk children in the community (e.g., Police, Fire Service, Child Welfare, School Boards)
3. Police/Community Referral Protocol
4. Recruit and train staff
5. Space to operate program
6. Community education strategy

ASSESSMENT/SCREENING

(Multiple Gating System - determines appropriateness for the SNAP® programs)

1. Referral Assessment to assess appropriateness for the SNAP program (meet stated mission criteria). If yes, go to step 2, if no, refer out.

2. Intake referral screen (e.g., SNAP Intake Screening Checklist) to determine child's behavioural/ social functioning and appropriateness for the program.

3. Early Assessment Risk Lists (EARL) – to assess child, family, community & responsivity risk issues.

4. SNAP Intake Review Face Sheet & Eco-systemic Assessment – case conference and treatment planning report.

5. Battery of assessment measures & forms.

OUTPUTS (Intervention)

Multi-faceted components:

- SNAP® Children's Group* (gender specific)
- SNAP® Parent Group*
- Individual
- Counseling/Mentoring/Community Connections
- School Advocacy/Teacher
- Support
- Homework Club/Academic Tutoring
- SNAPParenting: Individualized Family Counseling*
- Victim Restitution*
- TAPP-C (fire prevention)*
- Crisis Intervention
- Girls Growing Up Healthy
- SNAP Youth Leadership Club (available post groups)
- Continued Parent Problem-Solving Group
- Family Support Nights

* manualized component

Note: All the above multifaceted components can continue as long as needed. Time limited components are the SNAP® Children's Group and the SNAP® Parent Group.

MEDIATORS

Proximal Factors:

Children

- Poor emotion regulation (self-control & problem solving skills)
- Antisocial attitude
- Cognitive distortions/thinking errors
- Low empathy
- Poor social skills
- School failure
- Learning disabilities
- Poor coping ability
- Unstructured free time
- Susceptibility to peer pressure
- Body image distortion
- Gender identity

Parents

- Poor emotion regulation (self-control & problem solving)
- Punitive or laissez faire discipline techniques
- Inconsistency
- Poor monitoring and supervision
- Strained parent-child relationship

Distal Factors:

- Lack of supports
- Stressors
- Parents antisocial values & conduct
- Poverty
- Substance abuse

OUTCOMES Short/Medium Term

Short Term (post groups – 3 months)

Children:

- Emotional regulation: Use SNAP® (self-control and problem solving technique)
- Decreased antisocial behaviour
- No further police contact
- Increased social competence
- Able to replace "hard thoughts" with "cool thoughts"
- Healthy peer relationships
- School success: decrease in discipline issues
- Connected to positive community activities
- Improve body image and gender identity

Parents:

- Emotional regulation: Use SNAP® (self-control and problem solving technique)
- Effective child management strategies
- Enhance communication skills
- Able to replace "hard thoughts" with "cool thoughts"
- Positive support systems in place
- Connected to positive community activities
- Enhance problem-solving skills and coping abilities
- Positive pro-social values and conduct

Medium Term (12 months)

- Post group achievements, as indicated in short term results have been maintained.
- Continued improvement in the children's social competence and pro-social behaviour
- Continued improvement in the parents ability to use effective child management strategies

OUTCOMES Long Term

- No involvement with criminal justice system

EVALUATION: Internal

1. Ongoing collection of client (parent and child) and referral satisfaction questionnaires
2. Ongoing pre-post, and follow-up analyses
3. Random Control Studies
4. Long-term follow-up accessing young offender and adult criminal records
5. Specialized Research Studies (e.g., intensity of treatment, component analyses, risk)

EVALUATION: External

Various independent evaluations (full and modified replications) to ascertain whether the SNAP® programs can be successfully replicated with similar outcomes as those achieved at the Child Development Institute's lab site. Studies include implementation, process, and outcome evaluation/research activities. Some also include 3rd party external evaluations, random controls, quasi-experimental designs and neuroscience.

05.23.13

Stop Now and Plan (SNAP®) Model, Fig. 2 SNAP® logic model

Stop Now and Plan (SNAP®) Model, Table 1 SNAP® principles and indicators

Principle	Indicator
Scientist-practitioner	An interactive science-practice paradigm is sustained by regular cross discipline workgroups to support the high-quality evolution of SNAP® program development, outcomes, and research
Client centered	Services are informed by client personal and cultural narratives and goals, ensuring client responsiveness through growth-oriented engagement and alliances
Gender sensitive	Specific gendered factors which account for differential development, learning styles, and trajectories of boys and girls with conduct problems are integrated throughout SNAP® programs
Ecosystemic	Each client's ecological system (individual, home, school, community) is assessed to identify and inform strengths, needs, and risk and protective factors and to match them with appropriate service components and treatment intensity
Strength and skill based	Specific, consistent use of positive reinforcement, as part of our evidence-based, cognitive-behavioral practice, promotes and strengthens individual capabilities and the acquisition of primary SNAP® skills: emotion regulation, self-control, and problem solving
Continuing services	Continuing needs and commitment to service are regularly and jointly assessed to support and ensure high-risk families, children, and youth are engaged in services
Collaborative	Effective collaborations with appropriate child- and family-oriented services are conducted to ensure service coordination and family support system development during and after SNAP® services
Community responsive	SNAP® programs are adapted to diverse, cultural, and socioeconomic factors that characterize communities in order to be responsive to social determinants of child and family mental health
Accountable service excellence	Combination of high-quality staff development activities that include consistent supervision, training, integrity, and the attainment of accountable standards assessed through a series of well-developed research, evaluation, fidelity, and quality assurance activities fosters overall service excellence

unable to attend the SNAPP parent group, who need additional assistance/practice with parenting skills, or who need parenting support to address barriers to skill acquisition (i.e., mental health, parent cognitive restructuring, attachment).

School advocacy/teacher support – ensures that children receive the best possible education meeting their individual behavioral and learning needs. Teachers of identified clients are contacted at the start of the program to introduce the program skills and offer behavior management support if needed. Parents are supported in advocating for their children within the school system environment.

Crisis intervention – a service available to assist parents and children involved in the SNAP® program in dealing with challenging situations as they arise and/or referral to appropriate crisis services.

TAPP-C (The Arson Prevention Program for Children) – offered to children with fire interest or fire setting as a presenting problem. It involves a fire interest assessment and recommendations, a home safety visit, and education regarding fire by Toronto Fire Services.

Victim restitution – activities that encourage children to apologize to their victim, redress behaviors, and begin to learn how to take responsibility for their actions.

Homework Club/academic tutoring – provides remedial sessions for children functioning below grade level. Weekly 1 hour tutoring sessions with teachers or specially trained volunteers are held in the child's home or community.

SNAP® Youth Leadership Club – a component offered in both the boys' and girls' programs for youth who have completed the core components of the SNAP® program but continue to be high risk. Staff provide group, individual, and family work to prepare at-risk youth for self-sufficiency, increase motivation for school involvement and success, improve their workforce career trajectories, and reduce their involvement with the law.

Parent problem-solving group – a 9-week group component for parents who have completed the SNAP® parent group. The focus is on enhancement and refinement of family problem-solving skills in relation to ongoing issues the families are experiencing (i.e., keeping rewarding effective, difficulty with consequencing, school issues, media awareness) while providing continued support.

Long-term connections/continued care – families may continue to be involved in all components of SNAP® as long as there is a need and interest. In addition to previously listed components, this may also include activities such as participation as a peer or parent mentor.

Principles

Nine *principles* with specific indicators have been identified to describe the approach to service delivery and guide SNAP® programming. In addition, the *principles* ensure service and clinical excellence when organizations replicate SNAP® in their communities (sites). These are also used to assist in measuring implementation adherence, fidelity, and integrity of the SNAP® prevention and intervention programs (see Table 1).

SNAP® Theoretical Underpinnings

From the very beginning, the SNAP® model was built on well-known theoretical approaches showing promise in the early 1980s. These included social skills training, cognitive problem solving, self-control and anger management strategies, cognitive self-instruction, family management skills training, and parent training. As noted by Augimeri et al. (2011a), the model continued to evolve as SNAP® scientists and practitioners consulted with the Oregon Social Learning Center (OSLC) in Eugene, Oregon. These consultations helped to strengthen the SNAP® parenting component by adopting aspects of OSLC's Social Interactional Family Therapy's (now known as Social Interactional Learning) approach to working with families (Patterson et al. 2010). The SNAP® model programs have evolved to reflect the contributions of six core treatment theories, including Systems, Social Interactional Learning, Cognitive-Behavioral, Attachment, Feminist and Developmental Theories (see Fig. 2). It is important to note that these theories are not viewed as stand-alone entities, but as interactive in their contributions to the foundation and ongoing development of the SNAP® model programs.

The SNAP® Logic Model (see Fig. 2) also illustrates that the primary targeted outcomes include improved overall child and family functioning with an emphasis on emotion regulation, self-control, and problem solving for both parent/caregiver and child. As Strayhorn (2002) indicates, "self-control difficulties are of central importance for many psychiatric disorders. . .[it] is also a crucial, and often missing, ingredient for success in most treatment programs" (p. 7).

Research

Research on the SNAP® programs has been an integral part of the model's ongoing development since its inception and continues on an ongoing basis. Scientists and clinicians work within a collaborative process (SNAP® *principle: scientist-practitioner*) to inform and update the theoretical approaches of the model, ongoing evaluation, and program development. Rigorous internal and external evaluations of SNAP® programs (e.g., process and outcome evaluation, quasi-experimental designs, random control trials, long-term follow-up – criminal record searches, cost-benefit analyses, third-party external evaluations, and neuroscience) have consistently demonstrated positive treatment effects over time: children improve significantly more than children receiving an attention-only group, delayed treatment, or an alternative treatment with notable effect sizes (moderate to large); treatment gains are maintained at 6, 12, and 18 months; parents report less stress in their interactions with their children and increased confidence in managing their children's behavior; children report improved quality of interaction with parents, less yelling, and more limit setting; children report more positive attitudes and less anxiety and demonstrate more pro-social skills with teachers, peers, and family members. Longitudinal research analysis showed that

91.8 % of the boys and 95 % of the girls had no history of criminal offences by age 14 and approximately 68 % of the children have not had a criminal record by age 19 (Pepler et al. 2010; Augimeri et al. 2007, 2011b). Brain imaging studies conducted by the Hospital for Sick Children in Toronto and the University of Toronto showed that children who responded positively to SNAP® treatment manifest changes in brain systems responsible for cognitive control and self-regulation, and a number of SNAP® families showed an ability to "repair" after engaging in a difficult parent-child interaction (see Granic et al. 2007; Lewis et al. 2008; Woltering et al. 2011).

Designations

As a result of these promising research findings, SNAP® has achieved the highest levels of recognition from independent reviewers who rate evidence-based programs. In 2012, the US Department of Justice, Office of Justice Programs, designated SNAP® as an "effective" crime prevention model (see http://www.crimesolutions.gov/ProgramDetails.aspx?ID=231). In 2011, Public Health Agency of Canada designated SNAP® as a Canadian best practice under their Preventing Violence Stream – Canadian Best Practice Portal (see http://cbpp-pcpe.phac-aspc.gc.ca/intervention/707/view-eng.html; http://cbpp-pcpe.phac-aspc.gc.ca/intervention/706/view-eng.html. In an excerpt outlining effective options for young children with conduct problems, Cipriani (2009) highlighted the SNAP® model as the "best example" of effective early intervention strategies and discussed the program and its successes at length. In 2008, the Canadian *National Crime Prevention Centre* designated SNAP® as a "Model Program" (see www.publicsafety.gc.ca/res/cp/res/2008-pcpp-eng.aspx), in 2012 it was designated as an "Effective Program" by the US Department of Justice's OJJDP (see www.ojjdp.gov/mpg/mpgProgramDetails.aspx?ID=699) because of its robust treatment outcomes, and in 2006 it was given the highest effectiveness designation (Level 1) by the United States' Whitehouse program *Helping America's Youth*, now titled *FindYouthInfo.gov;* (see www.findyouthinfo.gov/ProgramDetails.aspx?pid=699). At the beginning of 2000, a study group on very young offenders led by Drs. David Farrington and Rolf Loeber found the SNAP® program was the "most fully developed intervention to date for child delinquents" (Howell 2001, p. 312).

Current Issues/Controversies

SNAP® Model Replication and Implementation

For a discussion of the program's replication standards and principles, licensing agreements, accreditation, and fidelity frameworks ensuring successful replication of the SNAP® model, see Augimeri et al. 2011b. In this discussion, having a team of dedicated scientists and practitioners was emphasized in order to create an effective, well-established, and recognized program, and it stressed that host organizations need commitment, support, and resources when incubating an evidence-based model program within a community setting.

Five important criteria were identified for the successful implementation and replication of SNAP®: (1) *Adherence* to the model is critical, (2) *restraint from making modifications* is essential, (3) *training and ongoing consultation* is mandatory, (4) *ongoing fidelity/integrity audits* are necessary to ensure the highest possible efficacy, and (5) *selecting the right staff* is paramount to program success.

SNAP® licensing agreements are established with the Child Development Institute. CDI's experience in disseminating SNAP® is that with adequate training and support, this model can be successfully replicated and implemented with strong fidelity in a variety of settings. SNAP® fits in the classroom, in the clinician's office, and at home. The program can be situated in a variety of diverse community settings and real-life community conditions. Currently, there are a number of successful SNAP® implementations in Canada, the United States, and Europe.

SNAP® Fidelity and Integrity Framework

For successful implementation and replication of evidence-based programs such as SNAP®, training and ongoing consultation activities between the site and its replicators are considered paramount (Augimeri et al. 2011b). As the SNAP® model incorporates a complex therapeutic approach, it requires strict documentation of the services being delivered and records of any integrity activities conducted to ensure successful replication and outcomes. As a result, there is a need to identify all the intricate elements of the various treatment components within the SNAP® model (e.g., SNAP® core groups, individual counseling/mentoring, family counseling) in order to effectively monitor if the delivery of these key elements is done correctly and skillfully, when and where necessary. The SNAP® principle, *accountable service excellence*, highlights the requirement of fidelity practices that include case file audits, consultations, adherence to group manuals, and consistency of facilitation skills. It is essential that the integral pieces of SNAP® related to long-term positive outcomes (e.g., decreased criminal activity) are delivered with appropriate timing, skill, and adherence. Ultimately, SNAP® researchers and facilitators are concerned with delivering an effective program that adequately meets all objectives that were predefined with the clients.

Key Aspects to Ensure a Successful International Implementation

Even though successful SNAP® sites have been established worldwide, we continue to recognize that there are many obstacles to successful implementation. As noted earlier, the implementation of an evidence-based model can be challenging on its own. This is especially true when it is being adopted in another country or culture. As SNAP® implementations continue to reach communities worldwide, the onus is on SNAP® developers to explore creative methods for ensuring successful replications. There are several important factors (e.g., language, culture, travel) that may need to be considered when replicating a “foreign” intervention, even though its core strategies are proven to have universal applicability (e.g., cognitive-behavioral therapy).

Future Directions

A sixth implementation criterion that would greatly contribute to not only the successful implementation of the program, but most importantly, its sustainability, would be the *adoption of community teams for children under 12* (Augimeri et al. 2001a; Goldberg et al. 1999). *Community teams* would be comprised of representatives from child welfare, school personnel, and criminal justice systems such as the police, health, and children’s mental health. The *community team* would be responsible for setting up police-community referral protocols, managing and maintaining a centralized referral intake line, conducting comprehensive risk and needs assessments/screenings, and connecting children and families to the appropriate gender-sensitive services to at-risk children and their families. The creation of a government-supported *National Advisory Working Group for Children and Youth Involved in Offending Behaviour* would act as a knowledge-based resource center (similar to CDI’s CCCO) dedicated to knowledge transfer activities that would support the dissemination of current research and services tailored to the needs of high-risk children and their families. This national working group would act as an external, unbiased body responsible for monitoring fidelity of implementation and replication, thus ensuring integrity and accountability from those engaged in assessment and/or services.

Conclusion

After numerous decades of working with young children in conflict with the law, their families, and communities, CDI and SNAP® continue to support and advocate on behalf of these “forgotten children.” CDI and SNAP® researchers and clinicians remain committed to keeping such children out of the youth justice and adult criminal systems. These vulnerable children deserve our utmost attention and help to develop to their fullest potential.

Strategies of Policing Terrorism

Simon Perry
Institute of Criminology, Faculty of Law, The Hebrew University, Jerusalem, Israel

Synonyms

Counterterrorism strategies; Internal security strategies

Overview

In the last decade terrorism has become a prominent topic in many areas, including criminology. Since terrorism affects almost every aspect of life, it has become a central priority for the police in Western democracies. American police and even countries that had been prepared to fight terrorism prior to 9/11, such as Great Britain and Germany, began after that date to review their readiness and rethink the role of police in counterterrorism (Weisburd et al. 2009a; Bayley and Weisburd 2009; International Association of Chiefs of Police 2005; Bamford 2004). Howard (2004) argues that police departments should start thinking of themselves as proactive valuable assets in deterring, defeating, and recovering from terrorist attacks. Law enforcement, intelligence, and security agencies are expected to team up, join forces, and work together with other organizations to uncover terrorist networks, foil terrorist attacks, respond to suspicious situations, and serve as first responders (Weisburd et al. 2009a). Yet there is a lack of evidence-based models for this new role of policing terrorism. A Campbell Collaboration (Lum et al. 2006) systematic review of strategies to combat terrorism could only identify seven studies that met minimal methodological requirements. None of these seven studies examined a police intervention. In fact, to date there are only a few descriptions of possible models for strategic and tactical activities of policing terror. Therefore, little is known about what the best antiterrorism strategies and tactics are. Furthermore little is known about how models can be systematically measured and assessed for their effectiveness (Weisburd et al. 2009a).

This entry will attempt to summarize recent developments in the field of counterterrorism. It will introduce and portray principal strategies, tactics, and practices that are presented in the literature and/or that have been widely adopted by practitioners in policing terrorism.

Why Police Bear Primary Responsibility for the Terrorism Threat in Democratic Countries?

Before discussing what these counterterrorism strategies, tactics, and practices are, four principal themes that naturally surface will be discussed: (a) the characteristics of the terrorism threat phenomenon, (b) the complexity of developing and evaluating a counterterrorism model, (c) the tension between preserving democratic principles and counterterrorism, and (d) why the police (according to Bayley and Weisburd 2009) bear primary responsibility for preserving public security in most countries.

The Terrorism Threat

In order to address the threat and develop an effective response to terrorism, one should first define this criminological phenomenon and its goals (Weisburd et al. 2009b). According to

Ganor (2009), even after the world recognized the scale of the terrorist threat after 9/11, there is still no agreement on a definition of terrorism. After studying various definitions of terrorism (Hoffman 2006; Ganor 2009; Martin 2009; Hasisi et al. 2009) in the context of seeking to develop an effective response to terrorism, one can conclude that the phenomenon of terrorism includes the following basic elements: (a) the creation of *fear and anxiety*; (b) doing so through the use, or threat of use, of *violence*; (c) non-state actors; (d) the goal of weakening the fabric and the *resilience of society*; (e) inflicting *random casualties* among the *general population*; (f) increasing the *frequency of attacks*; (g) targeting the *weakest and most vulnerable* members of society; (h) taking advantage of the *media*; and (i) all in order to pressure decision makers to *accept terrorist demands*.

The Complexity of Developing Strategic Policing-Terrorism Models

The lack of evidence-based models in the policing-terrorism field, as well as a lack of systematically evaluated strategic and tactical activities, is a result of two main reasons. First and foremost, law enforcement intelligence and security agencies are very reluctant to cooperate with such research, as they fear the possible ramifications including the exposure and compromise of counterterrorism methods, tools, sources, and tactics. Secondly, this type of research encounters difficulty in the measurement of success and the determination of cause and effect. These difficulties stem from the presence of other variables in the tested model, the effect of which is to make creating a control situation extremely difficult.

Preserving Democratic Principles and Human Rights in Counterterrorism

In counterterrorism the democratic liberal values of the society limit the capability of the state to make use of the full potential means and technological advantages that the state has. In its struggle against terrorism, the democratic state is obliged to select measures and utilize capabilities that will cause minimum damage to human rights. Innes (2006) argues that collecting and using intelligence is part of the "dirty work" of a democracy. Usage of superior capabilities harming those who have no connection to terrorism, as well as harming fundamental moral principles that are essential for the democratic state, would constitute a victory for the terrorist organization. And such misuse could alienate parts of society, playing into the terrorists' hands (Ganor 2009).

Bayley and Weisburd (2009) argue that legitimacy is the foundation of successful policing, whether related to terrorism or to crime in general. Even though protection from terrorism is a moral cause, it can lead to the violation of human rights, causing officers to approach individuals as suspects rather than as individuals who deserve service. Losing police legitimacy endangers the advantages of public cooperation that are greatly needed in the war on terror.

This is especially significant in minority communities that are linked ethnically or nationally to terrorist groups. For example, in the Israeli context, this applies to familial and national ties of Israeli Arabs to Palestinians in surrounding countries and in the Palestinian-controlled territories (Hasisi et al. 2009).

Why Should the Police Lead the Response to Terrorism?

There are five main reasons why the police force has been chosen to lead the response to terrorism in most countries:

1. Since *terrorists are criminals, and terrorism is a type of crime* in all essential characteristics (Clarke and Newman 2006), it is appropriate that, in democracies, the police force, which is best qualified to deal with criminals and crime, should lead the response to terrorism. **The criminal-justice model** for counterterrorism features terrorism as a crime and portrays the terrorist as violent criminal who should be arrested and punished according to the rule of law by the police and the criminal-justice system (Greene and Herzog 2009). According to Perliger, Hasisi, and Pedahzur (2009), most of the literature discussants on

democracy and counterterrorism believe that **the criminal-justice model** permits dealing with terrorism without seriously undermining the legal and moral foundations of the democratic system. Therefore, it is seen to be better for democratic countries to leave counterterrorism in the hands of the police which operate in the civilian arena. By contrast, **the war model** (Greene and Herzog 2009) features terrorism as an act of war that disputes and threatens the well-being of the state and the political system. Therefore, in this model, it is believed that the terrorist and the terrorist organization should be eliminated by the use of intelligence and military forces. However, employment of **the war model** paradigm would lead to situations in which military forces conduct combat warfare within their own territory, constituting a severe undermining of human rights and morality of the democratic state and its legal system.

2. *Many of the methods and means necessary to fight terrorism are used routinely by the police* in their daily operations. These include investigation and information and evidence collection; forensics (identification of weapons, explosives, victims, etc.); police-operated call centers which are first responders; and police liaison with the private sector, including the issuance of licensing to businesses. Moreover, many activities associated with the handling of terror attacks, whether before, during, or after such an attack, are an integral part of routine police activity (traffic control, managing crime scenes, and maintaining or restoring public order).
3. *The connections between terrorists and other criminals give the police an advantage.* Criminals facilitate terrorism with many necessary means such as weapons and explosives; documentation; vehicles; collecting, transferring, and laundering money; information; communications; technology; and even operational subcontracts for specific missions. Terrorist organizations, in order to finance their activities, have used classic organized-crime illegal activities such as money counterfeiting and the smuggling of drugs, counterfeit goods, and taxable merchandise like cigarettes. This connection gives the police, who have a familiarity with the criminal world, an edge in counterterrorism.
4. *Police are responsive to irregularities in the environments in which they operate routinely.* During their everyday policing of crime and disorder, the police can be on the lookout for suspicious indicators connected to terrorism activities in their communities (Innes 2006). This puts the police in an exceptional position to collect information (that remote intelligence agents generally cannot obtain, since they are not connected to the community) and develop critical counterterrorism intelligence that can be disseminated in real time to other law enforcement agencies (Connors and Pellegrini 2005). Perliger, Hasisi, and Pedahzur (2009) argues that it is better to leave the struggle against terrorism in the hands of the police as part of a more comprehensive model – the criminal-justice model – which treats terrorism as violent criminal action in the civilian arena.
5. *Legal authority to perform policing procedures*. In many democracies only the police have legal authority to perform policing procedures that are required in counterterrorism. The military, for example, in the USA, Canada, UK, and Israel, is not legally empowered to engage in ordinary police functions within the borders of the country. This situation is unlike many European countries (e.g., France, Spain, and Italy) where the military play an active policing role (Weisburd et al. 2009a).

Defusing Terrorist *Motivations* Versus Preventing Terrorist *Opportunities*

Based on the “rational choice” theory (Clarke and Cornish 2001), crime is mainly a result of a ***process*** in which the individual evaluates ***opportunities*** weighing the anticipated benefits against the expected costs of the behavior, in the context of a certain time and place. Terrorism, like any other criminal behavior, is an outcome of two necessary conditions: ***motivation*** to commit the terrorist behavior and ***opportunity*** to carry out a terror attack at a particular occasion (Clarke and Newman 2006). Therefore, any counterterrorism strategy should defuse *terrorist motivations* or prevent *terrorist opportunities* or do both.

The strategy that tries to prevent the terrorist from attacking by defusing the *terrorist motivation* is known as the **conciliatory model**. According to this model, terrorism is a political problem, and it should be given a political solution that will address the root cause of terrorism by the action of policymakers, brokers, and diplomats (Greene and Herzog 2009). However, Clarke and Newman (2006) argue that counterterrorism "must not rely on changing the heart and minds of terrorists. The motivation for terrorism results from long-term social, cultural and psychological pressures, which are difficult to alter" (Clarke and Newman 2006:11).

According to Weisburd and Waring (2001), the efficient approach for prevention of crime involves decreasing the ***opportunities*** (the core of the situational prevention approach presented by Felson and Clarke 1998) present in certain situations which encourage commission of a crime. Clarke and Newman (2006) argue also that in counterterrorism it is easier to reduce ***opportunity*** than to reduce terrorist ***motivation***. This is especially true in the case of suicide bombers that are very hard to deter. Therefore, the efficient approach to prevent terrorism is to adopt strategies that attempt to reduce the opportunities to commit terror attacks. In any case, they claim, easy opportunities encourage terrorists to attack.

In short, defusing terrorist motivations is mainly not a law enforcement intelligence operational task and seems to be less efficient in preventing terrorism than the approach of reducing opportunities. **Therefore, most counterterrorism strategies concentrate on attempting to reduce the *opportunities* rather than reducing *motivation*.**

Reducing opportunities could be achieved by the ***defensive model*** that aims to protect potential targets and victims from attacks, through "target hardening" (Clarke and Newman 2006), or by ***proactively preventing operational capabilities*** of terrorist organizations and individuals that pose the physical and psychological threat. According to Clarke and Newman (2006 p. 9), there are four "pillars of terrorism opportunity": targets, weapons, tools, and facilitating conditions.

The Responsive Approach and the Proactive Approach

Law enforcement practices have two main models of operation: the responsive approach and the proactive approach. In the responsive approach, after a crime or specifically a terrorist act has occurred, law enforcement responds by gathering intelligence, identifying perpetrators, collecting evidence, and arresting suspects. This responsive approach calls for defensive methods that could perhaps foil an attack that has been launched, or at least minimize the damage. Therefore, in counterterrorism we also refer to it as a responsive defensive approach. This approach better protects vulnerable places and effectively restores order in the event of a terrorist attack (Weisburd et al. 2009b).

The proactive model attempts to foil the crime **before** it is launched. This approach has been used for decades by law enforcement against organized and other forms of crime, especially drug trafficking. In this approach law enforcement intelligence identifies potential criminals/terrorists, gathers intelligence and evidence, makes the arrest, and foils the crimes/attacks before they can occur. The main goal of this approach, which can be classified as "high policing," utilizes covert intelligence gathering, surveillance, and foiling operational tools (Bayley and Weisburd 2009; Brodeur and Dupeyron 1993).

Terrorism seeks to create fear and anxiety, weaken the fabric and the resilience of society, and destabilize a social order, all by increasing the frequency of attacks and inflicting mass casualties. The objective of law enforcement is therefore to reduce the operational capabilities of terrorist organizations through counterterrorism measures which can be characterized as proactive, preventive, and offensive in nature. This goal is a crucial part of every democratic country's duty to protect its citizens (Ganor 2009).

The proactive method is intended to deter, disrupt, and prevent terrorist activities (Weisburd et al. 2009b; Hasisi et al. 2009). This counterterrorism strategy damages terrorist organizations physically, psychologically, and economically and hurts their operational infrastructures. It pushes them into a defensive mode, where they spend a great deal of time and resources concealing their activity, which thus limits their effectiveness and reduces their ability to carry out attacks. According to Hasisi et al. (2009), this proactive strategy is becoming more complex as a result of the ever-changing nature of terrorism. In the contemporary age of globalization, terrorist groups tend to be stateless, making them a more elusive target that readily exploits open societies and advanced communication technologies, while evading surveillance by traditional security agencies.

The ***responsive approach***, which is defensive in nature, and the ***proactive approach***, which is preventive and offensive in nature, complement rather than contradict one other.

Since, unfortunately, it is unrealistic to expect to entirely prevent all terrorist attacks, a good responsive approach is important to have in place alongside an efficient proactive approach. This combined approach both apprehends terrorists and damages terrorist organizations. By combining both approaches, counterterrorism forces can prevent or at least significantly minimize terrorist ***opportunities*** to attack before the attacks have been launched, ***responsively*** foil the attacks once they have been launched, and effectively minimize the extent of the casualties and damage, as well as restore order and evacuate the scene during and after the attack. Such a comprehensive method of counterterrorism makes it possible for the general public to maintain their everyday routines and preserves their morale and sense of personal security.

In the United States the view of local law enforcement officers as primarily "first responders" is slowly changing, and they are becoming viewed also as "first preventers" of terrorism. In New York City, the NYPD adopted this concept of "prevention" that has been used so successfully against crime, and adapted it for the war on terror (Bratton and Kelling 2006). Connors and Pellegrini (2005) claim that local officials and police in the United States must be prepared to take the lead in the war on terror and not to wait for direction from federal agencies hundreds of miles away, if they want to prevent or recover from any future terrorist attacks.

According to Innes (2006), in the United Kingdom as early as the 1990s, a new intelligence-led policing improved police agencies' effectiveness by proactively identifying problems and then targeting individuals who were most likely to cause harm to the general public. This change was aimed at pursuing a more proactive mode of working based on the principles of risk management. Given that the police have limited resources and developing effective live informants ("HUMINT") is difficult, a network of community intelligence contacts was established to provide fairly effective surveillance over potentially dangerous groups and individuals. Expert community engagement units were set up to develop and maintain this "community intelligence feed" that would serve both anti-criminal and anti-terrorist purposes.

The Israel National Police (INP) has a long history of experience struggling with terrorism and is considered highly efficient and professional in its approach to counterterrorism (Weisburd et al. 2009b). The Israeli model for policing terrorism applies this principal strategy of combining the ***proactive offensive*** and ***responsive defensive*** approaches. It is implemented in three circles of activity: (a) ***sources of terrorism circle*** – proactive early prevention, interdiction, and treatment of the sources of terrorism in order to foil terrorist attacks before they are launched; (b) ***the attack route*** – response activities once the attack has been launched, to foil terrorist attacks before they reach the target; and (c) ***the terrorist targets*** – defending and "hardening" potential targets before any attack and response activities at the scene during and after an attack.

In the Israeli antiterrorism model, there is a great deal of emphasis on the proactive model approach, since it enables capturing terrorists, decreases the frequency and severity of attacks, and results in fewer casualties. A proactive model is preferable since it has a greater counterterrorism effect, preventing terrorists from achieving their goals and making it possible for the general public to maintain their everyday routines.

Proactive Offensive Early Interception Counterterrorism

As discussed above, the offensive-proactive approach is the most effective counterterrorism strategy and is the key for preventing attacks before they are launched. This strategy identifies and responds to terrorist threats before they actualize, by developing intelligence, establishing operational capabilities, and uprooting terrorists and their infrastructure (Weisburd et al. 2009b). The proactive approach is based on three crucial competencies: producing ***quality intelligence***, building ***operational capability***, and creating a ***hostile environment for terrorists*'** ***operations***.

Effective counterterror thwarting operations rely on the ability to gather reliable information about the terrorists' capabilities, intentions, and specific plans. Quality intelligence takes away from the terrorist the element of surprise, which is a critical advantage for a terrorist attack. Intelligence allows security forces to efficiently protect in advance targets that may be selected by terrorists. Furthermore, intelligence puts the element of surprise in the hands of law enforcement.

Once a terrorist attack has already been set in motion, security forces utilize intelligence both for proactive offensive thwarting operations and for responsive defense measures (Perliger et al. 2009).

The Intelligence Process

Producing intelligence is a circular flow process which constantly aims to portray an accurate picture about the threats. The intelligence analyst defines (based on the initial information) the *information gaps*, which is the information he needs but does not have in order to portray a reliable *intelligence picture*. The *intelligence picture* is composed of all the information about subjects that are connected significantly to the different threats, which are called *topics of interest*, and all the information about individuals who are connected significantly and compose the threat; they are called *targets*.

In order to fill in the *intelligence gaps*, an *intelligence collection and coverage plan* is prepared. The plan includes three levels of coverage: the abovementioned *topic of interest* and *targets*, as well as the *territorial coverage*, which is the entire information about a specific area (neighborhood or town) including who is doing what, when, and where, and who knows about it. At the first stage, potential sources of information are identified in order to cover all three levels. The next stage is the preparation of the *recruitment plan*, which is the methods of recruiting and running live and technical sources. The various sources utilized for coverage are as follows: live informants ("HUMINT") and echnical sources (called "SIGINT") such as wiretaps, surveillance activities, investigations and debriefings, archives, and databases; public open information such as the news media and the Internet; and fellow agencies from the same country or international. The role of the analysts is to prepare and present an *integrative intelligence picture*. Their job is an unending process, since they are the "nerve center" of information: they direct the collection and thwarting of intelligence according to the requirements of the command guidelines, they assist in the preparation of an operational perception, they support the development of "HUMINT" sources, they acquire and deploy intelligence capabilities and tools, and they administer the Intelligence Database.

Unlike military intelligence, which tends to rely on advanced technological monitoring and surveillance capabilities, HUMINT sources are considered more effective for penetrating terrorist groups. Police intelligence generally deals with criminal organizations which are small active groups from within the civilian setting and whose structure and character resemble terrorist groups (Perliger et al. 2009).

Intelligence Sharing and International Cooperation

In many cases the terrorism threat is both national and international. Therefore, cooperation and quality intelligence sharing are essential for law enforcement and intelligence organizations to prevent attacks. Kelling and Bratton (2006) emphasize the importance of collecting and sharing intelligence in the fight against terrorism.

The mutual interrelation between terrorist organizations and the classic hardcore criminal organizations enables the police to extend the well-established national and international cooperation on fighting organized crime to the foiling of terrorism.

Special Operations Capabilities

The mere collection of counterterrorism intelligence is not sufficient, since intelligence without the ability to reach a target or prevent an attack is of little value. These tasks are performed by special operations units which are trained to enter locations where terrorist actions are being planned and prepared. The goal is to foil the attacks before they are launched and to threaten the terrorists' own sense of security, keeping them busy and on the run. Such units should be able to conduct undercover operations in which they reach their target and arrange an arrest without being detected. The police should have specialized elite counterterrorism units, trained to handle very specific terrorist situations, such as releasing hostages and carrying out special operations using small disciplined teams highly trained in commando style military operations.

Bratton and Kelling (2006) argue that the police need special training and a new mindset so they can proactively assault terrorism. Police departments from all over the world are already exchanging information with other countries as the war against terror is gradually becoming a global threat. The government of Israel, for example, has welcomed police forces from all over the United States for training and exchange visits.

Proactively Changing Terrorists' Operating Environment

Bratton and Kelling (2006) explain that the theory of "broken windows" is used to constantly create a hostile environment to potential criminals, building up the uncomfortable sentiment that they are the ones who are in danger. In the same way police officers should create a hostile environment, mainly through the potential terrorist support structures, in which terrorists will feel uncomfortable. Constantly changing the terrorists' operating environment by establishing "bottleneck passage" creates a hostile environment while taking away the element of surprise from the terrorist. Bottleneck passage, such as obstacles and barriers, compels the terrorist to take counteractions, involving other coconspirators by using communication channels. These communication channels leave "intelligence footprints," increasing the opportunities for intelligence collection, by both human and signal technical means.

Defensive Response

The ***defensive response*** to attacks (that were not foiled by the offensive-proactive activity) should be dealt with in two circles of activities: (a) response activities once the attack has been launched and it is on its way to the target and (b) response activities before, during, and after an attack has occurred on a terrorist targeted site.

Response Activities Foiling the Attack on Its Way to the Target

Once an attack is ongoing and the terrorist is on the route to the target, there are a series of possible tactics to delay the terrorist's movement, including setting up road blocks, creating traffic jams, and closing specific public facilities or streets. There are two main goals for creating such obstacles. The first objective is to slow down the terrorist as much as possible, thus delaying the attack. This gives the police more time to bring special operations units to engage with the terrorist on route and at the same time to organize a better defense at potential terrorist targets. The second objective of the obstacles is (as mentioned above) to compel the terrorist to establish communication channels that increase the opportunities for "HUMINT" and "SIGINT" intelligence collection. The enhanced intelligence and better police deployment increases the possibility for interdiction before the attack takes place.

Once there is a specific threat that terrorists have got through the security and are out of control, the police should consider making an announcement though the media, informing the public to stay away from crowded places.

Defensive Activities at a Terrorist's Potential Targeted Site Before an Attack

The number of potential target is endless, and police resources are limited. Therefore, the police need to conduct an efficient defensive effort, using risk assessment in order to build an effective protection plan. Vulnerability and risk analysis must then drive operational responses in order to create a truly effective policing apparatus against terrorism (Connors and Pellegrini 2005). The plan needs to prioritize the allocation of defensive tools in order to harden vulnerable potential targets. According to Davis et al. (2004) after 9/11 three-fourths of the police departments in the United States conducted risk assessment compared to only one-fourth that performed such analysis before 9/11. Private security firms are the police's main partner in "target hardening". In this partnership the police should train, provide necessary information, and supervise so that the private security firms can better protect their clients' facilities. In Israel, all malls, shopping areas, restaurants, hospitals, office buildings, or any other public facilities have private security guards who check customers entering the facility and conduct other security-related activities. The police, prior to approving the business licenses for a facility's operation, review the business facilities and their security procedures. Additionally the police perform periodic security checks, in which facilities that do not hold to the security standards set by the police may be forced to shut down through issuance of a court order (Weisburd et al. 2009a).

Realistically, not all targets can be rendered attack proof; thus, the protection plan should aim to minimize the damage in case terrorists are able to attack. To reduce the number of victims and amount of damage in terrorist attacks that were not foiled, the police work with the private security agencies to prevent terrorists from accessing public facilities. The underlying principle here is that an explosion that occurs within a closed environment (especially if crowded) will result in a much more destructive outcome than if the same explosion took place outdoors, hopefully away from the large crowd.

An important element of target hardening is educating the public and improving routine security preparedness. The police should play a central role in educating the public from an early age to be aware of indications of possible terrorism events and to provide information by reporting their suspicions to the police. In Israel, for example, police visit elementary schools, teaching the children to be attentive towards suspicious people and objects and to report to grown-ups or, if possible, to a policeman. Despite the fact that most security calls to the police are false alarms, the police treat each and every call as if it were an actual explosive device or other security threat. It is important to do so because of the potential damage from every terrorist attack and to demonstrate that the police are responsive, so that the public will continue calling (Weisburd et al. 2009b). Such responsiveness increases public confidence in the police, when in the field of counterterrorism, they are viewed by the public as responding efficiently.

These approaches are also deployed in the United Kingdom, where the police invest a great deal of attention in developing public awareness of suspicious behavior (suspicious short-term tenants, suspicious people who have bought or rented a car, etc.). The police in the United Kingdom develop suitable reporting mechanisms, alongside creating working relationships with the business community to protect businesses from potential threats and to provide guidance on appropriate security measures (Howard 2004).

Defensive Activities on a Terrorist Targeted Site During and After an Attack

The police, being the first responders, are naturally expected to act in response to a terrorist attack in such a way as to effectively manage the crisis. The Israel National Police (INP), which has tremendous experience managing many scenes of terror attacks over the years in Israel, has developed effective practices and protocols. Through the whole process, the highest territorial police commander who is on the scene is responsible for all activities that take place throughout the procedure, until he has been released by his commander or when the scene is cleared. The overall responsibility is never divided and it is always clear. During the entire process, all organizations that are involved are subordinated to the police commander, including the medics, the firefighters, and even the employees of the local city council who later clean up the area. The first mission is to secure the scene from secondary explosive devices or additional terrorists, to prevent a tactic that has been used by terrorists to hit the first responders – the policemen and the medics. Therefore, the first on the scene are the bomb-squad technicians, who close down and search the inner scene. At this stage, along with the bomb-squad technicians, only the medics who treat and evacuate the most critically injured are allowed on the scene. Only after the inner scene has been secured are the rest of injured treated and evacuated. Forensic units follow to identify the dead and – with a special unit – evacuate the bodies; collect intelligence and try to identify the type of explosive device or weapons used, for the purpose of linking it to a specific terrorist organization or laboratory; and collect evidence with the criminal investigators. At the same time traffic and patrol officers set up road blocks, closing down the outer ring and directing traffic, clearing the way for the ambulances, searching for accomplices who might have assisted the attacker and are trying to get away, and controlling crowds. Intelligence units collect information that may assist in identifying the source of the explosives and the people responsible

As mentioned, in order to defeat the goals of terrorism, the main object of the police in counterterrorism is to preserve and strengthen the resilience of the population, enabling the public to continue with their daily life routine. It is expected that a rapid clean-up of the terrorist scene will minimize the psychological effect of the attack. Therefore, timing is critical, both for psychological reasons and also for forensic reasons – to assure the collection of evidence before the scene is contaminated. In the Israeli model, all of these activities of clearing terrorist scenes are expected to be accomplished in no more than 4 h. Another important element in preserving public resilience and reducing distress and fear is keeping the important communication channels open to the public thru the media, in which the territorial commander (or deputy or spokesperson) reports calmly and informatively during and after the attack event to news agencies. The ongoing briefing prevents damaging rumors, giving the public the safe feeling that things are under control by providing such information as the description of the event, the areas or roads that have been shut down, and alternative routes (Weisburd et al. 2009a).

Organizational Elements in Policing Terrorism

A Clear Division of Authority and Responsibility Alongside Vital Cooperation and Partnership

Some countries have a highly centralized police organization at the national level, with a clearly distinguished purpose and responsibility related to crime, terrorism, and public order. However, even in such a setting, the police force has partners in the counterterrorism effort. Furthermore, any police force is composed of different units, so that harmonized cooperation doesn't always come naturally. In the chaotic reality of a terrorist attack, it is fundamental to have an unambiguous division of authority and responsibility that clearly directs who is the one person in charge at a certain time and place and who bears responsibility and accountability. Vagueness about who is running the show leads to confusion, lack of necessary decision making, and failure that will end with unnecessary victims and destruction.

For example, Israel has only one national police force (Israel National Police, INP), and it is highly hierarchical and centralized, with unique centralized operational combat special units. Since intelligence gathering is also centralized, it makes the processes of detecting, identifying, deterring, and thwarting potential terrorist attacks more efficient (Greene and Herzog 2009). There are close and ongoing formal and informal contacts between the police and the Internal Security Agency (ISA) (Weisburd et al. 2009a). This intimate cooperation between the INP, which has overall responsibility for internal security, and the ISA, which is the main source of counterterrorism intelligence, was not a trivial matter to achieve. It required tremendous effort to build trusting relationships at all operational and command levels. Such a relationship makes it possible in a matter of minutes to turn critical ISA information into an INP foiling operation. More broadly, the close connection between the INP and the ISA facilitates the exchange of intelligence while enabling consistency in both offensive and defensive counterterrorist operations (Hasisi et al. 2009).

Countries that do not have a centralized police system have to synchronize their counterterrorism activity on the national level as well as the local level. For example, in the United States before 9/11, there was a lack of intelligence coordination that has been strongly criticized (Weisburd et al. 2009b). Currently local, state, and federal law enforcement agencies exchange information on initiatives, as well as creating centralized special officers and units, including special response teams.

According to Bratton and Kelling (2006), intelligence-led policing is making its mark in the USA, and major efforts are being made to restructure police capabilities for an increasingly proactive intelligence gathering and analysis apparatus. Instead of relying on the federal government for intelligence, many state and local departments are now creating their own systems. Among other actions, they are assembling databases and sharing information. This very important development requires highly sophisticated coordination, especially in such a large country as the USA that has around 17,000 police organizations on the federal, state, and local levels. These organizations are adopting a set of national strategic guidelines that clearly define the division of authority and responsibility, setting vital cooperation and partnership procedures.

Recruitment, Training, Weapons, Equipment, and Relevant Exercises

Since counterterrorism is a major responsibility of the police, police officers need to be trained and equipped to confront the terrorism threat. Kelling and Bratton (2006) argue that counterterrorism has to be woven into the working protocols of every police department, so that it becomes part of the everyday thinking of the officers who are on the street.

All officers, including those whose main role within the police is *not* counterterrorism, should undergo basic counterterrorism training. The training should prepare officers for an unexpected encounter with a terrorist incident. It should focus on acquiring first response skills such as isolating the site of a terrorist attack and effectively handling the personal weapon. Fast response teams that would defuse terrorist situations and bring them to an end as soon as possible should be put together and trained. The goal of such teams is to be prepared for fast intervention to minimize the damage, and to control and contain the scene until the attack is defused or the special counterterrorism unit takes over. Response time is crucial in containing a terrorist attack; therefore, the fast response teams should have sufficient training (such as urban warfare), relevant exercises, equipment, and suitable transportation, such as motorcycles (Weisburd et al. 2009a).

Shortcomings of Policing Terrorism

The leading role of police in counterterrorism elevates new problems and dilemmas for the police in democratic countries. On the one hand, counterterrorism is a natural extension of the classic police duties, as previously mentioned. On the other hand, it is clear that terrorism may call for new responsibilities that emphasize “high policing,” which is characterized by its focus on strategic issues at a macro level, rather than local crime and disorder problems (Bayley and Weisburd 2009; Weisburd et al. 2009b). High policing emphasizes controlling rather than servicing the public, a standpoint very different from the community policing ideas that have reinforced community-police relationships. Counterterrorism functions of the police are likely to clash with the goals of creating closer police-community relations, especially with minorities, since it is difficult to be “officer friendly” and at the same time collect intelligence on suspects that are part of the community or related to it (Weisburd et al. 2009b).

Summary

Counterterrorism is geared to making it possible for the general public to maintain their everyday routines, thus preserving their morale, feelings of personal security, and resilience. This entry has introduced, described, and explained the following ***principal strategies***, ***tactics***, ***and practices*** that are presented in the literature and that are adopted by practitioners in policing terrorism:

1. Most of the counterterrorism strategies concentrate on attempting to reduce the ***opportunities*** for terrorist attack, since it is easier than to reduce terrorist ***motivation***.
2. Efficient counterterrorism combines ***proactive offensive*** and ***responsive defensive*** approaches in order to reduce terrorist ***opportunities***.
3. ***Proactive offensive*** counterterrorism identifies and responds to terrorist threats before the terrorists have an ***opportunity*** to attack.
4. The first crucial component of the ***proactive offensive*** approach is ***quality intelligence*** that is an outcome of a circular flow process. This process aims to constantly portray an accurate picture about the threats, turning information into timely action-operational intelligence.
5. The second crucial component of the ***proactive offense*** is establishing ***operational capabilities*** that have accessibility to uproot terrorists and their infrastructure, pushing them into a defensive and ineffective mode by keeping them busy and on the run, thus foiling attacks before they are launched.
6. The third crucial component of the ***proactive offense*** is constantly changing terrorists’ operating environment by establishing bottleneck passage such as obstacles and barriers, causing an intelligence footprint. Bottleneck passage compels the terrorist to take counteractions, involving other coconspirators and using communication channels. These communication channels boost the opportunities for intelligence collection, both human and signal technical.
7. Since in many cases the terrorism threat is both national and international, cooperation and quality intelligence sharing are essential for law enforcement and intelligence organizations to prevent attacks.
8. The ***responsive defensive*** model enables the general public to maintain their everyday routines, strengthening their resilience and preserving their morale and feelings of personal security. The model includes “target hardening,” foiling launched attacks, and effectively restoring order during, and efficiently evacuating the scene rapidly after, the attack.

9. In order to foil launched attacks, there are a series of possible tactics to delay the terrorist's movement, compelling the terrorist to establish communication channels. This allows enhanced intelligence gathering, potentially allowing special operations units to engage with the terrorist on route, as well as better police defensive deployment at potential targets, increasing the possibility for interdiction before the attack takes place.
10. In order to build an effective protection and "target hardening" plan, a vulnerability and risk analysis must be part of the police apparatus. Private security firms are the police force's main partner, to whom the police should provide necessary information and supervision so that the private security firms can better protect their clients' facilities and minimize the damage in case a terrorist was able to attack.
11. The police should educate the public from an early age to be aware and to report any possible threat, which should always be treated by the police as if it was a genuine attack.
12. It is fundamental to have clear division of authority and responsibility that clearly directs who is the one person in charge at a certain time and place in the event of an attack and who bears responsibility and accountability. Vagueness leads to confusion, lack of necessary decision making, and failure that will end with unnecessary victims and destruction.
13. At an attack scene the first mission is to secure the scene from secondary explosive devices and to treat and evacuate only the critically injured. After the scene has been secured, the rest of the injured are treated and evacuated. To minimize the psychological effect of the attack, the forensic units follow, to effectively and rapidly identify and evacuate the dead, and collect evidence and intelligence, allowing a quick clean-up of the scene.
14. The police commander needs to keep the important communication channels open to the public thru the media, reporting calmly and informatively during and after the attack in order to reduce distress and fear.
15. Countries that do not have a centralized police system need to synchronize their counterterrorism activity on the national and local levels, by adopting a set of national strategic guidelines that clearly defines the division of authority and responsibility, setting vital cooperation and partnership procedures.
16. All police officers should undergo basic counterterrorism training that should prepare officers for an unexpected encounter with a terrorist incident. Response time is crucial in containing a terrorist attack; therefore, the fast response teams should have sufficient training, relevant exercises, equipment, and suitable transportation.

Now that the policing-terrorism models have been described, the key question that remains is "How effective are these ***principal strategies***, ***tactics***, ***and best practices*** of 'policing terror'?" As Weisburd, Jonathan, and Perry (2009a) argue, it is clearly time for scholars to begin to evaluate the effectiveness of police responses to terrorism.

Structured Sentencing Outside the United States

Julian V. Roberts
Faculty of Law, Centre for Criminology,
University of Oxford, Oxford, UK

Overview

How much discretion should judges have at sentencing? If they have too much, disparity of outcome will be the inevitable consequence. On the other hand, removing their discretion entirely will result in injustice. The solution to this problem lies in the concept of sentencing guidelines which in theory at least provide direction to courts but without unduly restricting their discretion. The US-style grid-based guidelines are only one form of sentencing guidelines; other models are possible. This entry reviews the experience in jurisdictions other than the USA. Several countries have attempted to structure judicial discretion at sentencing in different ways. These other forms of guidance represent alternative approaches to promoting consistency at sentencing. After noting some developments in some other countries, this entry focuses on the experience in England and Wales which is the only common law jurisdiction outside the United States to have developed and adopted a comprehensive sentencing guidelines scheme.

Introduction

When most judges or other criminal justice professionals think about sentencing guidelines, the systems found across the United States come readily to mind. Sentencing guidelines have been evolving in that country for over 30 years now, at both the state and federal levels. Most states have a formal sentencing guidelines scheme to assist judges at sentencing. The best known guidelines model involves a two-dimensional sentencing grid – much like a mileage chart which shows the distance between two cities. Under a sentencing grid, the two dimensions are crime seriousness and criminal history. In order to determine the sentence that should be imposed, a court selects the appropriate level of seriousness and the appropriate criminal history category. Where the crime seriousness row and the criminal history column intersect, there is a grid cell containing a relatively narrow range of sentence length. Sentencing grids of this kind are found in a number of states including Minnesota (e.g., Minnesota Sentencing Guidelines Commission 2010a; Frase 2005, 2009).

If the guidelines are presumptively binding (some states use advisory guidelines, and the US federal guidelines are now considered advisory following several judgments from the US Supreme Court), the court must impose a sentence within the range found in the guidelines grid. A court wishing to impose a more or less severe sanction than that which is prescribed by the guidelines must first find "substantial and compelling" reasons to justify what then becomes a "departure" sentence, namely, one outside the official guideline ranges. Departure rates vary across the US systems. Statistics from Minnesota reveal that in 2009, 25 % of all felony offenders received a sentence different from that prescribed by the guidelines, while a further 14 % of all sentences of custody were outside the guidelines sentence length limits (Minnesota Sentencing Guidelines Commission 2010b, p. 26). The total departure rate for 2009 was therefore 38 %. Departure rates in other states are lower. In Pennsylvania, only 10 % of sentences imposed in 2008 fell outside the guidelines; over the period 1985–2008, the departure rate averaged 11 % (Pennsylvania Commission on Sentencing 2009, p. 46). In Oregon, less than one-fifth of sentences were outside the guidelines (Oregon Criminal Sentencing Commission 2003, p. 13).

Structuring judicial discretion at sentencing is one of the most significant challenges for a legislature. If they prescribe specific sentences – such as mandatory terms of custody – courts are prevented from doing justice by reflecting the individual circumstances of specific offenders. For example, legislating a mandatory sentence of imprisonment for all convictions of robbery means that offenders of different levels of culpability will receive the same sentence – a clear injustice. On the other hand, if legislatures leave the courts to regulate themselves at sentencing, outcomes may be too variable, leading to sentencing disparity. In short, it is a fine balance between offering too much and too little structure.

Sentencing Reform in Other Jurisdictions: Guidance by Words Alone

Sentencing guidelines do not have to be numerical in nature, providing a specific range of sentence for each crime. A number of Scandinavian countries have developed what may be termed "guidance by words" (see also Ashworth (2009) for discussion of techniques to reduce disparity through increased guidance). This approach to structured sentencing involves the legislature placing relatively detailed guidance in a sentencing law. For example, the Swedish Penal Code identifies proportionality as the primary rationale for sentencing and requires courts to assess the seriousness of the crime in order to determine sentence. A number of mitigating and aggravating factors are also specified in the Swedish sentencing law in order to guide judges in the determination of sentence. Finally, the law also contains guidance for courts with respect to the choices they should make between different sentencing options (for further information, see von Hirsch and Jareborg 2009). The advantage of the "guidance by words" approach is that it leaves courts with considerable flexibility to determine an appropriate and proportionate sentence. On the other hand, this may result in much greater disparity than would be the case in a jurisdiction such as Minnesota where judges have to follow detailed and prescriptive sentencing guidelines.

Sentencing Structures: Commissions and Councils

How would a country go about creating a sentencing guidelines scheme? The first step in any move towards structuring judicial discretion involves the creation of an independent authority to developing and issuing sentencing guidelines. All US guidelines schemes emerge from a sentencing commission, such as the Minnesota Sentencing Guidelines Commission or the US Sentencing Commission at the federal level. In other countries, these bodies are usually called Sentencing Councils, and there is significant variation in their structures and functions. The Sentencing Council of England and Wales is headed by the Lord Chief Justice and is tasked with devising and disseminating guidelines as well as a range of other functions (see Roberts 2011, 2012). On the other hand, sentencing councils in Australia such as the Sentencing Advisory Council in New South Wales are, as the name implies, advisory in nature. These councils do not issue sentencing guidelines per se but rather provide advice and conduct research upon a wide range of sentencing matters.

All sentencing councils are involved in public legal education of one kind or another. This may mean publishing reports to help the public understand the sentencing process better, or it may mean releasing comprehensive sentencing statistics. For example, some guidelines authorities publish periodic Sentencing Bulletins which summarize sentencing trends for specific offenses (see http://sentencingcouncil.vic.gov.au/page/about-us/council). The public typically rely on news media accounts of sentencing decisions, and these generally focus on unusual or exceptionally lenient sentences – those which are newsworthy in some respect. It is important therefore for a guidelines authority to dispel public misperceptions of sentencing.

Progress towards developing sentencing guidelines around the world has been fitful and slow. The Law Commission of New Zealand developed a comprehensive and principled set of guidelines, but the legislature in that jurisdiction has yet to proclaim the necessary legislation to permit implementation (see Young and Browning 2008). The New Zealand scheme involved a comprehensive guideline for each offense; the guideline contained categories of crime seriousness, each with an associated range of sentence. A sentencing court would match the case appearing for sentencing to the guideline category using information in the guideline. The system was more flexible than the US-based schemes. The New Zealand proposed guidelines also included "generic" advice – guidelines which apply to more than a single offense. For example, the guidelines provide guidance on considering the impact of the crime upon the victim and also the way in which courts should approach the sentencing of multiple crimes on the same occasion.

Other jurisdictions – including Scotland, Western Australia, Northern Ireland, and Israel – have explored the use of guidelines for sentencers but so far have not actually adopted a formal scheme. The Sentencing Commission for Scotland recommended creation of an Advisory Panel on Sentencing to assist the introduction of sentencing guidelines, but this has yet to become operational (see Hutton and Tata 2010). Following recommendations from a Sentencing Working Group (2010), Northern Ireland held a consultation on the possible options for a form of sentencing guidelines (Criminal Policy Unit 2010).

In January 2012, the Israeli Parliament (Knesset) approved a sentencing law. This law adopted parts of a Bill which provide for "guidance by words" but without establishing the guidelines authority which would have been empowered to develop and issue guidelines scheme involving "starting point sentences" (see Gazal-Ayal and Kannai 2010). Under the new legislation, courts are required to devise their own proportionate sentence range for the case being sentenced and to provide reasons if they impose a sentence outside this range. South Korea has also launched a guidelines scheme (see Park 2009). Several jurisdictions (including New South Wales and the state of Victoria in Australia) have created advisory bodies which disseminate information about sentencing but which do not actually disseminate guidelines (see Abadee (2008) and more generally, Freiberg and Gelb 2008).

Countries Without Guidelines

Finally, some countries – Canada, South Africa, Ireland, and India, for example – have resisted all appeals for greater structure at sentencing (e.g., Terblanche 2003; Doob 2011; Roberts et al. 2011). Although scholars and practitioners in those countries have long advocated creation of some kind of guidelines scheme, legislatures in these countries have so far rejected calls to introduce sentencing guidelines. The consequence is that judges in these jurisdictions continue to impose sentence much as they have for decades, with the only guidance coming from the appellate courts. This approach to sentencing may be termed "judicial self-regulation" (see Ashworth 2009). The limitation of this approach is that higher courts hear only a small proportion of cases on appeal, which means that the opportunities for guidance are limited. When a court of appeal does hear a sentence appeal, it does not always give general guidance.

Guidelines Structures

If appropriately constructed, and not subject to political interference, sentencing guidelines remain the best hope for constraining prison populations and achieving principled sentencing (see Stemen and Rengifo (2011); von Hirsch et al. (2009)), but the question remains: what form of guidelines is appropriate for any given jurisdiction? The guidelines movement remains strong across the USA, but despite its high profile, the model employed in states such as Minnesota has not proven a popular penal export. Canada was the first country to reject this approach to structured sentencing.

In 1984, the Canadian government created a term-limited Sentencing Commission which visited several American states (including Minnesota and Pennsylvania) and concluded that two-dimensional grids held no promise for sentencing in Canada (see Canadian Sentencing Commission 1987). Canada's flirtation with guidelines ended in the 1990s when its Parliament approved a modest sentencing reform package and declined to create a permanent sentencing commission or to create guidelines of an even advisory nature (see Roberts and Cole 1999; Doob 2011). A generation later the Sentencing Commission Working Group in England and Wales visited the home of numerical guidelines and drew the same conclusion (Sentencing Commission Working Group 2008). Western Australia considered adopting a two-dimensional sentencing grid in 1999 but also ultimately abandoned the idea.

The proliferation of two-dimensional sentencing grids across the USA since the 1970s may paradoxically have undermined the appeal of all presumptively binding guidelines. Sentencing guidelines of any kind are often regarded by judges as harbingers of grids and as being antithetical to sentencing as a "human process" (see Hogarth 1971). Calls for the introduction of any kind of sentencing guidelines system are perceived as an attempt to move towards the ultimate goal of a grid. Indeed, opposition in Canada (and England and Wales) to sentencing guideline schemes of all stripes was fueled by predictions that any move towards structuring judicial discretion would culminate in the imposition of a rigid two-dimensional grid. In England and Wales, despite considerable judicial and professional resistance to the concept of guidance derived from a source other than the Court of Appeal, guidelines have slowly emerged over the past decade. Definitive guidelines now exist for most high-frequency offenses.

Sentencing Guidelines in England and Wales

Distinguishing Guideline Schemes in the USA and England

The English guidelines offer a different but equally viable model to follow, and there are lessons for other jurisdictions seeking to impose greater structure at sentencing without adopting a US-style two-dimensional grid. Guidelines have been developing slowly in England and Wales since creation of the Sentencing Advisory Panel in 1998. In addition, the Court of Appeal has been issuing guideline judgments periodically over the years. Courts in England and Wales have therefore a tradition of guidance on which to draw. However, with the creation of the Sentencing Council in 2010 (see Roberts 2011), the guidelines entered a new area, and the new Council began issuing guidelines more frequently and in a new format.

How do the English sentencing guidelines differ from the US-based schemes? The principal difference is that guidelines in England and Wales promote consistency by requiring sentencers to proceed through a series of steps. This represents a different approach to promoting consistency in sentencing. The effectiveness of the English approach has not been evaluated, as the Council responsible for issuing the guidelines has yet to publish the data which will shed light on any changes in consistency of sentencing outcomes. The second principal difference between the English and the US guidelines is that Sentencing Commissions across the USA devise and issue a complete package of guidelines encompassing all offenses – usually, as noted, within a single guidelines grid. The English Sentencing Council issues guidelines sequentially for each offense category (such as all assault offenses, or drugs crimes). This means that it takes longer for guidelines to be available for all offenses. (All English guidelines are available at http://sentencingcouncil.judiciary.gov.uk/).

Step-by-Step Sentencing Methodology

How do the English guidelines work? The English guidelines structure contains a series of

Offence: Assault occasioning actual bodily harm

Step 1: Use the factors provided in the guideline which comprise the principal elements of the offence to determine the category which is appropriate:

- Category 1: Greater harm *and* high culpability;
- Category 2: Greater harm *and* lower culpability *or* lesser harm *and* higher culpability;
- Category 3: Lesser harm *and* lower culpability.

Step 2: Use the *starting point* sentence from the appropriate *offence category* to generate a provisional sentence within the *category range*. The guideline contains a list of additional aggravating and mitigating factors which should result in upward or downward adjustment from the *starting point* sentence.

Offence Category	Starting Point Sentence	Category Sentence Range
1.	18 months custody	12 months – 3 years' custody
2.	6 months custody	Community order – 12 months custody
3.	Community order	A fine – community order

Step 3: Consider if any reduction in the provisional sentence should be made to reflect assistance offered or provided to the prosecution.

Step 4: Consider the level of reduction appropriate to reflect a guilty plea.

Step 5: Consider whether the offender meets dangerousness criteria necessary for imposition of an indeterminate or extended sentence.

Step 6: If sentencing for more than one offence apply the totality principle to ensure that the total sentence is just and proportionate to the total offending behaviour.

Step 7: Consider whether to make a compensation order and/or other orders.

Step 8: Give reasons for and explain the effect of the sentence on the offender.

Step 9: Consider whether to give credit for time on remand or bail.

(For further information, see Sentencing Council (2012); Roberts and Rafferty (2011)).

Structured Sentencing Outside the United States, Fig. 1 Example of sentencing guidelines format in England and Wales

nine steps, of which the first two are the most critical. (See Fig. 1 for a summary of the steps). The idea is that if all courts follow the same step-by-step procedure, sentencing decisions across courts should be more consistent.

For the purposes of illustration, let us examine the guideline for *Assault occasioning actual bodily harm* (see Sentencing Council of England and Wales 2011). As with many offenses for which a definitive guideline has been issued, ABH has been stratified into three categories of seriousness. The guideline provides a separate range of sentence and starting point sentence for each category. Step 1 of the guidelines methodology requires the sentencing court to match the case appearing for sentencing to one of the three categories of seriousness. The three categories have been created to reflect gradations in harm and culpability, with the most serious category (1) requiring greater harm and enhanced culpability. Category 2 is appropriate if either greater harm or higher culpability is present, while Category 3 involves lesser harm and a lower level of culpability.

Determining the Offense Category

Step 1 of the guideline identifies an *exhaustive* list of sentencing factors which should be used to determine which of the three categories of seriousness is most appropriate for the particular offender appearing for sentencing. These factors constitute what the guideline describes as the "principal factual elements" of the offense. Their importance is reflected in the fact that determination of the category range is the step which will have greatest influence on severity of sentence. For example, if the court chooses the lowest category, the most severe sentence it should impose is a community-based (noncustodial) sentence. In contrast, the next category up has a maximum sentence of 51 weeks imprisonment. Having determined the relevant category range, a court should use the corresponding starting point sentence to move towards a sentence which will then be shaped by the remaining steps in the guideline.

Step Two: Shaping the Provisional Sentence

Step 2 requires a court to "fine-tune" the sentence by considering circumstances which provide "the context of the offense and the offender." The guidelines provide a non-exhaustive list of sentencing factors for courts to consider at this step of the methodology. The aggravating factors include committing the offense while on bail or license, while under the influence of drugs, or with abuse of trust. The guideline factors which reduce seriousness (and which result in less severe sentence) include an absence of prior convictions and the fact that the crime was an isolated incident. A diverse collection of factors is cited as relevant to personal mitigation, including remorse, the fact that the offender was a sole or primary carer and "good character and/or exemplary conduct."

Other Steps Towards the Final Sentence

Leaving Step 2 leads a court to the remaining seven steps of the guidelines methodology, which may be briefly summarized. Step 3 directs courts to reduce sentence in cases where the offender has provided or offered to provide assistance to the prosecution or police. Step 4 involves the reduction for a guilty plea. Offenders who plead guilty receive a reduction of up to one-third off their custodial sentence, depending upon how early they enter their plea. The remaining steps to be followed relate to other sentencing provisions such as the consideration of any time that the offender spent in remand while awaiting trial. (This time is taken off any custodial sentence ultimately imposed). The guideline steps also require the court to give reasons for the sentence imposed and to explain the effect of the sentence for the benefit of the offender. Finally, courts give reasons for the sentence and, in particular, if they have imposed a sentence which falls outside the guidelines range.

Legal Status of English Guidelines

As noted, in many US states, the sentencing guidelines are binding on courts: a judge may depart from the guideline range if he or she finds "substantial and compelling" reasons why the guideline sentence is inappropriate. The English guidelines are less restrictive, although they are formally binding on courts. When sentencing an offender in England and Wales, a sentencing court "must follow" any relevant sentencing guidelines – unless it would be contrary to the interests of justice to do so (see discussion in Ashworth 2010). However, courts may impose a sentence within a wide range and still remain compliant with the guidelines. In this sense, although they are required to follow the guidelines, courts retain considerable freedom to sentence offenders: first, they have considerable discretion within the guidelines, and second, they may depart from the guidelines if they believe it is necessary in the interests of justice.

Conclusion

What have we learned about the experience with structuring sentencers' discretion outside the United States? A number of lessons can be drawn. First, the Scandinavian model suggests that numerical guidelines are not necessarily the only model to follow. It is possible to offer guidance to courts without prescribing specific sentencing ranges in terms of numbers of months or years. Second, the English guidelines demonstrate that there is a middle ground lying between the relatively tight sentencing guidelines found across the United States and the looser systems of "guidance by words" found in countries like Sweden and Finland (see von Hirsch et al. 2009, Chapter 6). Along with the New Zealand proposals, the English guidelines offer a system which is numerical, prescriptive, and yet quite flexible in application. These two systems offer a plausible improvement upon the highly discretionary sentencing arrangements found in countries like Canada, South Africa, and India. Third, judicial acceptance of greater structure (and reduced discretion) is far more likely when the judiciary is heavily implicated in the development and evolution of the guidelines. The statutory bodies responsible for the guidelines in England and Wales have generally been dominated by the judiciary. The Canadian Sentencing Commission proposals failed, in part because judges perceived the guideline scheme to be a bureaucratic scheme created by academics.

Fourth, there may be an advantage to the gradual evolution of the guidelines. The English guidelines have been criticized for being slow to develop – with guidelines for specific offenses issued periodically over the years rather than in one step as was the case in the United States or the proposals advanced in New Zealand. There was no "big bang" to the English experience in the sense of a comprehensive guidelines package covering all offenses. In retrospect, this potential weakness of the guidelines may paradoxically have ensured their survival and development. They have evolved incrementally – from their modest origins in 1999 (see Ashworth and Wasik 2010) through to the much more comprehensive and detailed scheme of 2011. Judges who are traditionally resistant to any attempts to curb their discretion may be more likely to accept guidance when it comes in this format.

The ultimate question to pose, however, is the following: Are the guidelines proposed or implemented in other countries better or worse, more or less effective than those developed across the United States? Unfortunately the absence of truly comparative research makes it impossible to resolve the issue one way or another. In addition, the non-US-based guidelines such as those in England have yet to be evaluated. For example, we do not yet know how much the English guidelines have improved consistency in that country. At the very least, however, the experience in that country demonstrates that it is possible to introduce detailed and prescriptive sentencing guidelines even in a common law jurisdiction which, in the 1980s and 1990s, was committed to the traditional model of privileging judicial discretion (see Ashworth 2010).

Overview

An increasing body of literature reflects the heightened risk for suicide faced by justice-involved persons, whether they are in jails, in prisons, or in the process of transitioning from a correctional facility back into the community. Suicide and suicide prevention have garnered increased attention, efforts, and resources within correctional facilities. Despite this increased awareness of suicide and heightened efforts to prevent suicide in correctional settings, suicide rates among incarcerated persons in the United States have continued to exceed that of the general population (albeit less so than in previous decades). Pertinent case law clearly creates potential liability for both correctional and health-care staff in the wake of a death by suicide. This entry will review applicable case law; explore statistical trends, risk factors, and characteristics of suicides in correctional settings;

review methods for prevention of suicide supported by the literature; discuss select special populations of incarcerated individuals at risk; and explore the suicide risk surrounding the transition from correctional settings back into the community. This entry will validate the importance of the issue of suicide in correctional settings and highlight areas where further research and progress are needed.

Case Law History

The potential for legal liability resulting from suicide in correctional settings originates in two seminal cases: *Estelle v. Gamble* (1976) and *Bowring V. Godwin* (1976). In the *Estelle* case, the plaintiff filed suit claiming that the medical director and two correctional officers of a state correctional department violated the Eighth Amendment (cruel and unusual punishment) by not providing appropriate medical care for the inmate's back pain. Upon appeal, the US Supreme Court established the legal standard of "deliberate indifference" and by using this standard held that the inmate's medical care did not violate the 8th Amendment. Deliberate indifference requires more than mere negligence. Negligence typically involves the failure to exercise the care toward others which a reasonable or prudent person would do in similar circumstances, with the resulting harm generally being accidental. A reckless culpable mental state typically involves gross negligence, meaning that the individual could foresee the potential for harm, but was heedless of the consequences. The deliberate indifference standard is more akin to recklessness, necessitating that in order to be deemed liable, prison staff must have the subjective knowledge of risk for serious harm and then disregard that risk.

In the *Bowring* case, an inmate in a state correctional facility claimed Eighth Amendment (cruel and unusual punishment) and Fourteenth Amendment (due process) violations in lower court due to being denied parole, in part as a result of a psychological opinion that he would not be a successful parolee. The plaintiff argued that he was not provided the psychiatric or psychological diagnosis or treatment needed to address the psychological concerns of the parole board. The Fourth Circuit Court of Appeals held that psychiatric illnesses are medical in nature, thereby extending the treatment obligations incumbent upon correctional facilities to mental illness. The combination of these two seminal cases sets the stage for subsequent decisions finding liability in failure to prevent inmate suicide.

Concerning suicide specifically, circuit-level court findings in *Partridge v. Two Unknown Police Officers* (1986) and *Colburn v. Upper Darby Township* (1991) establish inmate suicide as a potential source of liability for correctional facilities (Scott 2010). The *Partridge* Fifth Circuit court determined that psychiatric illnesses potentially resulting in deaths by suicide constitute a "serious medical need." In *Colburn v. Upper Darby Township* (1991), the Third Circuit court established that correctional facilities have an obligation to train staff members to identify potentially suicidal inmates and to intervene in an effort to prevent suicide deaths. The court determined that the standard for correctional staff's competency in identifying potentially suicidal inmates would be comparable to that of a layperson's and that correctional staff would be held to a standard of "reckless indifference" when legally evaluating efforts to intervene and prevent an inmate death by suicide. The Third Circuit court confirmed the lower court's analysis, indicating that a plaintiff must prove not only that the deceased inmate had a "particular vulnerability to suicide" but that custody staff knew or should have known about the vulnerability and that the custody staff acted with "reckless indifference" in relation to the individual's particular vulnerability. Existing case law clearly sets a bar for correctional facilities' role in suicide prevention, though sets that bar relatively low.

Suicide Rates in Correctional Settings

Historically, suicide rates have been exceedingly high within correctional settings relative to the general population. In 1983, the suicide rate for jails was 129 per 100,000 inmates, and suicide accounted for 56 % of all jail deaths (Noonan 2010). Fortunately, suicide rates in both jails and state prisons have decreased since the 1980s. From 2000 to 2007, the suicide rate within jails decreased by approximately 25 %, from 48 per 100,000 to 36 per 100,000. Despite this relative decline in suicide rates, suicide remained the single leading cause of preventable death in jails. When jail suicide deaths rates from 2000 to 2007 are adjusted for demographic factors such as age, race, and sex, the rates still remain high relative to those observed in the general population in the United States (14 per 100,000). Overall, the adjusted rate for suicide in jail is 59 per 100,000 for males and 27 per 100,000 for females. Comparable rates of suicide in the US general population are 21 per 100,000 for males and 5 per 100,000 for females. It is worth noting that suicide rates within jails may vary substantially depending on the size of (and presumably resources available within) the correctional facility. Large jails had a lower suicide rate (27 per 100,000) relative to small jails (167 per 100,000), with small jails being defined as those housing 50 or fewer inmates. Noonan theorizes that a lack of suicide prevention measures, including appropriate mental health services and more inmate turnover in smaller jails, may account for this difference (2010). State prisons have also demonstrated a fortunate downward trend in suicide rates over the past few decades, though they still exceed that of the general population. The rate of suicide was 34 per 100,000 in 1980 (Mumola 2005) and decreased to a rate of 16 per 100,000 for the years 2000–2007. This rate has held fairly stable since the 1990s (Noonan 2010). Federal prison suicide rates are reported at 10 to 17 per 100,000 (White et al. 2002).

A poignant criticism has been raised regarding the method employed in measuring the rate of suicide in jails. These reported rates are based upon the total national average daily inmate population rather than the number of admissions to the specific incarceration facilities (Hayes 2010). If the rates were calculated based upon the number of admissions rather than the average daily population, calculated suicide rates would be lower. Calculating suicide rates based on the total number of admissions would arguably be more accurate because this method takes into account the high turnover of jails and thus more fully captures the at-risk population. Larger jails release approximately 46 % of inmates within the first 2 days of confinement and release 80 % of their population within an inmate's first month of incarceration. Calculations based on admissions would thus more fully take into account all the unique individuals incarcerated. Others argue that community suicide rates are not calculated on total "admissions" to the population, and moreover, the majority of admissions are brief incarcerations and thus should not be included in the statistical calculation. But, as will be discussed below, many suicides occur very early after incarceration, illustrating the potential importance of capturing all admissions when calculating rates.

Incarceration within correctional facilities does seem to carry increased risk for suicide. Why has the rate of suicide been high in correctional settings, and furthermore, why has the rate decreased since the early 1990s? Various investigations and expert opinions have proposed several possible explanations.

Prevalence of Mental Illness in Correctional Settings

One significant risk factor for suicide, applicable to individuals across settings (whether they are in jails, prisons, or the general community), is a diagnosis of mental illness. In one study of individuals who died by suicide in jails between 2005 and 2006, 38 % suffered from mental illness, 20 % had a history of being prescribed psychiatric medications, and 34 % had a history of self-directed violence, including suicide attempts and nonsuicidal self-directed violence (Hayes 2010). Patterson reported that 73 % of the California prison inmates who died by suicide in a 6-year period had a history of mental health treatment and 62 % had a history of suicidal thoughts or behavior (2008). Fazel conducted a systematic review of suicides in prison and found that history of attempted suicide, current psychiatric diagnosis, and current prescription for psychotropic medication were risk factors for suicide in prison (2008).

Rates of suicide in correctional settings are almost certainly related to the prevalence of mental illness. For jails and prisons, the number of admitted individuals suffering mental illness has increased over the last half of the twentieth century. Since the 1960s, the number of long-term care mental health institutions (such as state mental health hospitals) has decreased under the deinstitutionalization movement (Lamb and Weinberger 2005). Deinstitutionalization evolved from legal and ethical concepts favoring treatment of mentally ill individuals in the least restrictive environment possible. Under this theory, individuals would be released from highly restrictive psychiatric facilities and would instead be treated and supported in community-based mental health centers. Unfortunately, many experts agree that the deinstitutionalization movement has largely failed due to the inadequate creation and funding of needed community mental health centers, such that many severely, chronically mentally ill individuals are not receiving the treatment and support needed to sustain tenure in the community (Scott 2010). In the absence of such support, many of these mentally ill persons go on to engage in behaviors that eventually lead to incarceration. Hence, the failed deinstitutionalization movement has, over time, resulted in a shift in location for the severely mentally ill, from mental health facilities to correctional settings. In 1955, there were 559,000 psychiatric hospital beds for a total United States population of 165 million, compared to 59,403 psychiatric hospital beds for a total United States population of 273 million in 2000 (Lamb and Weinberger 2005). The notion that individuals suffering from a mental illness have shifted institutional settings, from mental health hospitals to correctional facilities, has been termed the criminalization of the mentally ill (Scott 2010). Other proffered explanations for this shift include lack of resources for community mental health care, peace officers assuming the role of triaging individuals to hospitals versus jail, and more restrictive involuntary psychiatric hospitalization laws (Lamb and Weinberger 2005).

Simultaneous to the deinstitutionalization of the mentally ill, the United States began its incarceration binge which has resulted in an increased rate and prevalence of incarceration. The total number of inmates in the United States in 1980 was 501,886, compared to over 2.2 million in 2009 (Glaze 2010). As a result, the total number of mentally ill incarcerated individuals increased with the incarceration binge. A study by Bradley-Engen supports this additional explanation (2010). The study reported the change in the total number of individuals admitted to Washington State prisons from 1998 to 2006 and the relative proportion of inmates diagnosed with serious mental illness and co-occurring substance use at time of admission. The results of the study suggest that the increase in the diagnosis of serious mental illnesses and co-occurring substance use disorders is related to the increase in total admissions to prisons during the study time period and is not due to an increase in the percentage of admissions involving serious mental illness. In other words, this study suggests that at least some of the increase of the total number of incarcerated mentally ill is a result of the overall higher number of individuals being incarcerated. Collectively, it seems that an unfortunate combination of factors, chiefly involving the failed deinstitutionalization movement and a criminal justice system featuring a strong predilection toward incarceration, has resulted in growing populations of mentally ill persons behind bars in the United States.

Estimates vary for prevalence rates of mental illness in jails and prisons depending on the method of the study. The Bureau of Justice Statistics reported that 56 % of state prisoners, 45 % of federal prisoners, and 64 % of jail inmates suffered from some type of mental health problem (James et al. 2006). Bradley-Engen reported that past studies suggest that the prevalence of serious mental illness in prisons ranges from 16 % to 24 %, compared to 5–7 % in the general community (2010). A recent study suggests that the rate of serious mental illness in jail is 14.5 % for men and 31.0 % for women (Steadman et al. 2009).

Risk Factors for Suicide Pertinent to Correctional Settings

Besides housing an influx of many individuals that might have otherwise been institutionalized in mental health facilities during an earlier era, the correctional setting tends to contain populations with high rates of other important risk factors for suicide. Many of the risk factors associated with inmates' suicide deaths match risk factors associated with suicide deaths in the community: male gender, Caucasian race, substance abuse, psychiatric treatment history, and prior suicide attempts (Anasseril 2006; Patterson and Hughes 2008; Hayes 2010). Fazel reported that being a male and being Caucasian were risk factors for suicide in prison; he also found that being African American was inversely related to suicide (2008). Noonan reported that the suicide rate for African Americans was lower compared to Hispanic and Caucasian inmates (2010). However, it is vital to appreciate that demographic risk factors of this kind are of very limited utility in determining risk at the single inmate level, keeping in mind that favorable demographic factors identified via population-based research do not keep individuals safe; inmates of any race or gender may of course present at heightened risk for suicide.

Complicating risk assessment in correctional settings is the fact that so many of the identified risk factors for suicide occur at a very high prevalence, higher than the prevalence in the general community. For example, inmates in correctional settings are predominately male (Glaze 2010). The male gender is dramatically overrepresented in correctional settings, is overrepresented in suicide deaths in the general community, and also represents approximately 93 % of jail suicides (based on figures from 2005 to 2006) (Hayes 2010). In federal prisons, despite having a 7 % female population, from 1993 to 1997, 100 % of suicides were completed by males (White et al. 2002). Noonan reports that white males in jail have a rate of suicide 5.7 times greater than white males in the general population (2010).

Substance use disorders also have a high prevalence in correctional settings. As a conservative estimate, 50 % of incarcerated individuals have substance use disorders, with jail inmates having a higher prevalence rate than prison inmates (Scott 2010). Hayes found that of the individuals that died by suicide in jail between 2005 and 2006, 47 % had a history of substance abuse; 20 % were intoxicated at the time of the suicide (2010). In New York state prisons between 1993 and 2001, 95 % of inmates who died by suicide had a history of substance abuse (Way et al. 2005).

Many incarcerated individuals have experienced violent trauma during their lifetime (Wolff et al. 2010). As cited by Wolff, at least 50 % of incarcerated women have reported victimization in their lifetime. Additional profile characteristics for individuals that committed suicide in prisons are low education level and limited social supports in the community (White et al. 2002; Anasseril 2006). The frequency of trauma, victimization, and limited support among correctional populations seems particularly relevant to suicide risk when one considers the interpersonal-psychological theory of suicide risk offered by Thomas Joiner (2005). Under this model, the convergence of acquired ability (relating to habituation to pain and suffering along with perceived burdensomeness and/or a sense of failed belongingness results in a heightened risk for death by suicide). The above-referenced research indicates that inmates are frequently themselves victims of trauma, potentially contributing to habituation to pain and suffering, and thus acquired ability to engage in suicidal behaviors. Additionally, limited psychosocial support and the impact incarceration has on families likely engender feelings of burdensomeness and failed belonging. It would seem that the convergence described by Joiner is probably a common occurrence among inmates and may in part explain the observed elevation in suicide rates.

The high rates of violent perpetration and aggression among correctional populations are a consideration when thinking about suicide risk and suicide rates. Violent offenders have been found to face increased suicide rates across a number of studies, with the Bureau of Justice statistics reporting a suicide rate nearly three times that of nonviolent offenders in jail, and violent offenders in prison being more than twice as likely to die by suicide. Hayes reported that 43 % of inmates that died of suicide had been arrested on personal and/or violent charges, including murder, negligent manslaughter, armed robbery, rape, sexual assault, indecent assault, child abuse, domestic violence, assault, battery, aggravated assault, and kidnapping (2010). Noonan also found that violent offenders had the highest suicide rate, with public-order offenders having the second highest rate of suicide, compared to individuals with property and drug offenses (2010). Inmates incarcerated for the alleged offenses of homicide, kidnapping, and rape had the highest rate of suicide (Noonan 2010). Notably, aggression features prominently in a theoretical model for suicide risk offered by Kerr et al. (2007). Under that model, aggression may lead to suicide attempts via various routes: aggression may lead to depression and then to suicidal ideation; aggressive acts may yield negative consequences leading to worsening depression and suicidal ideation; or aggression may more directly be turned inwardly resulting in self-directed violence and suicide attempts.

The incarcerated individual's coping styles, changing emotional states, or emotional traits have also been associated with suicide risk. Individuals that have a maladaptive style of interacting with the environment and coping with stress have increased risk for suicide and self-directed violence. Specifically, rigidity and dichotomous thinking, poor problem-solving ability, avoidant behavior, and poor positive reinterpretation are personality styles that lend themselves to suicidal behavior (Polluck and Williams 2006). Emotional states or traits involving anxiety, depression, aggression/agitation, hostility, fear, and impulsivity are characteristic of individuals who have suicidal behavior (Polluck and Williams 2006; Anasseril 2006; Way et al. 2005). An individual's self-report of feeling hopeless is arguably a highly significant risk factor for suicide in most if not all populations, including incarcerated populations (Anasseril 2006). Recent "behavior changes" of incarcerated individuals from baseline observations also has been noted as a characteristic profile of individuals who are at risk for suicide in prison (Way et al. 2005). For example, prior to some suicide deaths, staff members report that the inmate had not been acting in his or her usual manner.

Psychosocial stressors unique to incarceration and the criminal justice process may also contribute to increased suicide risk. For example, many jail and prison suicides occur during the initial incarceration phase or after transfer to a new facility (Anasseril 2006; Hayes 2010). After arrest and initial incarceration in jail, an individual has gone from living in a free society to living in isolation, or possibly in a cell under 23 h lockdown where freedoms are severely curtailed and most aspects of daily life kept under strict control (Patterson and Hughes 2008; Hayes 2010). Many recent detainees are unclear of the specific consequences of their legal charges or have not spoken with an attorney, are intoxicated or experiencing withdrawal from drugs or alcohol, and/or have not yet communicated with their primary supports in the community. Some detainees are experiencing guilt or shame concerning their charge and/or have just experienced a personal/family crisis that is related to their charge (Hayes 2010). Although the above-described stressors are challenging for all inmates, individuals from higher social economic backgrounds incarcerated for the first time seem to be particularly susceptible to such stressors and at higher risk for suicide (Anasseril 2006).

For longer stays in jail or prisons, stressors from both within the correctional setting or crises occurring outside the correctional setting can contribute to suicide risk. Specifically, death of a loved one, relationship problems/losses, financial losses, new charges or setbacks in court, gang problems, victimization, bullying, recent experience or risk of sexual assault, and recent institutional disciplinary action are often antecedents of inmate deaths by suicide (Way et al. 2005; Anasseril 2006). A life sentence is considered a risk factor for suicide in prisons (Fazel et al. 2008). Death row inmates have the highest suicide risk (Anasseril 2006). Although counterintuitive to some, marriage was found to be a risk factor for suicide in prisons and during periods of longer incarceration in jails (Fazel et al. 2008; Hayes 2010). It is interesting to note that jail and prison suicides were not associated with certain holidays but evenly distributed through the year (White et al. 2002; Anasseril 2006; Hayes 2010).

Despite curtails in freedom and relatively limited access to means (compared to life in the community), the correctional environment does offer sufficient opportunity for inmates that are having suicidal thoughts to engage in lethal acts of self-directed violence (Hayes 2010). A one-person cell, time spent alone in a cell, and access to lethal means (such as anchor points for hanging) provide the necessary means for an inmate to die by suicide (Patterson and Hughes 2008; Hayes 2010). Fazel found that single-cell occupation is a risk factor for suicide (2008). The most common method of suicide in both jails and prisons is hanging, featuring in over 80 % of suicides (Patterson and Hughes 2008; Hayes 2010). Other methods employed include overdose, self-inflicted laceration resulting in exsanguination, self-strangulation, swallowing objects, electrocution, poisoning, self-immolation, self-inflicted gunshot wound, and intentional fall (Felthous 2011). All these techniques are more easily accomplished when an inmate is isolated.

Suicide Prevention Programming

The primary method to mitigate suicide risk and implement protective factors is to create an effective comprehensive suicide prevention program in individual correctional facilities (Hayes 2010). Effective suicide prevention programs have been credited with reduction of suicides in correctional settings. National organizations and credentialing bodies such as the American Psychiatric Association, the National Commission on Correctional Health Care, and the American Correctional Association all recommend that correctional facilities have suicide prevention programs and articulate specific standards for these programs. Hayes recommends the following eight essential components for a comprehensive suicide prevention program: staff training, intake screening/assessment, communication, housing, levels of observation, intervention, reporting, and follow-up and morbidity-mortality review (Hayes 2010). A brief summary highlighting the major aspects of Hayes' recommendations for a comprehensive suicide prevention program follows.

Hayes states that all custody, mental health, and medical staff should initially have 8 h of training and 2 h of training annually (Hayes 2010). Training custody staff is crucial due to the large amount of time they spend with inmates, resulting in their significant role in identifying potentially suicidal inmates. Hayes asserts that staff training should include, at a minimum, "reasons why correctional environments are conducive to suicidal behavior, staff attitudes about suicide, potential predisposing factors to suicide, high-risk suicide periods, warning signs and symptoms, identification of suicide risk despite the denial of risk, liability issues, critical incident stress debriefing, [review of] recent suicides and/or serious suicide attempts within the facility or agency, and components of the facility's or agency's suicide prevention policy" (Hayes 2010).

Hayes recommends that individuals receive screening and assessment for suicide risk upon intake to a correctional facility (Hayes 2010). Hayes asserts that screening should include questions concerning suicidal thoughts/plans (including such thoughts during past incarcerations), past suicidal attempts, history of mental health treatment, recent stressors and losses, suicide behavior by family or close friends, and reports from arresting officers concerning suicide risk (Hayes 2010). As in other settings, suicide risk assessment is a process, not an event; suicide screening does not end after intake, but continues throughout the individual's incarceration. Inmates' self-reporting should be considered in concert with behavioral observations and other collateral information in determining the level of suicide risk.

Communication between arresting officer, correctional staff, mental health staff, and medical staff is essential to reduce suicide risk (Hayes 2010). Protocols for appropriate suicide precautions should be in place to enable staff to take appropriate action if an inmate is considered to be at risk for suicide in order to keep the inmate safe. Hayes suggests that custody staff should not be underestimated in their importance in identifying potentially suicidal inmates and communicating this concern to mental health staff (2010). In additions, barriers need to be reduced in order for inmates to obtain mental health care.

Appropriate housing of inmates with significant suicide risk is an important component of a proper suicide prevention program (Hayes 2010). Inmates with clinically determined differing levels of suicide risk should be housed in the least restrictive environment needed to provide the appropriate level of safety, such as medical/mental health units or general population housing where staff can readily interact with them. Only individuals with the highest acuity of suicide risk should be housed in a locked-down environment, and only when the appropriate suicide precautions are provided. Although segregation may be the safest option for individuals at imminent suicide risk, isolation may also be detrimental to the inmate's emotional well-being and seldom addresses the factors driving the crisis. Careful consideration regarding the risks and benefits of segregation is warranted. Cells used for individuals at acute risk for suicide should be free of methods which might be employed to act upon suicidal thoughts, such as anchors or hanging devices in the cell or on the inmate. Level of observation of a suicidal inmate in a particular housing setting depends on the particulars of the individual's suicide risk (Hayes 2010). Observation should be, at a minimum, staggered in 15-min intervals and, at least for inmates judged to be at imminent risk, should consist of continuous in-person observation. Cameras in cells can help monitor inmates at acute risk for suicide but do not replace the need for continuous in-person observation. Inmates flagged for suicide precautions should be closely followed for evaluation and treatment by mental health staff.

All staff with regular contact with inmates should be provided with first aid, cardiopulmonary resuscitation, and automated external defibrillator training to be prepared to intervene after a suicide attempt (Hayes 2010). Staff should be prepared to quickly triage the emergency situation, contact appropriate medical staff, and initiate the appropriate above treatment(s). Staff should not assume that the individual is deceased. If a serious suicide attempt or completed suicide has occurred, family and appropriate authorities should be notified immediately. Morbidity-mortality reviews and psychological autopsies are recommended. Within 24–72 h, Hayes recommends that staff involved in the incident be offered critical incident stress debriefing by a trained professional (Hayes 2010).

Correctional facility culture and environment seem to be related to suicide risk. Liebling argues that inmates that are already vulnerable to suicide and self-directed violence face even higher suicide risk if the institution creates feelings of lack of safety, lack of respect/fairness, alienation, and frustration (2006). In fact, she argues that institutions that provide individual support create a protective factor. She recommends that institutions focus on improving both correctional custody and healthcare staff culture, specifically avoiding environments that use excessive authority, have a lack of personalization of the individual inmate, and avoid addressing or listening to inmate complaints. An international study analyzed possible interventions or factors that reduced the incidence of suicide in prisons. "Purposeful activity" (as defined as classes or activities for inmates, such as education, substance abuse treatment, work, and family visits) was significantly associated with lower suicide rates (Leese et al. 2006). In a study conducted in one jail, protective factors included reasons for living and social connectedness.

Special Populations

Special populations mandate specific considerations when evaluating the risk for suicide and self-directed violence within correctional settings. A few examples follow.

Adolescents

In the United States general population, suicide is one of the leading causes of death for adolescents. Suicide is the fourth leading cause of death of individuals between the ages of 10 and 14, while suicide is the third leading cause of death for teenagers between the ages of 15 and 24. The Centers for Disease Control and Prevention reported that the suicide rate in 2007 for adolescents between the ages of 15 and 19 is 6.8 per 100,000. According to Roberts, a leading cause of death in juvenile correctional settings is suicide, with incarcerated juveniles having a risk for suicide approximately four times greater than juveniles in the general population (2006). As with incarcerated adults, confined juveniles have a high rate of mental illness compared to the general population. Hayes cited multiple studies which indicate prevalence rates of mental illness in the confined juvenile population to be well above 50 %, with many of the juveniles having multiple psychiatric diagnoses, including substance use disorders, conduct disorder, and history of childhood abuse (2009). Penn reported that 12.4 % of 289 adolescents recently admitted to a New England correctional facility had a previous history of attempting suicide (2003).

Characteristics of juveniles who have died by suicide while in confinement are similar to characteristics of adult victims of suicide in correctional settings. A review by Hayes of 79 juvenile suicides between 1995 and 1999 documented many characteristics similar to adult suicide victims in correctional settings, as well as some demographics unique to this population (2009). For example, juvenile suicide victims were 68 % white and 79.7 % male. Also similar to incarcerated adults, 73.4 % had a history of substance abuse, 74.3 % had a history of mental illness, and 69.6 % had history of prior suicidal behavior. The method of suicide, similar for adult suicide deaths, was hanging by 98.7 %. As with adult correctional facilities, the physical plant characteristics provided opportunities for suicide behavior with 50 % being in room confinement and 74.7 % housed in single-occupancy rooms. In addition, the data provided specifics for juvenile suicide victims, including a mean age of 15.7 with 70 % between ages of 15 and 17, 69.6 % confined for nonviolent offenses, and 78.5 % with history of previous offenses. Approximately 40 % of juvenile suicide victims confined in detention centers had died by suicide during the first 72 h of confinement. Other confinement settings including training school/secure facility, reception/diagnostic center, and residential treatment center had more diverse time frames of juvenile suicide deaths. Hayes argued that although adolescent suicide has gained national attention, suicide of juveniles in confinement has gained much less consideration. He recommended more research into investigating the possible precipitating factors of juvenile suicide in confinement (Hayes 2009).

Women

The total percentage of incarcerated women in the United States has increased by 14 % from 1990 to 2009 (Glaze 2010). Steadman estimated that the rate of serious mental illness for female jail inmates is 31 % (2009). The Bureau of Justice Statistics reported that the rate of suicide for female inmates in both jails and prisons between 2000 and 2002 (32 per 100,000 and 10 per 100,000, respectively) is lower than that for males (Mumola 2005). Recent rates using data from 2000 to 2007 reflect a decrease in the rate of suicide deaths for female jail inmates (28 per 100,000) (Noonan 2010). However, the suicide rate still remains five times higher than the general population when these rates are demographically adjusted (Noonan 2010). Noonan also reports that incarcerated Hispanic females have a rate of suicide 10.5 times greater than the rate of suicide for Hispanic women in the general population (2010). Incarceration does appear to substantially increase the risk for suicide among women.

Research on incarcerated female suicides has been sparse. Clements-Nolle reported that one risk factor for suicide attempts in prison is childhood trauma (2009). Marzano found that in English and Welsh prisons, there was a higher prevalence of current depression, two or more psychiatric diagnoses, history of inpatient psychiatric hospitalization, and history of suicide attempt in women with near-lethal self-directed violence compared to a control group (2010). Fazel hypothesized that substance use disorder and loss of contact with dependent children may contribute to incarcerated female suicide risk (2009).

Veterans

Another special population is veterans. Estimates suggest that nearly 10 % of incarcerated persons are veterans, although such estimates were derived from data that probably fails to fully reflect the impact of current conflicts in the Middle East. Clinical experience among those familiar with the population of returning veterans suggests that such numbers may be on the rise (Mumola 2000; Noonan 2004). The Veterans Administration now officially recognizes that veterans are arrested for a variety of offenses, some of which may be related to extended periods of battle readiness and combat exposure during multiple deployments and to maladaptive coping with the return to civilian life. The VA's Uniform Mental Health Services Package now calls not only for assistance for veterans reentering the community from state and federal prisons but also for outreach efforts to veterans who are interfacing with jails, courts, and law enforcement and for education to these agencies regarding mental health problems relevant to veteran populations, such as posttraumatic stress disorder (PTSD) and traumatic brain injury (TBI). Unfortunately, relatively little is known about the subpopulation of incarcerated veterans, including their suicide rates. It has been argued that suicide risk factors faced by the general veteran population may interact with risk factors specific to incarceration or justice involvement, potentially placing the incarcerated veteran at especially high risk for suicide. Additional research is needed to better characterize this potentially high-risk population to determine rates and opportunities for intervention (Wortzel et al. 2009).

Risk After Release

The suicide risk associated with incarceration unfortunately does not end upon release. Rather, research suggests that the time of release represents yet another difficult transition period that carries increased risk for mortality in general and increased risk for suicide specifically. A study by Pratt examined suicide following prison incarceration in England and Wales (2006). Compared to the rate of suicide of 18 per 100,000 in the general population, the rate for recently released inmates was 348 per 100,000, with 21 % of the suicides occurring within 28 days of release. Suicide risk was also found to be high for individuals after release from New South Wales, Australia, prisons (Kariminia et al. 2007). The suicide rate for individuals within 2 weeks of release from prison was found to be 3.87 times higher when compared with the suicide rate for individuals 6 months after release. Binswanger conducted a retrospective cohort study of inmates released from the Washington State Department of Corrections (DOC) and reported an adjusted risk of death among former inmates 3.5 times higher than that faced by other state residents (2007). More specifically, former inmates had a 3.4 relative risk for suicide, a 10.4 relative risk for homicide, and a 12.2 relative risk for accidental overdose. Meaningful efforts to mitigate suicide risk among recently incarcerated individuals will necessarily involve linkage to appropriate resources in the community.

Conclusions

The ongoing high risk of suicide death in correctional settings compared to the general population has resulted in more attention by the academic community, the courts, and correctional settings. This attention has led to a better understanding of the risks that exist in these settings and pragmatic solutions to decrease suicide risks. More recent studies have suggested that the rate of suicide in correctional settings has decreased over time. However, the decreased rates continue to remain higher than the general population rates, suggesting that efforts need to continue to find solutions to further reduce correctional suicide rates. The academic examination of suicide death and self-directed violence in correctional settings involving adolescents, women, and veterans is relatively new and is an area requiring further study. The high suicide risk/rate of recently released inmates from correctional settings is an area that is ripe for further study. Future studies could help provide direction in formulating a plan to target and reduce the high suicide risk/rate in this subpopulation. Finally, this entry demonstrates the responsibility that correctional institutions have in further developing policies and procedures that aim to reduce the risks of inmate suicide.

Surveillance Technology and Policing

Gavin J.D. Smith
Senior Lecturer in Sociology, The Australian National University, Canberra, ACT, Australia

Overview

Policing is in a state of transformation. Traditional paradigms founded on reactive and responsive principles are being superseded by contemporary risk-based models, proactive and preemptive approaches that encompass an array of stakeholders and sophisticated technologies. The "new policing" is underpinned and driven by intelligence-led doctrines, performance indicator metrics, and desires to better identify crime patterns. Although many relational factors account for these changes in policing ideology and praxis, the integration of – and reliance on - surveillance technologies and associated "visibility" rationalities has been particularly pivotal. Yet the widespread availability of surveillance technologies is simultaneously diversifying policing practices and responsibilities. Civil/commercial organizations and citizen/consumers are, for example, increasingly participating in the inspection and assessment of behavior, albeit for often differing purposes. The perpetual interweaving of visibility-inducing systems into the cultural fabric of everyday living and concomitant heterogeneity of actors who now engage in regulatory activities has generated two major effects: (a) policing opportunities have increased; and (b) supervisory webs have become progressively intricate and multi-dimensional in semblance. "Policing" is now a pluralized social practice that extends far beyond "the police." Indeed, the "policing creep" emerging from intensifying visibilities generates for criminologists important theoretical, empirical and ethical questions, some of which inform the substantive focus and thematic arrangement of this entry.

In order to arrive at an understanding of the surveillance technology-policing nexus, this entry commences with an overview of the emerging techniques of visibility now infusing the social orders of privileged global provinces. This will enable us to better grasp the assortment of observational devices being routinely deployed, the heterogeneous nature of operational procedures, and the differing populations now engaged in the policing of subjects. It will also permit us to comprehend some emergent social effects. A case study analyzing closed-circuit television (CCTV hereafter) camera system growth in the global north will then show empirically how surveillance technologies can modify and transform existing policing structures. This section draws further attention to the evolving labor force now performing, in this case, paid policing duties.

This entry, therefore, is not a story about "surveillance and the police" per se. Rather, it is an account describing how the widespread distribution of surveillance technologies ruptures previous modes of social control and instigates novel policing configurations. Criminologists are only beginning to comprehend the social implications attendant on these changes.

Surveillance Technologies and Rationalities

The rapid and extensive diffusion of surveillance technologies into the architecture of contemporary living has, in recent decades, been a particularly salient development in social governance. Everyday actions are targeted by an expanding arsenal of monitoring devices. Indeed, it has become well-nigh impossible to complete commonplace tasks in privileged wordly regions without encountering a diverse set of data capturing "probes." CCTV camera systems, airport body scanners, DNA swabs, X-ray scanners, and Web browsing cookies, for example, perpetually extract personal information "particles" from the data trails that accompany our daily activities. Tracking and transmission technologies such as radio-frequency identification (RFID) microchips and Global Positioning Systems (GPS) are now embedded in all manner of mundane objects: credit cards, cell phones, and smart passports being obvious illustrations.

Despite embodying differences in terms of technical components and physical dimensions, there are general similarities between and among surveillance technologies on an operational front. Most function to procure, transport, and then ultimately deposit data emissions derived from embodied acts – that is, from walking down a street, making an online purchase, and sending a SMS text message – into a complex cybernetic matrix commonly known as "the database." These vast informatic chambers decontextualize behaviors both by systematically removing them from their circumstantial origin and by rendering behavioral expressions into a series of discrete data flows. A person's consumption profile, for instance, can be inferred from analyzing her or his credit card statements. Buying habits, in this example, are deemed to reveal social status and thus customer "worth." Rather than take into consideration the infinite causal variables influencing the decision to purchase a product, these systems focus attention instead upon tangible outcomes and seek to aggregate data from multiple sources so that "tendencies" can be ascertained. Similar to how social research data is arranged, personal information is recurrently coded, collated, mined, or "recontextualized" by a set of surveillance workers – be they human (e.g., a CCTV operator) or nonhuman (e.g., a computer code) – in accordance with an assortment of organizational imperatives. This allows for historical activities to be logged, social relations to be mapped, actions to be compared, and causal patterns to be identified. Based on such information, risk/return evaluations of specific phenomena can be undertaken and decisions reached, for example, whether or not to invest capital in a specific enterprise, whether or not to trust a job applicant, and whether or not to proffer credit to a prospective customer. Direct human mediation in data analysis and processing is declining as systems of surveillance develop in capacity and sophistication. Computerized software is increasingly favored to autonomously dispose the information collected.

Surveillance technologies are a rationalized means to enhance visibility, to sharpen decision-making, and to more effectively manage resources, helping their overseers determine risk propensities, investment potentials, trustworthiness, and suspiciousness. They expose and scrutinize discrete social processes (such as disease intensity, voting patterns, or market relations) and help identify probable correlations between and among variables. They permit interest groups to accumulate intimate knowledge about specific phenomena (e.g., population health in specific regions) and to fashion corresponding interventions from an informed perspective (e.g., the proposed location of a health clinic). They provide a calculative lens through which all manner of truth claims can be assessed and adjudicated (e.g., an asylum seeker application or a credit request). As such, surveillance operates at the very heart of organizational protocol, specifically as it (a) enables social complexity in all its manifestations to be captured and (b) facilitates complexity governance and uncertainty reduction. Indeed the visibility – that is, the capacity to see and be seen – produced by systems of surveillance is fundamentally transforming the conditions of contemporary social life and how we relate to one another. Desires to know, order, govern, and entertain are exposing people and processes in much finer detail, and this situation is both diversifying and intensifying formal and informal policing arrangements.

Surveillance technologies reveal previously concealed facets of life and circulate mediated personal intimacies to an audience that increasingly is pluralized, remote and anonymous. An example of this process can be discerned from examining Web 2.0 engagement. Social media sites like Facebook proactively encourage users both to self-disclose/self-promote and to peruse the exteriorized musings ("newsfeeds") of fellow participants. User curiosity and voluntarism is exploited and manipulated in strategic ways, system programmers systematically designing and assembling an array of infrastructural mechanisms to sustain interest levels – and thus asset sustainability and value. Incentivizing architectures ensure that acts of revelation are celebrated and rewarded and that tracking the lives of others is experienced as an addictive and pleasurable pastime. The pellucid nature of these online registries permits emotive posts and graphic images to be accessed and deciphered by an army of unseen inspectors (e.g., peers, employers, marketers, and law enforcement agencies), the biographical information deposited revealing vital clues about a particular person's ideological values, consumer preferences, and psychological disposition. This knowledge can then be utilized by the various spectators to construct character profiles and to rationalize interventions, specifically procedures aimed at modulating and engineering conduct in some desired way (Trottier 2012).

We can perceive from this illustration the contemporary heterogeneity of policing, in terms of contributors and purposes. The operational reach and remit of policing continues to broaden as surveillance technologies extend purviews deeper into the backstage regions of personal life. Indeed, it is helpful to conceive people as "cyborg" entities, comprised of physical biomatter and informatic particles: the latter material being willingly emitted – and coercively extracted – from our embodied actions in the course of everyday living. The point to note is that personal data has become a highly valued unit of currency for problem analysis and decision-making, its textual content shaping significantly how particular individuals and social groups are perceived and subsequently treated by differing organizational systems. Rather than trusting a person's narrative or status claim at face value, interlocutors increasingly prefer to discern legitimacy and authenticity from the information encased within a set of corresponding archival records or what I term, "surveillance texts." Although often derived from certified or valid documents – for example, medical consultation notes, criminal records, bank statements, and tax returns – employers, law enforcers, and insurance actuaries also obtain knowledge fragments from unofficial and aspatial communicational mediums like Twitter and Facebook, and from personal email correspondence. Each source comprises discrete "event descriptors" that, when collated, depict previous conduct (e.g., consumption preferences) and circumstances (e.g., health conditions). It is believed that analysis of multiple surveillance texts will reveal (a) a detailed picture of a person's disposition and (b) a more accurate representation of her or his social positioning and future trajectory. This permits the adjudicating authority to effectively bypass or short-circuit what is perceived as the contrived nature of self-presentations, unveiling instead preconscious forms of cognition (Andrejevic 2010). In a world increasingly defined by information glut and uncertainty (a situation ironically accentuated by the intensification of visibility), surveillance systems act as critical arbitration tools, a means for truth establishment and narrative verification, a means for individuating and stratifying populations, and a means for regulating access to resources.

Surveillance systems mostly operate in hegemonic ways, functioning to maintain the interests of a privileged elite and thus a particular fiscal status quo. Yet the gradual diffusion and sedimentation of surveillance should not be understood as some ideological conspiracy that has been engineered by a state-corporate cartel. In contrast, a surveillance system or device intrinsically is neither benign nor malign, the sociocultural relations in which the apparatus is entangled effectively shaping its everyday orientation (see Smith 2013). Indeed, state authorities and administrators depend upon an assortment of surveillance machineries and practices to ensure the deliverance of democratic commitments and ideals: that voting rights are upheld, that law and order is maintained, that taxation thresholds are accurately set, and that designated populations are granted access to welfare services and benefits. Surveillance technologies, for example, are regularly utilized to assess and manage a nation's health. Disease epidemiologists use biostatistics to identify and gauge immanent biosecurity threats, while medical practitioners use hi-tech screening equipment to better envision patients' bodies so that malignant cells can be located and tissue injuries reliably evaluated. Law enforcers employ a range of surveillance techniques to investigate suspects, to acquire evidence and to direct operations. Moreover, surveillance is exploited strategically as both a thematic currency and a textual commodity by an assortment of cultural producers, be they formal commercial organizations or civic communities. People are regularly exposed to surveillance symbolism and output in the course of consuming a range of media broadcasts. Surveillance texts often depict graphic content the witnessing of which can be both shocking and entertaining. As a distinctive subject-matter, surveillance is artfully appropriated by groups possessing a diversity of political agendas, artistic aesthetics and economic motivations. The ensuing struggle over surveillance representations in popular culture encourages audiences to approach surveillance technologies with an attitudinal cynicism and ambivalence stimuli and representations. Surveillance is also deployed to increase the speed and simplicity of transactions between individuals and organizations and to enhance the flexibility, convenience, and efficiency of these encounters. In addition, surveillance is fast becoming a medium through which powerful groups can be made more accountable for their actions. Footage captured on a G-20 protestor's personal video camera, for instance, revealed a civilian being unlawfully assaulted by a police officer (see http://www.guardian.co.uk/uk/2009/apr/07/ian-tomlinson-g20-death-video, accessed 18/5/2012).

Despite notable exceptions – where surveillance technologies are harnessed to serve the interests of vulnerable individuals and periphery collectives – data-hungry social and commercial institutions are the overwhelming winners of surveillance ubiquity. This is because capturing and analysis technologies afford these agencies statistical knowledge on social trends and attitudes, allowing evidence-based responses – in terms of policy or commodity design – to be instrumentally engineered and actualized. Surveillance infrastructures and circuitries greatly abet elite groups, to the extent that they help to legitimize their domination, accentuate their expertise, foster their definitional capacities, and protect their capital, interests and resources.

Indeed, a core operational objective is the differential classification and division of groups in accordance with their perceived position in the social hierarchy, their projected risk level, and their assigned market value (Gandy 1993; 2009). Thus, in an economic order defined by mass consumption and in a political order characterized by omnipresent security concerns, population distrust, and risk-sensitive policies, it is people residing in disadvantaged locales without the means to consume, or those whose ethnicity, piousness, skin color, and occupation contravene a dominant (normative) security discourse, who are recurrently subject to disproportionate levels of scrutiny (Norris and Armstrong 1999; Lyon 2003). Procurement of a stigmatizing or discrediting label can mean that an individual or collective is denied access to certain spaces and/or refused basic rights, resources and privileges (Monahan 2008; Zureik et al. 2011). Thus, because surveillance systems embody the prejudicial essentialism of their controllers, they tend to produce exclusionary outcomes and perpetrate social injustices.

The Diversification of Policing Responsibility

A major outcome of neoliberal policy has been an aspiration by elite groups to instill a "responsibility ethic" and "cosmopolitan sensibility" within the psyches of the population: an expectation that citizens play an active role in managing risk. This expectation primarily relates to personal health and safety practices but also to deportment in the economic and ecological spheres. In the law and order field, adoption of a "responsibilization" rationality (see O'Malley 1996) by state authorities has profoundly transformed the meaning of "criminality" and "citizenship." What historically had been a matter for formalized policing agencies has now become a community issue demanding multiagency interventions; policymakers eager to enlist in quotidian supervision practices both civil society actors and the private sector. Criminality itself has been discursively reconstituted as a set of hierarchical thresholds, ranging from lower level civil transgressions to higher order terrorist/biosecurity risks. This stratification – and concomitant governmental desire to mobilize as "crime managers" various groups – has produced a distinctive set of stakeholders (e.g., citizens, proprietors, and council workers) who are now equipped with specialized powers – and ascribed specific obligations – for addressing particular expressions of disobedience (Rose 2000; Garland 2001).

The emergence of civil "on-the-spot" penalty notifications, laws persecuting parents for child truancy, community "wardens," neighborhood watch programs, and dispersal/antisocial behavior orders are notable empirical instances of a general trend to prescribe codes of etiquette and to assign any violation – or manifestation of deviance – with a particular regulatory custodian (e.g., a parent, a schoolteacher, a social worker, or a transport marshal). Indeed, the diversification of actors now responsible for everyday surveillance and social ordering marks a distinct paradigm transition in policing ideology and application, from a traditional model which was largely "reactive and localized/centralized," that is, post facto and exclusive, to one which is now "proactive and dispersed/pluralized," that is, anticipatory and inclusive (McLaughlin 2007).

Such changes in policing praxis correlate with the neoliberal state's remit to buttress declining security budgets/provision and to "govern at a distance" (Miller and Rose 1990) with a corresponding engagement (or exploitation) of community groups and corporate agencies in the collective "fight against crime" (Garland 2001). They also accord with an allied desire to sponsor the implementation of hi-tech surveillance infrastructures which operate according to intelligence-led axioms and preemptive principles (see Elmer and Opel 2008). The Texas Virtual Border Watch program is an apposite illustration (http://blueservo.com/vcw.php, accessed 30/5/2012). This online initiative effectively transforms citizens into custodial guardians of the United States–Mexico border. It encourages participants, through financial incentives, to identify and report suspicious mobilities and to adopt a nationalistic sensibility: a cognitive disposition that is hostile to the context prompting a decision to enter illegally a foreign sovereign territory. An uncompassionate and uncompromising mentality orientated to informing and supervising is, in this process, deemed to be a desirable civil ethic (Koskela 2011). These policy transformations (e.g., enlisting communities in addressing lower order criminality) simultaneously grant formal policing organizations special license to concentrate finite resources on tackling serious and organized crime and an assortment of high-level national security threats. Moreover, it is in this transitional climate that policing authorities have increasingly adopted surveillance technologies as ways of managing shrinking quotas and the complexities associated with transnational law enforcement in the information age.

The rolling out of large-scale socio-technical assemblages such as DNA databanks and CCTV camera networks demonstrates how responsibilities for managing crime and disorder are transferring from a dependence on theological precepts, authoritarian physicality, and human informants to a faith in scientific expertise and technical solutions. The fetishization or overprivileging of scientific discourse and technical systems by governmental actors, while partly operational, is in large part symbolic and in response to a perceived "crisis" in traditional policing approaches, brought on by austerity measures, rising crime fears, and high profile institutional failings/operational incompetence (McLaughlin 2008). Utilizing sophisticated technological infrastructures and computer-powered calculative metrics permits policing agencies to identify criminogenic patterns and to anticipate prospective security threats (Ericson and Haggerty 1997). It is now possible to collate previously discrete data fragments and create "criminality constellations." The Metropolitan Police's crime map (http://maps.met.police.uk/, accessed 20/5/2012) is an apt example. Based on the quantitative aggregation of crime reports and statistics, policing authorities are able to spatially and temporally envision felony rates and correlations within the urban metropolis. This ensures that any proposed crime prevention initiative or awareness-raising campaign has an empirical foundation and is measurable. It also means that resources can be rationally deployed in strategic and targeted ways and decision-making protocol as it relates to criminal investigations can be externally validated and legitimized. It additionally permits bureaucratic officials and police managers to set performance targets and impose evaluative frameworks.

Evidently, these applications have multiple users and serve numerous purposes. Insurance companies, for example, are keen to exploit crime data to calibrate premiums, privileged citizens to distinguish (un)desirable locations for settlement, and marketers to direct advertising toward amenable communities (and away from others). The employment of actuarial techniques by formalized policing entities means that, based on available indicators, persons and groups acquire a risk rating (Feeley and Simon 1994). This computer-generated calculation effectively comes to determine the type and intensity of scrutiny that is then actioned. Gradual erosion of the "innocent until proven guilty" legal criterion has been an outcome of these developments and wider anti-social behavior and anti-terror policies. Increasingly, policing logic has more unity with a "guilty until proven innocent" aphorism, as shown in recent UK legislation endowing extraordinary preventive and regulatory powers to police forces. These laws grant police officers special license to "randomly" stop and search individuals, to disperse groups of young people, to preemptively detain terror "suspects" without charge, and to demand that protestors register their personal details before attending demonstrations. They also permit law enforcers to acquire sensitive personal data derived from the activities of law-abiding persons (http://www.bbc.co.uk/news/technology-18102793, accessed 20/5/2012) and to ascribe "suspect status" to an individual on the basis of her or his communicative position within a criminalized informatic network (http://news.bbc.co.uk/2/hi/technology/8245056.stm, accessed 24/5/2012). Similarly, landmark statutes such as the USA Patriot Act (2001) bestow exceptional powers to national security agencies in terms of intelligence gathering and information sharing protocol, and facilitate the introduction of ever more intrusive surveillance measures. These bills tend to be passed with limited public consultation or debate in moments of intense emotionality, for example, in the immediate aftermath of a terrorist act or in advance of mega events like the Olympic Games or a G20 convention, when anger and fear – rather than critical rationalism and reflexivity – orientate the collective consciousness and the political will.

Surveillance Technologies and Surveillance Work

The previous sections described how and why governmental desires and reality-capturing devices have extended policing practices into the circuitries of everyday living. CCTV is an insightful example of how policing praxis has co-evolved with technological supplementation, specifically in terms of the emerging complexity of social relations and operational remits that now constitute such regulatory systems. There are additional reasons for considering CCTV. Focusing on the exponential growth of camera networks in the global north illuminates the complex politics and rationalities underpinning surveillance diffusion. Moreover, considering novel policing modalities such as CCTV focuses attention on the unique type of labor – or “surveillance work” – that the camera operators routinely practice. These “order custodians” are subsidized to remotely encounter, capture, and “manage” mediated scenes of criminality and disorder, transgressive spectacles to which such workers are repeatedly exposed but over which they have no direct control. Reflecting on how the introduction of CCTV cameras transforms policing practices in both intentional (official) and unintentional (informal) ways provides clues for envisaging the likely impact of additional surveillance technologies on conventional policing protocol.

CCTV provision has dramatically increased in recent years. This is particularly true of the UK, a world leader in terms of its camera coverage. While a complex politics, at local, regional, and national levels, surrounds the augmentation process (see Fussey 2007; Norris and Armstrong 1999), the 1980s economic recession was a decisive factor in the state’s decision to legislatively promote and financially sponsor a series of installation programs. Rising crime rates associated with growing unemployment, a declining welfare system and resource inequities, and a corresponding amplification of the issue by media reportage impelled a public perception that policing agencies were failing in their bid to control criminality. Successfully redressing this situation became a central political issue, Home Office officials desperate to introduce a progressive “silver bullet” solution that would enhance the policing service and “treat” in an effective manner the physical symptoms of structural disparities (note similarities between this scenario and the one depicted in science fiction movie, *Robocop* (1987)). The intelligence battles of the Cold War period meant that an array of advanced militarized surveillance technologies were available for civil market appropriation. CCTV was one such innovation (Norris and Armstrong 1999).

Preliminary evaluations of pilot projects in several jurisdictions showed that public space camera networks could reduce particular acts of disobedience by around 40%. Although this research was methodologically problematic and predominantly administered by self-interested practitioners, the extraordinary statistics persuaded ruling technocrats that CCTV camera networks were worthy of significant financial investment (Gill and Spriggs 2005). Cities were encouraged to compete with one another for allocated monies totalling millions of pounds, and camera systems rapidly became akin to a “fifth utility” service (Graham 2001).

The favouring of CCTV systems by urban authorities was also the outcome of neoliberal “urban renaissance” policies which advocated restructuring of the metropolis around commercial imperatives and resiliency ideals (Atkinson and Helms 2007; Coaffee et al. 2009). This principally involved spatial revitalization, market liberalization, and the assembly of vibrant, leisure economies. Manipulating consumer perception became a central directive of the project, and CCTV cameras were deployed to help promote an impression of safety that would facilitate increased consumption and a "feel good factor".

A further factor fostering CCTV's wider cultural appeal was the global circulation of images showing Merseyside toddler, Jamie Bulger, being abducted by two ten-year-old boys in a Bootle shopping mall (Norris and Armstrong 1999). Although the cameras did nothing to prevent the child's violent death, the moral outrage and anxiety associated with this act as symbolized by the grainy pictures was, for different reasons, exploited by an array of state, media, and industry actors. Notwithstanding an assortment of competing rationales and rationalities, each agency had a vested interest in sponsoring CCTV deployment. The government had an interest in endorsing system efficacy to accrue public support and thus political capital/leverage. The police had an interest in supporting CCTV implementation as cameras could bolster conviction rates, sharpen operational activities and enhance investigative practices. The media had an interest in acquiring "authentic" camera footage to both disturb and amuse a scopophilic audience, that is, an audience obsessed with the spectacle. The security industry had an interest in promoting CCTV's effectiveness to generate increased demand for the technologies and for training programs.

The symbolism embodied in these initiatives is worth reflecting upon. The cameras act as materialized signifiers of sovereign authority and symbolize a profound distrust of the public by ruling groups. They cultivate conformity to the consumer order and, in the process, reify dominant definitions of appropriate urban conduct. They become the instruments through which discrediting labels can be ascribed to and enacted upon particular stigmatized groups (Norris and Armstrong 1999). They operate as architectural barriers for rationally thinking criminals to circumnavigate, obstacles hindering the ease with which an act of criminality can be perpetrated in a particular locale. Camera networks are aesthetic additions to the urban landscape and represent a city's prosperity and progressiveness (Graham 2001). They become part of the political discourse on risk and security, and function as discursive horizons on which an array of propagandistic vistas can be fashioned. Such partisan conceptions tend to overemphasize the technology's disciplinary influence and to fetishize its role in crime reduction and public safety. CCTV camera initiatives are also a tokenistic reminder, at least in the public imaginary, that the state is actively engaged in addressing both the fear and actuality of criminality.

The above analysis demonstrates that surveillance technologies are much more than mere technical-material structures. It shows, in contrast, that they are also social enterprises. Although surveillance assemblages emerge as a result of political economic rationalities and comprise technical components, their everyday operational vitality and verve is entirely dependent on a complex chain of social actors and relations. Considering the role of workers in the daily production of surveillance is, therefore, an important part of the story. This focus permits us to discern the exploitative dimensions of policing reality, the artful practices comprising the operational lifeworld and the changing configuration of policing praxis.

Surveillance workers tend to occupy a privileged symbolic position, wielding discretionary interpretive powers and an anonymous and asymmetrical gaze. Recent research on the topic of surveillance work(ers) has illustrated (a) the extent to which such laborers impose their own definitional criteria upon that which is observed and (b) the consequences for those who are involuntarily exposed. Norris and Armstrong's (1999) ethnographic study of several CCTV control rooms in the UK is an illustrative example. The two scholars sought to establish the interpretive frameworks or "working rules" – effectively, subjective schemata – operators drew upon to determine camera positioning. The researchers show that suspicion is not an innate or discernible behavioral quality but is rather the outcome of social construction processes. It was racist, sexist, fascist, and classist ideologies that largely determined where and at whom cameras were pointed, the operators predominantly associating criminality with young males, minority groups, and underprivileged populations, specifically those not explicitly engaged in legitimized forms of consumption. These findings emphasize the categorical or labeling power surveillance workers exercise both in the arrangement of social reality and in concomitant decision-making protocol.

Another way of comprehending the social dimensions of surveillance work has been developed by Smith (see 2007, 2009, 2013). He found camera operators to be active consumers of social reality, attaching anecdotal stories to the mediated events encountered. The surveillance workers' musings comprised a mix of imagination and memory, and this creative interchange between the fictional and the real helped foster a set of ritualized occupational customs that made the trying work of watching a more pedagogically meaningful and pleasurable activity. It is easy to imagine and perceive "the gaze" projected by surveillance workers as inevitably embodying disciplinary properties and to assume watching practices as invariably empowering, rewarding and seductive. Yet surveillance work is ambiguous. It comprises important affective and exploitative components. Cameras operators, for example, are required to search for and identify events threatening a desired normative order and, as such, recurrently confront graphic scenes depicting social disorder and human suffering. They must dispassionately film people attempting suicide, injecting drugs, committing robbery, and being viciously assaulted. As a result of the labor that they practice and the traumatic spectacles to which they are habitually exposed, camera operators come to perceive the social world around them as chaotic, precarious, and dangerous. Being routinely subjected to mediated scenes of distress distils in such laborers a distinctive set of pathological beliefs about human conduct and relations, such values reorientating their everyday engagements with the world (Smith 2013).

A sequence of coping strategies are drawn upon by camera operators to manage their general estrangement both from the commodity that they are trying to produce (i.e., social order and its inherent fragility) and from the manufacturing process more generally (i.e., system technologies and occupational conditions). Cameras, for example, are used informally by operators in an attempt to escape, albeit temporarily, from the stresses and tensions associated with witnessing behavioral transgressions and social disarray. Nature becomes an attractive focal point. Its structural stability and intrinsic grace, as represented in dew-covered spider webs, cumulus cloudscapes, and majestic sunrises, helps operators reestablish a sense of trust and coherency in a world that so often appears fractured and anarchic. Thus, the same technologies fuelling the operators' general malaise with, and alienation from, social reality, also facilitate transcendental pursuits, in this case, identification of the natural order's aesthetical mechanics, internal consistency and harmonic patterns. Camera operators also partake in individualized and collective forms of emotional management. The application of black humor, bullying, and sensory detachment – and exploiting camera optics for voyeuristic ends, for instance – allows potentially pathological (and health degenerative) feelings to be channeled and mitigated (and to be projected onto external others).

Surveillance workers are situated within and stratified according to wider occupational hierarchies. They are increasingly embroiled in struggles over camera positioning/control and continually receive quasi indictments requiring them to publicly defend their productions in law courts (Smith 2009). Moreover, research by Goold (2004) and by Newburn and Hayman (2002) has shown how the introduction of CCTV into the public sphere and the custody suite has increased the visibility of policing practices and placed novel accountability pressures on law enforcement officers – and generated corresponding occupational dilemmas for camera operators. Despite the fact that CCTV networks are supposed to support the police in their pursuit of occupational goals, it is often the case that such systems challenge traditional structures in the police's occupational culture, particularly their monopoly on the legitimate use of violence. The routine exposure of policing practices has been further facilitated by the mass diffusion of portable capturing devices and by global circulations of information, especially as facilitated by Internet platforms such as Facebook and YouTube.

Future Directions

This entry has considered how emerging cultures of visibility transform the concept and practice of policing. In particular, the proliferation of surveillance devices into organizational circuitry and cultural canals has been shown to diversify the nature and meaning of policing. Institutions are becoming as much "the watched" as "the watchers." The same can be said of individuals. People embrace surveillance platforms to derive knowledge about social phenomena, to speed up their worldly transactions, and to be entertained. As such, persons increasingly find themselves experiencing surveillance regimes as both exposed "subjects" and contributory "agents." It would seem that, for many, scopophilia has become a seductive practice and voluntary disclosure a desirable state of being.

A plurality of conditions account for these transformations, and more research need examine the political economies, rationalities, and imaginaries underpinning the design and construction of surveillance technologies and attendant product marketing. Research on how different social groups understand, negotiate, and partake in surveillance activities is also required. Further criminological research, therefore, must excavate the nuances associated with surveillance "work," specifically how the introduction of computerized algorithms to autonomously determine patterns of causality in social reality – and to dispose specific interventions – demands a critical rethinking of how contemporary policing is increasingly performed. Today's world is defined by the visibility of particular social flows and the corresponding invisibility of general surveillance processes. The latent nature of computer processing and the overvaluing of technology means that power and domination are becoming harder processes to empirically locate, discern, follow, and – importantly – hold to account. If criminology is to remain analytically relevant to the rapidly evolving structures of social regulation, it must innovate methodologically and epistemologically, particularly appropriating knowledge and tools from quantum physics, mathematics and computing sciences. Policing now operates through informatic circuits, and it is to a better understanding of these cybernetic territories - as distinctive "fields of power" - that criminologists increasingly need focus their energies.

Domestic violence; Gender-based violence

Overview

The general consensus to measure violence against women is that population-based standalone surveys are the instruments of choice for collecting statistics on the victimization of women while recognizing that a well-designed module within a general or other purpose survey would be an appropriate tool as well. Several countries have measured violence against women using different types of survey methods. This entry examines different ways of measuring violence against women giving examples of national and multi-country surveys.

Introduction

The international community has been concerned with violence against women (VAW) or gender--based violence for a number of years. The first United Nations resolution on "Abuses against women and children" was adopted in 1982 calling upon the Member States to "take immediate and energetic steps to combat these social evils." The Convention on the Elimination of All Forms of Discrimination against Women was adopted by the United Nations General Assembly in 1979. The Committee on the Elimination of Discrimination against Women (CEDAW) monitoring the national implementation of the Convention defines gender-based violence as violence that is directed against a woman because she is a woman or that affects women disproportionately. It includes acts that inflict physical, mental, or sexual harm or suffering, threats of such acts, coercion, and other deprivations of liberty.

In 1993, the United Nations General Assembly adopted the Declaration on the Elimination of Violence against Women which also introduced the first internationally agreed upon definition on violence against women:

> For the purposes of this Declaration, the term "violence against women" means any act of gender-based violence that results in, or is likely to result in, physical, sexual or psychological harm or suffering to women, including threats of such acts, coercion or arbitrary deprivation of liberty, whether occurring in public or in private life. (United Nations 1993)

Soon after the adoption of the Declaration in 1993, the lack of reliable data on gender-based violence was recognized. The United Nations Beijing Platform of Action in 1995 recommended the collection of prevalence data to better understand different forms of violence against women. The recommendation has been repeated several times in different international forums.

The hidden nature of gender-based violence makes it difficult to measure its prevalence. Police records reflect no more than the tip of the iceberg. Victimization surveys have been seen as key to reveal the experiences of the victims of violence against women which could not be captured in the official records. The first large scale victimization surveys focusing on gender-based violence were carried out in the Netherlands and Canada. The prevalence rates for sexual violence and other violence were generally seen as shocking and caused disbelief. Soon after, other countries started to carry out surveys with similar results. Most violence against women surveys have been done at the national level. Comparative research involving several countries has proven to be problematic because of differences in cultural and legal definitions and data collection methods. However, there are now a growing number of comparative studies on different aspects of violence against women even though the number of countries participating in these surveys has been rather limited.

Measuring Violence Against Women

Indicators of Violence

Much of the research on violence against women has focused on domestic violence and intimate partner violence (IPV), but gender-based violence is a much wider issue. The United Nations, true to its commitment to human rights, has played an important role in broadening the concept. Gender-based violence can take many forms, and it can take place within or outside the family; it can occur in the workplace, the doctor's office, in state institutions, on the street, or other public places. The victims may be children, adults, or the aged, and the offenders can be total strangers or those that are known to the victim. Violence can take the form of harassment, emotional and psychological violence, economic abuse or exploitation, sexual and physical assault, or murder. Even though many forms of violence against women are criminalized, in many parts of the world women still experience violence outside the reach of the law. It is virtually impossible to capture this very broad range of harmful practices by any standardized measurement process (Kangaspunta and Marshall 2012).

Gender-based violence is a universal phenomenon which takes different forms in different cultural, social, and economic contexts. Our knowledge about the different forms of violence against women is spread very unevenly across the globe, the most developed countries often having the most sophisticated and elaborate survey data and record-keeping systems. This situation is likely to improve in the future, since important progress is being made on the development of global statistical indicators of violence against women.

In 2006, the United Nations adopted a resolution on "Intensification of efforts to eliminate all forms of violence against women" requesting the Member States to ensure systematic collection and analysis of data. Also, the Statistical Commission was requested to develop a set of possible indicators on violence against women in order to assist States in assessing the scope, prevalence, and incidence of violence against women.

Following the request of the resolution, the United Nations Statistical Commission adopted a list of indicators on violence against women which are based primarily on two criteria, that is, on the availability of data at the national level and the seriousness of the violence itself. The below list is suggested to be a starting point for initiating further work on identifying the most appropriate measurements:

1. Total and age-specific rate of women subjected to physical violence in the last 12 months by severity of violence, relationship to the perpetrator(s), and frequency
2. Total and age-specific rate of women subjected to physical violence during lifetime by severity of violence, relationship to the perpetrator(s), and frequency
3. Total and age-specific rate of women subjected to sexual violence in the last 12 months by relationship to the perpetrator (s) and frequency
4. Total and age-specific rate of women subjected to sexual violence during lifetime by relationship to the perpetrator(s) and frequency
5. Total and age-specific rate of women subjected to sexual or physical violence by current or former intimate partner in the last 12 months by frequency
6. Total and age-specific rate of women subjected to sexual or physical violence by current or former intimate partner during lifetime by frequency

In addition, harmful practices including female genital mutilation/cutting and early marriage were considered for inclusion in the indicators list. Also, a number of other manifestations of violence against women were identified that need to be assessed as possible topics for measurement, such as psychological and economic violence, stalking, physical and sexual violence in childhood, forced marriage, discrimination and economic violence at work, trafficking in women, impact of incidence of sexual violence against women on sexually transmitted diseases and HIV/AIDS, assessing risk factors, assessing the extent to which women recognize the suffered violence as a crime, and the percentage of hidden violence unreported to the authorities, or, indeed, even within the community.

It should be pointed out that currently only impressionistic and qualitative information is available for many countries. It is often collected by non-governmental organizations or, for those countries which lack accessible academic research on the topic, provided by the news media. In addition, in some countries we can glean information about gender-based violence through a review article by a local scholar (e.g., Simister et al. 2010; Wasileski and Miller 2010).

One of the most difficult tasks in measuring violence against women is to operationalize the definition of violence against women. During the1990s, there was a considerable controversy over the concepts and terms used in different studies. "Conflict tactics" was used to describe how couples try to settle their differences. Some other studies used rather "violence" and "force" to describe the incidences of violence against women. Also, the question on whether the act or the impact of the act should be measured created prolonged discussion (Walby and Myhill 2001).

Currently, it is widely accepted that surveys should use specific behavioral measures of a range of types of violent acts rather than general terms such as violence or assault. This can at least partly prevent different interpretations of violence among the respondents who might have individual and culture-bound understandings of what constitutes violence. For example, the International Violence against Women Survey used a list of concrete violent acts in its questionnaire including acts like throwing, hitting, pushing, grabbing, twisting arm, pulling hair, slapping, kicking, biting, strangling, suffocating, burning, scalding, and using a knife or gun. Also different acts of sexual violence were mentioned as well as the impact of violence and the steps victims take to obtain help (Johnson et al. 2008).

Measuring Prevalence

Official, administrative records, in particular police and court statistics, have as said limited capacity for measuring the prevalence and incidence of violence against women. Lack of victim willingness to report the incident to the police and reluctance by the police and court officials to record such reports in an adequate manner have historically been cited as impediments to using official data to measure violence and crime. Police statistics may be seen as measures of the criminal justice system's response to crime, rather than as measures of the crime itself. Police statistics about violent crimes against women such as sexual assault and rape, physical assault, and partner violence can be seen as indicators of social sensitivity and changing norms with regard to acceptable levels of interpersonal violence (see, for example, Mucchielli 2010). A number of countries now have specific legislation to record intimate partner violence or the more inclusive concept of domestic violence. However, these statistics primarily measure the social response of victims, bystanders, service providers, and the police to victimization (Kangaspunta and Marshall 2012).

The general consensus to measure gender-based violence is that population-based stand-alone surveys are the instruments of choice for collecting statistics on violence against women while recognizing that a well-designed module within a general or other purpose survey would be an appropriate tool as well. Several countries have measured violence against women using different types of survey methods. Targeted surveys usually cover all forms of violence against women including physical violence, sexual violence, intimate partner violence, and threat of violence. In some cases, also harassment and stalking have been studied.

Some countries use a specific module on partner violence which is added to general victimization surveys or to health surveys to assess gender-based violence. Also, a self-completion module about personal physical and sexual victimization has been added to the general victimization surveys. In some countries, only some forms of violence against women have been studied, usually addressing partner violence and sexual violence.

Surveys have also been targeted in different ways in different countries. In some countries, only women were included in the survey; in other countries also men could participate. Also age of the respondents differ: in most surveys the minimum age has been 18, while the maximum age has varied. The UN Statistical Commission recommends the surveys to be started from age 15.

The mode of interviewing has varied in different countries. Violence against women surveys have been conducted by interviewing respondents face-to-face or over the phone; also mailed questionnaires, self-completion on a computer, or combined methods have been used. While some research argues that the use of different methods might have an impact on the data collection, some others have not found much evidence for this. Face-to-face interviewing can build up more rapport between the interviewer and the respondent making it easier to speak about victimization experiences. On the other hand, the anonymity of telephone-based interviews and self-completed interviews may increase the likelihood to reveal sensitive information. In any case, the enquiry mode may have an impact on the response rate. In general, mailed questionnaires tend to have the lowest response rate compare to the other methods (Walby and Myhill 2001). However, the impact of the enquiry method might be different in different countries depending on cultural and other factors. For example, the first violence against women survey in Finland was conducted using a mailed questionnaire with a relatively high response rate of 70 % (Heiskanen and Piispa 1998, p. 8).

Violence against women data drawn from general victimization surveys should be interpreted with caution for many reasons. General surveys might not be able to include specific-enough questions on experiences of violence, and they may lack sensitive question wording. Also lack of selection of and training for interviewers needed to sensitively conduct interviews or the use of male interviewers may have an impact on the willingness to disclose painful memories of violence. Lack of efforts to facilitate victims to speak about their experiences such as ensuring privacy as well as the broad scope of crime victimization surveys not allowing adequately to address sensitive issues might prevent women to disclose their victimization experiences (Johnson et al. 2008, p. 12).

Also, data collection methods based on face-to-face or telephone interviews might lower the reporting of these crimes. When comparing different methods used in the British Crime Survey, it was noticed that prevalence rates for domestic violence from the self-completion method are around five times higher than rates obtained from face-to-face interviews (Flatley et al. 2010, p. 58).

The International Crime Victim Survey (ICVS) which has been carried out since 1989 includes questions on sexual violence which could be relevant in measuring violence against women. However, there are only small changes in the average sexual assault against women 1-year prevalence rate which varies between 0.6 % and 1 % in different sweeps. Measuring violence against women based on ICVS is not easy, and the figures should be interpreted with caution as mentioned above. Relatively low numbers of female respondents as well as low figures on sexual violence experiences make it difficult to ascertain statistically significant differences. Some findings also suggest that rates of sexual offences are less stable over the years than those of other types of crime. This may indicate that media campaigns or other measures can temporarily raise awareness about sexual violence which in turn increases the reporting of these incidents (van Dijk et al. 2007, p. 77). Even so, national victimization surveys (with larger samples) when used with due caution, may be a useful source for estimates of the rate of victimization of women.

National Violence Against Women Surveys

Targeted Stand-Alone Surveys

Targeted stand-alone surveys have been carried out in many countries. Examples of the first such surveys can be found in Australia, Finland, and the USA, besides Canada and the Netherlands. The first Women’s Safety Survey was carried out in Australia in 1996 to provide information on women’s safety at home and in the community and to depict the nature and extent of violence against women in Australia (Mc Lennan 1996). The survey was repeated in 2005 as part of the Personal Safety Survey in Australia (ABS 2005) updating the information of the first survey concerning women’s experiences of violence (Phillips and Park 2006). In Australia both male and female violence against women was studied, and the focus was on the experiences during the previous 12 months or during the relationship. In 1996, around 7 % of the respondents had experienced violence during a 12-month period; the corresponding figure in 2005 was around 6 % (ABS 2005).

In Finland, the first national survey on men’s violence against women and its consequences was carried out in 1997 (Heiskanen and Piispa 1998). Also in Finland, the survey was repeated, and the second report on Violence against Women in Finland was published in 2006 presenting information about the prevalence, patterns, and trends of violence committed by men against women in 2005. Also, figures on fear of violence and how victims have sought and received help from different agencies were presented. The results showed that in 1997, 40 % of women aged 18–74 had at least once been exposed to men’s violence or threats since the age of 15. In comparison, the percentage was 44 in 2005. In general, there were only small changes between 1997 and 2005 in women’s violence experiences, the most significant being the decrease of intimate partner violence and the increase of work-related violence (Piispa et al. 2006).

The National Violence Against Women (NVAW) Survey was carried out in 1995 and 1996 in the USA, and it sampled both women's and men's experiences with violent victimization. Respondents to the survey were asked about physical assault, forcible rape, and stalking they experienced at any time in their life by any type of perpetrator. Like the other surveys already mentioned, the US Survey showed that violence against women was widespread: nearly 60 % of surveyed women said they were physically assaulted either as a child or as an adult. The survey also showed that many American women were raped at an early age. Out of all women surveyed who said they had been the victim of a completed or attempted rape at some time in their life (18 %), 54 % were younger than 18 years when they experienced their first attempted or completed rape. The survey showed that violence against women in the USA was primarily intimate partner violence. Twenty-two percent of all surveyed women and 64 % of those who reported being raped, physically assaulted, and/or stalked since age 18 were victimized by a current or former husband, cohabiting partner, boyfriend, or date. Only 7 % of all men and 16 % of victimized men had similar experience of intimate partner violence (Tjaden and Thoennes 2000, pp. iii–iv).

NVAW was a onetime survey which has not been compared with any information collected after the survey. However, the Bureau of Justice Statistics' National Crime Victimization Survey (NCVS) has included a special module to their general victimization survey from 1993 to 2008. The findings cover nonfatal and fatal violent crimes committed against females including nonfatal intimate partner violence (IPV), fatal IPV, rape and sexual assault, and stalking. The victimization survey includes women and girls age 12 or older (Catalano 2009).

One of the first violence against women surveys was carried out in Ghana in 1997 where 3,047 women and men aged between 15 and 72 years were interviewed throughout the country. The high number of languages made the survey particularly challenging in Ghana since the country has more than 27 local languages. All the terms used in the study were dually translated into eight local languages representing the main ethnic groups. Another challenge was the access to the people especially women, because in many cases women need permission from husbands/household heads for interviews. Households also needed to confer with chiefs and elders (Ardayfio-Schandorf 2005).

The violent acts identified in the study included wife beating, rape, defilement, widowhood rites, forced marriages, and female circumcision. Around 23 % of the female respondents reported that they have been beaten by their husbands or boyfriends. Six percent of the female respondents stated that they had been defiled; 78 % of the perpetrators were either close relations, acquaintances, or family friends. Eight percent of women said they had been raped; 59 % of the respondents said they never reported these cases to anybody. On forced marriage, 22 % of the married females stated that their parents decided for them, and 30 % of the females reported that their parents and other closer relatives chose their partners for them. In addition, 12 % of the female respondents indicated that they have been circumcised. Respondents were also asked about widowhood rites. Thirty-one percent of widowed respondents said they were being asked to marry their dead husband's brother. Other widowhood rites which the respondents mentioned include shaving of hair, ritual bath, being confined to a room for days, and wearing of rope around the neck (Ardayfio-Schandorf 2005).

The latest targeted stand-alone surveys include the Nationwide Survey on Domestic Violence Against Women in Armenia, 2008–2009 and the National Research on Domestic Violence Against Women in Georgia in 2009, as part of the UNFPA project on Combating Gender Based Violence in the South Caucasus which was launched in April of 2008 (UNFPA 2008). In the Netherlands large scale surveys of violence against women have been conducted in

1988, 1997, and 2010 (Van der Veen and Bogaerts 2010).

General Victim Surveys with Special Module

Canada was the first country to carry out a series of large scale-targeted survey to measure violent victimization of women aged 18 and above. The survey found that 51 % of women had experienced violence at some point of life out of which 39 % was sexual violence, 34 % physical violence, and 29 % intimate partner violence (Statistics Canada 1993). The survey established a baseline to measure violence against women in Canada, and it was used to include a module on spousal violence in the Statistics Canada's General Social Survey (GSS) on victimization which is carried out every 5 years which collects information of Canadians aged 15 years and older; a spousal violence module has been used in 1999, 2004, and 2009 surveys. Sexual assault on the other hand is covered as one of the eight crime types addressed routinely in the general survey (Johnson 2006).

In Denmark, the survey information on violence against women is collected through health-related surveys. The 2000 and 2005 national health interview surveys included a self-administered questionnaire on violence against women including questions on specific forms of violence (Helweg-Larsen and Frederiksen 2008).

For France, there are two different types of surveys available. First, there is the general victimization survey in the Paris region conducted every 2 years between 2001 and 2009. It is not a national population-based survey, but it does cover a large population (representative sample of 10,500 households). This survey includes questions about sexual violence, sexual assault by an intimate, insults, and threats. Estimates of two-year victimization rates are possible. Since 2006, a more focused survey "Cadre de vie et securite" (CVS) is conducted annually by the Observatoire national de la delinquance (OND). This national survey has a representative sample of about 17,000 households. This survey uses a confidential self-completion module on personal violence asking respondents between ages 18 and 75 about annual victimization by physical or sexual violence, either by members of their household or by non-family members (INHESJ 2010).

Since 2004/2005, the yearly British Crime Survey (BSC) has included a self-completion module asking respondents aged between 16 and 59 about their experiences of domestic abuse, sexual assault, and stalking (Smith et al. 2011, p. 69). With this method the sensitive nature of the victimization related to violence against women is taken into consideration, and reporting of these crimes is evidenced to be higher (Flatley et al. 2010, pp. 56, 58).

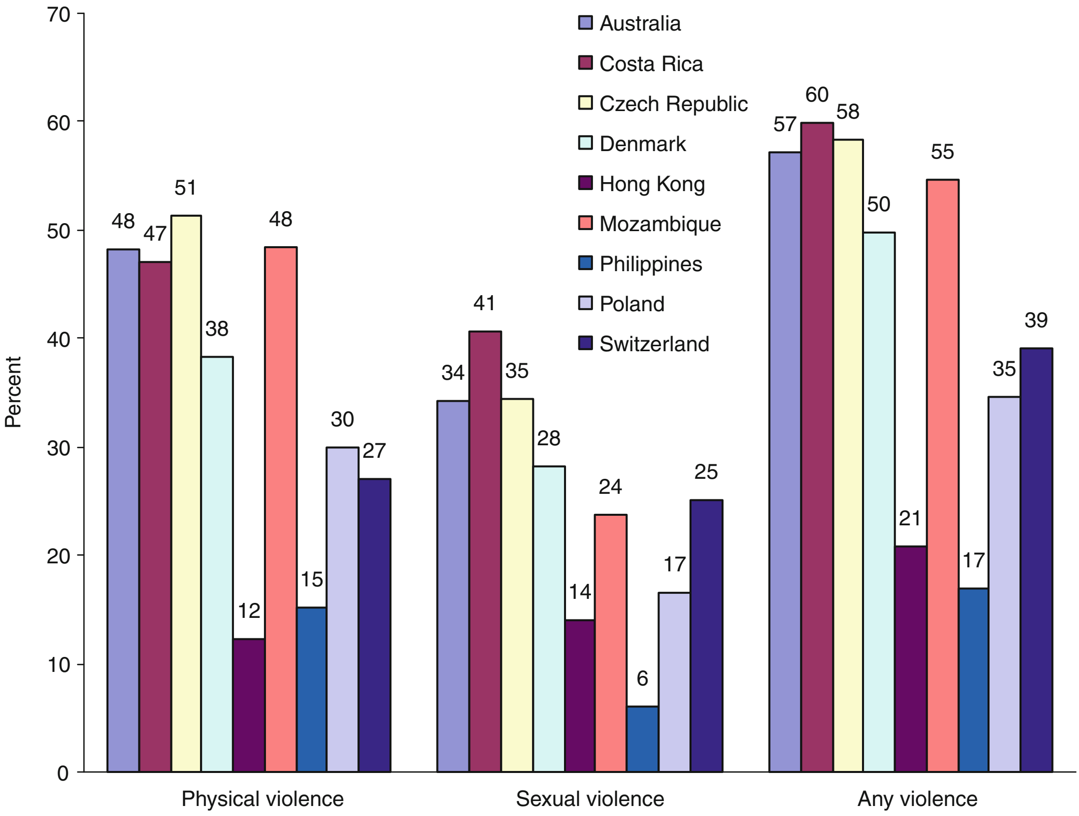
Comparing Victimization

Multi-Country Violence Against Women Surveys

As shown above, because of several differences in national surveys, they cannot be used to compare the level of victimization across different countries. For that reason, international surveys were developed where victimization data were collected in several countries using the same methodology in order to allow comparison between different countries. However, these surveys also have challenges particularly with the translation of questionnaires, interpretation of concepts, structural differences of societies, and other cultural issues.

The International Violence Against Women Survey (IVAWS) was specifically designed to target violence by males against women, assessing the level of victimization of women in a number of countries worldwide. The IVAWS relies largely on the methodology of the International Crime Victim Survey (ICVS). Between 2003 and 2005, standardized surveys were carried out in Australia, Costa Rica, Czech Republic, Denmark, Greece, Hong Kong, Italy, Mozambique, the Philippines, Poland, and Switzerland. The main findings of the IVAWS are:

- Between 35 % and 60 % of women in the surveyed countries have experienced violence by a man during their lifetime.
- Between 22 % and 40 % have experienced intimate partner violence during their lifetime.

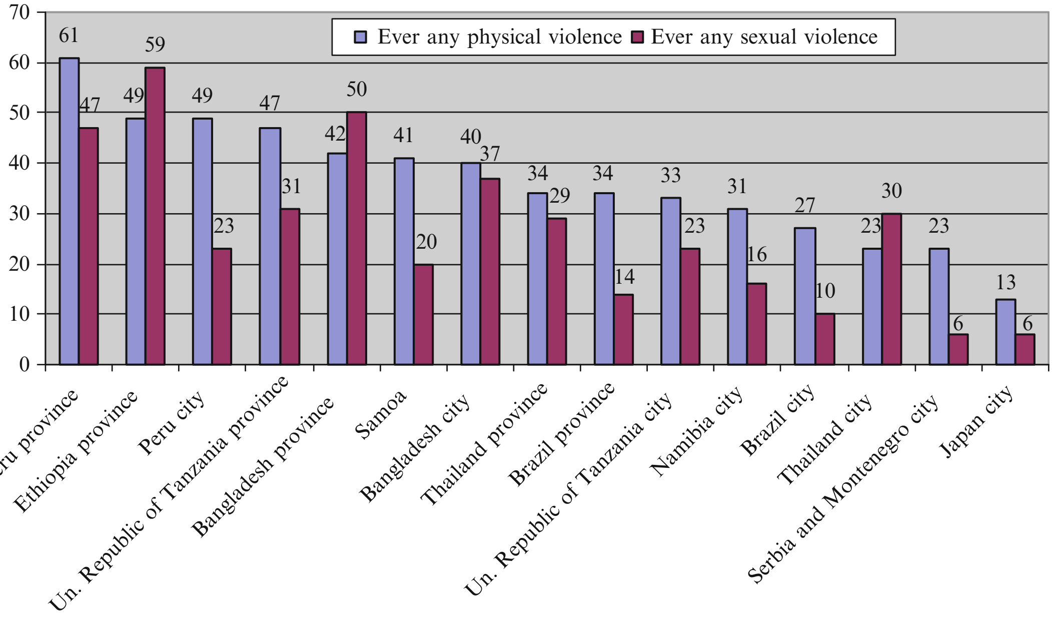


Surveys on Violence Against Women, Fig. 1 Percentage of lifetime physical, sexual, or any violence among adult women (Source: Johnson et al. 2008, 39)

- Less than one third of women reported their experience of violence to the police; women are more likely to report stranger violence than intimate partner violence.
- About one fourth of victimized women did not talk to anyone about their experiences (Johnson et al. 2008) (Fig. 1).

The WHO Multi-country Study on Women's Health and Domestic Violence against Women collected data from over 24,000 women between 2000 and 2003 in the following ten countries: Bangladesh, Brazil, Ethiopia, Japan, Peru, Namibia, Samoa, Serbia and Montenegro, Thailand, and the United Republic of Tanzania. The study estimated the prevalence of physical, sexual, and emotional violence against women, with particular emphasis on violence by intimate partners. The study consisted of standardized population-based household surveys which were carried out in different locations. In five countries (Bangladesh, Brazil, Peru, Thailand, and the United Republic of Tanzania), surveys were conducted in the capital or a large city and one province or region, usually with urban and rural populations. One rural setting was used in Ethiopia, and a single large city was used in Japan, Namibia, and Serbia and Montenegro. In Samoa, the whole country was sampled. The results showed that among women aged 15–49 years:

- Between 15 % (Japan) and 70 % (Ethiopia and Peru) of women reported physical and/or sexual violence by an intimate partner.
- Between 0.3 % and 11.5 % of women reported experiencing sexual violence by a non-partner.
- The first sexual experience for many women was reported as forced – 24 % in rural Peru,



Surveys on Violence Against Women, Fig. 2 Percentage of lifetime physical and sexual violence by an intimate partner among ever-partnered women (Source: WHO 2005, 29)

28 % in Tanzania, 30 % in rural Bangladesh, and 40 % in South Africa (WHO 2005) (Fig. 2).

Demographic and Health Surveys (DHS) are nationally representative household surveys that provide data for a wide range of topics in the areas of population, health, and nutrition. They also include a module on domestic violence assessing the prevalence of intimate partner violence (IPV) among married or cohabiting women. A comparative analysis was carried out based on data collected between 2001 and 2006 in ten developing countries including Bangladesh, Bolivia, Cambodia, Colombia, the Dominican Republic, Egypt, Haiti, India, Kenya, Malawi, Moldova, Nicaragua, Peru, Rwanda, Zambia, and Zimbabwe. The survey analysis showed that there was wide variation across countries in the prevalence of physical or sexual violence experienced by women and perpetrated by their partners: from 75 % in Bangladesh to 16 % in the Dominican Republic. The highest reported rates of physical violence were in Bangladesh (71 %), Bolivia (52 %), and Zambia (45 %), and the lowest reported rates were in Haiti (12 %) and the Dominican Republic (15 %). The highest rates of sexual violence were reported in Bangladesh (26 %), Kenya (15 %), and Bolivia (14 %), whereas the lowest rates were reported in Moldova (3 %), the Dominican Republic (5 %), and Zambia (6 %) (Hindin et al. 2008) (Fig. 3).

Ongoing Demographic and Health Surveys (DHS) can be found in many parts of the world; the latest ones were finalized in 2011 in Angola, Ethiopia, Liberia, Madagascar, Nepal, and Rwanda (Measure DHS 2012).

A standardized survey is also being carried out in all 27 European Union countries including the candidate country Croatia on women's well-being and safety in Europe. The survey will involve standardized face-to-face interviews with about 1,500 women in each country. The interviews will cover women's experiences of violence including physical, sexual, and psychological violence, harassment, and stalking by current and former partners and non-partners. The survey will also look at violence experiences in childhood in order to create a comprehensive

picture of women's experiences of violence during their lifetime (FRA 2012).

Trend Analysis

When trends in violence against women are measured, the comparison is not done between countries but within countries based on information from different time periods. For many reasons, the level of violence against women differs significantly between countries, but that is not the focus of a trend analysis. Rather, the interest is in seeing if the data suggest that the level of violence is increasing, decreasing, or remaining about the same in countries across the globe. An important methodological advantage of comparing trends across countries (rather than levels at one point in time) is that this tends to minimize the comparability measurement problems which hamper international comparisons of levels of violence (Marshall and Summers 2012).

A proper trend analysis is possible only if there is sufficient survey information on violence against women covering a prolonged time period. In a recent article Kangaspunta and Marshall (2012) found only seven countries with (repeated) victim surveys related to violence against women. They were Australia, Canada, Denmark, Finland, France, UK and the USA. There are also other countries which have conducted repeated violence against women surveys; however, they do not necessarily allow for a trend analysis. The case of Belgium presented below clearly shows some of the challenges of trend analysis.

Surveys on Violence Against Women, Table 1 Trend of different forms violence against women in Australia, Canada, Denmark, Finland, France, UK, and USA

Source: Kangaspunta and Marshall 2012

In Belgium, three large-scale studies were conducted on the prevalence of gender-based violence in 1988, 1998, and 2009. The first study in 1988 analyzed incidences of violence against women; the second study in 1998 was extended to men. The 2009 survey studied the occurrence, forms, and severity of the physical, sexual, and emotional abuse to which women and men are exposed. These studies illustrate some of the difficulties performing trend analyses. While the 1998 study was exclusively concerned with violent experiences over the course of the respondents' whole life, the 2009 survey included also the experiences during the past 12 months. In the 1998 survey, a violent act was defined in a detailed manner listing 17 acts of physical and 24 acts of sexual violence; in the 2009 study violence was measured in a more synthetic manner, by grouping physical acts into three questions and one general question on sexual abuse.

In the Belgian surveys of 1988 and 1998, the age group included in the sample ranged from 20 to 50 years; the 2008 survey studied individuals between the ages of 18 and 75. In the case of the 2009 study, only abuse experienced in adult life (after the age of 18) was taken into account, whereas the figures for 1998 concern abuse experienced over the respondent's lifetime. Also, the 1988 survey was conducted using face-to-face interviews, while the more recent surveys were carried out either over the phone or online. In the report presenting the findings of the 2009 results, the authors conclude that – given the differences in methodologies – the surveys do not adequately support trend analysis (Pieters et al. 2010).

In the USA, the National Violence Against Women (NVAW) Survey was a onetime effort which has not been compared with any information collected after the survey. The US violence against women trend analysis has been conducted by using data from the Bureau of Justice Statistics' National Crime Victimization Survey (NCVS), 1993–2008 covering nonfatal and fatal violent crimes committed against females including nonfatal intimate partner violence (IPV), fatal IPV, rape and sexual assault, and stalking. The victimization survey included women and girls age 12 or older (Kangaspunta and Marshall 2012).

The results of the trend analysis of violence against women in the most developed western countries suggest a drop in partner violence against women as measured by the standard surveys (Table 1). On the other hand, (non-partner) sexual violence appears to be increasing. This drop in partner violence is accompanied by an apparent increase in the level of female victimization reported to the police and other agencies. As Table 1 shows, homicides with a female victim were shown to be decreasing (possibly reflecting a general decline in homicides in general) (Kangaspunta and Marshall 2012).

Conclusions

The need to have sound and up-to-date information on violence against women is well recognized both at the national and international level. The United Nations as well as many other international and regional organizations has stressed the need to collect reliable and comparable data on gender-based violence. Many countries have responded to this call since 1993 when the first highly publicized violence against women survey was carried out in Canada. The first surveys were carried out in highly developed western countries only; however, soon after also countries in other regions followed with their own surveys. The latest efforts to conduct such surveys are covering more and more countries in all geographical areas. Also several new initiatives to collect comparative data have recently been launched.

Often, violence against women surveys have focused on intimate partner violence which raises particular concerns in many countries. Also other forms of violence have been studied including sexual violence and violence in public places. In general, all violence against women surveys have greatly increased our knowledge on the victimization of women, showing that high proportions of women in all parts of the world suffer from violence and abuse.

While some women face the dangers at home, most women need to be aware of the risks outside the private space as well. Women's everyday life contains numerous situations where harassment, abuse, and violence could take place such as during doctors' appointments, at the workplace, at school and other educational institutions, during leisure time – for example when participating in sports or just when having a walk in a park. Some of the new studies, particularly the survey on women's well-being and safety in Europe, aim at highlighting these latter forms of violence. The final objective of violence against women surveys should be to generate positive changes so that women all over the world could enjoy everyday life without fear of violence of any sort.

Synthesizing Biological and Social Theorizing

Jon Heidt[1] and Gail S. Anderson[2]
[1]School of Criminology and Criminal Justice, University of the Fraser Valley, Abbotsford, BC, Canada
[2]School of Criminology, Simon Fraser University, Burnaby, BC, Canada

Overview

The synthesis of biological and social environmental theories is a relatively recent phenomenon in criminology. While the early criminologists focused heavily on biological factors related to criminality, criminology eventually came to be dominated by sociological explanations of criminal behavior in the 1930s, and this continued for several decades. However, starting in the 1970s, criminologists began to reexamine biological findings relevant to understanding criminal behavior.

In modern criminology, there are several prominent attempts to synthesize biological and social environmental theorizing. In particular, these integrated theories in the biosocial and developmental research programs use a combination of biological, psychological, social, and environmental factors to explain criminality. These new theories have been successful fusing existing explanations of criminal behavior and explaining interactions between key variables from biology, psychology, and sociology.

The Reemergence of Biology in Criminology

For many years, biological explanations of criminal behavior were excluded from mainstream criminology. This was largely a product of the domination of sociological and environmental explanations in the study of crime from the 1930s to the 1970s (Ellis and Walsh 2003). However, during the late 1970s, some criminologists began to acknowledge the importance of biology and individual differences in the formation of criminality. The emergence of the biosocial perspective offered a way to synthesize existing social environmental explanations with important biological findings relevant to understanding criminal behavior (Ellis 1990).

Recent attempts to fuse biological and social environmental theories can be found in developmental-life course theories of criminal behavior (e.g., see Farrington 1992; Moffitt 1993) and biosocial criminology (e.g., see Ellis 2005; Robinson and Beaver 2009). The notion of gene-environment interaction is important to these theories. Genes determine the different traits that are passed from parents to offspring. In some cases, these traits lead to the formation of an impulsive or aggressive personality creating a predisposition towards antisocial and/or criminal behavior (Walsh 2009). If the environmental conditions are right, an individual with an impulsive or aggressive personality may become involved in crime.

Many of these recent contributions also rely upon a risk factor approach to theorizing (Bernard and Snipes 1996). The goal of the risk factor approach is to identify important variables from different levels of explanation and explain how they interact with one another (Robinson and Beaver 2009). Before reviewing the key contemporary biosocial theories of criminal behavior, it is important to be familiar with the origin of the biosocial perspective in criminology.

Origin of the Biosocial Perspective in Criminology

In the late nineteenth century, biological and multiple factor explanations of criminality were quite popular and could be found in the work of many well-known positivist criminologists including Lombroso, Ferri, Garofalo, and Hooton. However, starting in the early twentieth century, these explanations slowly started to lose favor and began to be displaced by theories that emphasized sociological and environmental explanations. Most prominent were theories offered by the Chicago School (e.g., social disorganization and differential association theory) and Merton’s strain theory.

Modern fusions of biological and social environmental explanations can be traced back to Eysenck’s (1964) theory of the criminal personality. He argued that criminality resulted from the interplay between neurophysiological and environmental conditions and that behavior was learned through classical (or Pavlovian) conditioning. More specifically, individual differences in neurochemistry may cause some people to condition less effectively which leads to the formation of various personality types some of which predispose people to criminality. He identified two personality traits, extraversion and neuroticism, as particularly important to proper conditioning. To summarize, Eysenck (1964) suggested that people with high levels of extraversion and neuroticism would have difficulties learning from punishment and other aversive stimuli, making them the most likely to engage in crime.

Eysenck (1964) claimed that extraverted individuals are especially prone to criminality because their behavior consists of attempts to stimulate their underactive arousal systems. The inactivity can be traced to a small bundle of neurons in the central part of the brain known as the ascending reticular activating system (Eysenck 1964). This system is responsible for keeping the cerebral cortex stimulated and alert. Extraverts are thought to have a pronounced insensitivity in this area of the brain. Consequently, they tend to seek out stimulation in their environment by engaging in risky, thrilling, and impulsive behaviors which often equate to various forms of criminal and/or antisocial behavior.

Neuroticism refers to how one reacts to stress. People with high levels of neuroticism are very sensitive to stress and have difficulties recovering from stressful situations. People with low levels of neuroticism tend to be calm and emotionally stable even when stressors are present and recover quickly after experiencing stressful events. According to Eysenck (1964), high levels of neuroticism are connected to high baseline levels of activity in the autonomic nervous and limbic systems in the brain. These systems are responsible for triggering one's fight or flight response in emergencies and other dangerous situations. Neurotics are thought to be more prone to criminality because the emotional instability created by the high activity in these areas can cause overreactions or inappropriate reactions to stressful situations which may result in criminal and/or antisocial behavior.

C. R. Jeffery (1978) was another early proponent of the biosocial perspective in criminology. He noted that for nearly a half century, criminologists had ignored the findings of the biological sciences that were an important part of a full explanation of criminal behavior. While he was clearly a pioneer in the field of biosocial criminology, Jeffery failed to produce a specific theory of criminality that synthesized biological and social environmental factors. However, he did suggest the application of systems theory to the field of criminology (Jeffery 1990). The systems approach would become a key component of Robinson and Beaver's (2009) integrated systems theory of antisocial behavior which will be discussed later in this entry.

Another early example of an attempt to synthesize biological and social environmental explanations can be found in Wilson and Herrnstein's (1985) *Crime and Human Nature*. Wilson and Herrnstein argued that certain biological predispositions (e.g., aggression, impulsivity, and low IQ) affect how people respond to punishment and, consequently, their propensity to commit crime. In this theory, biological predispositions are thought to affect the operant (instrumental) learning process; this is in contrast to Eysenck's (1964) theory which stressed classical (or Pavlovian) conditioning. In other words, one's susceptibility to deterrence is affected by individual differences in biology. According to Wilson and Herrnstein (1985), behavioral problems begin with parents who fail to discipline their children properly and continue with the criminal justice system which, in their view, had become overly lenient on criminals during the 1960s and 1970s.

It is clear that the work of both Eysenck (1964) and Wilson and Herrnstein (1985) are attempts to combine biological factors (i.e., predispositions) and social environmental factors (i.e., learning and conditioning) to explain criminality. One major shortcoming of these theories was a failure to seriously consider social factors involved in criminality outside of the family and psychological learning processes. In addition, these theories focused exclusively on explaining more serious crimes involving violence like murder and robbery while ignoring corporate and white-collar crime and other crimes common in the middle and upper classes (e.g., driving under the influence, tax evasion, and minor theft). It is interesting to note that early twin studies conducted by Mednick and his colleagues (1977) found stronger connections between heredity and petty crimes than between heredity and violent crimes. Finally, both theories seem to be geared towards explaining chronic and persistent forms of offending rather than sporadic or infrequent criminal behavior.

Contemporary theorists have attempted to address these issues by broadening the scope of their theories and by specifying interactions between key variables in their theories. These more recent theories will be reviewed in the following section.

Contemporary Syntheses

Farrington's (1992) integrated cognitive antisocial potential theory is one example of a recent attempt to fuse biological and social environmental explanations of criminal behavior. His theory also incorporates a developmental-life course approach meaning that it attempts to account for within-individual change as well as between-individual differences in offending. The key construct in this theory is the notion of antisocial potential (AP) which assesses one's potential to commit antisocial acts. In addition, AP serves as a vehicle for integrating existing biological and sociological explanations of criminality.

Two types of AP are identified: long term and short term. Long-term AP refers to between-individual differences in individuals that are relatively stable over time. Factors that contribute to long-term AP include low cortical arousal, impulsivity, high levels of strain, weak attachments, and exposure to antisocial models (Farrington 1992). This is a clear attempt to combine variables derived from key biological findings with prominent sociological theories of criminality (e.g., strain, social control, and social learning). Short-term AP focuses upon within-individual variation in criminality. Factors for this dimension of AP are situational (e.g., anger, boredom, and intoxication) and are drawn out of the rational choice, routine activities, and opportunity theories (Farrington 1992).

Like Wilson and Herrnstein (1985), Farrington's (1992) theory addresses street crime committed by lower-class males, so the scope of the theory is quite limited. In other words, like its predecessors, this theory fails to account for middle-class and elite forms of crime and "normative" crime committed by adolescents. The main advancement here is the use of a developmental-life course approach and the focus on within-individual change in criminality. This emphasis allows the theory to account for changes in offending patterns over time.

Another theory that incorporates a developmental-life course approach is Moffitt's (1993) developmental taxonomy. She posits the existence of two types of offenders: life-course-persistent (LCP) and adolescence-limited (AL) offenders. According to Moffitt (1993), LCPs offend frequently throughout their life and account for approximately 5–10 % of all offenders. LCPs are thought to suffer from neuropsychological deficits that affect verbal (i.e., speech, reading, and writing) and executive (i.e., impulse control and attention span) functioning. These deficits also cause problematic social interactions, especially with parents, school officials, and other authority figures. Family interactions are particularly problematic since, in many cases, parents tend to have similar neuropsychological deficits making interaction all the more difficult. In addition, these deficits predispose the individual to engage in risk-taking and impulsive behavior which often results in crime and other forms of antisocial behavior. Finally, these neuropsychological problems impede the learning of prosocial alternatives to crime, and eventually LCPs become ensnared by the consequences of crime (e.g., negative labeling and a reduction in legitimate opportunities that often lead to desistance from criminal activity). This portion of the theory is a clear attempt to explain how individual differences in biology (i.e., neuropsychological deficits) interact with various environmental factors (i.e., family and school interactions and negative labeling) to produce chronic offending patterns (Moffitt 1993).

Individual differences are thought to be much less important in explaining AL offending patterns; the key factors in AL offending are primarily social and environmental. AL offenders compose the vast majority of offenders (about 90–95 %) and commit crime during adolescent years but eventually desist by their early 20s. Moffitt (1993) argues that this type of crime is normative and is not the result of special traits or biological factors. Instead, AL offending occurs through a process of social mimicry of LCP behavior.

According to Moffitt (1993), modern society has created a "maturity gap" for teenagers in which they lack true roles. This also means that they are prohibited from engaging in adult activities like working, driving, voting, and living on their own until their late teens and early 20s. This role vacuum causes teens to search for other ways to feel mature and independent. For some of these adolescents, maturity and independence are defined as engaging in adult behaviors including drinking alcohol and having sex. Eventually, some of these individuals observe the LCPs getting rewards for their delinquent behavior (e.g., premarital sex, underage drinking, drug use, and possessions obtained through theft). For the ALs, these rewards symbolize freedom and autonomy. In order to obtain feelings of independence, the ALs begin to mimic the delinquent behavior of the LCPs.

AL offending has very little to do with individual differences per se; however, biological factors are still taken into account. Moffitt (1993) claims that societal changes have effectively lengthened adolescence by limiting or delaying roles that require responsibility and maturity. The factor of maturity and its role in development is the biological component in this part of the theory, while the notion of social mimicry and societal changes affecting developmental patterns of youth represents the social environmental component.

Ellis's (2005) evolutionary neuroandrogenic theory attempts to explain why sex is the strongest correlate of crime. To do this, Ellis (2005) suggests that high levels of testosterone give rise to competitive/victimizing behavior. Competitive/victimizing behavior is conceptualized along a continuum. On one end of the continuum are "crude" or criminal forms of behavior, which refer to attempts to injure people or deprive them of their property; in most cases, these acts have been criminalized by modern governments. Notably, white-collar or elite forms of crime are also addressed here as well. On the other end of the continuum are "sophisticated" or commercial forms of behavior, which include acts that "make no profits on the sale of goods or services, although those who administer and maintain the organization under which they operate usually receive much higher wages than do those who provide most of the day-to-day labour" (Ellis 2005: 288). According to this theory, the most serious criminality will be concentrated among adolescent and young adult males of low social status. Victimless forms of crime are left unaddressed by this theory.

This theory consists of two interrelated propositions. The evolutionary proposition suggests that aggressive and acquisitive criminal behavior evolved as an aspect of human reproduction. In short, females are thought to have mating preferences for higher status males that are capable of providing resources. These preferences have been observed in other mammalian species and are thought to hold true in humans as well. Consequently, the theory predicts that rape will always be more common among males who are unable to be stable providers.

The neuroandrogenic proposition identifies three important aspects of brain functioning that play a role in criminal behavior. First, high perinatal testosterone levels can alter brain functioning in ways that promote competitive/victimizing behavior. This is because higher levels of testosterone can affect brain development and may lead to suboptimal arousal levels, may make one prone to seizures, and may cause a rightward shift in neocortical functioning. These are all correlates that appear in other research on serious criminality (see, e.g., Eysenck 1964). Second, one's ability to learn or IQ can serve to inhibit criminal behavior. Third, executive functioning or planning ability is thought to inhibit "crude" or criminal forms of behavior. After adolescence, those with higher levels of learning and planning ability will move quickly from "crude" to "sophisticated" forms of behavior (Ellis 2005).

Because on it focuses upon testosterone and brain development, Ellis's (2005) evolutionary neuroandrogenic theory may appear to be a purely biological theory of criminality. However, the evolutionary proposition considers the role of social environmental factors relating to sex and social status. In contrast to some of the other formulations presented here, mainstream theories from the control, strain, and differential association/cultural deviance trajectories in criminology do not play a role in Ellis's (2005) evolutionary neuroandrogenic theory.

Robinson and Beaver's (2009) integrated systems theory is a wide-ranging and holistic attempt to combine biological and social environmental explanations into a unified theory. The approach used is composed of two key influences. First, the theory itself is derived from the evolutionary-ecological paradigm proposed by Vila (1994). Vila claimed that ecological, micro-, and macrolevel factors form the basis for the formation of personality (referred to as "strategic style") which determines the likelihood of criminal behavior.

Second, Robinson and Beaver's theory (2009) incorporates a systems theory perspective into the evolutionary-ecological paradigm. This is an interdisciplinary biosocial approach, meaning that it seeks to synthesize findings from a variety of disciplines. Systems theory posits six levels of analysis: cell, organ, organism, group, organization, and community/society. Each of these levels represents an individual system, and all of these systems interact with other systems above and below them. This is essentially a risk factor approach similar to the one offered by Bernard and Snipes (1996) and used by the developmental-life course theorists (Farrington 1992; Moffitt 1993).

The biosocial basis of Robinson and Beaver's (2009) formulation is made clear in the first proposition of the theory:

> All behaviours are the result of gene-environment interaction. Genes do not cause behavior; they predispose individuals to react to environmental stimuli in certain ways, meaning some will be more likely to behave in an antisocial manner. Genes are linked to numerous factors relevant for antisocial behavior, including but not limited to personality, drug use and abuse, IQ, violence, and mental illness. (367-368)

The rest of the propositions explain how various criminogenic factors contribute to antisocial and criminal behavior. A variety of factors and explanations from different disciplines are discussed and grouped into the various levels of analysis proposed by systems theory. Biological and psychological factors are considered to be part of the cell, organ, and organism levels. The cellular level of analysis refers to how genes may impact behavior and provide certain predispositions for antisocial behaviors. For example, genes determine IQ, neurotransmitter, and hormone levels all of which are connected to the brain. The main emphasis of the organ level is the brain since it plays a prominent role in behavior. The organism level is focused on the formation of personality which is considered to be a result of gene-environment interactions. This level also accounts for factors relating to diet and nutrition, drug consumption, and mental illness (Robinson and Beaver 2009).

The social and environmental factors are placed into the group, organization/community, and societal levels. The group level deals with small group interactions and incorporates explanations from sociological and social-psychological criminology like the social learning and social control theories. Community variables are derived from sociological theories like social disorganization, routine activities, and lifestyle theory which focus on how certain areas and neighborhoods produce high levels of crime. This level of explanation also considers the impact of organizational level variables proposed by deterrence and labeling theories (i.e., related to the criminal justice system and societal reaction) might have on criminal activity. Finally, societal level explanations are drawn from macrosociological explanations of crime and incorporate variables from strain, anomie, subcultural, and culture conflict theories.

Robinson and Beaver (2009) also attempt to specify how the levels and variables within them interact with each other. Other theorists (Eysenck 1964; Farrington 1992; Moffitt 1993) have identified some of these interactions, especially those at the biological and psychological levels, but none have done so with the level of rigor applied here. For example, Robinson and Beaver (2009) explain that abnormal neurotransmitter, enzyme, and hormone levels impact the formation of the brain and personality, which can later lead to problems in social interaction with parents, friends, peers, and teachers. However, they identify other variables like destructive labeling, economic stress, diet, and pollution that can also affect brain development and may influence subsequent behavior. In addition, larger socioeconomic factors (e.g., tax and corporate policies) may contribute to social disorganization in certain communities. Levels of social disorganization can influence incidences of family conflict, which can also affect biosocial development. Further, social disorganization often gives rise to unsupervised peer groups which play role in the formation of criminal and antisocial behavior (Robinson and Beaver 2009).

Robinson and Beaver's (2009) theory does an effective job of organizing the important findings from a number of disciplines. The attempts made to specify the relationships between the different variables are also useful; however, further research will be needed to truly understand, identify, and refine all of these relationships.

Problems in previous theories (Farrington 1992; Moffitt 1993) are also avoided because the scope has been broadened, allowing this theory to more seriously consider how white-collar and corporate crime may be explained.

Conclusion

The biosocial and developmental approaches have proven to be extremely useful as a starting point for synthesizing biological and social environmental explanations of criminal behavior. However, there are still a number of lingering controversies and contentious debates that should be discussed. First, early biosocial theories (Eysenck 1964; Wilson and Herrnstein 1985) generally downplayed the role of social and environmental factors in criminality. Much of this was related to an implicit emphasis on identifying serious and violent chronic offenders rather than explaining more common types of crime committed by youth or less serious offenders. Again, it is important to bear in mind that early studies of twins found biological connections to petty, and not violent, crimes (Mednick and Christianson 1977). This disjunction between theory and research indicates that there is still an interesting puzzle for criminologists to solve.

Later theories (Farrington 1992; Moffitt 1993; Ellis 2005; Robinson and Beaver 2009) attempted to address this problem by more directly incorporating social factors into the mix of variables. However, biological factors and individual differences still play a central role in these formulations. Further, many of these theories fail to account for white-collar and corporate forms of crime, so their scopes are somewhat narrow. Notable exceptions here include Ellis's (2005) evolutionary neuroandrogenic theory and Robinson and Beaver's (2009) integrated systems theory.

Second, some commentators have suggested that there is currently an overreliance on the risk factor approach in criminology (Moffitt and Caspi 2006; Wikstrom 2008). Specifically, these critics charge that simply assembling lists of key risk factors does not advance the state of criminological theory. The underlying issue here is confusion between correlation and causation; in other words, many risk factors are based on correlates of crime rather than causal factors. In order to break free of this problem, theorists have attempted to specify interactions between different variables and more specific causal processes that exist within theories (Robinson and Beaver 2009). Unfortunately, many of these relationships and causal mechanisms remain somewhat unclear and unspecified.

Despite these problems, biosocial and developmental-life course theories have done an admirable job of advancing criminological theories past the point of purely sociological explanations of criminal behavior. Recent attempts to integrate biological and social environmental explanations have clarified the relationships that variables have with one another and have identified some interactions that may exist between these variables. However, more unified theories will require more research that clearly specifies all of the potential relationships the various biological and social environmental factors may have with each other.

Overview

Systematic social observation (SSO) is the direct observation of social phenomena in their natural settings. It is often a group enterprise with many researchers using a systematized protocol to gather quantified data. Its application in criminology has been sparse compared to official data or survey methods, but it offers unique measurement capacity that can prove valuable for many issues in criminology.

Below, SSO is first defined, and then the method is described along with issues of validity and reliability. Next, a review of the application of SSO to criminological questions offers some insight into the variety of settings in which the approach has been used, and finally this entry concludes with speculation regarding the future configuration of SSO and its role in contributing to an understanding of important questions in criminology.

Definition of Systematic Social Observation

Many individuals engage in social observation, for example, standing on a street corner and people watching or observing audience members at a public event. Viewing persons in natural social settings (or even the setting itself, e.g.,, assessing the quality of neighborhood housing in a location one wishes to move) is an act of observation. What distinguishes SSO is the *systematic* application of rules and protocols that structure the act of observation. Those explicit rules determine what constitutes relevant information for the observer and how that information is to be structured (coded) for subsequent analysis. Explicit rules for observation and coding make meaningful comparisons of events observed by multiple observers and at different times and places (Reiss 1971). One might say that SSO is structured watching with a purpose. SSO is a powerful tool for the study of human behaviors. Its power derives from the focus and structure it brings to observation of human behavior in its natural settings.

History

In the late 1920s and early 1930s, scholars studying early childhood social development practiced systematic social observation, using methods "... designed ... to ensure consistent recordings of the same events by different observers ..." (Arrington 1943, p. 83). Systematic social observation came to criminology at the hand of Albert J. Reiss, Jr., who encouraged social scientists to shed some "nonsensical" views about the limits and benefits of different forms of observing social phenomena (Reiss 1968, 1971). Reiss objected to the notion that direct observation of social phenomena in their natural setting was work for solo researchers using qualitative methods, while survey research was suitable as a group enterprise with many researchers using a systematized protocol to gather quantified data. Reiss argued that both direct social observation and survey research were in fact forms of observation that must confront the same set of challenges to producing interpretable information, that both were amenable to either solo or group practice, and that both could be used effectively for discovery or validation of propositions about social phenomena. Beyond these insights, Reiss's important contribution to criminology in this area was the development and practice of the techniques of SSO. Reiss demonstrated how SSO could be used to answer important questions about what influences police-citizen interactions, with implications for theories about police-citizen relationships and for public policies concerning justice, race relations, and crime control.

Suitability of SSO

What makes SSO especially valuable to researchers gathering data directly in the natural setting are precision of the observations and the independence of the observer from that being observed (Reiss 1971, p. 4). For example, some classic qualitative field research pioneered researcher access to the police occupation, but the necessarily selective samples of these solo researchers appear to have overstated the uniformity of police practice (Skogan and Frydl 2004, p. 27). SSO researchers have observed considerable variation in the way police use their authority, and some have shown the high degree of variability that may be found with the same officer over time. Precision is also accomplished through the sequencing of events and the detailing of context, matters that may not be well documented by official records or accurately recalled by participants when interviewed – for example, how police encounters with the public escalate into rebellion or violence (Sykes and Brent 1983). Sometimes SSO precision derives from the application of complex standards or expectations to the practices of persons with obligations to perform in particular ways. For example, the extent to which legal actors conform to constitutional standards or a professional standard can be assessed. Further, SSO can be used to determine the extent to which justice officials comply with the preferences of citizens they encounter or whether citizens comply with the preferences of justice officials in everyday situations (e.g., Mastrofski et al. 1996).

SSO is especially desirable when the question demands detailed knowledge of situations, conditions, or processes that are not otherwise well illuminated or where there is reason to question the validity of knowledge based on other forms of data collection. SSO may also be useful in studying people who might find it difficult to provide an objective or accurate account of what the researcher wishes to know (such as their behavior and the context of that behavior in highly emotional situations). Where there are strong temptations to omit, distort, or fabricate certain socially undesirable features, such as illegal, deviant, or otherwise embarrassing situations, SSO offers an independent account. This is, for example, a limitation of survey-based citizen self-reports of encounters with police to deal with a problem caused by the survey respondent, and especially problematic if there is systematic variation in the degree of error across important subgroups within the sample, for example, according to race.

While much of the SSO research has focused at the level of individual persons as decision-makers, the 1980s saw the beginning of studies that use an ecological unit, such as the neighborhood block face, as the unit of SSO analysis. Noting that neighborhood residents find it difficult to offer accurate descriptions of their neighborhood's social and physical environment, Raudenbush and Sampson (1999) highlighted the value of an "ecometric" approach that uses SSO in conjunction with neighborhood survey research to more fruitfully characterize the state of neighborhood physical and social structure.

SSO may be especially well suited to situations and events where all of the relevant actors and events pertinent to the phenomenon of interest can be observed from start to finish in a limited, well-defined time period. For example, the police decision on how to deal with a traffic violator is clearly bounded in time and place. To the extent that the decision is heavily influenced by the context of the immediate situation (e.g., the offense, the evidence, the driver's demeanor), the decision on how to treat the traffic offender can be captured by SSO and has been especially useful in understanding informal sanctions, which are not completely captured in official records. In general, SSO lends itself to observing phenomena that occur either with high frequency, such as drivers' noncompliance with speed limits on public highways, or at predictable times and places, such as criminal trials, scheduled meetings between probation officers and offenders, or even field tests of prison security systems. Events that occur less frequently, such as acts of social disorder in public places, may require considerably more observation time to obtain reliable estimates (Raudenbush and Sampson 1999), or they may be so infrequent and unpredictable as to make SSO simply impractical, such as the police use of lethal force or the life course of criminality in a sample of individuals. One of the most frequent uses of SSO has been investigating how criminal justice workers operate in the context of role expectations generated by their organization or profession. Primarily focused on police, SSO research in criminology has been very concerned with how officers negotiate the tension between the formal (legal, bureaucratic, and professional) standards set for them and those that issue from the occupational culture. SSO could also be applied to role conformance in the context of informal or illegitimate organizations, such as gangs.

SSO is often used in conjunction with other forms of observation. Some studies have used SSO to measure the extent to which treatment conditions in randomized trials have been maintained (Sherman and Weisburd 1995, p. 685). SSO data have been linked to other forms of data collection on research subjects, such as census data (on neighborhoods), survey interviews of police officers, and follow-up interviews with citizens who were observed in encounters with police. And sometimes SSO is used to supply data not otherwise available, such as objective measures of the physical and social disorder in urban neighborhoods (Raudenbush and Sampson 1999).

Perhaps the most frequent reason that criminologists have turned to SSO is their dissatisfaction with the data they could obtain by other means, such as official records and survey research (Buckle and Farrington 1984, p. 63). Self-report and victim surveys have a number of biases and limitations, but since these are different from those inherent in SSO, it can provide an alternative perspective on specific phenomenon relative to those approaches (Parks 1984).

Unit of Analysis and Sampling

Planning the selection of what is to be observed is an essential element for SSO. Like survey interviewing, SSO requires a careful focusing of what is to be observed and makes it possible to estimate parameters and evaluate error. The first step requires establishing the unit of analysis. Given that much SSO focuses on social interactions, there are three distinct approaches (McCall 1984, pp. 268–269). One uses a time period as the unit of analysis, observing what happens within each discrete time segment, such as what behaviors police officers display in a 15 minute segment of time or the level of social disorder on a street segment during a one-hour period. Another uses a behavior or act as the unit, tracking the sequencing of different behaviors over time, such as the behavioral transactions between officers and citizens who engage each other. The third approach is to socially construct an event as a unit of observation, such as a face-to-face encounter between a police officer and citizen (Reiss 1971) or a public meeting between police and members of a neighborhood organization (Skogan 2006).

Once the unit of analysis is decided, the researcher must consider the sampling frame. The same principles of sampling apply to SSO as any other data collection method, such as survey research. The researcher must consider where and when the units of interest may be found and determine an efficient method of capturing a representative sample. An example of a straightforward sampling strategy is an SSO study of shoplifting that randomly selected shoppers entering a store, systematically varying the location of observers among entrances to the store (Buckle and Farrington 1984).

SSO researchers often use more complex sampling strategies focusing on geographic space. They have sampled police beats and specific days and times within them, oversampling places and times where higher levels of police-citizen encounters were expected. Some researchers rely upon the observed subjects making their own choices as to where observers conduct their observations. This makes sense when the object of study is a specific research subject, but when the object of study is the geographic entity itself, an independent sampling plan is required. For example, a study of public order in a park required researchers to conduct hourly park patrols to observe and record activities of persons by location within the park (Knutsson 1997). Some researchers have used a smaller geographic unit than a police beat or park. Several studies use the face block to apply SSO to the measurement of disorder on public streets, defined in terms of traces of physical and social disorder (trash, graffiti, loitering, public intoxication) (Sampson and Raudenbush 1999). In one study, observers drove through street segments videotaping what was viewable from the vehicle (ibid). Others have performed live observation at the “epicenter” of each block face (best location to observe the most activity), randomly selecting short periods of time for observation from that location and recording them on check sheets (Weisburd et al. 2006). But observers could focus on single addresses, as might be done if one were interested in observing the extent of different kinds of desired and undesired social activity at crime hot spots. Even smaller spatial units have served as the sampling frame. A study of the relationship between crowding and aggression in nightclubs selected high traffic areas within the establishment (10 m^2) to observe levels of patron aggression for 30-min time periods (Macintyre and Homel 1997).

While much of the extant SSO research must develop time- or area-based sampling frames that capture unpredictable or unscheduled events, some SSO studies have focused on scheduled events, such as the delivery of therapeutic community programs in correction institutions or the previously mentioned police-community neighborhood meetings. Sampling of regularly scheduled events is common in research on educational practices and physician behavior, a practice easily replicated for certain aspects of the legal process of interest to criminologists.

Sometimes the practicalities of conducting successful field observation make the research vulnerable to sample biases. In cases where consent of those to be observed must be secured, a clear bias is introduced when those who refuse to be observed differ in their behaviors from those who are willing to be observed. The practical requirements of observation can introduce bias as well. For example, the observation of disorder on Chicago block faces required light that was sufficient for observation only between 7 am and 7 pm (Sampson and Raudenbush 1999), meaning that researchers were unable to measure many forms of disorder that mostly occur in the darkness. It would also be challenging to observe many aspects of law enforcement inquiry and exchanges in the investigative and prosecutorial processes, because much of the effort is not limited to face-to-face encounters, but rather occurs through telephone and computer, modes of communication that may necessitate very different sampling frames and observational methods. Particularly challenging are studies that require a sampling of *cases* rather than individual decision-makers, inasmuch as it is difficult to track and observe the behavior of many different persons who may be involved in making decisions about a case.

Instrumentation

Principles that apply to other forms of research also apply to the creation of instruments for structuring and recording SSO. Sometimes the instrument takes the form of a tally sheet or log for recording the frequency at which phenomena were observed, such as counting disorderly elements at block faces (Sampson and Raudenbush 1999) – or the timing and duration of events, such as police presence in a hot spot (Sherman and Weisburd 1995). Often the instrument takes the form of a questionnaire that is directed to the observer. A study of police use of force, for example, might ask observers to code a series of close-ended questions about the citizens involved in an incident (their personal characteristics, their appearance, their behavior), the behavior of police (how much and types of force used), and other features of the situation (location of the event, its visibility, the presence of bystanders).

SSO instruments have the desired effect of focusing observers' attention on items selected for observation. Field researchers have demonstrated a substantial capacity to recall the relevant features of long sequences of these events, given the repetitive use of the protocols. Nonetheless, greater complexity in the coding system heightens the risk of error. The accuracy of such recall is undoubtedly variable, but researchers have not assessed most of the correlates of recall accuracy (e.g., observer characteristics, instrument characteristics, and the observational setting).

Recording Observations and Use of Technology

Two issues arise in recording of phenomena observed through SSO: (a) whether it is contemporaneous with the observation or later and (b) whether technological recording devices are employed. Resolving these issues requires choosing the highest priority and what must suffer as a consequence. The more contemporaneous the recording of an observation, the less the vulnerability to recall error and various forms of bias, but in many cases, the act of recording may increase the reactivity of the observed parties to the process of being observed, as, for example, when observers posing as shoppers follow actual shoppers to observe whether they are shoplifting (Buckle and Farrington 1984, 1994).

Employing technological aids is usually intended to increase the accuracy or detail of observation from that which would be otherwise available. Handheld electronic recording devices have been used in observing police-public interactions and in observing the social and physical environment of neighborhoods. Audiotaping of calls for service to police telephone operators has been used to gather data on police workload. Videotaping neighborhood block faces from a slow-moving motor vehicle has been used to observe neighborhood disorder. Use of handheld personal digital devices allows contemporaneous observation and recording of brief, frequent events and is most practical when the number of aspects to be observed per event is small in number, which minimizes the interference of recording events occurring in close succession with observing them (McCall 1984, p. 272).

The major advantage of initially recording events electronically and then encoding those records later for analysis is not only the elimination of recall problems but also that more detailed and accurate observations may be made, and the testing of interobserver reliability is facilitated. Further, field researchers may in some instances feel safer when they make the initial recording of their observations from the security of a moving vehicle or when events are recorded with a remote and unobtrusive device (time-lapse photography of a street corner). Nonetheless, there are a number of drawbacks that have concerned other researchers. Video recordings cannot exactly replicate what all of the available senses would communicate to an observer who was there "in the moment." The use of drive-by photography can be expensive; it raises ethical concerns because denizens of the neighborhood find them intrusive and perhaps anxiety producing; it may raise legal and human subject protection issues if alleged criminal acts are recorded; and they may cause significant reactivity among those being observed. In other instances, however, the pervasiveness of already-present surveillance technology that records observations in readily shared (digital) formats (closed circuit television in public and mass-private settings or in-car police video cameras to record traffic stops) may afford researchers a relatively unobtrusive source of data that does not encounter these problems. Dabney, Hollinger, and Dugan (2004), for example, used augmented video surveillance to study shoplifters. The researchers followed a sample of drugstore customers at a single location equipped with high-resolution video surveillance cameras. They were able to determine which customers engaged in shoplifting and coded data on customers' personal characteristics, as well as behavior. Increasingly, much technology-based surveillance derives its unobtrusiveness, not from its being unknown to subjects, but that it is taken for granted (Shrum et al. 2005, p. 11). And with the advent of nonlinear editing packages for digital video, the data itself (traditionally analyzed in quantitative or text format) can be readily manipulated and analyzed as images (Shrum et al. 2005, p. 5).

Error, Reliability, and Validity

SSO data are subject to the same range of threats that befall other methods. Error can be introduced by the observer, and issues of reliability and validity of the method must be addressed. Observers can introduce error intentionally (cheating) or unintentionally (bias or reactivity). Cheating is rarely reported in SSO, although its frequency is unknown. It seems likely that most instances of SSO cheating go undetected. Shirking, a more subtle form of cheating, may occur if observers attempt to reduce their workload by failing to record events that would require writing extensive narratives and structured coding. There has been no direct systematic assessment of the extent and impact of this form of shirking in SSO, but one researcher did examine the effects of time on the job (a proxy for burnout) on researcher productivity but found that productivity was not significantly related to time on the job lower (Spano 2005, pp. 606–608).

Sources of unintended biases in SSO are the mindset and prejudices that observers bring to the field or develop on the job. These may affect what they observe and how they interpret it. The research exploring these issues for SSO does not offer clear and consistent findings. Reiss (1968, 1971b, pp. 17–18) found that an observer's professional background (law student, sociology student, or police officer) did have consequences for some types of information, but not others. A later study attempted to determine whether a statistical relationship between observed police orientation to community policing and officer success in securing citizen compliance could be attributed to observers' own views on community policing (Mastrofski et al. 1996, p. 295). A clear association was not found between the observers' attitudes and the effects that their analysis produced.

Some types of observation judgment are undoubtedly more vulnerable to personal bias than others. Some research, for example, required field observers to judge whether police officers applied excessive force against citizens. But a more effective strategy may be to bifurcate the process into (a) recording narrative accounts of what happened (without asking the field observer to make a judgment about excessive force) and (b) having separate, specially trained experts review these accounts and make an independent judgment about whether they constitute a violation of some standard, legal, or otherwise.

No responsible researcher can casually dismiss the risks of reactivity in SSO, but a number suggest that it is dependent on the context of the observational setting and the nature of the relationship between observer and observed. In SSO of police it has been argued that reactivity to the observer can be reduced by the observer downplaying any evaluative role and emphasizing one's naivety as a "learner" (Mastrofski et al. 1998; Reiss 1968). Yet even this approach may generate more "teaching" or show-off activity in police subjects. Observed officers who engage in such teaching have been reported making contact with citizens to illustrate elements of police work to the observer (Mastrofski and Parks 1990, p. 487). And some types of observers (e.g., females in the presence of male police officers) may produce more of this effect than others (Spano 2007, p. 461).

One of the distinct advantages of SSO over solo field research is that it facilitates testing and improvement of the *reliability* of observations. Early on, much attention was given to the use of multiple observers and estimating their inter-rater reliability. Where many researchers can independently observe the same phenomenon by having multiple observers on scene or by using video recordings, the testing of inter-rater reliability is accomplished by measuring the extent of agreement among the pool of observers for the same set of events. Sometimes disparate independent observations of the same event are resolved by a process of discussion and negotiation. Where multiple independent observations of the same event are not possible, and that is often the case in situations where having more than one observer would be too disruptive, observers might be tested by using their detailed narrative descriptions to determine (a) if they are properly classifying phenomena according to the protocol and (b) the extent of agreement among persons who use those narratives to make classifications. For example, this has been done for characterizing a wide range of police and citizen behaviors in predicting citizen compliance with police requests (McCluskey 2003, pp. 60–74).

Recently, SSO researchers have broadened their reliability concerns to incorporate measurement accuracy and stability. Raudenbush and Sampson (1999) apply psychometrics to the development of "ecometrics" to better understand the error properties of SSO data gathered from observing physical and social disorder in urban neighborhoods. They adapt three psychometric analytic strategies: item response modeling, generalizability theory, and factor analysis to illuminate the error structure of their observational data and to make judgments about the best ways to limit different sources of error in future observational studies. For example, they find that physical disorder can be more reliably measured at lower levels of aggregation than social disorder, due to the much lower frequency of the latter in their observations (Raudenbush and Sampson 1999, p. 30).

While textbooks often note that field studies are less vulnerable to validity problems than surveys because the method places the observer "there" while events are unfolding, they are of course only valid insofar as they produce data that measure what the researcher intends for them to measure. This suggests that issues of validity are related to the protocols, rules, and frameworks that guide the observation. For example, the validity of observations is weakened when observers make inferences about motives or psychological conditions, which cannot be directly observed.

SSO Contributions to Criminology and Future Opportunities

SSO data have made major contributions in two areas of criminological research: the behavior of rank-and-file police officers and the measurement of disorder in urban neighborhoods. SSO has dominated the empirical research on the discretionary choices of police officers: making stops and arrests, issuing citations, using force, assisting citizens, and displaying procedural justice (Skogan and Frydl 2004:ch. 4). One of SSO's special contributions has been the scope of explanatory elements made available for the researchers' models. These include many details of not only the officer's behavior but also the context in which it occurs (nature of the participants, their behavior, the location, and the neighborhood). SSO has also been instrumental in detailing the nature of the *process* of police-citizen interaction, illuminating the interactive quality of temporally ordered micro-transactions or stages that may occur in even a relatively short police-citizen face-to-face encounter (Sykes and Brent 1983). And SSO has also allowed researchers to observe elements of organizational control and community influence on the work of police officers. For example, researchers can learn more about the influence of police supervisors on subordinates' practices (Engel 2000), the dynamics of police-community interaction and their consequences when police and neighborhood residents deal with each other at community problem-solving meetings (Skogan 2006).

A second area where SSO research has concentrated is the examination of neighborhood physical and social disorder. It has been used to test the impact of police interventions in hot spots, showing that police interventions in these "micro-places" not only reduce crime and disorder, they also diffuse those benefits to nearby areas (Sherman and Weisburd 1995; Weisburd et al. 2006). The largest project in this area has focused on Chicago neighborhoods and has produced a number of insights relevant to the testing and development of theories of the role of neighborhood disorder in causing crime in urban neighborhoods (Raudenbush and Sampson 1999). Using SSO-based measures of "objective" disorder described earlier in this entry, researchers have examined the sources and consequences of public disorder. The research has demonstrated the importance of "collective efficacy" in predicting lower crime rates and observed disorder, controlling for structural characteristics of the neighborhood (Sampson and Raudenbush 1999). Collective efficacy also predicted lower levels of crime, controlling for observed disorder and the reciprocal effects of violence. The researchers found that the relationship between public disorder and crime is spurious, with the exception of robbery, which is contrary to the expectations of the well-known "broken windows" theory of neighborhood decline.

In general, SSO has afforded precision that has in many cases shown the phenomena of interest to be more complex than other forms of data collection had indicated. For example, SSO researchers have found rich variation among police officers in their patterns of discretionary choice and even noted the instability of those patterns for individual officers over time. And the independence of SSO observers from the phenomenon of interest has provided a means to understand the contributing factors to the social construction of phenomena, such as the contributions of a neighborhood's racial profile in assessing its level of disorder (Sampson and Raudenbush 2004).

There are many opportunities to expand the use of SSO to increase knowledge and understanding. Largely untapped is the observation of crime and disorder, especially at the microlevel, where observers have the opportunity to make detailed observations of offenders in the act. SSO studies of shoplifting and aggressive or disorderly behavior in bars and clubs show that this is feasible where observers can easily blend into the environment. Where that is not possible, access to unobtrusive surveillance technologies appears to offer opportunities for detailed observation that reduce reactivity concerns. It is highly likely that criminologists will take advantage of the ubiquity of electronic surveillance to capture events that would otherwise be costly to observe. For example, the growing sophistication of surveillance and identification technology may make it possible to use facial identification software to gather data for a network analysis of persons who frequent hot spots. This includes not only the growing use of video recording devices by government and private sector organizations but the now ready availability of miniaturized recording devices to the general public (through cell phone recording devices).

In searching for efficient ways to use SSO, criminologists will likely capitalize on the growing body of evidence about the predictability of crime and disorder occurring in small geographic spaces. Because much "street" crime is so highly concentrated in a relatively small portion of addresses or face blocks, the location of observers or observational devices can very efficiently generate lots of information on what occurs, especially in public areas. In addition, given heightened levels of obtrusive surveillance in public places, SSO should prove an excellent way to understand how security and surveillance operate, why certain methods are effective, and the collateral impacts of various methods of monitoring and control designed to increase public safety.

Another venue for SSO to be used fruitfully is in experimental studies. SSO can be used to measure key aspects of the process that presumably operate to link treatments to outcomes. For example, if the physical redesign of bars and serving practices of bartenders are intended to reduce violence in those establishments, do patrons in fact alter their patterns of behavior in the ways that are expected to produce less violence (Graham et al. 2004)?

Conclusion

Four decades ago Albert Reiss showed criminologists the utility of systematic social observation, but it remains a method used infrequently. This is due in no small part to two things. First, criminologists are rarely exposed to training and opportunities to do SSO during their course of study. Second, those who know a little about it may often expect that it requires more time and resources than they have available. This may indeed be the case. Many projects could be taken on a smaller scale with a narrower scope of questions than the better-known, large SSO projects, especially if technological advances are leveraged for both recording and coding purposes. Some researchers may decline to use SSO because of reactivity concerns, but the available evidence suggests that these problems are often manageable and may be no more severe in any event than found with other data gathering methods.

Increased use of SSO will undoubtedly attract and stimulate greater scrutiny of its limitations, as well as its advantages. The error properties of most SSO data sets have been underexplored, and more attention here is needed. Expanding the use of SSO and more comprehensively assessing its strengths and limits could be fruitfully combined into a more comprehensive assessment of other methods of gathering data on crime and justice phenomena.

SSO deserves the consideration of researchers because of its many advantages. It offers enhanced prospects of validity for the study of crime and justice phenomena, and it increases confidence in reliability because of the researcher's direct access to the phenomenon of interest and greater control and transparency of data encoding. It affords greater precision in capturing details of the phenomenon and its context, such as the sequencing of what happens before, during, and after those events. In many cases it may be the least problematic method for acquiring information. Criminology, which has strong roots in the traditions and methodologies of sociological research, remains heavily reliant on the use of sample surveys and official records (McCall 1984, p. 277; Reiss 1971). But as the field matures and diversifies intellectually, more of its researchers may with justification be inclined to make systematic social observation the method of first, not last, resort.

Telemetric Policing

Pat O’Malley
Sydney Law School, The University of Sydney,
NSW, Australia

Overview

In the past 50 years, policing has undergone a major change as a result of the development of new technologies of telemetric surveillance. The new surveillant technologies, in theory at least, are perfectly accurate, tireless, produce photographic evidence, cost little to operate after installed, and may generate revenue through fines. Telemetric policing technologies move one step further, linking surveillance with electronic identification of offenses through built-in algorithms. In other words, they *perform* a police function by registering offenses and infractions directly. The information revolution has enormously enhanced the impact of this by embedding telemetric policing into a fully digital “simulated” justice wherein all phases of justice from detection to sentencing to expiation of sanction can be performed online. Telemetric policing with respect to traffic has been credited with reducing offending, rates of injury and death, and costs of policing. However, many of the advantages attributed to it have been challenged by conflicting data, and the instrumentation itself has proven fallible. Resistance has also focused on telemetric policing as merely revenue raising, on human rights grounds, fears of “Big Brother,” and demands for more personal forms of justice. Nevertheless, it continues to expand: new technologies allow automated intervention in vehicle control, and applications of the telemetric model may be extended to many minor public order infractions.

Telemetric Policing Distinguished

“Telemetrics” refers to measurement at a distance, and telemetric policing is thus an assemblage of actors, instruments, technologies, and so on that operates through the remote measurement of offending. It involves the electronic apparatuses of surveillance now familiar parts of everyday life: CCTV, traffic “safety cameras,” bar code readers, magnetic strips, RFIDs (radio frequency identification devices) and so on. Not all of these measure offending,

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

or at least, not most of the time. CCTV, for example, usually operates as a "dumb" technology recording actions in its field of view but doing nothing with the images, which are accessed (if at all) when policing agents seek information. Tracking the movements of the London underground bombers via CCTV turned out to be an important means for identifying offenders. But this process relied upon live police agents scanning the hours of recordings. Even if aided by facial recognition software – important because it may improve the speed, reliability, and costs of police identification – the assemblage remains passive, merely recording specific presences or absences. Whether an offense has occurred remains a question for the interpretation and intervention of live policing agents. Such forms of policing technology have rightly been the focus of a considerable volume of research; they merge criminology with some of the most exciting new areas of social theory, and have given rise to an enormous volume of political attention and concern (Norris and Wilson 2006).

Because much of the development is quite recent, and perhaps because there is no clear cutoff point from what could be referred to as such surveillant policing, police telemetry has been subject to rather less attention. Yet when algorithms are built into the electronic platform of surveillance to register problematic identifiers (e.g., license numbers, passport chips) or patterns of action, a major step toward telemetric policing has been taken, into "automated surveillance" or "algorithmic surveillance" (Norris et al. 1999). The use of CCTV to identify patterns of movement associated with potential suicides on the subway, or processing of a variety of electronic identifiers on passports are two examples. With the former, the action identifies a risky pattern of action, alerting live agents and calling for intervention (Graham and Wood 2003: 236). It remains, however, merely a televisual record and live agents must both interpret and intervene. With the example of the passport, things become more complex. It may not simply be the identity of the passport holder that trips a risk switch, but a variety of other data linked to that identity through various data banks, algorithms, and so on. Amoore (2011), for example, outlines the ways in which algorithms modeled on those used in derivatives markets throw up alarms based on correlations between such factors as the previous patterns of travel, the traveler's destination, or whether the airline ticket was paid for in cash. But while these are cutting edge surveillant technologies – venturing into a regime of estimations and suggestive possibilities – they still do no more than mobilize agents to investigate further.

Telemetric policing is achieved where one more step is taken, and the offense itself is identified through informatic calculation: by a machine deploying an algorithm, that does not necessitate the intervention of live agents. It is, literally, *a policing machine* (O'Malley 2010b). Policing agents may then be mobilized, for example, to effect apprehension of the offender, but identification of the offense has been carried out by the machine. One example that has received attention is electronic tagging of those under a restraining order forbidding access to or exit from certain spaces. Through satellite telemetry, any breach of the order – for example approaching too close to a schoolyard or a former spouse's residence – can be registered automatically (Jones 2001). The offense may still have to be confirmed by later investigation. For example, if the subject fled the house because it was burning down. But as far as the policing process goes, the offense *prima facie* has been registered and apprehension and arrest normally will follow.

Yet while such forms of active surveillance are within the territory of telemetric policing, a still more familiar assemblage takes things one step further by dispensing with apprehension by police, at least in the vast majority of cases. The diverse systems of policing traffic through "safety cameras" – speed cameras, red-light cameras, point-to-point cameras, and so on register an offense through telemetry. They also issue a penalty notice in the form of a reverse-onus money sanction (and/or issue license demerit points and license cancelation). In the vast majority of cases – generally well in excess of 90 % – the policing process is thus entirely operated through information technology, without the intervention of live agents. Where fines are paid electronically or by check through the mail, as is normal, no live agents have been involved even to the point of sanctioning: this is simulated justice (O'Malley 2010b).

An understanding of the nature, significance, and potential of telemetric policing is thus best effected through analysis of these traffic assemblages. Far from "trivial," these operations of telemetric policing very likely constitute the bulk of citizens' experience as subjects of police interventions. They result in the imposition of significant fines and/or license cancelation, and in the case of dangerous driving charges (or nonpayment of fines), quite possibly involve imprisonment.

The Rise of Telemetric Policing

In 1935, a new innovation hit the streets of downtown St Louis, Missouri. Little more than a coin-driven alarm clock on a pole, it contained within it the key elements of telemetric policing. The parking meter itself was the solution to a series of challenges. As downtown parking became an acute problem in the USA, it became necessary to optimize the circulation of traffic, shoppers, and workers. Parking time – limits were established early on, but these soon proved to present significant policing problems. Sworn officers were deployed to ensure that drivers did not overstay the time limits, primarily by chalking tires and returning to book those who infringed. This was expensive, absorbing a considerable amount of police time, but was made more so by its openness to dispute. Drivers claimed that tire marks were from some previous occasion and disputed the officers' time calculations. Defense lawyers exploited every loophole and ambiguity. Police were taken off the beat to testify in court, adding considerably to the cost of policing, while vulnerability to contestation in prosecutions made for many other inefficiencies in policing (Fogelson 2001).

While parking meters did not sweep all these problems away, they had a major effect. It was far easier for infringements to be detected and established, police time was saved and court disputes over timelines and tire marks dropped away. The invention spread rapidly, and often the "objective" nature of the parking meter made it possible to displace expensive sworn police with cheaper "parking officers." What had been an alarming demand for ever-growing volumes of police time was significantly curbed as policing had in key respects become automated. Telemetric justice of the twenty-first century can be seen simply as an electronic extension of this mechanical innovation, for it displaced police through the process of automatically registering an offense or infringement – albeit it that this still required policing intervention to record and process the matter.

Apart from the technology, a second aspect of this development was that citizens were paying on the spot for being policed. Fees and fines made this machine-governed process a form of self-funding regulation. The machines did not merely displace expensive police time; they produced revenue that could be used to fund more machines and other costs of enforcement. In principle therefore, it illustrates a key potential of telemetric policing: it is capable of almost infinite expansion. In pursuit of further economies and efficiencies in policing, a new generation of meters today takes timed and dated digital photos of the registration number of any vehicle overstaying a limit, and transmits this to a central computer that issues a fine. Even parking officers are displaced by virtual police: this is the maturation of telemetric policing. Indeed, a huge volume of policing already has become virtual in this way, transforming the policing not merely of parking but – in the name of public safety – of many "moving offenses" such as speeding, crossing double white lines, and running red lights (Fogelson 2001).

At the turn of the twentieth century speeding, dangerous driving and similar offenses presented problems similar to those giving birth to parking meters. The principal technology for assessing speeding was either the stopwatch, the subjective judgment of the police office, or the speedometer reading of a pursuit police cruiser. All were time consuming, and all were seen to require sworn officers – in good measure because all were easily and often challenged in court. Gaining convictions was difficult especially because motoring then was an elite activity. High status motorists faced courts often unwilling to proceed against such "reputable" citizens. As well, speeding was widely regarded as an illegitimate offense – a "tax on progress" and an excuse for revenue raising (Simon 1998). If charges of dangerous driving existed, then what could the justification be for merely speeding? Motorists' organizations mounted further pressure, and motorists of the time could afford the best in legal representation. Failed prosecutions were frequent. So draining was this of police time, and so difficult to achieve success, that police avoided pressing charges: indeed the British Home office had to issue instructions that speeding had to be enforced (Plowden 1971).

The rise of the automobile as a prime feature of modern life exacerbated problems by vastly increasing the volume of offending. And if courts became more sympathetic to police, nevertheless police prosecutions still relied on primitive technologies of detection vulnerable to court challenge. From an early date, American states attempted to deal with this by establishing traffic courts with greatly simplified procedures. But speeding retained its status as a "merely technical" offense in the eyes of many. The great change in this respect – and vital to the rise of telemetric policing – was the rise during the 1970s of risk management as a widespread technique for government. During this period, alongside drink driving, speeding changed its character. Now increasingly it appeared not as a merely "technical" offense, but as an "objectively" demonstrable risk factor for traffic casualties (O'Malley 2010a). As the road toll emerged as a high-profile problem for governments at all levels, they mounted major campaigns against speeding and drink driving. This move was matched both with increased levels of policing and the application of new technologies. Most significantly at this time this meant mobile speed cameras in police cruisers, and within a few years, fixed speed cameras and more recently point-to-point cameras. The development of fixed speed cameras was a key step in the genealogy of telemetric policing: policing that was *completely performed* (not merely assisted) by remote electronic sensing devices.

It is important to recognize that telemetric policing was shaped by risk-based governance in two ways. First, by directly linking these offenses – especially speeding – to public safety by "objective" scientific means, a new strength was given to the morality of traffic law. Public and personal safety came to be "the" issue in a new and demonstrable fashion. Second, this moral jurisprudence was transformed by risk's creation of a *quantitative morality*. Analysis of speeding and red-light violations in terms of risk calculation created a precisely measurable offense. As speed increased so too did risk and thus the moral wrongness of the offense. And with this went increases in the penalty. The new telemetric machines could not only simply detect offending, but also calculate seriousness of the offense. The next step, logically, is for them to calculate the penalty also.

Risk techniques and informatic technologies are thus vital to telematic policing. But no understanding of the phenomenon, its implications and resistances to it, is possible unless the crucial role of a third element – money penalties – is recognized. Because the penalty predominantly appears as "only money" rather than imprisonment (sidestepping liberal shibboleths of liberty and freedom), this has permitted a considerable streamlining of legal procedure (O'Malley 2010a). Even before the emergence of telemetric policing, the sheer volume of traffic offending led to a series of innovations aimed at speeding up the processing of cases, culminating in the "on the spot fine" or "infringement notice" in the 1960s. Their most salient features include a fixed monetary penalty and a reverse-onus provision (Fox 1996). These innovations created the conditions of existence for telemetric policing to become part of "simulated justice" – that is, justice completely transacted in the virtual environment. Once fixed penalties apply, then a computer can receive the information transmitted by a camera – identifying vehicle and its precise speed – and calculate the penalty. The computer can then issue the infringement notice and email or mail it to the presumed offender. (Usually this is the registered owner of the vehicle. But even where the owner claims another to have been driving, this involves only a minor bureaucratic formality.) It is here that other key features of money come into play. Money is anonymous and can be digitized. Because one lot of money cannot be told from another, courts have had to allow that fines may be paid by someone other than the offender. This makes possible payment remotely, by check. In turn, because money can be digitized, it is a small step to allow payment through electronic banking. At this point, justice itself becomes virtual: electronic and informatic. But because, nevertheless, it retains its reality – imposing real sanctions on real people – the real and the virtual are identical: hence "simulated" justice (O'Malley 2010b).

In turn, the rise of simulated justice means that telemetric policing substantially displaces police from court appearance in relation to traffic offending. Apart from the reverse-onus assumption in infringement notices, incentives for offenders not to go to court are manifold. Fines paid promptly and without challenge are generally "rewarded" by a substantially discounted fine and often without a conviction being recorded. Money, trauma, and time are saved by transacting the whole matter remotely, and simulated justice virtually secures the public anonymity of the offender (Fox 1996). Again, little of this happened by accident: it was precisely the pressure of mounting police work and backlogs in processing cases that forced through this mode of justice to deal with what is, in effect, the principal modern form of mass disobedience to the law. Further, once set in motion, the process of growth becomes self-sustaining. As telemetric policing, operating 24/7 and with unwavering attention, can detect and process unprecedented numbers of offenses and infringements, so there is little choice for administrators but to expand the realm of simulated justice more or less in lockstep. Conversely, as simulated justice efficiently processes cases and generates revenue to fund itself, so telemetric policing encounters no obstacles to expansion arising from organizational problems of logistics. A world of infinite regulation opens up.

The Impact and Effectiveness of Telemetric Policing

Governments and their agencies routinely promote telemetric policing in the traffic domain. Typical is the New South Wales Road Transport Authority (RTA 2012) in Australia that argues that "mobile speed cameras have been introduced because they are recognised internationally as a best practice road safety countermeasure to reduce speeding, leading to a reduction of crashes. The introduction of mobile speed programs in Queensland and Victoria has reduced casualty rates in those states by at least 25 %" (RTA 2012). With respect to fixed safety cameras – which may be speed cameras, red-light cameras, or both – the claim is made that "the use of cameras to enforce speeding has proven road safety benefits." It points out that where cameras have been installed, there has been a 70 % reduction in speeding, resulting in a 90 % decline in fatalities and a 23 % reduction in injuries. These are very high estimates. In an international study, Thomas (2008) found that fixed cameras reduced the number of personal injury accidents by between 20 % and 25 %, figures that correspond to the findings of Gains' (2005) analysis of UK camera sites, while Ercke and his colleagues' (2009) international meta-analysis indicated a 35 % reduction in personal injury crashes. If these claims are taken at face value, then as noted, they are a powerful justification for rolling out even more widespread and sophisticated telemetric policing. However, there is no shortage of contradictory evidence. The most frequent challenges involve indications that data are far more varied and unclear than is admitted to be the case by police and road safety authorities.

One general criticism is that such figures ignore the effects of regression to the mean. In other words, cameras are installed in high accident areas, but accidents in such areas will tend to revert to the mean level even without any action being taken. Figures showing a reduction in accidents after installation rarely allow for this, and consequently exaggerate impacts (Mountain et al. 2005). Likewise, it is frequently argued that speed cameras displace traffic to other routes, and thus, their effectiveness in one site needs to be set against possible rises in accident frequencies elsewhere. This is argued to explain why, in many jurisdictions, traffic cameras are effective in specific locations but overall rates of accidents and casualties do not decline. Indeed, in some settings, speed cameras appear to have *increased* accident rates. One study reported that in Britain, 28,000 road accidents have been triggered by speed cameras as drivers slowed down ahead of them and then sped up once passed (Cavenagh 2008). The introduction of speed cameras and new speed limits in Australia's Northern Territory was associated with a 36 % increase in road deaths, and in Cumbria, England, they were reported to have risen by 40 % after the introduction of speed cameras (Cavenagh 2008). A UK Ministry of Transport (2008) study showed a 55 % increase in injury accidents when speed cameras are used on highway work zones, and a 31 % increase when used on freeways where there were no road works. Likewise British government figures "showed for 32 speed camera sites there were an average of 48 more accidents involving death or serious injury" over the previous 12 months, while at 38 red-light camera sites, there had been an average of 62 more accidents (Williams 2005: 5).

In Britain, such evidence led to decisions by local councils in 2010 to scrap the widespread use of safety cameras because of doubts as to their effectiveness. Prior to this, in 2005, the UK government had blocked the installation of nearly 500 new speed cameras on the same grounds. The 38 traffic safety partnerships' nationwide (involving local government and police forces) were ordered not to use cameras in any new sites (Wilson 2008). It is worthy of note that the Association of Chief Police Officers condemned this ban saying that it could cost lives because dangerous roads were being left unprotected by cameras (Webster 2011). As in Australia and other jurisdictions, police in England and Wales generally are heavily supportive of such telemetric policing. But this argument seems largely to have been ignored in the face of contradictory evidence.

As the British were winding back speed camera installation around 2010, other objections emerged in that country. It was reported that the Department for Transport was reviewing the rules on deploying cameras after concerns that partnerships had failed to consider alternatives such as improving junctions or erecting warnings. Even the Parliamentary Advisory Council for Transport Safety had admitted that while it supported speed cameras, "in some cases partnerships may have chosen to install a camera when an engineering solution may have been better" (Ministry of Transport 2008). Findings by Mountain et al. (2005), for example, indicate that engineering solutions such as speed humps have twice the impact on lowering accident rates (44 %) than do speed cameras (22 %). It has been argued strongly by opponents that cameras represent a considerably cheaper and easier option than engineering – even if less effective – where concerns had arisen about accident rates. Indeed, in 2010, the UK Road Safety Minister stated that the government would cut funding because local governments had relied too heavily on safety cameras for too long, and the focus needed to be on other safety measures.

Red-light cameras have come in for an almost equal amount of criticism. Overall, research reports indicate that their benefits are mixed, with a tendency for right angle crashes (which are more often fatal and injurious) to decrease, but for tail-end accidents to increase significantly – largely attributed to drivers braking suddenly at camera-controlled intersections. However, some studies, including a 7-year study of red-light cameras in the District of Columbia, conclude there is no evidence of reductions in accidents or injuries, and there was evidence of significant increases in certain locales. As a result of such mixed findings, several US states that had installed red-light cameras abandoned the program, including Virginia and Hawaii, while an array of others banned their future use (Texas House of Representatives 2006).

Finally, claims to the success of speed cameras have been undermined by challenges on various technical grounds. Concerns have arisen around demonstration that individual speed cameras exaggerate recordings, resulting in unjustified prosecutions. In 2011, Alberta canceled around 100,000 speeding tickets issued in the previous 14 months due to concerns with the accuracy of equipment (Edmonton 2011). The switching-off of speed cameras on Melbourne's Ring Road system in 2004 was the direct consequence of an admission by the government that possibly thousands of drivers had been fined as a result of faulty cameras.

By challenging the scientific standing of the jurisprudence of safety in key respects, these difficulties represent a major source of vulnerability of telemetric policing: its apparent objectivity and justification in safety. Perhaps precisely because telemetric traffic policing's moral ground is that of safety, and because its techniques for producing safety are scientific technologies, in no other domain of justice does the practice of policing appear so vulnerable to empirical critiques of ineffectiveness.

Public Resistance

As may be seen by reference to the history of speeding, without the justification of harm-minimization, telemetric policing and simulated justice may appear simply to tax motorists, and thus come to be regarded either as an unjust tax or as an implicitly illegitimate source of state revenue masquerading under a guise of security. Necessarily, this leads to a consideration of telemetric policing's seemingly essential nexus with money sanctions. There could be a reasonable expectation that money sanctions would lessen resistance to telemetric policing, certainly compared with imprisonment. This would render them just another annoying but relatively trivial (for middle class offenders) cost of life in modern society. However, in this respect, fines have proved to be a vulnerable strategy. In the USA, in particular, campaigns around this issue were prominent among factors leading to cameras being turned off in Texas as early as the 1980s, and later in Arizona, Illinois, and Alaska (Texas House of Representative 2006: 6–8). In 2011, the New South Wales government banned further rollout of speed cameras and removed 38 out of 141 cameras after public complaints, because they were shown not to have contributed to safety and thus appeared merely as cash cows. Two of these cameras alone had generated in excess of $2 million in the previous year (*The Sydney Morning Herald*, 28 July 2011, p. 1).

Equally problematic has been the widespread use of arrangements with private security companies to install and operate safety cameras under contract. Commonly, governments would license companies to install and maintain cameras, placed according to official guidelines. In exchange, the company kept a certain proportion of the revenues generated. Unsurprisingly, this model generated very high levels of opposition, on the grounds that it was a direct inducement to maximize fines rather than produce road safety. In many jurisdictions, this practice has been curtailed and been replaced by funding private telemetric policing through fees paid by the relevant government. Even so, public opposition to private contractors operating speed camera systems remains high, and this was a factor in the curtailments to camera operations in Arizona during 2010.

It may be imagined that opposition to telemetric policing could rarely get coordinated: for offenders are widely dispersed geographically and are comparatively un-homogeneous – especially when compared with wealthy early motorists. All the more so, because their offending is not normally a matter of public record and visibility, being sheltered from the public gaze by the online environment of telemetric policing and simulated justice.

While rendering the subjects of telemetric policing publicly invisible, information technologies, especially the internet, unexpectedly have proven an important resource for opponents. Innumerable online discussion forums, blogs, online media publications, websites, and so on have sprung up, focusing on the issue of new traffic-tracking technologies. Such mobilizations are an example of a new form of political coordination that has emerged in a society seemingly fragmented and loosening its ties with identity politics. Separated from large-scale political movements, they form political groupings around single issues – such as telemetric policing – that, as Agamben (1993: 86) expresses it "form a community without affirming an identity." Many of the objections to, and critiques of, speed and red-light cameras were generated, or contributed to, by online politics (O'Malley 2013). As Introna and Gibbons (2009: 238–239) argue, "a virtual network may be a powerful actor through the enactment of *information politics*." They suggest that such information networks connect with traditional media and thus traditional politics becoming "an important element of resisting state surveillance practices."

As could be predicted, and as O'Malley (2013) and Wells and Wills (2009) found, key themes of popular resistance were focused on the problems with the accuracy of the telemetry apparatus. Linked with this, many drivers and online opponents raised questions about the appropriateness of rigid and universal criteria of speed limits. Echoing arguments raised in a theoretical context by Wynne (1996), opponents argued that risk was very much shaped by local road and weather conditions, local knowledge of the road, and the skills of the driver. In effect, a counter-expertise was mobilized which drew upon local knowledge and contributed to critical assessments of the effectiveness and accuracy of the telemetric policing apparatus. Thus, while it may be easy to dismiss such resistance as merely based on anecdotal and "subjective" evidence, the findings reviewed earlier in this entry indicate that there are effective and valid grounds for "local" opposition to universal expertise. As Wynne argues, even the categories of "lay" or "subjective," when applied to such resistant views of risk, may be inherently problematic. Simply because universal knowledge always requires adjustment to specific contexts, he argues that the "local" is no less "expert" just because not based on questionable "universal" and "objective" data.

Apart from an information politics, forms of guerrilla action have emerged. Some activists began destroying cameras. In the UK, in Essex alone, six cameras were set on fire (with each unit costing an estimated GBP 24,000). In one instance, websites created a social bandit out of a figure named "Captain Gatso" (GATSOMETER is the name of a brand of speed camera) who grandly announced a struggle "against an unjust form of taxation" and threatened "increased operations across the country" (Khan 2003). A group called MAD (Motorists Against Detection) which reported itself as having a hard core of 200 members claimed responsibility for having destroyed 1,000 cameras since 2000. The group claimed to use internet chat forums, encrypted email, and pay-as-you-go phones to keep in touch and plan campaigns. In practice, this group may have involved only handful of isolated individuals, although news media estimated that some 700 cameras had been destroyed across the nation with particularly active cells in Wales and London. The importance of such accounts is not so much the reality of the threats they posed. It is, rather, the symbolic role they appeared to occupy in an active online opposition movement. This was mobilized primarily by the perception that money fines were an index of government agencies using the jurisprudence of risk as a cover for oppressive imposition of questionable universal standards and for thinly disguised revenue raising.

Even so, it could be imagined, telemetric policing would offer considerable attractions because it is objective and impersonal, a technical policing apparatus free from accusations of bias that frequently dog physical policing. As well, the procedures are streamlined and anonymous. However, Wells (2008) found that while her sample of speeding drivers objected to what they regarded as an unfair system of justice for all the reasons outlined above, in addition, they objected strenuously to the denial of a "voice." That is, the fact that the automated nature of policing and justice effectively denied them the opportunity to put their side of things, to offer issues of mitigation, criticisms of the placement of cameras, denials that speeding in a specific site was dangerous and so on. Regardless of whether they believed in the opportunity to have their say would make any difference to the outcome, the loss of voice was seen to undermine the legitimacy of this form of justice.

Perhaps, more than any single issue, it might have been predicted that privacy, and also related human rights issues, would have been matters receiving most attention in public opposition and related politics. In the USA, such concerns have been raised as contributory concerns influencing several states (Arizona most recently) to wind back or even shut down camera systems. In part, more specific debates in the USA have been curtailed by argument stemming back to the case of Katz v. United States 389 *US* 347 (1967) that the Constitution does not protect the privacy of those who are engaged in breaking the law, and that there is no privacy interest in what is routinely and regularly displayed in public. Much the same argument is regularly aired in relation to cases before the European Court of Human Rights that found the Human Rights Act 1998 was not being violated where the owner of a vehicle was required to identify the driver in relation to a speeding offense.

Nevertheless, what is perhaps surprising is that issues of privacy and human rights comparatively rarely seem to be pushed by online and other opponents – unlike the issues of accuracy and revenue raising. Wells and Wills (2009), for example, found that in the array of issues objected to by drivers caught by automated speed cameras, privacy, civil rights, and "Big Brother" matters were not major concerns. This is also reflected in O'Malley's (2013) findings in relation to analysis of internet sites dedicated to opposing safety cameras.

Futures of Telemetric Policing

The uneven but marked success of campaigns against telemetric policing has focused in many ways on what could be seen as its perceived strengths: objectivity and impersonality, low cost to state budgets, the low profile of money sanctions, and the discourse of safety. This is more than simply an irony. It suggests that, apart from the matter of inaccurate recording of offenses, these are not simply technological glitches that are likely to be resolved. Rather they go to the heart of the features that make telemetric policing attractive to governments and police. It should therefore not be assumed that telemetric policing will simply advance inexorably. Additionally, new oppositions will spring up as the technology progresses. Two examples are significant.

First is Intelligent Speed Adaptation (ISA), where telemetric policing is enabled to intervene directly in offender behavior by taking over operation of vehicle speed and ignition controls. Such technology has existed for some years and is deployed by private vehicle fleets where warnings are transmitted to an offending vehicle and if ignored, the accelerator and/or brakes may be operated remotely. Of course, to allow for emergencies, these can temporarily be overridden by the driver – in much the same way that cruise control works – but in the event this override proves unjustified, a more serious offense may be registered. As well as speeding matters, erratic driving, red-light transgression, crossing double white lines, and so on are all capable of being governed in this fashion. In addition, it is already the case that stolen vehicles can be located and immobilized, a technology publicly available but not yet deployed widely by police. But in principle, all vehicles could be immobilized remotely for all manner of policing purposes. Such interventions, however, are unlikely to escape strong public reaction, and as the level of intervention escalates in this fashion, it would seem reasonable to expect that opposition would likewise become more concerted and widespread.

Second is the use of facial recognition technologies. While, once more, the technology is now well developed, many police forces have as yet abstained from introducing it in telemetric contexts – preferring to rely on automatic number plate recognition (ANPR). In some instances, this self-imposed restriction has been to avoid an anticipated level of public outcry (O'Malley 2013). Here, privacy issues that so far have been rather muted may come more to the forefront. Certainly, the forces promoting such advances in technology are considerable. Not least are concerns that drivers accruing demerit points against their licenses may – policed by ANPR alone – be able to persuade (or pay) others to state that they were driving the detected vehicle. Thereby, dangerous drivers are not removed from the roads. But privacy commissions (NSW 2005) already have noted that the records of telemetric policing are unlikely to be restricted to the issues of traffic control to which they appear dedicated, and are likely to be fed into or linked with many other data bases tracking citizens in everyday life.

The outcome of these kinds of development is difficult to predict. Certainly the suspension and closure of many safety camera schemes should caution against simple assumptions that policing and security concerns will always trump citizen concern and resistance. Even so, some of the more concerning developments may be arising in areas where resistance may be more muted because they touch far less on the lives of the ostensibly respectable "average" citizen. As mentioned, most obvious among these has been the development of electronic tracking devices for offenders released into the community and/or who are subject to restrictions on their movement as part of other sanctions and orders. Yet other developments create new possibilities and new concerns.

The rise of telemetric policing was closely linked with the development of streamlined forms of procedure culminating in the infringement or penalty notice. While well in excess of 90 % of these notices are associated with traffic issues, penalty notices have been extended to govern many kinds of civil and criminal transgression. Lansdell et al. (2012), for example, record 120 agencies with the power to issue notices with respect to 2,000 kinds of infringement in the Australian state of Victoria alone. They also note the widening use of such notices with respect to minor public order offenses, and elsewhere in Australia, it has been noted approvingly that such developments are extremely cost-effective for police (NSWLRC 2010: 145). Of course, the ongoing spread of penalty notices does not imply the necessary growth and extension of telemetric policing per se. However, the further development and implementation of, for example, face-recognition technologies in CCTV begins to open out new directions in telemetric policing in relation to public order offenses. While identification of rioters in recent UK civil disturbances has been mediated by live agents aided by facial recognition software, it is not a huge step for more minor offending to be handled in much the same telemetric way as traffic infractions. This should not be thought of as fanciful. The inducements to the wrongdoer offered by a penalty notice scheme have been seen with traffic issues to be a powerful factor in reducing challenges in court settings, and this assemblage already operates in other aspects of "street justice" (Slapper 2010). Resistance to telemetric policing may thus be overtaken by inertia, lack of resources, and representation. Likewise, while alleged inaccuracies in identification have been effective in some traffic instances, this has been uneven and the advance of telemetric traffic policing has generally extended over the past decade: the same could well be true for facial recognition in telemetry. Telemetric policing of moving traffic appeared fanciful 30 years ago, yet within 10 years, it had become normal in many jurisdictions. As "criminal" law and civil law become increasingly blurred around questions of low-level public disorder (Crawford 2009; Lansdell et al. 2012), and as the intake of increasing numbers of public disobedience infringements consequently expands – as happened with traffic – it would not be at all surprising to see innovations in this telemetric direction within the next few years.

Overview

Unlike many types of violence, terrorist attacks are frequently conceived of, planned, and executed within the framework of a group or organization rather than by isolated individuals. As a result, a key element of understanding terrorism involves understanding the groups and organizations that engage in terrorism. This entry explores the fundamentals of terrorist organizations in a historical and global context, focusing on three general areas: definitions, data, and dynamics. First, what constitutes a terrorist organization and what implications do definitional complexities have for analysis and policy? Second, what is the current state of data and scholarly analysis on terrorist organizations? Finally, how do terrorist organizations vary on key dimensions such as formation, typologies, attack patterns, organizational structure, and evolution?

Defining Terrorist Organizations

Insofar as terrorist organizations are simply organizations that engage in terrorism, the practice of comprehensively defining terrorist organizations inherits all of the complexity that goes along with defining terrorism and then some. The elusive definition of terrorism is discussed at length elsewhere (Schmid and Jongman 1988; Schmid 2004), with the conclusion that there are many definitions used and though they share common themes, none is universally accepted. Beyond this challenging inconsistency, defining terrorist organizations is further complicated by the fact that organizations are typically multifaceted, engaging in a wide variety of legal and illegal activities. Classifying organizations as terrorist organizations requires consideration of how many acts of terrorism a group must commit before this becomes a key identifying characteristic. Further, how great of a threat must the organization pose, and to whom? Finally, groups of individuals that engage in terrorism range from very small, clandestine, informally related clusters of people, to broad networks united by “leaderless resistance,” to formally established, even hierarchical organizations that are more explicit about their existence and their objectives. This structural dimension also impacts the problematization of terrorist groups. One man’s terrorist organization may be another man’s insurgent group, or criminal gang, or even political party.

In light of these issues, identifying terrorist organizations is ultimately in the eye of the beholder. A number of international entities and nations formally designate terrorist organizations for the purpose of law enforcement and sanctioning. Many of these designations originated or expanded following the unprecedented terrorist attacks carried out by al Qa’ida in the United States on September 11, 2001. The most widely adopted list is that established by the United Nations Security Council (UNSC). The UNSC (resolutions 1267 (1999) and 1989 (2011)) maintains a list of “entities and other groups and undertakings associated with al Qa’ida,” which member nations are bound to sanction by (1) freezing the entity’s funds, assets, and resources; (2) preventing transit to or through their territory; and (3) preventing the supply, sale, or transfer of arms or related material. The UNSC’s list includes 68 entities, both terrorist organizations linked to al Qa’ida and organizations that provide financial and material support to al Qa’ida and related groups.

In addition to upholding the sanctions established by the United Nations, the European Union maintains sanctions against additional groups involved in terrorist activity identified through a process governed by the Common Foreign and Security Policy (CFSP). The Council Common Position 2001/931/CFSP indicates that the function of the EU's list of terrorist groups is twofold. It combats the financing of terrorist activity insofar as the European Community will freeze the assets and resources of listed groups, and it facilitates cooperation in criminal justice matters by stating that the EU and its member states will "afford each other the widest possible assistance" with respect to police and judicial enquiries regarding the entities on the list. Until recently the list included a distinction between groups that are subject to both provisions and groups that are subject to only the latter provision regarding cooperation among states. In fact, the initial list of terrorist groups identified by the EU in 2001 included only two whose funding and financial assets were targeted: Hamas-Izz al-Din al-Qassem (the terrorist wing of Hamas) and Palestinian Islamic Jihad (PIJ). The remaining groups, for which member states pledged assistance in criminal justice matters, included the Continuity Irish Republican Army (CIRA), Basque Fatherland and Liberty (ETA), the Anti-facist Resistance Group First of October (GRAPO), the Loyalist Volunteer Force (LVF), the Orange Volunteers (OV), the Real Irish Republican Army (RIRA), the Red Hand Defenders, (RHD), the Revolutionary Nuclei, the Revolutionary Organization 17 November, the Revolutionary Popular Struggle (ELA), and the Ulster Defense Association/Ulster Freedom Fighters (UDA/UFF).

The EU list is reviewed and updated regularly, however, and as of January 2011, it has changed considerably. It now includes 26 groups that are all fully covered by the provisions of Common Position 2001/931/SCFP. Furthermore, the organizations on the list are far more geographically diverse than the originally designated list, including groups not only from Europe and the Middle East but also Latin America (e.g., the revolutionary Armed Forces of Colombia (FARC), Shining Path), Asia (e.g., Aum Shinrikyo, the Liberation Tigers of Tamil Eelam (LTTE)), and Africa (e.g., Gama'a al-Islamiyya).

Other international organizations have not engaged in explicitly designating terrorist organizations to the extent the European Union has. The Association of Southeast Asian Nations (ASEAN) has released declarations affirming its commitment to combating terrorism in 2001 and 2003 (2012). They pledge to uphold UN anti-terrorism resolutions and, among other things, enhance the sharing of information on terrorist organizations and their movement and funding but stop short of formally designating particular organizations for investigation. In 2009, however, ASEAN established a "Comprehensive Plan of Action on Counter Terrorism" that includes the following provision:

> 10.2 Introduce a system for the designation/proscription of terrorists/terrorist groups, without prejudice to domestic law and in accordance with international standards, and share such information with other ASEAN Member States in order that they may take the appropriate action, including, inter alia, monitoring and deterring terrorist movement, freezing assets/property, and preventing recruitment. (2012: 72)

Likewise, the African Union has resolved to strengthen its capacity and that of its member states to address the problem of terrorism (2004). Despite the fact that the AU is actively involved in combating the al Qa'ida-linked militant group al Shabaab in Somalia, thus far it has only officially designated one terrorist organization, the Lord's Resistance Army (LRA) based in Uganda. This designation took place in 2011, according to a November 2011 *Reuters* report.

Individual states have unique protocols for designating terrorist organizations as well and typically focus on those that are specific threats to the interests of the country or its allies. For example, the United States Department of State (2012a) describes its practice of "listing" Foreign Terrorist Organizations (FTOs) as follows:

1. It must be a foreign organization.
2. The organization must engage in terrorist activity or terrorism or retain the capability and intent to engage in terrorist activity or terrorism.
3. The organization's terrorist activity or terrorism must threaten the security of US nationals or the national security (national defense, foreign relations, or the economic interests) of the United States.

There are several legal implications of a US Department of State FTO designation. It is illegal for a person subject to the jurisdiction of the United States to provide material support or resources to the FTO. Also, members or representatives of the group who are not US citizens are not allowed to travel to the United States. Finally, US financial institutions are required to freeze any funds known to belong to designated FTOs. The Department of State notes several informal sanctions that come with an FTO designation, namely, the potential deterrent impact on donations and financing for FTOs and the stigmatization of the organizations, signaling to the public and to other nations the United States' view of them as a threat to national security. As of September 12, 2012, the United States designates 51 organizations as FTOs.

A number of other countries follow similar protocols for identifying and sanctioning terrorist organizations, with similar implications of sanctioning. For example, the United Kingdom's Home Office maintains a list of proscribed terrorist groups that, as of July 2012, includes 45 "international terrorist organizations" as well as 14 proscribed Northern Irish groups (Home Office 2012). Likewise, the Australian government (2012) officially identifies 17 organizations that have been designated either by a court in the context of a prosecution for a terrorist organization offense or "listed" by the government under the Criminal Code Regulations. Under Canada's Anti-Terrorism Act, the Governor in Council has established a list of entities that have participated in or facilitated terrorist activity. This list, which is reviewed every 2 years, currently includes 44 entities. India's Ministry of Home Affairs maintains a list of 34 banned organizations declared as terrorist organizations, in addition to the al Qa'ida and Taliban-related organizations designated by the United Nations Security Council pursuant to resolutions 1267 and 1989.

Listing and delisting terrorist organizations can be contentious and influenced by many factors, often including political considerations. For example, the Mujahedin-e Khalq (MEK) is an anti-government Iranian group currently exiled in Iraq that has carried out numerous violent attacks since the 1970s. The MEK has recently been successful in its controversial campaign to be delisted by a number of states. A 2012 background report on the organization published by the Council on Foreign Relations indicates that the MEK engaged a number of advocates, including many paid high-profile officials, to lobby on its behalf claiming that it is no longer a terrorist threat. As a result, the MEK has been delisted by the European Union, the United Kingdom, and most recently the United States. The United States, which initially listed the MEK in 1997, cited the group's "public renunciation of violence, the absence of confirmed acts of terrorism… for more than a decade, and their cooperation in the peaceful closure of Camp Ashraf, their historic paramilitary base" in its decision to remove them from the FTO list in 2012 (Department of State 2012c).

Likewise, there is often great deal of debate about which groups should be added to sanctions lists. For example, in 2012 media sources including the *Wall Street Journal* and the *Jerusalem Post* reported that representatives from several governments, including the United States, Israel, the United Kingdom, and the Netherlands, have applied pressure to the European Union regarding the absence of the Lebanon-based group Hezbollah from the EU's list of designated terrorist organizations. The EU, citing a lack of consensus, diplomatic concerns, and lack of tangible evidence of Hezbollah's involvement in acts of terrorism, has long resisted this pressure. A more recently emerging group, Boko Haram, is reportedly responsible for the deaths of over 1,000 people in Nigeria since 2009, leading US authorities to consider designating it as an FTO. However, the *International Business Times* reports that despite ongoing violence against Nigerian targets, Nigerian officials are concerned that doing so would have unintended negative consequences for travel and trade between the United States and Nigeria.

Given the many special considerations that produce such disparate and incomplete lists of officially defined terrorist organizations, scholars interested in systematic analysis of terrorist organizations may seek a more comprehensive solution to establishing this problem space. One alternative is to define terrorist organizations empirically, based on an objective definition of terrorism that is exhaustively, rather than selectively applied. Analysts have increasingly turned to terrorism incident databases, which are discussed in more detail below, to establish a comprehensive record of terrorist organizations insofar as they are simply those organizations identified as perpetrators of terrorist attacks. This approach is not without limitations. For example, its all-inclusiveness provides a rather poor initial assessment of a group's potential threat outside of the basic question of how many attacks it has executed and the severity of those attacks. Activity related to the preparation, planning, funding, or material support for violent attacks is rarely accounted for in such sources. However, this post hoc approach certainly avoids the inherent biases that exist in governmental strategies to define terrorist organizations.

Data on Terrorist Organizations

Despite the typically clandestine nature of terrorist organizations, an impressive amount of information about them exists in unclassified literature, though the level of detail is not uniform for all organizations. Due to terrorists' reliance on the media to disseminate their message, primary media sources have proven to be fruitful sources of information on the activities of terrorist organizations. In addition, court documents pertaining to the prosecution of terrorism often include information about groups and organizations. In certain cases, researchers have been very successful at obtaining valuable information through archival documents or interviews with members or former members of terrorist organizations.

There are several general types of data or information on terrorist organizations. These include in-depth case studies, narrative profiles compiled into reference volumes or online portals, structured data on terrorist organizations, and structured data on terrorist activity. Each of these contributes a unique and important perspective on terrorist organizations, and together they provide a more complete understanding of the nature and dynamics of organizations that engage in terrorism.

Case studies offer in-depth analysis of the motivations, structure, and functions of terrorist organizations, covering the entire spectrum of their violent and nonviolent activity such as recruitment, planning, strategy, financing, activism, communication, and criminal activity. They typically take a broad view of the organization, placing it in a broader historical and political context. Case studies typically focus on a particular group or conflict, such as Wright's (2006) chronicle of the history of al Qa'ida, Wickham-Crowley's (1992) comparative study of guerrilla groups in Latin America, or Sayigh's (1997) exhaustive account of the Palestinian National Movement. Each of these covers approximately half a century of events in great detail, drawing on archival records, published documents, and personal accounts to illustrate the inner workings of terrorist organizations. Others compile case studies on contrasting organizations, typically with the aim of identifying common patterns of activity. Examples of this include Crenshaw's (1995) edited volume, *Terrorism in Context*, which includes chapters on terrorism and terrorist organizations in Europe, Russia, Italy, West Germany, Argentina, Peru, Ireland, India, Spain, Algeria, Israel and Palestine, and Iran. Ross (2006) seeks to illuminate the causes and consequences of political terrorism using case studies of three key organizations, al Fatah, the Revolutionary Armed Forces of Colombia (FARC), and the Provisional Irish Republican Army (PIRA), as well as a review of terrorism and various terrorist groups active in the United States.

These are just a few examples of the use of case studies to compare, contrast, and better understand the organizational nature of terrorist activity. There are certainly many other studies that synthesize a great deal of information about particular organizations, both large and small. The studies mentioned above tend to aim at providing exhaustive accounts of the organization's existence, but others may isolate a particular dimension of interest. For example, a compilation of case studies written by a team of researchers at the RAND Corporation (Jackson et al. 2005) analyzes five terrorist groups: Aum Shinrikyo, the Radical Environmentalist Movement, Hezbollah, Jemaah Islamiyah, and the Provisional Irish Republican Army, focusing specifically on exploring their aptitude for organizational learning and adaptation. Others use the case study method to investigate how terrorist organizations decline (Alterman 1999; Crenshaw 1991; Cronin 2009; Jones and Libicki 2009; Ross and Gurr 1989). While the richness of case studies has obvious benefits for understanding how terrorist organizations operate, they do sacrifice breadth for depth. Case studies generally focus on a small number of high-profile groups that are not necessarily representative of the global landscape of terrorist organizations. In fact, more inclusive sources of information on terrorist organizations tend to indicate that these high-profile groups, while responsible for a great deal of terrorist violence, are actually quite atypical.

Compilations of narrative profiles of terrorist organizations provide a far more comprehensive, though less detailed, source of information. Several of the official listings of terrorist organization discussed above include narrative descriptions of the groups in question that serve as justification for their designation as terrorist organizations (e.g., United Nations 2012; US Department of State 2012b). There are a number of reference texts that are far more inclusive, however, such as the "World Directory of Terrorist and Other Organizations Associated with Guerrilla Warfare, Political Violence, and Protest" compiled by Albert Jongman in collaboration with Alex Schmid (Schmid and Jongman 1988). This directory is based on information from a variety of journals, newspapers, and magazines and includes profiles of approximately 3,000 groups, parties, movements, and organizations worldwide that have engaged in violence, including state agencies that have engaged in gross human rights violations.

Similarly comprehensive reference resources on terrorist organizations include Janke's (1983) *Guerrilla and Terrorist Organizations: A World Directory and Bibliography*, Jessup's (1998) *An Encyclopedic Dictionary of Conflict and Conflict* Resolution 1945–1996, Hill's (2002) *Extremist Groups: An International Compilation of Terrorist Organizations, Violent Political Groups, and Issue-Oriented Militant Movements*, Kushner's (2003) *Encyclopedia of Terrorism*, and Atkins' (2004) *Encyclopedia of Modern Worldwide Extremists and Extremist Groups*.

More recently, several online portals including information on terrorist organizations have been developed. Perhaps the first and most well known of these, the Terrorism Knowledge Base (TKB), was developed and maintained by the Memorial Institute for the Prevention of Terrorism (MIPT). The TKB included narrative profiles and basic structured information on aliases, bases (countries) of operation, date formed, group size, ideological classification, sources of funding, key leaders, related groups, and official designations for over 800 organizations. Although the TKB was discontinued in 2008, these profiles were transferred to the National Consortium for the Study of Terrorism and Responses to Terrorism (START) where they are published online in their original form under the name *Terrorist Organization Profiles (TOPs)* (2008). Similar resources have since been developed, including the Violent Extremism Knowledge Base (VKB) at the Institute for the Study of Violent Groups (ISVG) and Crenshaw's Mapping Militant Organizations project at Stanford University (Crenshaw 2012; ISVG 2012). The VKB contains profiles of over 150 groups and organizations around the world. The Mapping Militant Organizations project, though currently limited to Global al Qa'ida, Iraq, Italy, North Caucasus, the Philippines, Somalia, and Pakistan, includes both general profiles and in-depth timelines documenting the complex evolution of dozens of organizations in these contexts.

Structured, quantitative datasets on terrorist organizations are extremely resource intensive to collect and therefore are quite rare. Due to the large number of terrorist organizations active worldwide, along with their clandestine and continually evolving nature, it is difficult to systematically collect reliable, comprehensive data on these groups. Certain group-level datasets do exist, though they are somewhat limited in scope either by time or place. For example, the Big Allied and Dangerous (BAAD) Lethality database collected by Asal, Rethemeyer, and Anderson contains data on organizational ideology, location, size, structure, funding, and relationships to other groups for those organizations that were active worldwide between 1998 and 2005 (2009). Likewise, the Profiles of Perpetrators of Terrorism in the United

States (PPT-US) database collected by Miller and Smarick (2011) contains over 100 variables regarding the organization's history, structure, and violent and nonviolent activity for 142 groups that have carried out or attempted to carry out terrorist attacks in the United States between 1970 and 2010.

The final piece of the data puzzle for understanding terrorist organizations is incident-level data. In order to fully understand the dynamics of terrorist organizations, one must consider their patterns of activity, including the location, timing, tactics, and lethality of their attacks. With the increased availability of incident-level datasets on terrorist attacks, analysts are able to aggregate data on the perpetrators of these attacks to first identify the universe of perpetrator groups and then conduct analysis on any of these dimensions of activity. Several such global datasets are currently available, including the RAND Database of Worldwide Terrorism Incidents (RDWTI) (RAND Corporation 2012) and the International Terrorism: Attributes of Terrorist Events (ITERATE) dataset (Mickolus 1982). The ITERATE dataset, distributed by Vinyard Software, now includes structured data on international terrorist attacks from 1968 through 2007, and the RDWTI includes data on international terrorist attacks from 1972 to 1997 and both international and domestic attacks from 1998 to 2008.

For a complete account of an organization's terrorist activity, it is important to consider both international and domestic attacks. The Global Terrorism Database (GTD) is maintained by the National Consortium for the Study of Terrorism and Responses to Terrorism (START 2012). The GTD, which includes over 104,000 domestic and international terrorist attacks that occurred worldwide from 1970 to 2011, identifies names of over 2,000 organizations as perpetrators of the attacks.

Dynamics of Terrorist Organizations

Ultimately, it is extremely challenging to establish a "ground truth" universe of terrorist organizations, given many divergent interests that influence official designations and various methodologies for collecting data on these groups. It is critical that researchers make appropriate inferences with this in mind. Nonetheless, drawing on the variety of sources described above, analysts have built a considerable body of research on the dynamics of terrorist organizations, how they form, what drives them, how they evolve, and how they ultimately end. The common theme in much of the literature is that terrorist organizations are extremely diverse with respect to many of these dimensions.

How Terrorist Organizations Begin

Martha Crenshaw (2001) contrasts two theoretical paradigms of terrorism, one *instrumental* and the other *organizational*, both of which have important implications regarding how terrorist organizations form and begin to engage in violence. An instrumental approach is entirely goal based, suggesting that everything an organization does, including choosing to engage in violence, is decided because it is in the best interests of achieving the group's stated goals. The organizational framework suggests that the stated ideology or goal of the group is actually secondary to its true objective: simply continuing to exist, even as political purpose evolves over time. In this scenario, insofar as the potential for grievance is universal, the formation of potentially violent organizations becomes critical to understanding and combating terrorism.

A number of factors influence the formation of terrorist organizations. Crenshaw suggests that the necessary components include skilled, committed leaders who are able to attract and incentivize other members, a demand for the organization among an actual or potential constituency, available mobilizable resources, and a salient purpose marked by ideas that legitimize violence. Likewise, Oots (1989) explores the importance of not only entrepreneurial leadership, recruitment of members, and political and financial support but also a group's ability to form coalitions with other groups, internal and external competition, and internal cohesiveness. The salience of these factors with respect to terrorist organizations suggests that in many ways they are not unlike other types of organizations, particularly other political organizations.

Research on the experiences of group members indicates that the incentives to join a terrorist group often have little to do with the group's objectives (Crenshaw 2001; Sageman 2004). Crenshaw highlights the importance of factors like personal daring, social rebellion, action, and feelings of belonging, acceptance, solidarity, and contribution. Furthermore, Sageman observes that the key to understanding modern Salafi jihad terror networks is not found in conventional wisdom about "top-down" recruiting efforts and brainwashing. Instead, it is frequently the case that adopting an alliance with al Qa'ida and forming a terrorist cell is about social relationships involving friendship, kinship, discipleship, and worship. That is, terrorist cells are formed among personal acquaintances within social circles as a "bottom-up" phenomenon.

Typology

Analysts frequently organize terrorist groups into typologies to provide a framework for understanding the groups and their activities. These typologies are most frequently based on the groups' ideology or goals (Ganor 2008; Merari 1978; Schmid and Jongman 1988). The motivational underpinnings of terrorist groups may be political, religious, social, economic, philosophical, practical, or a complex, shifting combination of many of these. Although ideology is frequently the basis for classification of terrorist groups, it is not the only basis and it has certain limitations. For example, in some cases, the group's ideology is held universally, and in other cases, it may be largely immaterial to the violent activity of members. Likewise, it can be challenging to articulate a meaningful classification scheme when the organizations themselves are often complex.

For example, the *dominant ideology* variable in the Profiles of Perpetrators of Terrorism (PPT) database is a fairly typical ideological classification of perpetrator groups based on the following five categories: Extreme Right-Wing, Extreme Left-Wing, Religious, Ethnonationalist/Separatist, and Single Issue. Variations on this scheme may disaggregate these categories further; however, even at this fairly high level of abstraction, certain groups fall into more than one category, compromising the mutual exclusivity of the typology. Often these complexities contribute to rifts within groups that lead to the development of factions or splinter groups. For example, the Moro National Liberation Front (MNLF) is a Muslim group based in the Philippines that sought for decades to establish independence for the Moro people. Because the Moro people are Muslim, the MNLF is frequently classified as Religious/Nationalist-Separatist, despite the fact that their ideology is generally secular and somewhat left leaning, guided principally by the goal of Moro nationalism (ISVG 2012; Tan 2007). In contrast, however, MNLF splinter groups such as the Moro Islamic Liberation Front (MILF) and Abu Sayyaf Group (ASG) have adopted a far more "overtly religious" radical Islamist ideology, establishing links with the global jihadist movement and al Qa'ida (Tan 2007, pp. 13, 34).

Fitting groups like this into a typology based on ideology can be challenging and, as Merari (1978) suggests, not particularly useful with respect to forecasting a group's strategy or tactics or the efficacy of counterterrorism measures. Instead, Merari recommends a two-dimensional typology that classifies terrorist groups based on (a) whether they fight against a foreign or domestic government, organization, or population ("xenofighters" vs. "homofighters") and (b) whether their base of operations is domestic or abroad relative to their constituency. Merari's typology of terrorist organizations focuses particularly on their operational goals and how they relate to group behavior. For example, he suggests that xenofighter terrorist groups tend to adopt more indiscriminate tactics and are more likely to harm innocents or use weapons of mass destruction because they do not rely on the target population for support like homofighter groups do. Likewise, in Merari's typology, homofighter groups are more likely to use targeted tactics such as assassinations or kidnappings of key figures.

Ganor (2008) articulates an exhaustive list of typological dimensions that extend beyond an organization's motivations. He suggests that violent groups vary meaningfully with respect to targets of violence (military vs. civilian), size, extent of public support, characteristics of the decision-making process, degree of independence or subordination with respect to sponsor states, financial strength, arena of operations (rural vs. urban), geographic range, control of territory, demands, seniority, place in organizational development, activities, and structure. Ganor recommends concentrating in particular on the two elements that are most likely to impact an organization's activity: degree of motivation and degree of operational capability. Although any number of these dimensions might individually or in combination provide insight regarding an organization's capabilities and threat, it is often difficult to comprehensively and systematically classify groups because reliable information on these characteristics is typically scarce and the characteristics themselves are often dynamic. Consequently, the application of typology-based strategies for understanding terrorist organizations is poorly developed.

Attack Patterns

Although it is difficult to obtain systematically collected data on many of the more clandestine attributes of terrorist organizations, information about their attack patterns is more readily available from incident-level databases like the Global Terrorism Database (GTD). The most widely recognized terrorist organizations are long lasting and either highly active, highly lethal, or both; however, a comprehensive analysis of the perpetrator groups identified in the GTD indicates that while some groups endure, the vast majority (74 %) last less than one year and are associated with only a few attacks (Dugan 2012). Not surprisingly, given this high proportion of short-lived groups, Dugan's analysis also indicates that 26 % of terrorist organizations identified in the GTD are responsible for over 93 % of all attacks for which a perpetrator was identified.

The attack patterns of terrorist organizations are quite diverse and multifaceted. The Liberation Tigers of Tamil Eelam (LTTE) in Sri Lanka and the Irish Republican Army (IRA) in Northern Ireland are both nationalist/separatist organizations among the most active and longest active groups between 1970 and 2007, yet the LTTE is nearly twelve times as lethal on average than the IRA. Conversely, al Qa'ida is responsible for the most lethal terrorist attacks in history on September 11, 2001, but is not among the most active terrorist organizations, though several al Qa'ida-linked groups are, such as al Qa'ida in Iraq (AQI).

The most recent version of the GTD indicates that between 1970 and 2011 there were 91 groups that carried out suicide attacks. Although the Taliban and the LTTE are the most frequent perpetrators of suicide attacks, this tactic represents only 9.8 % and 6.5 % of their attacks, respectively. Among groups that have carried out more than ten attacks, several adopt suicide tactics in more than one third of their attacks, including the Haqqani Network (71.8 % of attacks), al Qa'ida in Iraq (40 % of attacks), and al Qa'ida (36.8 % of attacks).

The GTD also indicates that perpetrator organizations attack a wide variety of targets. Although some of the typologies discussed above seek to classify terrorist organizations based on target selection, terrorist organizations vary considerably with respect to both targeting practices and diversity of target selection. For example, among perpetrator groups that have carried out at more than ten attacks between 1970 and 2011, only one organization attacked exclusively military targets, the 16 January Organization for the Liberation of Tripoli which attacked 24 Syrian military targets in Tripoli, Lebanon throughout 1989. A far more prevalent pattern of attacks involves a wide variety of target types including military, police, government, business, and private citizens and property. The GTD includes 21 different types of targets and over half of the perpetrator groups that have carried out more than ten attacks have attacked more than seven different types of targets.

How Terrorist Organizations Evolve

Just as the activity of terrorist organizations is highly variable, the organizations themselves are not static but rather dynamic and often subject to extensive evolution over time. Careful examination of the perpetrator attribution data in the Global

Terrorism Database reveals that terrorist organizations do not exist in a vacuum, but instead they frequently splinter, create factions, merge with other groups, or form coalitions or umbrella groups. They often change names, key personnel, base of operations, or even ideology. Terrorist organizations may form strategic alliances or partnerships with each other or rivalries that lead to further violence. The evolution of terrorist groups and the often scarce information about their organizational development have important implications for analysis. Naming conventions alone, and the extent to which they reflect meaningful shifts in group identity, can pose critical challenges for the analysis of terrorist organizations. Consider, for example, the following narrative about Devrimci Halk Kurtulus Partisi/Cephesi (DHKP/C), the Revolutionary People's Liberation Party/Front, from the Terrorist Organization Profiles (TOPs):

> The DHKP/C (Revolutionary People's Liberation Party/Front) is a Marxist, anti-Western splinter group of the Turkish terrorist group Devrimci Sol (Dev Sol). Dev Sol originated as a splinter group of Devrimci Yol (Dev Yol) which was itself a splinter group of the Turkish People's Liberation Party-Front (THKP/C). The THKP/C was an offshoot of the broader Revolutionary Youth movement (Dev Genc) within Turkey.
>
> In the early 1990s, infighting within Dev Sol resulted in the emergence of two factions. Dursun Karatas, who founded Dev Sol by combining splintered factions of Turkish radical leftist groups in 1978, changed the group's name to DHKP/C in 1994. Bedri Yagan, also a founding member of Dev Sol, broke from the Karatas faction and created a new faction, THKP/C (not to be confused with the original THKP/C). Confusingly, the Yagan faction of DHKP/C is still often referred to as Dev Sol.

The evolution of DHKP/C described here represents only a small segment of the broader Turkish Left and is not particularly atypical. Many organizations with different names in some way represent the same broader entity and often organizations with the same name are actually different entities. Furthermore, individual membership to a group is rarely a discrete status and various groups with similar interests share members. These qualities frequently make it difficult to determine where one terrorist organization ends and another begins.

The Mapping Militant Organizations project led by Martha Crenshaw at Stanford University is an extremely useful resource that chronicles the family trees of terrorist groups that are part of the global al Qa'ida network, as well as those that have been active in specific countries and regions. It includes a web-based application that graphically displays relationships between key organizations, including alliances, affiliations, mergers, rivalries, splits, and umbrella organizations. The "maps" illustrate clearly the complex reality of terrorist group dynamics and allow analysts to understand how interrelated these organizations are.

How Terrorist Organizations End

For many years research on terrorist organizations concentrated primarily on how they form and their attack patterns; however, recently scholars have devoted more attention to the question of how terrorist organizations decline and ultimately end. Many of these studies focus primarily on articulating and evaluating typologies of reasons for decline among terrorist organizations (Alterman 1999; Crenshaw 1991; Cronin 2009; Ross and Gurr 1989). In addition, several scholars have used statistical analysis of terrorist organizations and terrorist attacks to help understand patterns of decline (Blomberg et al. 2010; Jones and Libicki 2009; Miller 2012).

The proposed typologies include a range of factors, such as success or achievement of goals, perhaps coinciding with a transition to the legitimate political process; loss of popular support; and repression by the state. Various frameworks share in common the contention that organizational desistance from terrorism results from both internal influences (e.g., organizational breakdown) and external influences (e.g., military intervention) and likely results from several factors operating simultaneously. Scholars also observe that an effective strategy for countering one terrorist organization might have unintended negative consequences for countering another terrorist organization, depending on various factors. For example, killing or capturing a key leader of a group may lead to its decline or its resurgence, depending on the group's organizational structure.

Statistical analysis of how terrorist organizations decline and end has been growing increasingly sophisticated and accountable to the complexities of terrorist organizations. The first large-N quantitative analysis of how terrorist groups end classified 648 groups as either active or inactive and then described the reason for decline among those groups that had ended (Jones and Libicki 2009). Although groundbreaking, this strategy oversimplifies both the status of terrorist organizations and the factors that impact decline. Subsequent efforts have improved upon the analysis by using statistical tools like duration modeling which accounts for the entire length of an organization's life span (Blomberg et al. 2010) and group-based trajectory analysis which accounts for the organization's level of activity across its life span (Miller 2012).

General findings from this body of research suggest that the effectiveness of counterterrorism policies remains largely untested with respect to the goal of bringing about organizational decline. Reasons for decline appear to be varied and politicization and suppression are equally common. The cause and rate of decline may be influenced by key characteristics of the group, such as ideology, size, organizational structure, or attack patterns. It is important to note that these findings are not yet robust enough to fully account for the complex evolution of organizations within a broader movement as discussed above. Rather than signifying the death of a terrorist organization, cessation of activity under a particular group name may indicate organizational splintering, merging, or simply a change of name. Future research on the decline of terrorist organizations must take into account a realistic appreciation for the complex and vague boundaries between groups.

Conclusion

The fact that terrorist attacks are frequently planned and executed by groups and organizations presents important challenges to understanding both terrorism and counterterrorism. The task of identifying terrorist organizations is subject to numerous influences and interests, leading various sources of data to produce widely divergent accounts of the prevalence and activity of terrorist organizations. A number of useful data sources exist, however, including in-depth case studies on particular groups, narrative profiles or structured data on a wider range of groups, or incident-level data that can be aggregated to provide details of organizations' activity. Each of these has strengths and limitations but contributes an important perspective to the landscape of knowledge about terrorist organizations. From these sources of information, we know that terrorist organizations are extremely diverse with respect to many dimensions such as lethality, tactics, targeting practices, ideology, and organizational evolution. Existing research reveals complex relationships between terrorist organizations that analysts must take into account in order to fully understand patterns of terrorist activity.

Overview

Theft at construction sites is recognized as a concern by the United States as well as many other countries around the world. Estimates from the United States indicate that between one and four billion dollars worth of materials, tools, as well as large and small equipment are stolen every year. This type of crime occurs at a number of different places including individual house construction sites, subdivisions of homes, larger multifamily sites, and commercial sites; however, there are a number of factors that contribute to opportunities for these crimes that result in their concentration at construction sites and the areas around them. This entry reviews the theoretical foundation and current research literature that seeks to explain why crime occurs at construction sites, the factors that contribute to these crimes, and ends with a discussion of the next steps in understanding this specialized crime type.

Introduction

Some crimes have the potential to occur throughout much of the environment. For others, opportunities are less ubiquitous. Construction site theft is recognized as a concern by the United States as well as many other places around the world such as Canada, Australia, Europe, and Japan (Berg and Hinze 2005; Lambertson 2005). Estimates from the United States indicate that between one and four billion dollars worth of materials, tools, as well as large and small equipment are stolen every year (Berg and Hinze 2005; Lambertson 2005). The wide range of these estimates is attributed to the lack of reporting to both police and insurance by builders and contractors (Lambertson 2005).

In addition to property losses, there are indirect costs that are often not quantified but are important as they show the overall impact of construction site theft. They include, among others, job delays, downtime for operators, higher insurance premiums, and possible cancellation of insurance (Berg and Hinze 2005). The impact of these losses is often not borne by the construction companies themselves, but the costs are passed on to the home buyer with an average of a 1–2 % increase in the cost of a new home (Patton and Oleck 2005).

This type of crime is specific to the nature of the place where it occurs (i.e., the construction site) and may not be present in a community on a continual basis (i.e., may be seasonal or appear every few years when there is a construction boom). However, because it can be a significant problem and impacts nearly every community at some point, it is important to understand the nature of the crime and particularly how it concentrates by place. Thus, this entry reviews the crime and place theoretical foundation and the current research and practice of construction site theft to identify the specific factors that facilitate this specialized crime.

State of the Art: Crime Concentration at Construction Sites

There are a number of reasons why construction sites are vulnerable to theft. Opportunity theories offer a lens through which to consider how the ecology of an environment affects the likelihood of crime occurrence. They shift the attention from seeking to understand the individual criminal motivation of offenders to understanding how the convergence in time and space of an already motivated offender with a suitable target absence of a capable guardian (Cohen and Felson 1979) might affect the probability of a crime taking place.

In terms of construction site theft, *guardians* are people who have the ability to protect movable property of buildings by watching over them, such as construction workers, residents living nearby, and business or other people in the area. *Handlers* are people who know potential offenders and are in positions that allow them to monitor and/or control potential offenders' actions. Depending on who offenders of construction crime are, the people might be construction site supervisors (for offenders who work on site) to parents (of juvenile offenders living near the construction site), among others. Place *managers* are those who are responsible for the construction sites, such as construction site supervisors or the owners of construction companies. These people set rules and employ practices that can encourage or discourage crime, so that the rules, how they are enforced, and the physical environment of the place all affect the crime opportunities. An important aspect of the effect of guardians, handlers, and managers is that they have the ability to *both* discourage or reduce opportunities as well as encourage or increase the opportunities for crime.

Consequently, the nature of the construction site environment is an important factor in understanding patterns of construction theft because often it is something about the place, not the offenders or the victims that best explain crime (Eck et al. 2007). However, even though some practical research has found that there is not direct repeat victimization at construction site locations (Boba and Santos 2007), we know more generally from research that crime is not randomly distributed across the geographic landscape, but rather, it is concentrated in space and also by type of place (Sherman et al. 1989).

The following sections break down specific factors that may contribute to theft at construction sites and how they are generated in terms of the nature of the construction site environment, the influence of place management practices of construction companies, the timing of crimes committed at these types of places, the nature of construction site theft offenders, as well as repeat victimization at and goods stolen taken from construction sites. The factors are derived from theoretical components discussed above as well as from research results which, unfortunately, are somewhat limited. However, the factors indicate that opportunity and the nature of the place plays a significant role in construction site theft.

Nature of the Place

A characteristic of construction sites that make them an environment different than most places where crime occurs is that they are in transition. Clarke and Eck (2005) define open or transitional environments as "areas without consistent or regular designated uses" (Step 15). They note, for example, that these types of places differ from parks that are used for a consistent purpose (i.e., recreation) by many different people even if they have not been specifically designated for such purpose. More specifically, construction sites exist only temporarily as environments where construction occurs and subsequently become residences, businesses, or other types of environments within a reasonably short amount of time. This is a key factor when considering the explanation for crime at these places.

Because of their transitional nature, construction sites are places of interest and curiosity. Those living or working near construction sites may want to examine what type of residence or business is being built near where they spend time. Others simply pass by occasionally or regularly look to see what is being built, and may even stop and walk through a site. Many of those interested likely visit the sites multiple times to see the "work in progress" and what new changes have been made since their last visit. Eventually, this curiosity may become tempting for some which may after repeated visits provoke those individuals to trespass and take property that has been left unprotected.

For example, an individual living near a residential construction site is curious about the site and begins by simply walking through the site when no one is around to see what type of house is being built, the layout, design, etc. During this first visit, the individual may notice several unused boxes of ceramic floor tile on the site. As the construction continues, the same individual visits again to check on its progress and changes to the home, and notices the same floor tile has not been used, but the floors are nearly complete. In a final visit after several days of thinking about it, the individual goes to the site one last time in the evening when no one is around with a vehicle and loads several, not all, of the unused boxes of tile and takes them home. In this case, the curiosity leads to the identification of an opportunity which in the end was too tempting for the individual to pass up, especially since the opportunity was nearby, the site was semi-private, there was minimal guardianship and no clear ownership, and the property itself was easy to take.

Another characteristic of the construction site environment is that they are places with a large number of transient employees; that is, people who conduct work for a short period of time on the site and then move on. If security is lacking and management indifferent, the temptation for these employees to take items that are improperly secured or unaccountable may be too much to resist (Fennelly 1996). For example, a construction worker who freelances for different companies and is in need of building supplies for a new job and/or newer tools and equipment may decided to take the property from a site he is working on for a day or two.

For all places, the physical environment impacts the amount of opportunities for crime (Felson and Clarke 1998). Studies of residential burglars find that burglars consider occupancy cues (e.g., presence of cars, visible residents, and noise/voices), surveillability cues (e.g., can neighbors see them), and accessibility cues (e.g., how well is the site protected with doors, fences, and locks) (Cromwell et al. 2002; White 1990). Nearly all the cues that would prevent an offender from committing a crime are lacking at construction sites (e.g., lack of neighbors, inability to lock buildings).

Additionally, research has shown that crime is more concentrated in areas with physical disorder, such as abandoned buildings, broken streetlights, junk-filled and unmowed vacant lots, litter, graffiti, and the visible consequences of vandalism (Skogan 1990) because it indicates to potential offenders that residents have little attachment to their neighborhood, symbolizing to offenders a lack of capable place guardianship. Construction sites are locations that, by the mere nature of their existence, are in physical disarray. With so many different types of work being conducted on a site (e.g., building construction, electrical wiring, plumbing, finishing) by different contractors for different periods of time, construction materials (e.g., lumber, dry wall, pipes) are often lying around because they are delivered and sit on the site for a time before installation. Even after work has been done, there can be a significant amount of scraps and other materials that appear as trash but could be, in fact, valuable.

Place Management

Another key characteristic of construction site environments is the fact that various contractors, sub-contractors, and even sub-sub-contractors often come and go from the site and have minimal concern for the appearance and well being of the site. As Newman (1972) asserts, defensible space is a place that allows inhabitants or users of the space to become key agents in ensuring its security. On a construction site, there is not always a clear feeling of ownership; that is, the construction company is not the true owner of the land or what is being built, but is temporarily overseeing it during the construction process. Therefore, it may also not be clear who is responsible for protecting the site and its materials from theft. For example, there are cases in which the builders have required homeowners to purchase insurance to cover any theft or damage that occurs during the home construction period, before they even own the home (Boba and Santos 2007).

Because construction sites are transitional, the different stages of construction, such as clearing the lot, laying a foundation, installing the roof, installing doors and windows making the building lockable, create different stages of opportunity for theft. Different materials are necessary and vulnerable at different times. In addition, the speed of construction can affect the amount of time the construction site is at risk. That is, the less time the construction takes, the less opportunity for theft since the property is vulnerable for shorter periods of time.

Additionally, construction sites are not yet occupied by residents or employees, so they lack the guardianship an inhabited home or office building would provide. Some sites may be isolated from view by being set back from the road, on large lots, or next to nonresidential land (e.g., parks, waterways, wooded areas), which reduces the chance that neighbors or passersby will see or hear a thief. Finally, construction sites may not have fencing or other mechanisms to protect the location from trespassers. Property left on the site is often left unprotected lying on the ground, in open garages, or in a partially constructed, unsecurable buildings. Some property, such as air conditioning units, can be vulnerable even when it is installed because it is located outside the building, virtually unprotected.

Productivity is a key component of the construction business (Lambertson 2005), and the management practices that maximize productivity may also maximize opportunities for crime. For example, delivering appliances or other materials several days or weeks before installation ensures that there is no delay once installers are there; however, this practice increases the time and opportunity for theft, especially in a building or a site that is not secured. Another example is a lax policy of tracking tools. Builders and contractors save time by not checking them in and out daily, but lack of control and oversight may give employees the perception the builders do not care if they are taken and decrease their perceptions of being caught (Berg and Hinze 2005). Finally, many builders see theft as a cost of business (i.e., trust luck and swallow any losses) (Clarke and Goldstein 2002) and cover their losses by simply increasing the price of a home or incorporating it into the price of a construction bid. Thus, there is little incentive for improving their practices.

Timing of Construction Site Theft

Unlike residential and commercial burglaries, there is little research that indicates when construction site theft predominantly occurs. Opportunities for theft at construction sites indicate that thefts could occur any time of day because of the lack guardianship and the large number of workers that frequent a site. In addition, because there are typically no witnesses to construction site theft, the exact time of occurrence is difficult to determine. However, one study found from interviewing several CEO’s and managers of construction companies that they believed the majority of thefts occurred during the day in the late afternoon hours after the site manager had visited the construction site the last time for the day (Boba and Santos 2007).

The stage of building when a construction site theft occurs may be more important than the time of day it occurs. For example, logic tells us that the most vulnerable time for theft at a single-family home construction site may be between when the house is securable (i.e., has windows and doors that are lockable) and when the home is handed over to the resident since a large number of desirable types of property (e.g., washers, dryers, refrigerators, heating and cooling units, etc.) are in the home. Construction also can vary by area of the country, by national and local economics, and by weather which may cause crime at these locations to also vary.

Nature of Construction Site Theft Offenders

Research on burglars in general indicates that they engage in crime because of the desire for money, the ease of the crime, and influence of others (Piquero and Rengert 1999). They do not tend to think about the consequences of their actions, or they believe there is little to no chance of getting caught. They often know their victims, who may include casual acquaintances, neighborhood residents, people for whom they have provided a service, or friends or relatives of close friends. Although very little research has been done on construction site thieves, researchers group them into three categories in order to understand the motivations and opportunities they exploit (Boba and Santos 2007, 2008; Clarke and Goldstein 2002).

Amateur opportunists are offenders who live near or travel near construction sites, see movable property on the site, and take it based on an immediate assessment of rewards and risks. They do not necessarily plan their crimes and tend to seize the opportunity at hand. However, they may also take property after seeing it unprotected for a long period of time since they may drive by or live near the construction site. These offenders might be more likely to take smaller, generic materials and tools at times when workers are not present. The example previously mentioned of the neighbor taking the box of tile is an example of this type of offender.

Professional thieves are offenders who make a living at theft and selling high dollar stolen goods. They spend time planning their crimes and tend to have intricate knowledge of the environment and areas where the crimes are committed because the reward is very high. For example, Boise law enforcement agencies arrested two men and recovered $750,000 worth of material and equipment stolen over 7 months, including tractors, trailers, generators, and power units (Anderson 1999). In another case, a Detroit man had rented lockers to store a large amount of stolen property and had nearly 200 thieves working for him, even filling orders (Bouffard 2004). Unfortunately, there is no research on the nature of professional construction thieves to know how they differ from professional thieves of other crimes or why and how they commit crimes in this environment.

Insiders are a third type of offender who are or work for builders and contractors or rival companies. They are called “insiders” either because they have knowledge of a specific builder’s construction practices and access to keys, tools, and materials, or they have more general knowledge of construction practices, such as how to disassemble an air conditioning unit and handler and what stage of building appliances or other desirable items are typically delivered and installed. Research shows that generally, a high percentage of employee thefts begin with opportunities that are regularly presented to them, which is similar to the example given about the amateur opportunist (Fennelly 1996). The inside knowledge and the benefits of acquiring materials and tools for free make these crimes very rewarding for these types of offenders. The type of offender that falls into this category of “insiders” appears in some research to be the most prevalent of the three. In Boba and Santos (2007), interviews with builders reveal that they believe that employee or “insider” theft was a significant problem. The same study found that the nature of the crimes, the type of property taken also indicated the prevalence of insider offenders.

Repeat Victimization and Goods Stolen

Repeat victimization is an important consideration because it indicates systematic patterns of opportunity that exist for a particular type of crime and identifying when repeat victimization is occurring assists in prioritizing crime prevention efforts (Farrell and Pease 1993). For example, one of the biggest predictors of residential burglary is whether the home has been burglarized in the past (Farrell and Pease 1993).

However, repeat victimization for construction site theft does not seem to be as obvious as it is for other types of crime because construction sites are transitional places. First, victimization may be difficult to determine since the place starts as a construction site but eventually becomes a residence, business, or other type of place which means the systematic opportunities that are the basis for identifying repeat victimization also change. Furthermore, the change of the place from one type of environment to another makes the crimes themselves hard to aggregate and count since they will be coded as different crimes (e.g., construction site theft, residential burglary, commercial burglary).

In examining repeat victimization of construction site theft, researchers have found it is more fruitful to focus on aggregating crime by individual builders or type of property rather than by individual place (Boba and Santos 2007). For example, a comprehensive study in Port St. Lucie, FL found that only 12 of 254 individual sites were burglarized twice within 1 year but that 20 % of the builders were named victims for nearly 70 % of the burglaries (Boba and Santos 2007). This implies that repeat victimization is explained by the general practices and policies of a particular builder, such as systematic delivery lag times, use of fencing, and storage of materials, rather than the specific opportunities present at a specific construction site. Repeat victimization might also be explained considering virtual repeats (Pease 1998), which are places that are virtually identical, although not necessarily close, to one another, because they share some of the same physical characteristics as well as place management practices. Examples are electronics retail stores with similar store layouts and materials used or residential homes that are designed and built by the same builder.

In terms of goods stolen, property taken in construction site theft is rarely recovered (Berg and Hinze 2005). Property types that are stolen include building materials such as drywall, plywood, and studs; appliances, such as refrigerators, ovens, air conditioners; construction equipment and tools, such as drills, saws, generators, cement mixers; pool equipment; internal cosmetic materials such as carpet, toilets, sinks, ceramic tile, and other flooring; as well as other property (Anderson 1999; Berg and Hinze 2005; Boba and Santos 2007; Clarke and Goldstein 2002). Yet, the type of goods that are taken may indicate the motivations of the offender. Amateur opportunists may take generic building materials they need to repair or use in their own homes, such as drywall, lumber, or ladders. Professional thieves may take property they know they can sell in an unregulated second-hand market (e.g., the Internet), such as appliances ceramic tiles, faucets, toilets, doors, and windows (Bradley 2005). Insiders may be more likely to take materials, tools, and small equipment they have access to on a regular basis or items that take some skill or effort to remove.

Related to the discussion of “insiders,” the high cost of construction materials induces some people to steal materials from construction sites in order to reduce their own building costs. In recent years, there has been a dramatic increase in the price of construction materials. For example, from January 2003 to May 2004, the price index of 11 key construction materials more than doubled (Bradley 2005; Bouffard 2004; Scarcella 2005) and the price of precious metals, such as copper, fluctuates as well. Increases such as these create incentive for contractors as well as individuals to take materials from construction sites to save money themselves or trade the materials for cash (Sidebottom et al. 2011).

Controversies and Key Issues

There are a number of considerations that make it difficult to conclude generally about the nature of thefts at construction sites. First, patterns of victimization are difficult to determine because of data coding. Because construction sites are transitional and become commercial, residential or other types of places, crimes that occur at different stages of development are coded differently, thus are difficult to aggregate. Even something as simple as searching all crimes at a particular address may be difficult for construction sites as many sites may not have addresses when the crimes occur or their addresses may change once construction is complete. Second, in general, thieves are rarely caught (FBI 2011) and even though rates for construction theft are not recorded nationally, those taking from construction sites seem to be caught even less often (Boba and Santos 2007) making it difficult to understand who the offenders are and why they are committing these crimes. Third, the business of construction varies significantly by area of the country, by national and local economics, and by weather; therefore, construction site theft might also vary by these factors.

In addition to these concerns, there are a number of questions that still need to be answered in more detail to further the understanding of theft at construction sites. They include, but are not limited to:

- How do levels of crime vary by type of construction location (e.g., single family residential, multi-family residential, commercial, retail, public roadways)?
- How do levels of crime compare to other types of public sites (e.g. parks, universities or hospitals)?
- Are the "professional" thieves specialized and focus only on construction sites or are they "professional" offenders for other types of crime as well?
- How do current crime recording practices affect the evidence that we have about this crime and how can they be improved?
- Are construction sites that cluster spatially and are of a specific type (e.g., bars, homes, industrial) at a higher risk for crime?
- What is the rate of "virtual" repeat victimization of theft at construction sites?

Conclusion

Bringing together the previous discussion of the nature of construction site theft and the opportunities for this crime to occur, several key conclusions can be deduced from the theory and research results. The first is that the mere nature of a construction site and the use of the area and the area surrounding the construction site is typically in disarray, is in transition, and appears to have no owner. All of these characteristics are relatively unique to crime place and are significant contributors to increased opportunities for any type of crime at construction sites. In addition, construction sites themselves are typically concentrated spatially, especially when they are managed by the same construction company, thus it follows that the crime would also be spatially concentrated.

Secondly, place management practices are likely the most important factors in understanding and subsequently preventing theft at construction sites. Theory indicates and research shows that practices for securing property and equipment, managing employees and subcontractors, and providing guardianship for sites (e.g., security) have a significant impact on which sites are more vulnerable than others. Typically, these place management practices vary by builder/construction company rather than by individual construction site, which is supported by research that shows that repeat victimization tends to occur, not by individual address or area, but by individual builder.

Finally, there are several types of offenders that find construction sites appealing based on the fact that the construction sites are places of interest and employment (e.g., amateur opportunists and insiders) or are targeted because of the availability of high dollar items (e.g., professional thieves). The most prevalent type of offender seems to be the insider because they have the most knowledge of management practices and activity space, the most direct motivation for committing these crimes, and, therefore, have the most opportunities to commit the crimes.

Theories for Situational and Environmental Crime Prevention

Richard Wortley and Nick Tilley

Crime Science, University College London,
London, UK

Overview

The situational and environmental perspective in criminology refers to a collection of theories and approaches that focus on the role that immediate circumstances play in producing criminal acts. This contrasts with criminology's more usual preoccupation with what creates offenders' criminality: depending on the disciplinary orientation, the disposition to commit crime is accounted for by genetic makeup, developmental experiences, or current social, cultural, and economic conditions. Correspondingly, the usual solution to any crime problem is deemed to require altering these long-term and systemic causes of criminality, for example, by investing in early intervention with at-risk families, increasing educational opportunities, removing social and economic disadvantage, or providing treatments for known offenders.

Situational and environmental perspectives, on the other hand, focus instead on the dynamics surrounding crime events. Attention shifts from distal causes of criminality to proximal factors that enable and encourage specific crimes. Individuals highly disposed to commit crime do not do so all of the time. Moreover, many of those lacking any particular criminal disposition will occasionally commit crimes and account for a high proportion of all crimes. Even those individuals determined to commit crime can only do so when there is opportunity, while some situations can induce ordinarily law-abiding individuals to commit crimes that would not otherwise have been committed. Whether crimes occur in any given location or at any given time depends upon the conduciveness of the conditions there. The prevention of crime, therefore, is conceptualized in terms of altering the criminogenic aspects of the immediate situations most liable to produce crime.

This entry presents the key theories underpinning situational and environmental crime prevention. These are of two broad sorts. One set addresses the situational basis of criminal behavior. The other examines the patterning of crime in time and space according to the distribution of criminogenic environments.

Situational Models of the Offender

While situational and environmental perspectives are concerned with crime events rather than with criminality, in order to understand the role played by the immediate environment in crime, we must begin with a coherent model of the offender that explains how his or her behavior is influenced by momentary contexts. That all behavior occurs as a function of a person-situation interaction has become a commonplace principle of much social science (Mischel 1968). Behavior can be highly variable from one situation to the next; how an individual acts is shaped by where he or she is and with whom he or she is interacting. The mechanics of the person-situation interaction have been explained by numerous theories. As for the application of the person-situation interaction to crime, two main approaches have been taken. The first approach is to view offenders as rational, utility-maximizing actors whose choices are informed by available criminal opportunities and how they perceive them; the second approach is to view the offender as a respondent to situational pressures and provocations, which sometimes positively encourage crime.

Rational Choice

In 1967 Ron Clarke published a research paper on absconding from a residential school for juvenile delinquents (Clarke 1967). He noted that the best predictors of absconding were aspects of the environment – hours of daylight, features of the school's regime, and the distance home – and not any individual factors associated with the absconders. These and similar findings ultimately led Clarke to conclude that opportunity was a central and neglected cause of crime (Mayhew et al. 1976). In order to explain how opportunity leads to crime, Clarke and Cornish (1985) reviewed a wide range of research from sociology, criminology, economics, and cognitive psychology examining the variability of criminal behavior across situations. From the array of perspectives reviewed, they settled on a rational choice model as their preferred way to account for the mechanisms through which opportunity leads to deviant behavior.

The basic premise of the rational choice perspective on crime is that individuals make cost-benefit assessments of their situations in deciding whether or not it is in their interests to offend. Criminogenic environments are those that offer ample opportunities for prospective offenders: where they can expect the benefits from committing a crime to outweigh the costs of doing so. Situational crime prevention involves altering such criminogenic environments in ways that will lead prospective offenders to conclude that the expected costs of offending outweigh expected benefits. Note that while the label "rational choice theory" is frequently used in the literature, Cornish and Clarke have generally eschewed the term "theory," preferring instead "model" or "perspective" (see Cornish and Clarke 2008). They present rational choice as a heuristic that provides a framework for practitioners seeking to implement situational crime prevention. For this purpose it's a "good enough theory."

Underpinning the rational choice perspective is a view of offenders, like all others, as goal-driven, rational agents (Cornish and Clarke 2008). People commit crime for the purpose of deriving some benefit. These benefits are not restricted to the obvious economic ones that accompany property crimes. Offenders can also commit crimes because doing so is exciting, because it gives them a sense of power, because their friends will approve, because they receive sexual gratification, and so on. The costs and benefits attached to crime vary from one crime to another and also vary within crime types. The reasons for committing rape are very different from the reasons for committing car theft. Likewise, the goals of a professional car thief are different from the goals of a joyrider. Furthermore, the goals pursued by offenders – money, sexual gratification, and excitement – are universal motivators, even if the means by which they pursue these goals are illegal. When viewed from the offender's perspective, the decision to commit crime is rational and represents the most effective strategy for achieving his or her goals at that moment.

Critics have challenged the presumption of offender rationality that underpins the rational choice perspective, arguing that many of the choices made by offenders do not result in benefits and may be ultimately self-defeating (e.g., leading to imprisonment). A related criticism of the rational choice perspective is that it cannot explain so-called expressive crimes that appear to be spontaneous, associated with psychological disorder or committed when the offender is in a state of emotional arousal. Cornish and Clarke acknowledged that offender rationality is not perfect. Borrowing from the work of Simon (1957), they describe offender rationality as "bounded." The concept of bounded rationality recognizes that there are limits on the offender's capacity to make rational decisions. Rationality may be limited by cognitive biases, lack of information, time pressures, emotional arousal, drugs or alcohol, individual values, and a range of other factors. The utility of an anticipated outcome, therefore, is not necessarily consciously or accurately worked out when someone commits a given crime. Even crimes carried out in the heat of the moment, however, or which are the product of psychological disorder, are committed for a purpose. Offender decisions may be suboptimal, but they are "satisficing" – satisfactory and sufficient to meet the offender's immediate needs (Cornish and Clarke 2008).

Although at first sight rational choice approaches may seem to imply that offenders systematically weigh up the options each time they are about to act, few rational choice proponents believe this to be the case. As people become practiced in a behavior, the thought processes surrounding that behavior become automatic and take place below the level of conscious awareness. A common example is driving. When people first learn to drive, they focus on every aspect of the task; with practice they can drive "without thinking" as if on autopilot. (Every driver will have had the experience of reaching their destination and realizing that they have little or no recollection of the journey just completed.) So too offenders learn with practice to commit crimes without going through a laborious decision-making exercise, but proceed on the basis of "standing decisions" (Clarke and Cornish 1985). Experienced burglars, for example, make much more rapid and efficient judgements about suitable burglary targets than do inexperienced burglars (Garcia-Retamero and Dhami 2009). They may even use terms such as "instinctive," "automatic," "routine." and "second nature" when they describe how they go about committing their crimes (Nee and Meenaghan 2006).

As the above discussion of standing decisions suggests, many criminal events are not confined to single points in time but involve a sequence of stages and decisions and may extend over a prolonged period of time (Cornish and Clarke 1985, 2008). Throughout the crime commission process, the offender must make many choices as the offense unfolds. Cornish (1994) developed the concept of crime scripts to help elaborate the stages that comprise the criminal event. Crime scripts are "step-by-step accounts of the procedures used by offenders to commit particular crime" (Cornish 1994, p. 31). They are templates of the required elements of an offense and may include associated activities that occur both before and after the commission of the crime. By way of illustration, to commit a burglary a burglar will typically (1) research likely targets and assemble the necessary tools, (2) drive to the target suburb, (3) drive around the suburb, (4) scan houses for a likely target, (5) approach a likely target to check for occupancy, (6) break in and search for goods, (7) select and steal the goods, (8) load up the goods and departs, (9) avoid attracting attention, (10) leave the target suburb, and (11) store or sell the goods (Cornish and Clarke 2008). Breaking the criminal event down in this way helps identify "pinch points" for intervention. For example, prevention of burglary may include improving household security (step 4), introducing neighborhood watch (step 9), and clamping down on pawnshops that accept stolen goods (step 11).

Crime Precipitators

As Clarke and Cornish (1985) recognized when they first proposed the rational choice perspective, there are many different ways to account for the role situations play in behavior. Decision-making models such as rational choice assume that the prospective offender enters the crime scene already motivated to offend; the emphasis in these models is on the role played by the actual and perceived consequences of criminal behavior. Other explanations of the person-situation interaction, however, examine aspects of immediate environment that create or intensify the offender's motivation to offend; the emphasis in these approaches is on the antecedents of behavior. More than just enabling crime to occur (i.e., through providing opportunities), some environmental conditions may actively precipitate criminal events. The various psychological mechanisms that have been proposed in the literature to account for the precipitating effects of situations on behavior can be collected into four categories – prompts, pressures, permissions, and provocations (Wortley 2001, 2008).

Prompts refer to environment features that bring to the surface thoughts, feelings, and desires that may be lying dormant. Prompts jog people's memories, stimulate them, tempt them, evoke moods, and provide examples for people to follow. The primary theoretical underpinning for prompts is learning theory, which holds that for behavior to be produced on any given occasion, it needs to be evoked by an appropriate environmental stimulus. Hence, Pavlov's dogs did not salivate randomly but only when a bell was rung. Alternatively, prompts may be explained by the concept of priming – the capacity of environmental stimuli to facilitate retrieval of information stored in memory – described in cognitive psychology. Applying the principle of prompting to crime, the immediate environment may trigger the impulse to engage in criminal acts. For example, it has been shown that increased levels of aggression follow exposure to a range of violence-related stimuli including guns, knives, Ku Klux Klan clothing, aggressive verbalizations, vengeance-themed bumper stickers, aggressive films, and boxing films (Carlson et al. 1990).

Pressures refer to the effects that the presence of others has on an individual's behavior and are examined in social psychology. Human beings are social animals, and a great deal of social behavior is influenced by the demands and expectations of other members of the species. Social pressures include the tendency for individuals to conform to group expectations, to obey the instructions of authority figures, to submerge their identities in a crowd, and to try to please significant others. Under certain conditions, these social influences can allow good people to do bad things, a phenomenon that Zimbardo (2007) has been labelled the Lucifer Effect. Zimbardo, famous for the Stanford prison experiment (Haney et al. 1973), applied these social influences to explain the abuses of power that occurred at Abu Ghraib prison in Iraq in 2003, where US soldiers guarding the prison punched, sexually abused, urinated on, threatened, and tortured detainees. Zimbardo argued that the behavior of the soldiers could not be understood in terms of individual pathology, but as a consequence of the social dynamics of the prison that promoted a mob mentality.

Permissions refer to the neutralizations that offenders invoke to excuse their crimes (Bandura 1977; Sykes and Matza 1957). Offenders may deny the essential wrongness of their actions ("It is nothing compared with the things politicians get away with"), minimize their personal accountability ("I lost control and couldn't help myself"), deny causing any harm ("The shop was insured"), and minimize the worthiness of the victim ("She was just a whore"). Neutralizations can be facilitated by situational conditions that help obscure the relationship between the offender's behavior and its negative outcome. For example, Bandura (1977) argued that the division of labor within organizations facilitates corruption by allowing individuals to hide behind a collective responsibility ("I was just doing my job"). One of the common defenses of Nazi prisoners at the Nuremberg trials was that while they might have played a role in the deportation of Jews to the concentration camps, they were not personally responsible for any deaths.

Provocations refer to aspects of the immediate environment that induce emotional arousal and so facilitate aggression. Aversive arousal-inducing experiences include being thwarted, constrained, frustrated, insulted, threatened, annoyed, overwhelmed, crowded, and discomforted. Physiological arousal prepares the individual for a flight-or-fight response as means of managing or adapting to noxious conditions and events. In a series of studies Homel and colleagues (Homel and Clark 1994; Homel et al. 1997; Macintyre and Homel 1997) examined the relationship between violence in licensed premises (bars and nightclubs) and aggravating features of those premises. Violence was associated with a range of environmental irritants including overcrowding, the amount of cigarette smoke, poor lighting, lack of ventilation, aggressive security staff, and poor floor plans that promoted jostling as patrons tried to buy drinks.

The notion of precipitation is not proposed as a rival to rational choice but as a complementary process. Both precipitation and rational choice may play a part of every crime, but the relative importance of each may vary from crime to crime and from individual to individual. To capture the respective contributions of precipitation and rational choice, Cornish and Clarke (2003) put forward an offender typology comprising three types – antisocial predators, mundane offenders, and provoked offenders.

Antisocial predators are stereotypical, calculating criminals. They actively seek out or create criminal opportunities and enter the crime scene with preexisting motivation to commit the crime. They utilize situational data to weigh up the relative costs and benefits of criminal action, and as such their behaviors may be largely accounted for by rational choice. Mundane offenders vacillate in their criminal commitment and are opportunistic in their offending. They have generalized impulse-control weaknesses, committing their crimes with minimal planning and forethought. Like predatory offenders, they seek to derive benefits from their crimes. However, they are easily tempted into crime and may use neutralizations to help them ease any lingering feelings of guilt they may be experiencing. Provoked offenders are reacting to a particular set of environmental circumstances – situational frustrations, irritations, social pressures, and the like – that induce them to commit crimes they would not have otherwise committed. They may have conventional value systems and lead otherwise law-abiding lives. Their involvement in crime may represent an aberration and would not have occurred if it were not for the precipitating events.

As with all typologies, the categories should not be viewed as hard and fast. The offender types may be more appropriately regarded as *offending* types, and an individual offender may commit crimes across all three types. In particular, antisocial predators are versatile and prolific offenders and are likely to also commit opportunistic and provoked crimes as the situation arises (Wortley 2012).

Crime Patterns

It is a fundamental principle of the situational and environmental perspective that crimes do not occur randomly. Because crime is dependent upon criminogenic situations, it is patterned in time and space according to the distribution of those criminogenic situations. Nightclub violence, for example, will invariably be concentrated in a relatively small number of premises and will peak on certain days of the week (usually the weekend) and at certain times of the day (usually in the early morning as patrons leave) (Graham and Homel 2008). Crime hotspots are the logical places to direct policing and crime prevention resources. Thus, the set of theories that is examined in this section is concerned with explaining spatial and temporal crime patterns that follow the assumption that situations are crucial to the production of criminal acts. Two approaches are examined – routine activities and crime pattern theory.

Routine Activities Approach

At the heart of Cohen and Felson's (1979) routine activity approach lies the most parsimonious account possible of the crime event. Direct contact predatory crime events require the coincidence in time and space of three minimal elements: "(1) motivated offenders, (2) suitable targets, and (3) the absence of capable guardians against a violation" (p. 589). For example, a residential burglary occurs when a motivated burglar encounters an unguarded premise that contains desirable products. If any one of the three elements is absent – a motivated offender does not pass by the house, the property is guarded, or it contains nothing of value – then burglary will not occur. The routine activities account makes no assumptions about the psychological history or attributes of the offender beyond the fact that he or she is motivated to commit crime. In fact, in later writings, Felson (e.g., 2008) substituted "likely offender" for "motivated offender."

For such a deceptively simple idea, the routine activities approach has important implications for the distribution of crime. Cohen and Felson argued that the convergence of likely offenders, suitable targets, and unguarded locations is dictated by the natural rhythms of everyday life that produce predictable crime patterns. They set about demonstrating their thesis by examining crime rates after World War II. They noted an apparent paradox in the data – crime rates after the War rose substantially at the same time that economic conditions improved dramatically. This finding defies conventional criminological theory that predicts that crime increases with poverty. Cohen and Felson argued that higher crime rates could be explained by the changes in the routine activities of the population that accompanied economic prosperity. As economic conditions improved, the three necessary conditions for crime were often brought into alignment. Consider the case of burglary. Growing affluence and technological advances meant that there were more compact, valuable personal possessions available to steal in the average home (suitable targets). At the same time, as women increasingly took up work outside of the home, more houses were left unattended during the day (absence of capable guardians). These changes altered the behavior of likely offenders and resulted in significant shifts in burglary patterns. Between 1960 and 1975 rates of commercial burglary in the United States almost halved, while the rates for domestic burglary doubled as offenders chased the more lucrative pickings in suburban houses. Furthermore, burglary went from being a nighttime to a daytime activity, as offenders targeted the growing numbers of properties that became temporarily empty when women took paid employment outside the home.

There are many examples of crime patterns that can be explained by the respective routine activities of victims and offenders. Young males experience high rates of physical victimization because they have risky lifestyles that involve visiting bars in dangerous districts, staying out late at night, and mixing with other alcohol-affected youths (Jensen and Brownfield 1986). Juvenile violence peaks in the hour or so around the close of school in the afternoon when large numbers of young people – potential offenders and victims – spill into the streets (Snyder et al. 1996). Burglary is more likely to occur when the weather is fine and people are likely to go on excursions away from home (Hipp et al. 2004). As the previously discussed negative association between poverty and burglary demonstrates, an appealing feature of the routine activities approach is its capacity to explain apparently counterintuitive crime patterns. In a further example of this, Felson (2002) cites research showing that young people who have part-time jobs unexpectedly commit *more* crime than those who do not have jobs. As Felson explains, a job allows a young person to fund a relatively risky lifestyle (in terms of crime opportunities) that might include taking illegal drugs, drinking alcohol, visiting shopping malls, and driving his or her own car.

While Cohen and Felson were concerned with the impact of macro-level social forces on patterns of criminal behavior, subsequent theorizing has explored the compatibility of the routine activities approach with the rational choice perspective and situational crime prevention (Clarke and Felson 1993). It was realized that the three necessary elements for crime – an offender, a target, and an absent guardian – provided a framework for analyzing the dynamics of individual crime events and for determining points of intervention for crime prevention. The familiar crime triangle ("hot" offenders, "hot" locations, "hot" targets) used in operational policing has affinities with the routine activities approach (Clarke and Eck 2003). All prevention efforts involve neutralizing one or more of these three elements. Some crimes occur because of the presence of motivated offenders and so intervention involves strategies to divert them from likely trouble spots. Other crimes are the result of poor management of facilities and so require interventions that strengthen guardianship in those locations. And other crimes occur because of the easy accessibility of vulnerable targets and so intervention requires target-hardening strategies.

Crime Pattern Theory

Crime pattern theory was developed by Brantingham and Brantingham (1991, 2008) to account for nonuniformity and nonrandomness in the geographical distribution of criminal events. As with the routine activity approach, crime pattern theory assumes that crime is associated with the everyday movements of offenders and victims in time and space. However, while the routine activity approach emphasizes the supply, distribution, and movement of suitable targets, likely offenders, and capable guardians for explaining crime patterns across space and time, crime pattern theory is concerned specifically with the role played by the urban landscape. According to crime pattern theory, crime is associated with the distribution of key facilities and activities in a community that shape the offender's daily movements and consequent familiarity with his or her environment.

Crime pattern theory explores the role in crime of three key urban elements – nodes, paths, and edges – that individuals encounter and become familiar with in their daily movements. Nodes are locations that an individual regularly visits in the course of his or her routine activities. They include places where a person lives, works or goes to school, shops, and goes to for entertainment and recreation. Paths are the usual routes the person takes to move between nodes. An edge is the boundary between areas of land use, which individuals encounter at the fringe of their nodes and as they traverse paths between their nodes. The most common edge is the dividing line that separates one neighborhood from another.

Together nodes, paths, and edges form an individual's awareness space. Awareness spaces are the parts of the urban environment that the individual knows well and in which he or she feels comfortable. Most people, for example, have a set way that they travel from home to work or school, and they become very familiar with the environment along that path. They may, however, know little about the environment just one or two streets outside of their usual route and feel disoriented if they stay too far from their awareness space.

Crime pattern theory predicts that crime will occur in locations in which crime opportunities intersect with an offender's awareness space. Crime opportunities cluster around certain nodes referred to as crime generators and crime attractors. Crime generators are locations that attract large numbers of people for legitimate, noncriminal activities. They include sports stadiums, shopping malls, and transport hubs. The presence of so many people provides many criminal opportunities (e.g., pickpocketing) for offenders who may happen to be mixed in with the general crowd of patrons. Crime attractors are districts or premises that attract potential offenders for the specific purpose of committing crime. They include certain bars, red light districts, and non-secured parking lots. Offenders frequent these areas to sell or obtain drugs, to fence stolen goods, to pimp for prostitutes, and so on. Crime attractors are particularly likely to be located near freeway exits and public transport hubs, which provide convenient access and escape. Crime generators and attractors are likely hotspots for crime. Edges, too, are often high-crime locations, where strangers come together and offenders can commit crime with little fear that they will be recognized. Edges can also be sites for conflict between those identifying with areas on either side and for graffiti to mark territorial claims (Brantingham and Brantingham 1995).

Crime pattern theory can be used to help explain specific movement patterns of offenders. One such pattern is the so-called journey to crime. A prediction that follows from crime pattern theory is that offenders generally will not travel far from their key personal nodes – their home, work, or school – in order to commit crime. They will prefer to access criminal opportunities that occur within their awareness space, but at a distance that reduces the chance that they will be recognized. This prediction may at first seem counterintuitive – it might be expected that offenders would travel away from their usual haunts in order to search out the most desirable targets and to put a safe distance between themselves and the crime. However, the prediction is also consistent both rational choice perspective and routine activities approach. Going out of one's way to offend requires more effort than committing crimes in locations that are encountered in the course of one's daily routine. Research examining the travel habits of offenders confirms that the frequency of offending decays as a function of the distance the offender is from home. Snook (2004) examined data from 41 serial burglars. He found that the median distance travelled to commit a burglary was 1.7 km and that 85 % of burglaries were committed within five kilometers from the burglar's home. The rate of decay was rapid; 33 % of burglary sites were within one kilometer from home, 25 % between one and two kilometers, and 15 % between 2 and 3 km. Offending not only occurs close to home but also along familiar pathways. Rengert and Wasilchick (1985) examined the direction of burglary sites in relation to the burglar's home. They found that over 75 % of burglary sites were within a 45° arc around the path between the burglar's home and place of work, while 57 % were in a 45° arc around the path between the burglar's home and place of recreation.

Conclusion

A common criticism of the situational and environmental perspective in criminology is that it is atheoretical, naive, and ignores the "root causes" of crime. Prevention efforts based on the situational and environmental perspective are, in turn, often characterized as amounting to little more than a "locks and bolts" approach to reducing crime. The purpose of this entry has been to provide an overview of the theories that underpin situational and environmental prevention. The intention has been to show that human behavior – and hence criminal behavior – is by its very nature situational. All crime involves a complex interplay between the disposition of the offender and the situation he or she is in at the time of the offense. The situational and environmental perspective does not ignore root causes of crime; the immediate environment is a root cause of crime.

The models of offender behavior and the accounts of crime patterns described in this entry provide the bases for situational and environmental crime prevention. There are a number of different approaches taken to prevention, but all are based on the basic premise that altering some aspect of the immediate crime environment has the potential to disrupt crime. Crime Prevention Through Environmental Design (CPTED) is one of the earliest formal models of situational/environmental crime prevention. Its focus is on the role that architecture and urban design play in crime and crime reduction. Situational crime prevention (SCP) presents a microanalytic approach to crime reduction. Its focus is on identifying and altering the specific elements of the crime scene that permit or encourage specific crimes to occur. Design against crime (DAC) examines the implications of the situational and environmental perspective for the design of products and systems. It explores the premise that some products encourage crime and that these criminogenic features may be designed out at the production stage. Crime science is the newest model in the situational and environmental perspective. Crime scientists argue that crime prevention initiatives need to be based around the scientific method. They also argue that the crime prevention task should be viewed in truly multidisciplinary terms and take in contributions of "hard" scientists – mathematicians, engineers, computer scientists, and so on – as well as social scientists.

Theories of Co-offending

Frank M. Weerman
Netherlands Institute for the Study of Crime and Law Enforcement (NCSR), Amsterdam,
The Netherlands

Overview

This entry is focused on theories and theorizing about co-offending. This includes explaining why people co-offend in the first place, how co-offenders find each other and initiate their crimes, and how co-offending may have consequences for offenders and offending rates. The entry starts by outlining three general approaches in the field. After that, a small number of "Theories of co-offending" are addressed in more detail—elaborated theoretical publications about understanding the causes of co-offending or certain aspects of it. Finally, a number of other theoretical issues are addressed, which have received quite some attention in the field. Following each of these issues, a short outline is provided for the remaining questions that are still in need of further theoretical elaboration.

Introduction

One of the basic findings of criminology is that a substantial part of crime is committed in the company of others—"co-offending." Early twentieth-century scholars already signaled that co-offending is abundant, particularly among juveniles. Since then, a body of empirical research has emerged in which considerable knowledge has been gathered about the regularities of co-offending and the characteristics of co-offenders (see the other entries in this area).

Co-offending is not only an interesting subject for empirical study, it also poses many interesting and profound theoretical questions. Since breaking the law does not necessarily require others, the sheer phenomenon of co-offending itself is meaningful and in need of explanation.

Not everyone is willing and capable to break the law, and it is important to understand how multiple offenders find and choose each other and communicate to make co-offending possible. And since co-offenders interact with each other, offending in company may have important consequences for the modus operandi of the offense and the criminal careers of those who are involved. Co-offending implies that the "antisocial" activity of offending must have many social aspects. It may teach us many things about the relationships and social structures that govern the collective behavior of offenders (Weerman 2003).

Although theorizing about co-offending has received much less attention as empirical study of the subject and much less attention as theorizing about crime and delinquency in general, a few contributions in the field explicitly aimed to theorize the causes and consequences of co-offending (Felson 2003; McCarthy et al. 1998; Tremblay 1993; Weerman 2003). More theorizing about co-offending, explicit or implicit (scattered notions and hypotheses), can be found in several empirically oriented studies (e.g., Carrington 2009; McGloin et al. 2008, McGloin and Stickle 2011; Morselli et al. 2006; Reiss and Farrington 1991; Van Mastrigt and Farrington 2011; Warr 1996). It is possible to distinguish a few general approaches or perspectives and a couple of more formally elaborated "theories of co-offending." However, there are also remaining theoretical questions about co-offending that are in need of further elaboration.

Three General Perspectives

Sometimes explicit, but more often implicit, basic assumptions are made about the nature of co-offending, and scholars build their arguments upon them. Some regard co-offending as living proof of the "group character" of crime and the importance of peers; some scholars think of co-offending as a merely coincidental convergence of offenders at the same place and time; and others view co-offending as an instrument to optimize the execution of an offense. These three diverging views coincide with important general perspectives in criminology (social learning theories, control theories, and the routine activities or rational choice approach), and as such they may be regarded as competing perspectives. They may also be seen as points of view that highlight different aspects of co-offending.

Co-offending as the Result of Peer or Group Influence

Many scholars writing about co-offending see it as the necessary result of peer influence or group dynamics. For example, Shaw and McKay (1931) regarded delinquency as mainly group behavior and co-offending as one of the ways in which offending was transmitted among young people. Delinquents learned their techniques from older, more experienced offenders. Scholars who revived interest in co-offending in the 1970s also regarded it as the result of group dynamics. Some of them argued that the abundance of co-offending is an indication that "delinquency is still group behavior" (Erickson and Jensen 1977). More recently, Warr (2002) argued that co-offending, together with the association between delinquency and delinquent peers, provides evidence of the social nature of criminal behavior.

If one would reconstruct the basic arguments of this perspective, the causal path would run from being part of a group and/or having delinquent peers to being exposed to peer influences that lead someone to join others in offending. Peer influence may consist of social learning mechanisms and the acquisition of delinquent definitions and group processes like fear of ridicule and the urge to show loyalty and obtain status during adolescence (see Warr 2002). People co-offend because the group in which they became delinquent also leads them to join in criminal activities within the group.

Co-offending as the Result of Social Selection

Some scholars explicitly denied that peer influence is a major cause of delinquent behavior (e.g., Hirschi 1969). According to them, other causes, mainly within the individual and the family (e.g., a weak bond of society or lack of self-control), are responsible for the onset of delinquency. Having delinquent peers is a byproduct: criminal or delinquent groups are formed because offenders find each other in the same circumstances or select each other as friends ("birds of a feather stick together"). Their argument also accounts for co-offending: this is the result of offenders who are in each other's company because of social selection. Most explicit about this is Kornhauser (1978), who argued that co-offending is nothing special, since adolescents do most of their activities in groups. More recently, Stolzenberg and D'Alessio (2008) posited that co-offending among juveniles is "theoretically inconsequential." They argue that youths tend to be more gregarious than adults (having a tendency to spend time with others), and therefore also tend to commit their crimes more often in groups as adults and more often than alone.

The basic arguments of this perspective would be that co-offending occurs as byproduct when offenders associate together and spend a lot of time in groups. For reasons other than peer influence, offenders are prepared to join criminal activities, and they will co-offend when they are coincidentally together and an offense opportunity emerges.

Co-offending as an Instrumental or Rational Choice

Finally, several scholars analyze co-offending from an instrumental or rational angle. According to the rational choice perspective in criminology, decisions of offenders may be regarded as if they were rational calculations of the expected rewards and costs of certain actions. The decision to co-offend is also analyzed as a rational or instrumental decision. Researchers who have studied specific crimes like burglary and robbery often adhere to this approach, when they describe co-offending as a way of making the offense easier and more rewarding (e.g., Walsh 1986). Also a number of scholars who explicitly theorized about co-offending have reasoned from an instrumental view on co-offending. For example, Tremblay (1993) assumes that co-offending is required for many types of offending, including organized crime, and many motivated offenders need to find suitable co-offenders. According to him, this quest can be regarded as the outcome of individual decision making depending on situational circumstances (see the next section). Likewise, McCarthy et al. (1998) analyzed co-offending as a form of cooperation between in essence selfish parties to optimize the perpetration of the offense. However, they went a step further by looking at collective forms of rationality and ways in which co-offenders deal with the risks of being betrayed.

The basic arguments of this perspective would be that the decision to co-offend is more or less rational, and that it involves weighing advantages of co-offending against the potential costs. Co-offending can ease the execution of the offense and increase the expected catch, but it also implies that profits have to be shared and that co-offenders may cheat or talk to the police. Co-offending is chosen when it is expected to be easier and more rewarding than solo-offending.

Explicit Theoretical Contributions to the Literature About Co-offending

A few publications can be regarded as more or less explicit theories of co-offending, focused on explaining the phenomenon itself, particular aspects of it, and/or variation in co-offending among offenders and situations. These publications will be addressed in more detail below.

Understanding How Co-offenders Find Each Other (Tremblay, Felson)

One of the first scholars who explicitly theorized about co-offending was Tremblay (1993). In a paper titled (Searching for Suitable Co-offenders), he theorized about the criteria for suitable co-offenders and how they may be found. This paper employed a broader conception of co-offending than usually followed in the literature: encompassing not only the actual companions during the crime but also accomplices and acquaintances that are needed before and after the offense—advisers, fences, and sellers and buyers of illegal goods.

According to Tremblay, many acts of crime become possible only when an offender can find suitable co-offenders. This is more complex as it may appear: an offender needs to get in contact with someone that can be trusted and is able to provide the needed services, which can be very specialized. The availability of co-offenders may be increased by certain social circumstances: neighborhoods with relatively more offenders, periods of high unemployment, and time spent in a prison. However, even if there are high concentrations of potential co-offenders, choices need to be made on who is actually a partner in a particular offense or a series of crimes.

Tremblay assumes that there are two main criteria to decide which co-offenders are suitable and how many: trustworthiness and usefulness. Trustworthiness is most benefited by a small number of co-offenders with who one has a strong relation or bond (e.g., family or friends). However, because this is often not possible, offenders often adopt a basic attitude of distrust towards potential co-offenders. The criterion of usefulness is most benefited by a large social network of friends and vague acquaintances. These relatively weak bonds may enhance contacts with others who have skills and knowledge that the offender needs.

The two basic criteria imply that offenders would be best served by two kinds of social networks at the same time: a cohesive network of strong ties to enhance trust and a large and relatively loose network of weak ties. In practice, this is usually difficult to achieve and Tremblay supposes that most offenders choose one of three strategies to deal with the problem of finding suitable co-offenders. In the "exclusive strategy," offenders choose one type of network and concentrate on establishing strong bonds with trustworthy others or getting a large social network with many potentially useful co-offenders. In the "mixed strategy," offenders try to develop a few strong relationships as well as many weak ties. Finally, in the "avoidance strategy," offenders keep out of the problems by committing only solo-offenses.

More recently, Felson continued theorizing about the problem of finding suitable co-offenders in a paper titled "The process of co-offending" (Felson 2003). Felson concentrates on actual types of co-offending in which at least two offenders are directly and simultaneously cooperating. Drawing on the routine activities approach, combined with a social learning perspective on co-offending, Felson develops a theory that emphasizes the importance of meeting places for offenders, or as he names it "convergence settings." According to him, these places strongly facilitate co-offenders to find each other and strongly enhance offending rates.

A basic assumption in Felson's theory is that "access to accomplices is inherently criminogenic" (Felson 2003, p. 151). Several arguments are provided for this stance. First of all, when potential offenders get together there is an increased chance that they will persuade each other to break the law in the near future. Here, Felson clearly adheres to a peer influence perspective on co-offending. Second, offenders may learn a lot of practical things from each other. They may provide each other with information about potential targets and their locations, about the best way to approach them, and dispose of stolen goods. And third, access to accomplices is needed when an offender wants actual assistance and help in carrying out an offense. By getting into contact with other potential offenders, one may find some necessary extra manpower or someone with specialized skills or knowledge.

Having stressed the importance of getting access to co-offenders, Felson argues that finding them is less easy as it may appear. Drawing on routine activities theories, Felson formulates three requirements. First of all, co-offenders need to get together at the same place and time. Second, they must be able to interact with each other without outside interference. And third, they need to have substantial time available to socialize with each other. With regard to the latter, Felson emphasizes that screening the availability and suitability of potential co-offenders is a slow and informal process: offenders need to size each other up and bond together by talking, drinking, or other informal activities. These three requirements imply that "convergence settings" need to be stable and predictable sources of potential co-offenders. In practice, a small number of places apply: places like street segments, bars, houses, and neighborhood facilities, often only during particular hours. This relative rarity implies that they are important determinants of crime in a certain area, making them potentially interesting targets for intervention.

Understanding How the Risks of Co-offending Are Dealt With (McCarthy et al.)

Co-offending involves risks and costs. In a paper titled "Uncertainty, cooperation, and crime: understanding the decision to co-offend," McCarthy et al. (1998) ask themselves how it is possible that offenders cooperate, despite their conflicting interests and basic uncertainty about the real intentions of the other. Offenders, they argue, can never be sure whether co-offenders stick to their agreements and refrain from cheating or talking to the police. Co-offending has resemblance to a "prisoner's dilemma," in which the least preferred option for co-offenders would be the situation in which they would cooperate and the other would cheat. To explain how co-offending is possible in this situation, McCarthy et al. draw on sociological literature about social dilemmas, situations in which individual and collective goals are contradicting. This literature suggests that people are capable of reasoning with "collective rationality." Individuals can take other people's wishes and needs into account when the end result is also in their own interest. In the case of co-offending, collective rationality dictates that it is in each other's interest not to talk to the police and share the profits of the crime, to ensure future collaboration. Adding to this, trust is needed to be confident that co-offenders also take collective rationality into account in their decision making.

A complicating factor is that not all offenders have the luxury to contemplate who is trustworthy and who is not. McCarthy supposes that offenders who are low in status and live in adverse circumstances (e.g., the street youths that were studied by the authors) will be more inclined to join others than others who are less dependent upon others.

Understanding Who Is Co-offending and Why: Co-offending as Social Exchange (Weerman)

An attempt to integrate many of the then-existing perspectives on co-offending was undertaken by Weerman (2003) in an article titled "Co-offending as social exchange: explaining characteristics of co-offending." This paper aimed to formulate a comprehensive theory about why people co-offend and about variations and regularities in co-offending. The theory is based on the social exchange perspective from sociology and psychology. The basic idea of the theory is that co-offending can be analyzed as an event where goods are exchanged between offenders. The "exchange goods" in co-offending are not only material or instrumental, like a share in the gains of the offense (the catch or a payment), but also immaterial, such as social approval and acceptance. According to Weerman, people co-offend because it is a way of obtaining rewards through the exchange of goods that cannot be obtained by solo-offending. Because the exchange is not limited to the material "catch" of the offense, co-offending can occur even when it is not necessary to carry out a specific crime or it can be done in ways that are not the most efficient to complete the offense.

Six types of "co-offending exchange goods" are distinguished in the theory: services, payment, "catch," appreciation, acceptance, and information. The category of "services" can be considered as basic: these are the co-offenders' activities that make the offense possible (actual help during the offense, providing devices or resources, being a lookout or just being present during the offense). The category of "catch" consists of the share in the money or goods from the offense, often divided among the co-offenders. The category of "payment" consists of all the material rewards (money or goods) that a co-offender gets from another as payment for his service. The category of "appreciation" is immaterial: the social rewards for the actions of the co-offender (approval or praise). The category of "acceptance" is also immaterial: the social rewards for the person of the co-offender (ranging from toleration in a group to affection, status, and respect). The category of "information" is also immaterial: this refers to knowledge obtained through co-offending (practical knowledge about techniques or contacts or knowledge about the capacities and trustworthiness of co-offenders).

Based on these "exchange goods," the theory distinguishes different forms of co-offending. In instrumental forms of co-offending, services are exchanged with a share in the catch or with payments. In strategic forms of co-offending, the goal is to obtain important information apart from the catch (e.g., to test someone or to learn a special technique). Material and immaterial rewards are both involved in quasi-instrumental forms of co-offending, when co-offenders try to impress each other with their skills or with their bravado, or when participating in co-offending is required to be a member of a group. In expressive forms of co-offending, only social rewards are involved (e.g., youth groups committing acts of vandalism). Further, co-offending may be equal or unequal, depending on the exchange goods that everyone is receiving.

The theory explains variation among offenders and offenses by referring to three conditions that make co-offending possible. The first condition is that the offender is willing to co-offend. This depends on whether someone perceives co-offending as "profitable enough" and offering material and immaterial exchange goods that exceed the potential costs (sharing the gains, investing time and energy, the possibility of being caught). The theory also assumes that offenders who have mainly immaterial needs, for example, young adolescents who offend to be accepted and appreciated, are in many cases rewarded by co-offending. Offenders with mainly material needs, like professional or addicted criminals, are only rewarded when they get a lot of catch or payment out of co-offending or when co-offending is the only way in which they can obtain the goods they want.

The second condition is that one or more potential co-offenders are directly available or easy to contact. It is assumed that having a large criminal network and being part of a delinquent group facilitates access to potential co-offenders. Further, regular meeting places and times are expected to ease access to potential co-offenders (cf. Felson 2003). The third condition is that offenders need to convince others that they are worthy and useful to co-offend with. This is only the case when the offender has resources that make offending with him "profitable enough" for others. This attractiveness is mainly influenced by the criminal capacities and possibilities of the offender to offer valuable material and immaterial rewards. Someone can be attractive by his or her physical capital (tools like guns and crowbars), human capital (knowledge, smartness, and criminal insight), and social capital (knowing other useful people).

Other Theoretical Issues and Pending Questions About Co-offending

This section elaborates some important theoretical issues about co-offending that received considerable attention in the literature, though not in the form of systematic theoretical papers. Current notions and hypotheses about these issues are described, and pending questions and gaps in our knowledge are signaled.

Understanding the Process Leading to Co-offending: Recruitment, Instigation, and Decision Making

An interesting theoretical issue is how co-offending is initiated and whether particular offenders serve as recruiters or initiators. This issue has been the subject of several empirical studies which are based on various theoretical assumptions (see the entry about co-offending and group crime for empirical results). Reiss (1988) and Reiss and Farrington (1991) suspected that within the population of offenders, there is a small number of high-rate offenders who act as recruiters. These recruiters would initiate many offenses with less or non-experienced co-offenders. They theorized that these recruiters may get many others involved in their crimes who would otherwise commit no or much less offenses. Recently, Van Mastrigt and Farrington (2011) further investigated the existence of recruiters. They suggested that the developmental taxonomy theory of Moffitt (1993) offers an additional angle to understand recruitment. This theory would predict that recruiters are usually life-course persistent offenders who differ strongly in their characteristics from joiners, presumably adolescent-limited offenders.

In a seminal paper titled “Organization and instigation in criminal groups,” Warr (1996) proposed that the organization of co-offending is much more dynamic and situational as the term “recruiter” suggested; instead co-offenders may act as “instigator” or “joiner” depending on the situation. Based on his empirical results, he supposed that instigators of co-offending do not have certain stable personality characteristics; instead who initiates a crime largely depends on the situation and the group composition among co-offenders. Those who appear to be the oldest among the present adolescents would have the highest probability of becoming an instigator in that situation, because older offenders generally have the highest status in a group.

Recent contributions to the literature suggest that it is also possible that co-offending emerges in other manners, not because one of the present offenders takes an explicit initiative but because subtle processes occur in which offenders become mutually aware of each other’s willingness to commit a crime in a certain situation. Based on a qualitative study among convicted robbers, Hochstetler (2001) distinguishes three ways in which co-offenders may arrive to their decision to commit an offense together. One way is that co-offenders signal to each other with implicit verbal and nonverbal expressions that they recognize a crime opportunity and are willing to act. This is a decision that is slowly built and sometimes only reached in the last moment before the actual offense. A second way is that co-offenders know from each other that they are willing to offend and only need a gesture or a few words to act. A third way is that co-offenders have developed a common identity around a certain type of offense and do not need any communication at all. They commit these offenses with no need for discussion.

A potential next step in theorizing the initiation of co-offending would be to integrate these different opinions and formulate hypotheses about when co-offenders initiate crimes as sole instigators or recruiters and when they do so in concert with other offenders. It might be helpful to distinguish different roles within groups of (potential) co-offenders, each with their own group status and motives to participate in the offense. A further step would be to theorize how co-offending evolves after different ways of initiating it. Social psychological literature about group processes and decision making in small groups may be helpful in this regard (see the entry about co-offending and group crime).

Understanding Co-offending Over the Life Course

Another issue that has received much attention in the co-offending literature is the relation between age and co-offending (as offenders become older, they tend to co-offend less often or with less accomplices on average). Much of the literature on this issue is covered by the entries of Van Mastrigt and Carrington. Within these studies, several explanations have been put forward to explain the relationship. Reiss and Farrington (1991) offer two competing hypotheses, which are in fact based on the group influence perspective and the selection perspective on co-offending. One possibility, they suggest, is that most co-offenders are predominantly breaking the law because of group processes; they usually end their criminal career at the end of adolescence, while those who offend alone continue. The other possibility, Reiss and Farrington suggest, is that some co-offenders change their modus operandi as they grow older, partly because they get more experience, but also partly because the availability of co-offenders decrease after adolescence. This would be the logical result of the age-crime curve, which implies that there are relatively many potential co-offenders during adolescence, but increasingly less when offenders grow older. Adding to this, Carrington (2009) suggests that the relation between age and co-offending partly stems from the general tendency of young people to spend time together and do things in groups. He argues that delinquent behavior is just another type of group activity among many others during adolescence (see also Stolzenberg and D’Alessio 2008).

Empirical studies on the relation between age and co-offending offer contradictory findings (see the entry about co-offending and offender attributes). This has led some scholars in the field to theorize that co-offending over the life course depends on the type of offense, or that there are actually different types of co-offending trajectories over the life course, with some categories of offenders who do not change their level of solo- or co-offending and other categories with offenders who switch from co-offending to solo-offending (Carrington 2009; McGloin et al. 2008). This is interesting since it suggests that co-offending over the life course is a heterogeneous and dynamic phenomenon: it may differ among offenders, offenses, and situations. Carrington (2009) formulates a number of hypotheses about the relation between co-offending and criminal careers, based on the distinction that Reiss (1988) made between low- and high-rate offenders and the distinction that Moffitt (1993) made between life-course persistent and adolescent-limited offenders. Low-rate offenders would usually start their career with co-offending and may shift towards solo-offending when they get more experienced; high-rate offenders develop their delinquency independent from other offenders and mix solo- and co-offending from the start.

The logical next step in theorizing about the link between age and co-offending would be to understand further why there are different trajectories of co-offending over time, how these trajectories are connected to different motives for co-offending, and, more generally, how co-offending careers are linked to the etiology of delinquency in general.

Understanding the Consequences: When and Why Does Co-offending Lead to (More) Delinquent Behavior

Many contributions about co-offending stress the fact that it represents a large share of the total amount of crime, in particular if one considers the fact that one act of co-offending involves multiple people (see, e.g., Andresen and Felson 2010). Several studies also suggest that co-offending may have consequences for future offending, in the sense that it may lead to increased levels of (violent) delinquency. An important theoretical issue, then, is to get insight in the consequences of co-offending: does it lead to more crime in the future, and if so why and when?

To start with, opinions diverge whether co-offending is related to increasing levels of crime. According to those who adhere to a selection perspective on co-offending, the phenomenon mainly represents the group character of many activities during adolescence (Kornhauser 1978; Stolzenberg and D'Alessio 2008). The real causes of delinquency are found somewhere else, and this would imply that co-offending would not substantially increase involvement in crime.

Most scholars, however, believe that co-offending is associated with increased levels of offending. Several theoretical arguments have been offered to substantiate this expectation. First of all, co-offending may actually mark the onset of delinquency for many adolescents. Scholars who assign a substantial role to "recruiters" (Reiss 1988; Reiss and Farrington 1991; Van Mastrigt and Farrington 2011) or "mentors" (Morselli et al. 2006) believe that initiators of co-offending often lead inexperienced or novice offenders into (more) offending. Second, many adolescents start their first offense in situations of "pluralistic ignorance," when young people believe that rule breaking is expected from the others in a group, while in reality this does not need to be the case (see Warr 2002).

Many have also provided arguments why co-offending may enhance involvement in crime. An important mechanism that is offered is social learning. Conway and McCord (2002) suggested that offenders learn particular types of crime through co-offending. Young offenders who would commit their offenses in the company of violent offenders, for example, would imitate this behavior more often in their own future criminal career (see also the entry about co-offending and group crime). Other group mechanisms may be responsible as well. McGloin and Piquero (2009) suggest that offending with relatively many accomplishes facilitate collective behavior and the diffusion of responsibility, which increases the chances of violent behavior in the future.

Another argument why co-offending may lead to increasing and more serious involvement in crime is that it offers access to knowledge, skills, and contacts that make future offending possible. Felson (2003) argues that this is a reason why co-offending not only leads to more future co-offending but also to more future lone offending. Further co-offending increases because accomplices learn how to work together and how to get access to future accomplices. Lone offending is also facilitated when skills and knowledge are obtained through co-offending. Kleemans and Van de Bunt (1999) argued that co-offending often leads to a "social snowball effect." Offenders who become involved in an ongoing criminal operation use the knowledge and resources that they get from co-offending to set up new and separate illegal businesses that attract other co-offenders.

Future theorizing may focus on the question which categories of offenders are influenced and stimulated most by their involvement in co-offending. It seems logical to connect this question to the issue of recruitment and instigation, because this suggests that some co-offenders may initiate law breaking and convince others to join them. Another fruitful route may be to use life course and developmental criminology. Co-offending may facilitate involvement in crime at particular moments during a criminal career, and life events may counteract these effects or make offenders more susceptible to them.

Understanding Failure and Success in Co-offending

Another interesting theoretical issue relates to explaining the results of co-offending: when is it rewarding or not and which offense and offender characteristics contribute to the failure or success of co-offending?

In the past, several scholars suggested that co-offending results in higher apprehension risks for those who participate in it, in what has become known as "the group hazard hypothesis" (e.g., Hindelang 1976). They supposed that the presence of two or more offenders increases the chance that one of them makes a mistake, is caught by the police, or when caught, gives in to the pressure to talk about the others. A similar tendency has been suggested in studies focused on offenders of burglary and robbery (e.g., Cromwell et al. 1991). These studies also suggest that burglars and robbers may take more risks when they are in groups. Further, co-offenders may betray each other or cheat by taking an uneven share in the catch (McCarthy et al. 1998).

Whether co-offending exceedingly results in apprehension or not is still an open empirical question. Some studies have suggested that this is the case, but others did not find any difference (see Feyerherm 1980). More importantly, insight is needed on the conditions and circumstances that increase or decrease the risks of co-offending. Several scholars have suggested that social network characteristics of co-offenders and potential co-offenders may facilitate or counteract detection. There is a trade-off between success and risk in criminal networks: having a lot of ties gives you a lot of opportunities, but also adds to the risks of betrayal and apprehension (Morselli 2009). Further, it is suggested that offenders with a central position in the network (having many contacts with others) are the most vulnerable, not only to harmful actions of co-offenders but also to interventions by law enforcement agencies, because they are the "most visible players" (Morselli 2009). Offenders with more strategic but less visible positions are expected to be less vulnerable, because they are often not recognized as the "big man."

The other side of co-offending (positive from the perspective of the law breaker) is that it may lead to higher gains and more success. Many scholars assume that this is usually the case. Tremblay (1993) supposed that co-offending is required for more sophisticated and organized types of offending, Felson (2003) suggests that co-offending leads to the combination of specialized skills and knowledge that make certain offenses within reach of the individual offenders, and Morselli (2009) argues that co-offending leads to "pooling of resources."

Several authors have theorized that it may be particularly interesting to co-offend with more experienced offenders to get "on-the-job training" and learn the profession. Shaw and McKay (1931) already emphasized the importance of learning from experienced others in the development of criminal careers. Recently, Morselli et al. (2006) argued that having a "mentor" may add directly to criminal success in the sense that it may increase the financial gains that are obtained from offending. Having a mentor may lead to "criminal maturation": being committed to a criminal lifestyle, carefully planning offenses and taking effort to decrease the risks. Mentors are also pointing others towards their apprentices as being a "criminal talent", which may offer access to other people and resources.

More generally, many scholars who adhere to a social network perspective assume that access to many potential co-offenders is a key to a successful criminal career. Morselli (2009) argues that the acquirement of new criminal contacts is a leading force behind the criminal careers of major players in organized crime. Success in co-offending may also be acquired by the use of existing social bonds and structures. In this regard, Kleemans and Van de Bunt (1999) emphasized the importance of strong social ties in understanding success in organized crime. Co-offenders who know each other as friends or, even better, as family may have common interests and have access to each other's resources. Further, they may have built trust in each other, because they have a history together and very probably will meet each other in the future again.

An interesting question is which types of criminal contacts are most beneficial to success in co-offending. Recently, several scholars emphasize that strategic positions in criminal networks offer important advantages in this regard. Offenders who connect relatively distinct parts of the network can act as a "broker" and bring different parties in contact with each other. They have unique access to information and opportunities, and with this position they have the potential to provide important services to others and to take initiatives to co-offend themselves (Morselli 2009). More generally, having relatively few redundant contacts (people that do not know each other) is hypothesized to be associated with criminal success. It implies that someone's co-offenders provide a high variety in knowledge and skills, which may lead to more offending versatility and opportunities for criminal gains (McGloin and Piquero 2010).

A next step in theorizing success and failure of co-offending would be to combine the literatures about co-offending and social networks with notions about the risks of co-offending and the "group hazard hypothesis." Further, current thinking about this issue seems to be divided between scholars interested in adolescent group crime and researchers on sophisticated and organized forms of offending. It would be highly interesting to understand when co-offending remains limited to minor and simple forms of illegal behavior, when co-offending enables more serious and sophisticated types of crime, and how simple forms of co-offending may evolve towards serious and successful illegal enterprises.

Final Remarks

After decades of relative silence, interest in co-offending has emerged again since the early 1970s and seems to have increased recently. The last two decades have resulted in several systematic attempts to formulate theories of co-offending or certain aspects of it, and apart from that, an increasing amount of less systematic and explicit theorizing is provided in various empirical studies on co-offending, juvenile delinquency, and organized crime. Nevertheless, in comparison to the large amount of theories on crime and criminal behavior on a general level, theorizing about co-offending is still scarce. What is lacking most are systematic attempts to combine various notions and insights we already have.

Apart from further theorizing, a lot of work is needed in empirically testing the existing theories and hypotheses. Several studies are available yet in which competing perspectives about certain aspects of co-offending are analyzed (e.g., Reiss and Farrington 1991) and in which competing perspectives on co-offending are tested indirectly, for example, by distinguishing peer influence from co-offending (McGloin and Stickle 2011). Yet lacking are explicit attempts to empirically test theoretical notions about fundamental processes behind co-offending directly.

It is important to note that the study of co-offending is not only interesting in its own regard. It may also provide crucial information about the nature of delinquent behavior itself. The three general views on co-offending outlined earlier in this entry (which we can summarize as the group, selection, and instrumental perspective) represent major perspectives in criminology. In this regard, empirical knowledge and further insights in co-offending may offer crucial information about the validity of etiological theories like social control, self-control, and social learning theory and of the usefulness of more situational approaches like routine activities and rational choice theories.

Finally, theoretical insight into co-offending may be useful to improve criminal justice efforts to prevent and intervene in crime (see also the entry about co-offending and offender attributes). As many authors have argued, the impact of co-offending on the total amount of crime may be very large, and preventing offenders to cooperate with each other may offer a substantial contribution to crime reduction (see Andresen and Felson 2010; Felson 2003; Van Mastrigt and Farrington 2009).

Theories of Punishment

Anthony Ellis
Department of Philosophy, Virginia Commonwealth University, Richmond, VA, USA

Overview

Taking punishment to be the infliction of suffering for an offense, we may say that, traditionally, theories about the justification of punishment have been divided into retributivist and non-retributivist, with further sub-categories in each category. In this entry, we shall take retributive theories to hold that the connection between the aim of punishment and the method used to achieve this aim is conceptual, not causal.

A simple retributive theory holds that the justification of punishment is simply that offenders *deserve* to be punished – for no further reason than that they have done wrong. A different theory is that offenders take an unfair advantage over non-offenders and punishment restores the just balance of benefits and burdens. A third theory also emphasizes the desert of the offender, but holds that what offenders deserve is the opportunity to reform: punishment provides the occasion for this. A fourth type of theory holds that the point of punishment is allow the community to express its condemnation of the offender, or of the offense. Such condemnation might be intrinsically good; or it may be that it is required for the offender to admit wrongdoing and be reconciled with the community.

Non-retributive justifications of punishment usually, though not invariably, hold that much the most important point of punishment is the reduction of crime, and probably the most common way in which it is thought to do this is by deterring potential offenders, sufficiently so as to justify its costs. Quite differently, some forms of punishment also make it impossible, or at least very difficult, for offenders to re-offend (prison and execution being the most obvious examples). A third non-retributive theory, paralleling the retributive version of the reform theory, is that punishment reforms offenders, or at least gives the opportunity for them to be rehabilitated, but, unlike the retributive version, this theory holds that punishment is simply one method among other ways of achieving this aim, a method to be discarded if it is not found to reduce the level of crime. And there is also a non-retributive version of the expressive theory, which also holds that punishment helps to reduce crime, perhaps by educating the population about the wrongness, or illegality, of offenses, or by allowing the vicarious desire for revenge an official outlet, or inducing shame in the offender.

Preliminaries

Punishment we may take to be the infliction of suffering for an offense. We may thus distinguish punishment from restitution and compensation. One is punished for an offense: One is not required to make restitution or to compensate for *an offense* but for the damage that one has caused. (When courts order “punitive damages,” punishment and compensation are being run together.) We may also distinguish punishment from medical treatment. Medical treatment is not administered *for* an offense, though it may be administered *because of* an offense.

The aims of punishment may be many and various: They might include, for instance, propitiating the gods, or trying to make it rain. But this entry will deal with the main aims that have been put forward as justifications for the modern state in punishing its citizens.

So we are concerned here with the classifications of punishment according to what its aims are thought to be. There are, of course, other theories of punishment, such as theories about its historical origins, or its evolutionary purpose, but these theories are not our concern.

But speaking of “aims” too is ambiguous. The word could refer to its sociological function, for instance, but again this is not our concern. We are concerned with the aims that might be thought to *justify* punishment, and to justify it *morally*, not merely *explain* it. The sociological claim that punishment serves some function such as promoting solidarity, for instance, is not typically offered as a moral justification for it, though it may explain its origin or persistence.

Punishment requires a moral justification because when we punish someone we do to them something which, in most other contexts, it would be wrong to do: Punishment involves the infliction of suffering. The suffering might be relatively slight (a small fine) or it might involve serious deprivation of liberty or even of life. The theories we shall be concerned with aim to offer a moral justification for this. There are a few theorists who think that punishment is not in fact justifiable; (Boonin 2008) takes this view, suggesting that restitution should take the place of punishment. Others have suggested that restitution, instead of replacing punishment, should be thought of as its main aim. But most people think that punishment, in its normal understanding, is justifiable by one or more of the traditional theories.

Justifying punishment might be thought to be either, or both, of two different things. First, the focus might be on finding a justification for a particular act of punishing someone. Such an act, it might be thought, could be carried out, properly called “punishment,” and justified, even if there were no penal institutions of any sort. Second, the focus could be on the justification of a penal institution or system itself: Why is it permissible for a state, or a community, to set up a system in which people are actually punished if they contravene some set of norms? And a theory might try to answer both of these questions.

Theories

“Retributivist” Theories

A traditional way of classifying theories of punishment divides them into *retributive* and *non-retributive* theories. It is questionable how precisely theorists have used this classification: Retribution has been defined in lots of ways that are clearly not logically equivalent, and it will be useful to stipulate a definition that captures something like the basic thought. By a “retributive theory” will be meant a theory of punishment which holds that the connection between the aim of punishment and the method used to achieve this aim is conceptual, not causal. All other theories will be called “non-retributive.” So a theory that holds that the aim of punishment is simply to make offenders suffer for their offenses will be retributive: On such a theory, it is conceptually necessary for achieving this aim that one can make offenders suffer for their offenses. By contrast, the deterrence theory is a non-retributive theory: It holds that the aim of punishment is the prevention of crime, but the connection between punishment and the prevention of crime is purely contingent and causal.

This division lines up fairly closely with some other characterizations, such as that retributive theories are “backward looking” (since the justification for punishment lies in what was done in the past), whereas other theories are “forward looking.” But it is not an obvious necessary truth that future actions cannot merit retribution – New (1992) suggests that future acts may legitimately be the object of punishment and of retribution. The common use of the word "consequentialist" to denote non-retributive theories is, however, misleading, because it does not distinguish between causal consequences and logical consequences. The perhaps more common use of the word "utilitarian" to denote non-retributive theories is even more misleading, since most such theories are not actually utilitarian in the proper sense of the word. But there is, of course, no possibility of exactly aligning a precise theory with a range of theories which is not precise.

In any case, "internalist" and "retributivist" will be used interchangeably here, and likewise "externalist" and "non-retributivist".

In popular thought, the idea of retribution typically suggests that a punishment should consist of "eye for eye, tooth for a tooth…", sometimes referred to as the *Lex Talionis* (see, e.g., *Exodus* 21:22ff., *Leviticus* 24:17ff., *Deuteronomy* 19:16ff.). This is not necessarily a retributivist theory, since it does not actually mention an aim of punishment. But in any case, it is inapplicable to most offenses (loitering, speeding on the highway): The phrase is also sometimes used to justify punishments that clearly do not follow its rule, such as cutting off the hands of thieves. And despite the, perhaps, poetic justice in such amputations, they are usually justified by reference to their deterrent effect. Few serious thinkers now regard the *Lex Talionis*, as just described, as a viable theory of punishment, though some defend it at least as an ideal to which punishment should aspire even if it never fully realizes that aspiration (Reiman 1985).

Simple Desert

A more sophisticated attempt to justify punishment on retributive grounds we may call the *Simple Desert Theory*, which simply holds that offenders deserve to suffer *in proportion to* their wrongdoing: Their wrongdoing is some function of the harm that they caused and their culpability in causing it (Moore 1993; Moore 1997; Moore 2009). In principle, perhaps, their deserving to suffer gives anyone the right or the duty to punish them because if they remain unpunished the "universe is morally out of joint." Typically, however, the state takes this role by setting up institutions that are thought to be the most efficient and just way of seeing to it that offenders get the suffering they deserve; but however elaborate the penal system may be, the individual punishment does not derive its justification from the system; the reverse is the case. There is no further explanation of why wrongdoers deserve to suffer: This is simply a basic, foundational moral truth.

Some people think that a punishment and an offense are strictly incommensurable, so that no sense can be attached to the idea that offenders deserve punishment "in proportion" to their offense, so that assigning punishments in this way can be, at best, expressing the arbitrary will of the community. For an attempt to overcome this problem, see Davis (1983). Others find it hard to accept that desert here is a basic notion with nothing further to explain it. Others think that no one *deserves* to be made to suffer (Braithwaite and Pettit 1990, p. 175; Parfit 2010, p. 455). And many think that the notion of simple desert is merely vicarious revenge dressed in the language of justice.

Just Distribution

But this is not the only way that the notion of moral desert can be the basis for a theory of punishment. One might agree that offenders deserve to suffer, but hold that there is a further, more basic, reason for this. That is the position of what might be called the *Just Distribution Theory* and it has been held by many theorists (for two out of a great many proponents, see Morris 1976 and von Hirsch 1976). Here, the general idea is that society requires its members to make certain sacrifices in return for the goods that society makes possible; the members must, e.g., curb their desires to harm other members of society, and this represents a cost to them. The offender, in offending, in not curbing such desires, does not carry his fair share of this burden, and so has gained an unfair advantage over the other members of his society. Fairness requires that this advantage should be taken away, and the suffering involved in a proportionate punishment achieves this. (This theory requires, of course, a functioning society but not, in principle, any set of penal institutions; but, again, questions of efficiency and justice might justify the state in taking over this function).

This theory need not suffer from the problem of incommensurability. It will depend on the precise account of the burden that was not carried in an offense. Merely described as not curbing one's desires might suggest that some form of imprisonment might match this, but not, say, a small fine, and small fines are the majority of punishments administered, even in the USA. There has been considerable dispute among adherents as to how to specify the nature of the wrongdoing so as to overcome this question. We may add that the theory, originally a least, was based upon the so-called Principle of Fair Play. There has been considerable discussion about this principle itself and its applicability to punishment.

Reform Theory

Jean Hampton has argued that the ultimate aim of punishment is the prevention of crime (Hampton 1984, p. 211), but that offenders, like anyone else, can deserve only *good* (in this life, at least), not unproductive suffering. So punishment must be a good to the offender. So long as that is true, then it seems as if the ultimate aim of punishment can only be through reform of the offender. She was also impressed by the thought that punishment, like all human actions, must respect a demanding conception of autonomy and thus not coerce the offender's reform. So punishment must make real to the offender the wrong that he did by making him suffer for it, but it leaves him to decide whether to accept the lesson or not.

But this is not an easy thesis to sustain. There is, as we shall see, a non-retributivist reform theory. However, the claim that punishment reforms offenders, offered as an empirical claim, has little evidence to support it. (The classic work was R. Martinson et al. 1974. The conclusion, based on recidivism, itself part of a larger study using other measures, did not conclude that "Nothing Works," as is often said, but only that nothing had been shown to work.) And indeed Hampton claims that it is a conceptual claim. This seems to rest upon the further claims that the wrongness of offenses consists in their causing suffering (which is surely not true for all offenses) and that offenders do not fully understand the suffering that they cause (which seems doubtful in many cases) and that making them suffer is the only way to get them to appreciate this (which also seems doubtful).

Expressive Theories

In later work, Hampton moved toward an *Expressivist*, or *Denunciatory* theory (Hampton 1992; Murphy and Hampton 1988). An offense, she claims, demeans the victim, does not show him the respect that he deserves, a respect which, as rational beings, we all share equally. So a moral statement has been made, a message sent, that the wrongdoer is superior to the victim, and this has to be effectively countered. Official pronouncements that the offender is not superior to the victim will not do, because the offense still stands and "counts as evidence that he is" superior (Murphy and Hampton, 128). Punishment is all that can do this: In its mastery of the offender, it reestablishes the worth of the victim. And only punishment can do this, because "*any... method*, so long as it was still a method for *defeating* the wrongdoer, *would still count as punishment*" (Murphy and Hampton 1988, p. 125f.) or "retribution" (Hampton 1992, p. 16).

This theory has many moving parts. For instance, that an offense "sends a message" can be true in only the most trivial sense, since few offenses have that even as a subsidiary aim; and even if such a message is sent, it is not clear that it will necessarily be heard, or believed: and the claim that any method for defeating a wrongdoer would count as punishment does not seem clear: when an unjust invader has been expelled from the invaded country, it has been mastered but not punished.

Antony Duff forges a closer connection between the prevention of crime and the expressive function of punishment. While the ultimate aim of punishment is the prevention of crime (Duff 2003, p. 112), this aim must be achieved by repentance and reform on the part of the offender, and reconciliation between the offender and the community (Duff 2003, 107f.; see also Duff 1986). Duff's theory is complex, but at its heart lies the notion of penance. Like Hampton, Duff founds his theory on the Kantian requirement of respect for persons, i.e., respect for rational, moral autonomy (Duff 1986, p. 6). His theory also has built into it a "liberal communitarianism": The legal system should express the community's moral consensus as to what the law should be. He thinks that these requirements preclude a deterrence theory of punishment because deterrence, instead of appealing to the community's sense of morality that underlies the law, is simply a system of threats which create reasons for obedience and play upon the potential offender's fear. The real justification must lie in the goal of reforming the offender and reconciling him with the community. But how is making the offender suffer supposed to achieve this goal? Duff's answer seems to be through the idea of penance. The offender's trial and punishment are an expression of the community's condemnation of the offender's conduct with the hope that this will bring him to repent of his wrongdoing and condemn himself. Duff thinks that punishment is crucial here because punishment is a form of penance which will induce repentance in the offender (Duff 1986, p. 245; cf. Duff 2003, p. 106). Duff candidly admits in his early work that punishment, as we know it, rarely achieves this end and that moral disaster would follow if we were to give it up. In his later work, he favors such things as victim-offender mediation schemes, probation orders, and community service orders. These are not alternatives to punishment, he says: They, like an imposed penance, "more less fit" the standard definition of punishment and should be understood as punishment "even if this requires us to modify conventional understandings of both mediation and punishment" (Duff 2003, p. 97). (Such programs are in fact typically regarded as forms of punishment, since they involve, at a minimum some sort of deprivation of liberty).

There is much to be discussed here, but, as with Hampton, the main problem is the claim, to which Duff steadfastly holds, that it is a conceptual truth that only punishment – the infliction of suffering – can bring about repentance and reform in the offender. The empirical claim that it *can* do this is obviously beyond question: that it does so in a significant number of cases seems doubtful. The claim that it is a conceptual truth and that only punishment can do this seems yet more doubtful.

However, the general idea that a justifying aim of punishment is that it expresses denunciation of the offender or the offense has been very influential.

Andrew von Hirsch, for instance, argues that punishment has two aims, neither of which justifies punishment alone, but both of which, taken together, do so. One aim is the prevention of crime. But the mere prevention of crimes does not, by itself, justify punishment: This would leave out a crucial moral dimension. That dimension is supplied by the fact, as claimed by von Hirsch, that punishing an offender necessarily expresses moral disapproval. And the overt expression of disapproval of those we think have done wrong calls for no justification: It is, conceptually, part of what it is to think that someone has done wrong. To express denunciation *by causing harm*, however, does need justification, and that is presented by the claim that punishment also reduces crime.

Victim Compensation Theory

Last, we should perhaps also mention what are called "victim compensation theories." The idea here is that victims of a crime deserve not just material compensation, but the satisfaction of seeing those who offended against them brought to justice: If being brought to justice involves being punished (as opposed to merely being convicted), then this aim cannot be achieved without the offender being punished. It is therefore an internalist theory. But, as with many theories, there is in externalist version too: If the ultimate aim is to reduce the likelihood of victims using "Lynch law" to satisfy their desire for justice, then it will be an externalist theory (for there is no conceptual guarantee that making offenders suffer is either necessary or sufficient for diminishing the incentives to "Lynch law").

Justice is an impartial idea, and it is not clear that victims have any greater right to see *justice* being done than does anyone else; so the suspicion is strong that we are really talking here about the desire for vicarious revenge.

Non-retributivist Theories

Despite the current popularity of retributivist theories (among philosophers at any rate), it seems likely that the majority of post-enlightenment penal theorists have held that the connection between punishment and its aims is causal and contingent rather than conceptual. Widely different such aims have been ascribed to punishment, but it seems likely that the dominant two are now deterrence and incapacitation.

Deterrence

It is difficult to find explicit theories of punishment before the fourth century BC, though *Joshua*, 17.12 seems to refer to a deterrent aim for punishment; but it is hard to believe that at least part of the aim of the gruesome punishments mentioned in, e.g., the Code of Hammurabi (C17 BCE) was not deterrence. Plato (though in the mouth of Socrates) explicitly accepts deterrent punishment for "incurable" offenders (*Gorgias*, 525b; see also *Protagoras* 323c–324a). Locke also accepted the deterrence theory (Locke 1690, §§ 8, 12; this is what Locke means by "restraint"), as did Beccaria (1764, Chap. 12) and Bentham 1789, Chap. XIII, fn. a.).

In its simplest form, deterrence assumes that potential offenders are roughly rational, economic agents who will weigh the likely costs and benefits of their actions before acting. They will take into account the costs and benefits of all of the actions that are available to them and take that course with the most favorable cost-benefit ratio. The aim of punishment is to make the cost-benefit ratio of prohibited actions less eligible by increasing one or both of the likelihood of conviction and the severity of the punishment if convicted.

It seems clear that most people do not adhere strictly to this simple model. And it is clear that there are many other deterrents to crime than the fear of punishment (the fear of retaliation from victims, socialized aversion to crime, fear of the loss of valued relationships, the possible shame attached to criminality, etc.). So the question for the deterrent theorist is whether the costs of the penal system add sufficiently to other disincentives to crime to justify itself. Answering this question, however, is very difficult, precisely because it is difficult to disentangle the motives that drive people to offend, or to avoid offending. That is all the more so because, it is generally thought, the fact of punishment *itself*, contributes to the sort of informal sanctions just mentioned. For a brief account of the methods used in deterrence research, see (Zimring and Hawkins 1973; Nagin 2000).

Despite these difficulties, most penologists agree that punishment, in tandem with these other factors, and when separated from them, does make some contribution to deterring crime. The classic econometric work was done by Becker (1968). For a more general survey, see also, e.g., Nagin 1998; and Nagin 2000 ("I am persuaded that the collective actions of the criminal justice system exert a substantial deterrent effect", at p. 346). For a more skeptical view about "deterrence-optimizing analysis," see Robinson and Darley 2003 – who do, however, accept that punishment actually does have some deterrent value ("There seems little doubt that having a criminal justice system that punishes violators. . .has the general effect of influencing the conduct of potential offenders. This we concede: Having a punishment system does deter"). For a (perhaps) contrary view, see Meares, Katyal and Kahan (2004) who think the evidence for the deterrent effect of punishment is "speculative and inconclusive" (p. 1186), but it is not clear that they think it has no deterrent effect (see, e.g., p. 1196).

Deterrence is traditionally divided into "special" deterrence (punishment's effect on the person punished) and "general deterrence" (the threat of punishment on the population at large). Strictly speaking, however, this is a confusion. Punishment cannot itself act as a deterrent: Only the *threat* of punishment can do that. That is a conceptual point. And punishing an offender is not usually, in itself, a *threat* of punishment; in very peculiar circumstances, one could perhaps punish someone precisely as a threat of further punishment, but that is not how punishment works in penal systems. All that punishment itself can do is to make the person punished a more deterrable character, by making real to him the nature of the punishment. But making someone a more deterrable character is not itself deterring him: It is a way of *reforming* him. All that can deter him is a further *threat*. So there is no such thing as "special deterrence:" If the person who is punished is thereby made into a more deterrable character, he is then simply a member of the general population to be deterred by "general deterrence." With sufficient publicity, actual punishments may have a similar effect on the general public too, by making the threat of punishment more credible, but that is not "general deterrence" either. The effect on potential offenders of the *threat* of punishment is all that is properly called deterrence.

To the extent that general deterrence works, it works by threats. One might then wonder why it is necessary actually to carry out the threat if the threat fails to deter. The usual answer is that if the threat were not typically carried out, then it would lose its credibility and so become ineffective. So the point of actually punishing offenders, as opposed merely to threatening potential offenders, is to make the threat credible. And this has added to a worry about deterrence that we have already encountered: In actually punishing offenders we are using them as a means to an end, using their suffering to mold the behavior of others. And this does not seem, in normal circumstances, to be morally acceptable behavior.

Incapacitation

The idea here is simple: Punishment, either by execution or incarceration, actually prevents offenders from committing more crimes. But this cannot be a justification for punishment in general, because most punishments, fines for instance, have no significant incapacitative effect. Revocation of driving licenses may be thought to be incapacitative, but they do not prevent anyone from driving, only from driving legally.

The use of prisons, until fairly recently, was not widely thought of as a method of keeping offenders out of circulation. They were mainly used to hold suspected offenders until trial, or to coerce them into paying debts. But transportation, begun in Britain in the reign of Elizabeth I as an extension of hard labor, must surely have also been intended to remove offenders from society. And it exceeds credibility that monarchs and others did not use prisons simply to keep troublemakers out of harm's way (The Tower of London was built specifically to house the king's enemies, not to punish them).

As a justification for imprisonment generally, the idea has simple charm, but is not without problems (see Zimring and Hawkins 1995). For one thing, crime is often committed by groups, and if not all the group is imprisoned then others may take their place in the group. Again, high-ranking offenders can often carry out their criminal purposes from behind bars. And confining offenders is highly expensive, and increasingly so as they get older: There must be some question as to whether the money required for this could not be used in other ways to reduce crime, and to do so without leaving offenders with a stigma makes a continued life of crime difficult to avoid.

Enhanced prison sentences for recidivist offenders are typical in most jurisdictions. But here the problem has been the accurate prediction of which of these offenders would in fact offend again, and the results have not been encouraging. One suggestion has been to try to identify a few offenders who are particularly "dangerous" and confine them to long, perhaps indeterminate, sentences simply as a matter of protection of the public (see Floud and Young 1981). A somewhat less subtle strategy has been pursued in many US states and by the Federal government: to sentence those who have committed a third felony to very long sentences, usually without the possibility of parole. This, of course, typically provides a perverse incentive to those who are committing their third felony not to mitigate the offense.

And there is a moral worry in all of this: Offenders are being confined not for what they have done, but for what it seems likely that they would do if set free. Even if our predictions were accurate, some might still find this morally troubling.

Reform

In its very broadest sense, "reform" may be regarded as any sort of treatment that makes the offender less likely to offend: At the limit, this would, of course, include capital punishment.

More usually, the aim has been simply to change the offender's desires so that he loses the desire to offend. More narrowly still, the aim has been to change the offender's desires while, in some way, not reducing his autonomy. More extendedly, the aim has been to *rehabilitate* the offender so that he can resume a useful life in society.

The reform theory has a long history, dating back at least to Plato, and including Aristotle (*Nicomachean Ethics*, Bk. II, Chap. 1). Jeremy Bentham also thought that reform was one of the main aims of punishment, though less important than deterrence (Bentham Chap. XIII, fn. A). As a matter of policy, reform became the main aim of punishment, imprisonment in particular, during the first half of the nineteenth century, an aim which led to the redesign of prisons so that prisoners were effectively isolated from each other and under constant supervision. Jeremy Bentham's Panopticon became the model for such prisons and many prisons were designed according to its model. But, despite remaining one of the official aims of most penal systems, it has had a mixed history since then, and since the 1970s the lack of any evidence of success has led largely to its demise.

As we have already seen, it is unclear how punishment can reform offenders to any significant degree. Plato thought that wrongdoing was, roughly, a matter of ignorance, and if that were true it would go some way toward answering the question – but, as we have already seen, not very far. In modern times, the reform movement has often been linked with the idea that criminality is some sort of disease, or mental abnormality, but, unless the claim is to be a mere tautology, this can be shown to be true of only a very small proportion of offenders. Starting in the nineteenth century, prisons in particular came to be seen not so much as the reforming vehicle as the *place* where the reform could be carried out, and thus gave rise to the idea of prisons as places where offenders could be rehabilitated. In the last few decades, such programs as probation or community service have been tried with certain sorts of offenders (Ashworth 2005, Chap. 9). There is some dispute about whether such programs are punishments, or alternatives to punishment, but there is in any case little evidence of their efficacy.

Expressive Theories

Just as internalist reform theories have an externalist counterpart, so to do internalist expressive theories. These theories claim that, as a contingent matter, punishment or penal systems reduce crime by sending some sort of message. Most popularly, it has been held that they do so by expressing *denunciation* or condemnation of offenses. This may be thought to reduce crime by educating citizens as to what is acceptable behavior. Or it may be thought to siphon off feelings of outrage which otherwise may lead to social disorder. Or it may be thought that the actual experience of punishment expresses condemnation to the offender, thus inducing shame and the greater likelihood that he will not offend again.

All of these claims are empirical and very difficult to confirm. It seems likely that some such effect operates entwined with such other effects as punishment may have, but it is difficult to be more precise than that.

Assurance Theory

The assurance theory holds that the point of punishment is to assure law-abiding citizens that other citizens will obey the law too (Lacey 1988, 182f.). If they did not have this assurance, it is thought, they would be less likely to obey the law themselves – perhaps, e.g., because they would see the legal system as operating unfairly, or because they would think it foolish to obey laws that others did not obey too, or perhaps because, without that assurance, they would be more likely to take the law into their own hands.

There is no doubt some truth in this. However, this theory is parasitic on one or more of the theories mentioned above: Assurance will be given to law-abiding citizens only if punishment reduces the level of crime, and it can only do that if one of the theories mentioned above (or more than one) is actually correct.

Concluding Remarks

Some of the theories outlined above are easily combined: There is no problem about holding, for instance, the traditional version of the deterrence theory along with the incapacitation theory. Other combinations will produce simple incoherence: One could not coherently hold that the only appropriate response to an offense is punishment and, at the same time, hold that, if punishment does not reduce crime then we should turn to other methods (but see Duff 1986, p. 296ff.). Yet other combinations will not be incoherent but will seem to embody a moral tension, as might be the case if one derived the justification of punishment from a utilitarian desire to reduce crime *and* the demand that we give offenders what they deserve. Whatever the views of theorists may be, however, it seems likely that most people would agree that punishment is in fact justified, and that the justification will consist of more than one of the theories outlined above. But an account of a suitable combination is beyond the scope of this entry.

Theories on Policing and Communities

Christian Mouhanna
Centre de Recherches Sociologiques sur le Droit et les Institutions Pénales (CESDIP), CNRS, Guyancourt, France

Overview

In most countries with an elaborate theory on policing, any discussion on topics such as "the police" and "the community" is bound to raise the issue of community policing. Although somewhat eclipsed in the early 2000s, the concept remained quite popular among policing organizations, many of which had built upon it in the 1980s–90s to reshape their outreach strategies. The actual meaning of the word "community" across the various countries, however, turns out to be rather loose and inconsistent: While in the USA or the UK, in particular, it is understood spontaneously as a rather obvious piece of common knowledge (Lewis 1969) with a natural impact on policing actions, in other countries such as France, for instance, it has a clearly negative aspect, linked to communitarianism as a perceived threat to the nation state. Beyond local discrepancies, a closer examination of the concept of community from an academic perspective raises complex epistemological issues that reach to the very foundations of sociology and which this entry will not be able to cover. While refraining from delving too deep into intellectual discussions, however, this entry will examine how the emergence of the concept influenced the perception of crime in societies and the subsequent responses by police forces. Indeed, policing actions are literally shaped by how the police perceive the people they are serving and/or controlling. Hence, a given community may be recognized by policemen either as an entity they belong to, or as an intruder in their own community, to be watched or even fought.

After an examination of the concepts and interpretations that tie together communities, social processes, and the modes of regulation of these processes, the link between community and policing will be explored via a literature review. Interestingly, the invention – or reinvention – of community policing in the 1970s–80s owes a lot to scholars – Anglo-Saxon scholars in particular – whose research on police efficiency and impact on people had led them to offer an alternative model to traditional policing. In many countries, especially those that never experienced a close-knit relationship of police forces with the people, such research elicited strong opposition from field professionals. Many a policeman found it hard to accept being challenged, sometimes painfully, from outside their profession. Resistance and reversals were frequent reactions. Why a model that has so often been advocated as ideal proved so difficult to deploy will have to be analyzed and explained. Whatever tensions were triggered by the implementation of community policing may have been underestimated by scholars, even though some studies did eventually tackle the issue later on. As for opponents to this policy, their perspective will be interesting to explore as well.

The Concept of Community, Cities, and Security

In a human and social science perspective, the concept of community was first and foremost meant to describe some form of primarily rural social organization, as described by Tönnies (1887) and the early Max Weber (1948). This matters to us insofar as, in countries where rural and urban policing are organized separately, community policing practices are sometimes nothing more than successful country police endeavors transposed to urban policing. Tönnies (1887) distinguished the community (*Gemeinschaft*) from the society (*Gesellschaft*). To him, the community was a form of organization peculiar to traditional rural life, where people are bonded by family, neighborhood, and religious and custom ties. Community (*Gemeinschaft*) members understand each other and form a closely knit group, organizing their lives together. The *Gesellschaft*, on the other hand, is a by-product of modernity characterized by truly diverse ways of thinking. Far from sharing common values, individuals compete, hence the rise of individualism. Such an outlook generates a "naturally" pessimistic view of modern societies and how to regulate them. As far as this entry's field of study – namely security – is concerned, policing such societies obviously seems more complex and difficult than policing communities, where self-regulation does prevail somehow.

The vanishing agrarian community – understood as a community of interests uniting farm workers and landowners – was a theme that also appeared in Weber's work, albeit in a slightly different sense. Rural exodus was compounded by a refusal to further community ties. Weber's communities were not fossilized (Weber 1971): although rooted in feelings and emotions – *Vergemeinschaftung* –, they also involved a process of rational consultation among individual members – *Vergesellschaftung*. Weber's contribution to the understanding of the agricultural world notwithstanding, his analyses are useful to us for at least three reasons. First because he took research themes that hitherto pertained specifically to rural world communities and applied them to urban communities, thus probably influencing scholars from the School of Chicago. Secondly because Weber is the one who connected and matched social organization matters and legitimation mode issues (Weber ibid.): Modern societies are regulated by law, and this legal, rational legitimacy forms the foundation of the State's authority. And thirdly, within the framework thus designed, the State holds the monopoly of legitimate physical coercion on its territory. By contrast, as can be seen, such lines of reasoning highlight another issue, namely, the tensions that may appear between a given political community, legally endowed with this monopoly, and other types of communities which, although embedded in this larger political community, nevertheless challenge its legitimacy.

Building up on this body of research, and confronting it to extensive field work, the School of Chicago of the 1930s–40s inscribed this concern for the community in its treatment of crime, adding what at the time was a novel dimension: preventing crime and looking for its roots. Scholars working on the Chicago area Joliet prison – Clifford Shaw in particular (Shaw 1930; Shaw and Mc Kay 1942) – were instrumental in the inception of these groundbreaking theories. Following up on the works of Robert E. Park (1952), they identified as the main source of juvenile delinquency the changes undergone at the time by primary institutions – the family, the church, the social group – because of urbanization. Outside the rural context, the socializing power of these institutions, whereby they traditionally induced young people to adopt conventional – or at least noncriminal – attitudes, was being upset by the characteristics of urban life. Scholars found that city life allowed a manifold increase in social exchanges that led to segmented, superficial, and utilitarian relationships, with social ties becoming too numerous, heterogeneous, and instable (Wirth 1938). Faced with the opportunity of making varied acquaintances outside the groups "covered" by primary institutions, young people were less supervised and had more occasions to go astray. Crime and delinquency were thus viewed as a by-product of urban life, as opposed to individual instances of misbehavior. Massive immigration only contributed to reinforce this disruption pattern.

To address such "drifts," the socialization of young people in urban areas was entrusted to schools and police forces – secondary institutions as per the above-mentioned scholars' classification, who considered such institutions as generally unable to tackle the problem. The main option to address this desocialization process, they thought, would have been to restore some social control by helping primary institutions adjust and strengthen themselves. One of the key ideas is that communities should solve their problems on their own, possibly with some help from support groups. Some of these scholars envisioned a radical shift in the role of police forces, who should not restrict themselves to law enforcement, but actively partake in the reinforcement of the capacity of primary groups to socially integrate young people. Social control would thus become the main weapon in the struggle against deviance.

This primarily "environmental" view of crime – and its implications on policing – attracted early and numerous criticisms, including those voiced by Robert Merton or William F. Whyte. The former (Merton 1938) considered that deviance stems from a discrepancy between whatever goals society offers to its members and the means it affords them to reach these goals. For instance, barring adequate educational or social networking resources, underprivileged youths willing to "strike it rich" – one of the major values in modern societies – will be led to seek alternative means of achieving their goal, i.e., they will resort to deviant behavior patterns. In such a framework, deviant behavior patterns are not ascribed to discrepancies between the norms of the various groups embedded in a given society and the ensuing imbalances. Quite the opposite, actually, all members of society share common values and goals, but follow different paths to reach them.

Then, W. F. Whyte showed that while traditional rules inherited from peasant societies do tend to decline when confronted to modern society, new rules and groups emerge as well (Whyte 1943). Whatever anomie scholars may have found is largely attributable to their looking for a model of society that would replicate theirs, thus diminishing their ability to identify rules that do not fit prior knowledge. It should be noted that, in Whyte's Cornerville, local police were integrated to the local society, through corruption and gift practices in particular. According to Whyte, policing can be conceived of in two different ways. The middle class considers that police forces should fearlessly enforce the law and refrain from any preferential treatment, while Cornerville people and the police themselves think that the latter should be trusted by locals so that they can solve problems without arresting anybody. Both perspectives are largely antagonistic: Extreme law-abidance makes it impossible for policemen to act as conciliators, while excessive familiarity stands in the way of their repressive role.

The Impact of Victimization

In the USA, the late 1960s gave new impetus to discussions on the relationships between the police and the community, thanks to a new approach that, instead of focusing on wrongdoers only, started to take victims into account. The idea was to explore the causes of "crime fear" and measure the potential link between such a fear and actual victimization: in other words, to distinguish facts – direct or indirect (i.e., through personal acquaintances) confrontation with crime – from the perceived level of fear of persons who never experienced such a confrontation themselves. So-called victimization surveys, by confronting concerns and actual life experiences, were supposed to help test how relevant this link between fear and actual crime was. More importantly perhaps, they offered an opportunity to check the relevance of existing measures, i.e., to test police statistics. Surveys conducted directly with the population allowed scholars to spot potential discrepancies between statistics provided by policing organizations and their own, later dubbed the "dark figures of crime." This eventually led to questioning the propensity of victims to lodge complaints, their faith in policing actions, or the actual willingness of the police to register complaints. Such interrogations on fear reflect – more or less directly – questionings on the actual role of police forces, how much citizens trust them, and their ability to penetrate the various communities.

Victimization surveys revealed a conspicuous lack of congruence between actual crime and the feeling of insecurity, or more precisely between the number of registered criminal acts – thefts, burglaries, assaults, abductions, murders – and crime fear levels (Ennis 1967; Reiss 1967). This lack of direct causality triggered many interpretations, from the concept of vulnerability (Stinchcombe 1978), allegedly explaining highest fear levels among women and senior citizens, to the linking of crime fear and fear of foreigners – foreign to the neighborhood, or foreign in the sense of not belonging to the same ethnic community –, a frequent staple of research at the time (Skogan 1976). John Conklin established a link between crime fear and the community (Conklin 1975). He opposed Durkheim's idea that crime contributed to bonding the community together by reinforcing social ties between "honest" people (Durkheim 1998). In fact, his field studies rather tended to show that crime produced insecurity, defiance, and a negative view of the community. It seemed to him that crime reduced interactions between neighbors, since fear and suspicion tend to estrange people rather than unite them, at which point social control on deviant behaviors becomes impossible. Faced with crime, people react individually, with fear and withdrawal, rather than in the collective fashion Durkheim envisioned. To Conklin, individual responses to delinquency tend to sever social links, a vicious circle that reinforces fear – including the fear of one's own neighbors – and, as a backlash, fosters criminal behavior patterns, which are encouraged by the resulting lack of social control. In a similar vein, James Q. Wilson highlighted the fact that crime impedes the building of sustainable communities (Wilson 1975). Following up on Tönnies' conception of individualism, he insisted that crime tends to destroy the formal and informal links that bond people to their neighbors, which "atomizes society" and turns all of us into increasingly individualistic schemers. Thus, a shared response to crime would be the only option granting us an opportunity to build or rebuild the community.

Policing is also impacted in this approach: Subjection to crime, when individualized, reduces public support to law and order enforcement institutions. Impacted people are reluctant to press charges, preferring to criticize police activity, or the lack thereof, feeling that the authorities are unable to protect them or prevent crime. Conklin listed several potential collective responses to crime, which included "work[ing] for a political candidate who promises to restore law and order", "call[ing] meetings of community residents", "band[ing] together in a civilian police patrol [. . .]". Residents of the areas most exposed to threats or fear should simultaneously be involved in a reassessment of police work and priorities. Similarly, the fear of foreigners should be tackled by countering the general hostility of the police toward them.

Community and Policing

In the wake of these and similar analyses, the late 1980s saw the emergence – first in the USA, then in Europe – of various concepts and methods aiming both to restore this community bond and profoundly renovate the role of police forces. While in France, any estrangement of the *Police Nationale* from the citizenry was largely attributable to the primacy of law and order in the policing agenda, municipal police forces in the USA mainly had to answer charges of corruption and nepotism. Still, in the 1980s, although their organizational structures and guiding principles differed significantly, both forces conjured up a rather similar imagery of brutality, racism, and social conservatism (Skolnick 1966; Westley 1970; Ericson 1982). Both also reflected a classical phenomenon, pervasive in policing literature, namely, the freedom of action enjoyed by street policemen, who may cherry-pick whatever cases they are interested in. Such discretionary behavior can be held in check by community control (Mastrofski 2004).

In the USA, the rebuilding of communities was thus also dependent on improving policing as a service to the public through far-reaching amendments of its practices, and transforming the relationships between the police and the people they were confronted with. Still, community policing remains hard to define in general terms – after all, adjustment to the local context is supposed to be one of its salient features in the first place. To simplify, one might say that it is more a process and a state of mind than a fixed operating model. *"In a definitional sense, community policing is not something one can easily characterize. It involves reforming decision-making processes and creating new cultures within police departments; it is not a packet of specific tactical plans. It is an organizational strategy that redefines the goals of policing, but leaves the means of achieving them to practioners in the field. It is a process rather than a product."* (Skogan and Hartnett 1997). Lowering the feeling of insecurity is just as much – possibly even more – a goal as lowering the crime rate or actual criminality, but it should be done with the community in mind, i.e., the locals should be involved. Community policing should contribute to improving communication between the police and the people, with the former working to achieve goals fixed by the latter. This general goal can translate into multiple practices, from satisfaction surveys to local meetings, neighborhood watches, activities for the youth, bicycle or foot patrols, etc. The basic idea is to decentralize and scale down policing to increase proximity with the field. Skolnick and Bayley identified four elements that make community policing the future of policing (Skolnick and Bayley 1986): police-community reciprocity, areal decentralization of command, reorientation of patrol and civilianization. Capitalizing on their privileged relationship with the citizenry, policemen are expected to “coproduce” security.

On a related note, Herman Goldstein (1990) noticed that police forces mostly focused on their means – organizational structure, staffing, equipment – as opposed to their objectives, considering that improving or increasing the former must result in an improved quality of service. Goldstein offered an alternative in the concept of “problem-oriented policing,” an operating mode that would put a stronger emphasis on meeting the public’s needs. He particularly insisted on the necessity for the police to respond not just to crime, but also to other problems raised by people, always with a nongeneric, non-stereotyped, customized response. This was meant to deal with minor disturbances, such as noise, which trigger repeated incidents and police interventions, but find no real solution. Besides, problems should not be addressed through legal channels only. Other resources, including partnerships, are available. Generally speaking, it can be said that problem-oriented policing explicitly raises the issue of how to assess police work and its efficiency. Beyond corporatist demands, policemen are encouraged to question their own methods as well as the impact of their action on identified problems.

On this basis, many local police forces in the USA implemented their own, more or less preventive, repressive, wide-scale, or focused on one specific department versions of community policing and problem-oriented policing, eliciting a rather keen interest from the management and active volunteer participation, but with mixed interest at best from many rank-and-file policemen. In Europe too, the problem-solving approach and the idea of closing the gap between the police and the people enjoyed a real, if uneven success, depending on the country. More often than not, in France or the UK, for instance, this rapprochement was made to look like a “back to basics” approach, with the management building up on the image of an idealized policing past – Robert Peel’s bobbies, the Paris *îlotiers* – to convince policemen to establish better relationships with the people.

This drive toward community-oriented policing, however, never took the shape of a unanimous, universal wave. Starting in the 1980s, law and order rhetoric and policies gradually took over in western democracies, so much so that even such an ideal of the iconic English bobby was weakened (Reiner 2000).

Zero Tolerance: A Backlash?

To a certain extent, the so-called New-York model and its corollary, “zero tolerance,” are usually considered to be the antithesis of community policing. To many commentators, only one facet of this model has ever mattered: increased repression whereby each and every illegal act is penalized – the judicial system (or other institutions) even starting to take “acts of incivility” into account. It appears, however, both to promoters of this strategy and to many commentators that this course of action is not entirely at odds with community policing, theoretically at least (Silverman 1999). The New-York Police Department, although sometimes reluctant to admit it, was inspired by a peculiar reading of James Q. Wilson and Georges L. Kelling’s now famous broken windows theory (Wilson and Kelling 1982). While the theory is unanimously recognized for explaining with utmost clarity the absolute necessity of bringing a swift response to any urban phenomenon that could be construed as suggesting that law enforcement authorities are giving up the fight, many beg to differ as per the “coercive” reading of it. Some, including G. Kelling (Kelling and Coles 1996), deny that they ever automatically associated the broken windows theory and the aggressive policing strategy known as zero tolerance. Others, possibly encouraged by further publications by Wilson himself, do however see a direct link between both, and either praise or criticize it. They insist on the fact that the “soft policing” interpretation of this theory neglects the fundamental function of police forces, namely, coercion, while inevitably advocating the existence of unrestrained, as opposed to legally constrained, police forces (Terrill and Mastrofski 2004). The underlying idea, quite popular among police officers, is that community policing stands in the way of their "real" job, which consists in fighting crime. The zero tolerance discourse is well received insofar as it focuses back on this priority.

In practice, the New-York police were seen implementing a policing strategy aimed at certain criminal activities – narcotics trafficking, illegal gun possession, car theft, corruption – while also focusing on street crime and "quality-of-life" policing – coercive police practices targeting street disorder, including prostitution, public alcohol consumption, public urination, littering, panhandling, or even "squeegeeing." Heckling youths were targeted as well. Against such behaviors, reconquering the streets involved arresting, controlling, warning people, and resorting to force whenever necessary. Tolerance zero strategies flourished in the Western world, next to community policing. The popular success of discourses and practices based on this concept – not just with policemen, but also with part of the general population – begs the question of what a community is and how useful the concept can be in the modern, even postmodern, individualistic world where even its definition is problematic. Is it dealing with ethnic, religious, generational, or just territory-based communities? In which case, how can a common policing strategy be designed to meet the needs of all citizens, although their interests diverge – the youth vs. the elderly, those who enjoy an animated life vs. those who long for a quiet environment, shopkeepers vs. people living on the street, etc.? More often than not, community policing may dissimulate some favoritism toward specific social groups – the well-off, the most integrated, those who "most resemble the police" – at the expense of others. As compared to zero tolerance, community policing, instead of fostering a police force able to restore communities and fight anomie, may prove to be nothing more than an ersatz of evolution, some sort of concealment and circumlocution (Klockars 1988). In other words, announcing a shift toward community policing may not be enough to alter the fundamental practices and philosophy of the police. In particular, a zero tolerance policy may turn out to be nothing more than a pretext to increase police pressure on those who are considered uncivil or unruly – beggars, prostitutes, youths occupying public spaces.

"Who does the community police force work for?" is a question that can also be framed in ethnic or racial terms. As pointed out by Skogan (2006) about Chicago, one of the areas where community policing has been most efficiently implemented, it was perceived quite differently in each the "three Chicagos" identified by him: White, African-American, and Latino. In Europe, several countries have faced racial riots that highlighted the urgency of questioning the adequacy of policing with regard to racial issues. In this respect, a comparison of the French riots of 2005 and the English riots of the years 1980–2005 provides a case in point (Waddington et al. 2009). Few policing systems are more dissimilar indeed: Ever since 2002, the French model has been characterized by the rejection of any notion of proximity policing (Monjardet 1996), whereas historically, English police forces are known to have consistently championed community policing. Still, in both countries, young people from ethnic minorities and underprivileged neighborhoods are specifically "targeted" by the police (Bowling et al. 2003). Such groups are always subjected to more surveillance and more zero tolerance policies than others. Besides, it is quite clear that the general attitude of the police toward them has been a key factor in both outbreaks of riots. The triggering factor has often been the arrest and subsequent death of a youth at the hands of the police. Integrating youths from these very minorities in the police forces is an option that has been implemented in some English cities, with disappointing results, especially as far as discriminations with regard to identity checks go. France, however, is adamant that such a differential treatment conflicts with a "republican" tradition holding that no discrimination can be made among French citizens based on ethnic criteria. Theoretically, all nationals have equal legal rights, regardless of their origins. Hence, no community is ever recognized as such. Yet, in practice, several studies did reveal the existence of ongoing discriminatory practices.

The emergence of stringent anti-terrorist policies in the wake of 9/11 and the developing struggle against illegal immigration in most western democracies only accentuated this drive toward the "targeting" of ethnic or religious minorities. At this point, not only do the professional habits of the police incite them to focus their action on minorities and youths from alleged rough areas, but the struggle against illegal immigration officially encourages this. As a matter of fact, illegal immigrants are primarily sought among visible minorities, which reinforces police pressure on these and makes them acutely aware of not quite belonging to the national community. The conscious or unconscious amalgamation of matters such as illegal immigration, terrorism, and incivilities concurs to the gradual estrangement of these ethnic or religious communities. Again, the USA, with their wide range of practices, gives us some food for thought. While many cities responded favorably to the federal policy initiated in 2002 to reinforce the struggle against immigration, many others, among the largest – including San Francisco, Los Angeles, Detroit, Chicago, Houston, Seattle, or Washington – flatly declined to engage in this. Refusing to allow the police to inquire into the immigration status of persons arrested for minor offenses, they started designating themselves as "sanctuary cities" for immigrants (Skogan 2009). The arguments put forward are key to this discussion. When the local police is deeply involved in community policing programs, any mass action against illegal aliens that might jeopardize progress made in terms of cooperation with immigrants will simply be ruled out. Information from these communities can only be accessed on the basis of a trust-based relationship, which in turn rests on a benevolent attitude from the police. The bottom line is that illegal immigrants are an ideal prey for criminals, insofar as they do not have the option of lodging complaints, for fear of being convicted themselves. Besides, because they entered the country illegally, they can only gain illegal access to whatever services, housing, jobs, or usury they might need. They become potential recruits for criminal organizations.

In that case, the presence of a lenient, understanding police force is an asset in the fight against this multiform criminality. From this point of view – and not unusually, as far as policing studies are concerned – establishing privileged contacts that might yield useful, legally exploitable information entails building a mutually beneficial relationship: Using their discretionary, police officers may turn a blind eye on some petty offenses in order to gain access to such information. Which raises yet another issue, one that obviously impacts not just illegal immigrants and cooperating offenders, but the citizenry as well, namely, the increasing judicialization of policing activities, which restrains the discretionary leeway of police officers.

Scrupulous law-abidance is indeed a growing trend among police officers, both because of increased surveillance from police control institutions – magistrates, internal control departments, ombudsmen, human rights NGOs – and because of the higher education officers have received in legal matters, which has improved dramatically. This can only be positive, since police abuse should considerably decrease as a result. There is, however, a downside in that this judicialization induces the police to reject all flexibility in order to abide by the law, which is detrimental not just to their efficiency, but also to their negotiation margins. They are less inclined to adjust their behavior to the members of the various communities they are facing, and refuse to engage in such negotiations as mentioned above, trading leniency for information. Given increasingly restricting modes of management, this legal burden is hampering all attempts at developing any kind of proximity police. While problem-solving policing requires bottom-up operational processes, police management is increasingly top-down orientated.

Avatars of Community Policing

The coexistence of such different logics as community policing and law and order policies has bred hybrid practices that make it difficult to unambiguously interpret their induced effects. A case in point here is intelligence-led policing, a more recent concept that is quite illustrative of the ambiguities produced by the various interpretations of community policing and its confrontation to other logics. Intelligence-led policing was developed in the 1990s when authorities in Great-Britain and Australia were striving for efficiency in both policing and cost-management (Ratcliffe 2002). Even prior to 9/11, it was recognized that the traditional policing model needed to be reformed because it was unable to cope with the major changes induced by globalization. The idea was to turn the police into “knowledge workers” trained in dealing with the risk society (Ericson and Haggerty 1997). This could only be achieved by constantly maintaining high levels of awareness to the environment and the changes it was going through. Next, with the help of analysts organized in support teams, they had to be able to build up an understanding of this changing environment. Finally, they were expected to transmit their findings to decision-makers. The targeted goal was increased efficiency: Analysis is expected to help define clear-cut priorities, not letting the police spread themselves too thin and operate too routinely on day-to-day habits. Efficiency and budgetary requirements are two closely intertwined factors here.

From a theoretical perspective, intelligence-led policing is perfectly compatible with both community policing and problem-solving policing. All three approaches share the common purpose of trying to bypass mundane bureaucratic police procedures and adjust the priorities imposed upon the organization to the ongoing changes of the environment. In practice, intelligence-led policing has helped remotivate a number of policemen who had grown disenchanted of community policing. Indeed, given the lack of enthusiasm elicited by community policing – particularly in the general context of developing terrorist threats and focus on zero tolerance – entrusting a proximity police force with intelligence assignments certainly contributed to enhancing its professional legitimacy. Undoubtedly, promoting rank-and-file community policemen, who occupy the lowest echelons in the informal hierarchy of policing, to the status of intelligence and analysis agents could only be perceived as gratifying.

The discourse on intelligence-led policing, however, is certainly not devoid of contradictions, either intrinsic or relative to the principles of community policing. Its very implementation is fraught with practical difficulties, to begin with. But what is primarily interesting here are the tensions generated by the confrontation of beat policemen, who spontaneously adjust to their environment, with external analysts. This is a classic dilemma of policing, and one which was already covered here: should the policing agenda be set by public demand or by uninvolved analysts who do not in any way relate to the contingencies of police-public interactions? Whether such people belong to the traditional hierarchical organization, as in the classic militarized model, or are mere “technocrats” outside that hierarchy makes no difference from this point of view. Secondly, performance evaluation raises more questions than it can answer, being based on criteria that are all too prone to excesses and manipulations. Policing productivity criteria have lots of pernicious consequences, including in particular the targeting of “small fry,” minor offenders that generate high productivity statistics, instead of the “big fish,” who require more work for a seemingly inferior output.

Finally, to conclude on community policing, it should be noted that recent developments may be taking us toward absolutely novel forms of community policing. In countries with highly centralized, nation-wide policing processes, such as France, local forces are increasingly tasked with proximity assignments, leaving “real policing” to the *Police Nationale*. More generally, communities tend to rely on themselves to assume a regulation role that traditional police forces do not, or not properly, fulfill. In upscale neighborhoods, this leads to the creation of gated communities. In poorer areas, either self-defense groups get organized to protect the community, or criminal groups see to the security of those they consider part of their own community, thus effectively supplanting the police, who are alien to it. Indeed, the concept of “community” has a risky side to it, and can lead to self-imprisonment and withdrawal.

Overview

Therapeutic jurisprudence, developed in the late 1980s, is a field of inquiry. It is a lens through which to examine the effects of substantive laws, legal rules, legal procedures, and the behavior of legal actors, including judges, lawyers, court personnel, and service providers, on the psychological and emotional well-being of justice system participants, including the legal actors themselves. Therapeutic jurisprudence is a perspective or framework, and its use suggests the need to conduct empirical research to determine whether outcomes resulting from the application of substantive laws, legal rules, and legal procedures and from the behavior of legal actors have therapeutic (helpful) or antitherapeutic (harmful) consequences, both intended and unintended. In addition, therapeutic jurisprudence involves a reform agenda, as it urges that findings from the behavioral and social sciences be used to transform laws, rules, procedures, and the behavior of legal actors in a manner that promotes well-being. This interdisciplinary focus enables therapeutic jurisprudence scholarship and practice to encompass a broad array of subject areas.

From its beginnings as a concept developed in relation to mental health law, therapeutic jurisprudence now enjoys wide and international application in almost every area of the law, including criminal law, family and juvenile law, contract law, tort law, and health law, to name a few. The task of therapeutic jurisprudence in each area of the law is to ensure that therapeutic outcomes can be maximized, while still honoring other justice system values, such as due process. A comparative law approach now is advancing which allows therapeutic practices and approaches from one country's legal system to be assessed in relation to another country, and therapeutic jurisprudence scholarship now exists in many languages.

Although the use of therapeutic jurisprudence principles is best known in the context of problem-solving or solution-focused courts, therapeutic jurisprudence is by no means so limited. The first essay explicating the perspective predates the establishment of problem-solving courts. In addition, from its beginning, principles of therapeutic jurisprudence have been used in general judicial contexts, particularly in criminal cases (Wexler 2005).

Defining Therapeutic Jurisprudence

David Wexler became interested in the notion of law as therapy and of therapy through law as a result of his work in the area of law and mental health. In the summer of 1987, he wrote a paper in preparation for a National Institute of Mental Health workshop. In that paper, which he presented at the workshop in October 1987, he referred to this perspective as "juridical psychotherapy." That term, however, did not survive the meeting, and Wexler thereafter began to use "therapeutic jurisprudence" to define this approach. Wexler's first anthology on the subject was published in 1990 (Wexler 1990).

The late Bruce Winick shared Wexler's interest in mental health law and in the notion of law as therapy. Both were interested in civil commitment, the insanity defense, incompetency to stand trial, and the fact that the mental health system often functioned in a manner that impeded people's recovery (Wexler 2010b [hereinafter Application to Criminal Justice]). The two men became collaborators and codevelopers of therapeutic jurisprudence doctrine and, in 1991, jointly published a book on the subject (Wexler and Winick 1991). For the next two decades, until Winick's untimely death in 2010, these two scholars often worked together. With a growing group of other professionals, they brought psychological insights into the development of legal thought, scholarship, practice, and reform.

Now, after Winick's passing, his legacy continues to be felt. Wexler and a large number of colleagues internationally and across a number of disciplines are developing energetically in the therapeutic jurisprudence field.

Since its origins as an academic approach to mental health law, therapeutic jurisprudence has spread to almost every other area of the law, including criminal law, family and juvenile law, tort law, health law, and housing law, among others. The breadth of its application is evident in a 1,000-page anthology published by Wexler and Winick in 1996, *Law in a Therapeutic Key: Developments in Therapeutic Jurisprudence*. In addition, multitudes of international scholars and practitioners are engaged in the study and practice of therapeutic jurisprudence, as evidenced by postings on and membership in the International Network on Therapeutic Jurisprudence, a therapeutic jurisprudence listserv, a Facebook page, and several international conferences to date on the subject. Many law school course offerings worldwide focus on therapeutic jurisprudence, as referenced in *TJ Across the Law School Curriculum* (Wexler 2012). One United States law school has created a family law and family justice system center, the University of Baltimore School of Law Center for Families, Children and the Courts, whose work is grounded in therapeutic jurisprudence.

Some scholars and practitioners have criticized the use of the word "therapeutic" as "too vague" or "too medical sounding." Winick has suggested that anything related to psychological functioning is therapeutic (Johnston 2012). Others have commented that "jurisprudence" is inappropriate, as they have searched for a comprehensive theory, which they find lacking. Wexler and Winick themselves have encouraged wide scholarly inquiry and debate (Johnston 2012). Nonetheless, the term therapeutic jurisprudence has survived and is thriving.

Therapeutic jurisprudence is a field of inquiry – a research agenda, so to speak. It has evolved from a focus on mental health law to a mental health approach to the law in general. It has contributed to a deeper understanding of the law. Therapeutic jurisprudence is the study of the role of law as a therapeutic agent by serving as a lens that focuses on the law's impact on an individual's emotional and psychological well-being. Therapeutic jurisprudence looks at the law as a social force that can produce therapeutic (helpful) or antitherapeutic (harmful) consequences. These consequences flow from substantive law, legal rules, and legal procedures (the "legal landscape") and from the behavior (the "practices and techniques") of legal actors, including lawyers, judges, court personnel, and others working within a legal context. Returning to Wexler's original idea of law as therapy, therapeutic jurisprudence sees the law itself as the therapist or healing agent. In the same manner as iatrogenic or harmful consequences exist in medicine, law has the potential to produce psychological harm, which Wexler has referred to as "law-related psychological dysfunction" or "juridical psychopathology" (Wexler 1992). Therapeutic jurisprudence instructs that we seek to maximize the therapeutic consequences of the law and its intervention and to minimize its antitherapeutic consequences.

As a field of inquiry, the task of therapeutic jurisprudence is to identify relationships between legal arrangements and therapeutic outcomes. In contrast to the traditional legal analogical process, therapeutic jurisprudence research involves applying a body of social science literature to a body of law and determining their interactions. The ultimate goal of the inquiry is to examine these pairings empirically, and the research has the potential to be interdisciplinary by involving law, philosophy, psychiatry, psychology, social work, criminal justice, public health, and other fields. This empirical understanding then can serve as a basis for policy and law reform (Wexler 1992). In fact, bringing relevant social science research into the legal arena is an important undertaking for therapeutic jurisprudence (Wexler 2001). According to

Wexler, therapeutic jurisprudence is an optimistic and creative perspective, as it tries to identify promising practices from the social sciences and to import those practices into the law. Therapeutic jurisprudence aims to produce tangible, positive change; to promote the well-being of all legal actors; and to improve the justice system so that it is more relevant and helpful for participants and their communities (Goldberg 2005). Therapeutic jurisprudence seeks to determine whether the law can be made, applied, or practiced in a more therapeutic way (Wexler 2010b [Application to Criminal Justice]).

One important question when approaching legal problems and issues from this perspective is whether the goals of therapeutic jurisprudence always should prevail. According to Wexler and Winick, therapeutic consequences should not trump other considerations, such as due process, nor is the approach paternalistic or coercive, as it emphasizes the importance of self-determination and autonomy. Abiding by the notion of therapeutic jurisprudence, if all other judicial and legal issues are equal, the law ought to be restructured to accomplish therapeutic outcomes. The difficulty arises when determining what normative values should take priority. Therapeutic jurisprudence does not answer this (Wexler 1992). It initiates the question and then sharpens and focuses the debate (Wexler 2010b [Application to Criminal Justice]).

Therapeutic jurisprudence has the added value of identifying some of the more subtle, unintended consequences of substantive law and legal rules (Wexler 2010b [Application to Criminal Justice]). It also offers a platform from which to ask and raise questions that otherwise might go unaddressed (Wexler 2010b [Application to Criminal Justice]).

Therapeutic Jurisprudence and Problem-Solving Courts

In August 2000, both the Conference of Chief Justices and the Conference of State Court Administrators endorsed the concept of problem-solving courts and the application of therapeutic jurisprudence by these courts (Wexler 2001). The resolution adopted by both groups focused on methods founded in therapeutic jurisprudence, including the following: the integration of treatment services with legal case processing, ongoing judicial intervention during the case, close monitoring of and responsiveness to a party's behavior, multidisciplinary involvement in a case, and collaboration with community and government organizations (Wexler 2001). The therapeutic purpose of these courts was found in their intent to promote positive behavioral change on the part of the participants (Wexler and King 2010).

Problem-solving courts, such as drug treatment courts, domestic violence courts, prostitution courts, mental health courts, and reentry courts, to name a few, exemplify therapeutic jurisprudence as applied or therapeutic jurisprudence in action. These courts, which now operate internationally, create reciprocal accountability among the judge, the parties, and the services providers that differs markedly from the traditional adversarial roles (Dorf and Fagan 2003). Problem-solving courts seek to identify and address on an individual basis a legal problem's underlying issues or causes of the criminal behavior, such as substance abuse, family violence, and mental illness, thereby promoting positive behavioral, psychological, and emotional change in court participants – all therapeutic outcomes. By focusing on the reasons for offending and by consciously attending to them, a problem-solving approach strives to decrease recidivism and to impede the revolving door of the criminal justice system.

The first scholars to connect therapeutic jurisprudence to problem-solving courts were Peggy Hora and William Schma, along with John Rosenthal, who posited that therapeutic jurisprudence formed the explicit framework for drug treatment courts, which began to operate in 1989 (Hora et al. 1999). Building on their work, most, if not all, problem-solving courts now routinely are associated, implicitly or explicitly, with therapeutic jurisprudence.

While not abandoning the place of therapeutic jurisprudence, Michael King has suggested that problem-solving courts be recast as solution-focused courts (King 2011). King argues that this solution-focused approach relies less on the court's ability to solve a problem than on an individual's self-efficacy and own ability to initiate and sustain positive behavioral change (King 2011). The judge functions as a facilitator of change rather than as the problem-solver, thereby empowering the participant (King 2011). King suggests that this approach also should guide lawyers and other professionals involved in problem-solving courts. He states that the focus on self-determination and intrinsic motivation is more consistent with therapeutic jurisprudence than is the potentially more coercive, paternalistic approach of a problem-solving court (King 2011). Therapeutic jurisprudence acknowledges that the individual must confront and solve her own problems (Wexler and King 2010). King also cautions, however, that therapeutic jurisprudence does not place the focus on the individual above all other justice system values, including the integrity of the justice system (King 2011).

Adopting a therapeutic, problem-solving, or solution-focused approach to legal problems does not mean that judges and lawyers function as therapists or social workers. Instead, it requires that legal actors consciously consider the problems that may have precipitated the criminal behavior and how to effectively address those concerns. Legal actors need to recognize their potential to function as change agents and to acknowledge the impact that their behavior can have on the participants (Goldberg 2005). Through a non-adversarial, team-based approach to an individual's legal problems, the focus of problem-solving or solution-focused courts is on offender compliance with treatment and rehabilitation (Goldberg 2005). To be truly meaningful and therapeutic in these settings, all legal actors' interactions with participants must be characterized by empathy, respect, active listening, a positive focus, non-coercion, non-paternalism, and clarity (Goldberg 2005). In support of these notions, Goldberg provides wonderful examples of behaviors under each of these characteristics in the document she edited for the Canadian National Judicial Institute (Goldberg 2005).

Many problem-solving or solution-focused courts require signed contracts with the offender that outline goals and conditions, along with appropriate rewards and sanctions. In order to maximize the therapeutic outcomes from these contracts, they should adhere to the following guidelines: involve the offender, identify high-risk situations, require the offender to take responsibility for his actions, set specific goals, enumerate specific rewards and sanctions, encourage the participation of family and community members, treat the offender with dignity and respect, and schedule regular review hearings with judicial supervision (Goldberg 2005). Again, Goldberg offers examples of how to accomplish each of these considerations (Goldberg 2005).

The integration of therapeutic jurisprudence into the design and operation of problem-solving or solution-focused courts is paramount. It reminds us that all legal actors must operate from and embody an ethic of care, recognizing that the law truly is a helping and healing profession (Wexler and Winick 2003).

Therapeutic Jurisprudence and Related Doctrines

In the study, practice, development, and reform of the law and legal processes, therapeutic jurisprudence has become partnered with many other doctrines, which has served to enhance the power and relevance of the perspective.

One of the first such pairings was the collaboration between therapeutic jurisprudence and preventive law. The development of a preventive law approach preceded that of therapeutic jurisprudence by many years. Preventive law encouraged lawyers to try to identify potential legal problems early and to address those problems before they developed into true legal issues. It advocated that lawyers anticipate and attend to "legal soft spots," including both "trouble spots," or attempts to avoid legal problems, and "opportunity spots," or areas upon which to focus in order to achieve desired outcomes (Wexler 2010a [hereinafter From Theory to Practice]). Applied to the practice setting, preventive law emphasized the importance of "periodic legal checkups," analogous to regular medical checkups, and the use of the "rewind" technique, or replaying a situation back and determining what could have been done differently to avoid any legal problems encountered (Wexler 1999). Wexler and Winick joined Dennis Stolle, who first suggested the therapeutic jurisprudence/preventive law partnership, to create the alliance (Stolle 1996). According to them, preventive law offered law office practices, including client counseling approaches, and a framework within which to apply the law therapeutically. Therapeutic jurisprudence expanded preventive law's focus on "legal soft spots" to "psycholegal soft spots and strategies," suggesting and justifying that attorneys, judges, and other legal actors consciously address the psychological and emotional issues often accompanying both civil and criminal legal problems (Wexler 2010a [From Theory to Practice]). Therapeutic jurisprudence also enhanced the notion and actions of lawyers as counselors (Wexler 1999).

Another powerful partnership occurred in the family law context, where therapeutic jurisprudence was joined with Urie Bronfenbrenner's research paradigm from the social sciences called the ecology of human development (Babb 1997). This ecological approach to family legal issues and to family justice system reform offered a method to promote consideration of the interaction among individuals, institutions, and the social environment; to assist with a more complete identification of problems; and to contribute to the development of more comprehensive, effective solutions. The ultimate aim of this approach was identified as strengthening the connections among these interactions, institutions, and influences to improve families', children's, and communities' functioning. In order to reform the family justice system, Barbara Babb advocated applying a therapeutic and ecological framework to restructure family law decision-making forums into unified family courts (Babb 1998). She suggested that these courts, if designed and implemented according to her blueprint, could improve families' and children's lives by identifying and addressing holistically all the related legal and nonlegal issues contributing to the underlying family legal problems (Babb 1998).

In a similar vein, Susan Brooks and Robert Madden linked therapeutic jurisprudence with a social science doctrine often applied in the social work context and known as family systems theory (Brooks and Madden 2010). The authors examined the use of a holistic approach to the practice of law through the application of this conceptual framework, similar to the ecological approach described above, and designated by them as "relationship-centered lawyering" (Brooks and Madden 2010). Their paradigm was not limited to the family law context, however, but was applicable to most areas of the law.

Procedural justice, or the focus on legal proceedings and processes themselves rather than exclusively on decisions or findings, also has complemented therapeutic jurisprudence. As Susan Goldberg has noted, for example, therapeutic outcomes for individuals depend largely on their sense of feeling fairly treated, of being accorded respect, of being able to understand the proceedings, and of being heard during the legal process (Goldberg 2005). Goldberg also emphasizes that people who are satisfied with legal proceedings are more willing to comply with courts' decisions and, in turn, have greater trust and confidence in the justice system (Goldberg 2005). As Wexler and Michael King suggest, in the criminal law context, procedural justice must be coupled with some principles and techniques of therapeutic jurisprudence in order to decrease recidivism (Wexler and King 2010).

In the criminal law area, restorative justice often is paired with therapeutic jurisprudence. Restorative justice aims to hold offenders accountable and, at the same time, attempts to address the needs of crime victims and the community at large, as the offense is characterized as harm done to both (Goldberg 2005). Generally, the offender, the victim, and the community engage in an active dialogue to identify a resolution that allows offenders to apologize, make amends, pay restitution, and give back to the community (Goldberg 2005). The aim of this approach, then, is conflict resolution that promotes a healing or therapeutic outcome on the part of all participants, including rehabilitation of the offender and strengthening of the community (Goldberg 2005).

Wexler and King also note that in the criminal law area, therapeutic jurisprudence has adopted a "tripartite" framework (Wexler and King 2010). Under this framework, they urge attention to (1) the pertinent legal landscape or a jurisdiction's substantive law, rules, and procedures; (2) the treatments and services available to defendants; and (3) the possible practices and techniques that the array of legal actors (judges, lawyers, court personnel, therapists) can employ (Wexler and King 2010). Each of these three areas may be either therapeutic jurisprudence-friendly or therapeutic jurisprudence-unfriendly, with the aim being to enhance their affinity to therapeutic jurisprudence (Wexler and King 2010).

Susan Daicoff has included therapeutic jurisprudence as one of the vectors of her legal framework, the comprehensive law movement (Daicoff 2000). This approach to the law is intended to be more holistic and humane.

Critiques of Therapeutic Jurisprudence

Over the years, there have been a number of critiques of therapeutic jurisprudence, well-summarized by Australian barrister and academic Ian Freckelton (2008). Some commentators have questioned whether therapeutic jurisprudence is truly a new approach or whether it is just "old wine in a new bottle" (Freckelton 2008). Similarly, others have argued that the concept of "therapeutic" is problematic and is not distinct enough to differentiate itself from current mental disability law (Arrigo 2004; Petrila 1993; Slobogin). Additional critiques are that therapeutic jurisprudence is covertly paternalistic through involuntary or mandated treatment and that therapeutic jurisprudence attempts to balance many values that are at odds with one another, giving it unclear applicability to judicial decision-making (Slobogin 1995).

Bruce Arrigo argues that therapeutic jurisprudence is too conservative, in that it views the public as homogenous, without recognizing individual and group differences (Freckelton 2008). Samuel Brakel has characterized therapeutic jurisprudence as redundant and not helpful to understand the interface between law and human behavior (Brakel 2007). Brakel also has argued that therapeutic jurisprudence intrudes upon civil liberties by resisting mandated inpatient treatment; therapeutic jurisprudence places some offenders at a disadvantage, as some mental illnesses might be resolved through treatment during brief hospitalization (Brakel 2007).

Freckelton responds to each of these critiques. Generally, however, he notes that many are based on a perspective that "therapeutic jurisprudence has purported to be what it does not claim to be – a coherent body of scholarship with a unified focus that proffers coherent and straightforward answers to complex issues in law and practice" (Freckelton 2008, p. 591). Instead, proponents such as Winick and Wexler merely have claimed that therapeutic jurisprudence can provide a new perspective on the law and that a legal system where therapeutic consequences factor into law and policy when appropriate is preferable to a system in which they do not.

Perhaps the strongest frontal attack on therapeutic jurisprudence and lawyering in the criminal context comes from Mae Quinn. Quinn argues that therapeutic jurisprudence principles should not extend to criminal defense practice – essentially making defense attorneys "rehabilitative change agents" – because doing so undermines the core traditional value of zealous representation. Quinn points to a lack of data showing that traditional criminal defense lawyering has antitherapeutic consequences as evidence that good defense lawyers already effectively take client needs into account in plea-bargaining and defending their clients.

Wexler has responded to Quinn that a defense lawyer who takes therapeutic jurisprudence into account would still exercise due diligence in investigating all possible offenses but would incorporate therapeutic jurisprudence principles as an "add-on." Wexler views therapeutic jurisprudence lawyers as holistic, using psychologically sensitive practice techniques. If, as Quinn maintains, this is simply good lawyering, therapeutic jurisprudence may add a conceptual scheme to examine these practices and to consider other areas of application (Wexler 2008).

As noted above, therapeutic jurisprudence has been criticized for going too far or doing too much. But lawyer/commentator/journalist Mark Satin has criticized therapeutic jurisprudence for not going far enough. Satin argues that therapeutic jurisprudence should be viewed as the basis for an alternative approach to justice, rather than as a lens relative to the existing legal system (Satin 2008).

Future Directions for Therapeutic Jurisprudence and Conclusion

A focus on therapeutic jurisprudence encourages creative thinking in all areas of the law, including practicing, judging, administration, teaching, policymaking, scholarship, and reform, among others. As Wexler indicates, we are called upon to search for promising developments and practices in the behavioral and social sciences, including psychology, psychiatry, criminology, and social work, even if these practices appear to have nothing to do with the law (Wexler 2010b [Application to Criminal Justice]). The task is to determine if any of these promising developments can be introduced into some aspect of or undertaking involving the law (Wexler 2010b [Application to Criminal Justice]).

In the general criminal law context, therapeutic jurisprudence principles have been applied to the granting of probation – especially to the process of crafting probation conditions with which the probationer is likely to comply (Wexler 2008).

Therapeutic jurisprudence also is used in the correctional system, such as in encouraging confined persons to adopt a perspective consistent with a law-abiding future (Wexler 2006) and to the context of parole release (Wexler 2011a [Retooling Reintegration]). A recent article on cognitive interviewing has applied the therapeutic jurisprudence perspective to police investigations (Fisher and Geiselman 2010).

A daily opportunity that has the potential to incorporate therapeutic jurisprudence is at judges' sentencing of criminal defendants who are convicted of some offense. At sentencing, by the way the judge interacts with the defendant, the judge has the opportunity to assist the defendant to confront the wrongdoing and to begin to change behavior (Goldberg 2005). This may include making some type of amends to both the victim and the community. In other words, judges can adopt a problem-solving approach to sentencing based upon restorative justice principles.

Judges can perform another important function relative to therapeutic jurisprudence. Once they have grasped the importance of therapeutic jurisprudence to the justice process and to the work of the courts, judges can draft or assist with the drafting of justice system mission statements that explicitly account for therapeutic jurisprudence (Wexler and King 2010). An example of one such mission statement exists for the Family Divisions of the Maryland judiciary, which has adopted and codified a therapeutic, holistic, ecological approach to family law decision-making (Babb and Kuhn 2003).

One promising practice Wexler details is a "reentry moot court" for incarcerated individuals who are about to participate in the parole process (Wexler 2010b [Application to Criminal Justice]). Through this reentry moot court, the prisoner would participate in a rehearsal of his parole board appearance before a group of incarcerated peers and at least one trained facilitator. This group would assist the prisoner to identify important issues regarding his release and reentry. In addition, the reentry moot court could be useful to the other prisoners as a means to assist them to prepare for their own parole hearings (Wexler 2010b [Application to Criminal Justice]). Practices that could be included in the reentry moot court include restorative circles, modified restorative circles, and relapse prevention programs discussed below.

Hawaii currently offers two "circle" programs for incarcerated individuals. In the restorative circle, the incarcerated person plans for reentry by meeting with loved ones and prison representatives. Together, they create a detailed reentry plan to assist with the inmate's return to society (Wexler 2011a [hereinafter Retooling Reintegration]).

By involving loved ones, this model is a pure restorative justice model. In the modified restorative circle, loved ones are absent, and trained facilitators work with inmates to detail their reentry plans (Wexler 2011a [Retooling Reintegration]). Both programs have had therapeutic effects on inmates' attitudes, including enhancing their feelings of optimism, hope, and readiness to return to society (Wexler 2011b).

Relapse prevention planning, or RPP, is a practice that examines an individual's past behavior in an effort to determine how that individual can move forward in life without further harmful results or effects (Wexler 2011a [Retooling Reintegration]). These programs appear to achieve positive results, such that policymakers are becoming more receptive to incorporating them into the prison setting (Wexler 2011a [Retooling Reintegration]).

A new type of specialized problem-solving court that shows great promise is a child support collection court operating in Colorado. It is a criminal nonsupport docket where individuals appear who are in contempt of court for failure to pay child support. Instead of being called the nonsupport docket, it is called simply "Problem-Solving Court" (Griego 2011). The court team has built a network of services to connect court participants, most of whom are fathers, with substance abuse treatment, free mediation services, vocational rehabilitation, workforce development, GED programs, and fatherhood programs (Griego 2011). Since the court began operating, the number of participants sentenced to jail has decreased dramatically, and the amount of back child support paid has increased substantially.

In an effort to capture all of the innovative practices incorporating therapeutic jurisprudence that judges and attorneys are employing with increasing frequency, Wexler hopes to develop a body of therapeutic jurisprudence case law (Wexler 2010a [From Theory to Practice]). Through this process, therapeutic jurisprudence cases could be continuously gathered for distribution, discussion, and revision or rewind, including suggested improvements for future practice. In addition, it would be possible to create a new body of "practical interdisciplinary scholarship," once there is a method to collect these approaches (Wexler 2010a [From Theory to Practice]).

Wexler also suggests creating continuing education programs on therapeutic jurisprudence for lawyers, judges, and mental health professionals. These programs could include time for input by the group regarding promising therapeutic practices and techniques (Wexler 2010a [From Theory to Practice]).

While law school clinical programs have begun to include the study and application of therapeutic jurisprudence into both their seminar components and into their practice of law, there exists a rich opportunity for even more programs to incorporate this perspective (Wexler 2010a [From Theory to Practice]). Law school clinical programs also represent another opportunity for law students and law faculty to write about their experiences, thereby increasing the available literature about therapeutic jurisprudence as applied (Wexler 2010a [From Theory to Practice]).

Within the law school setting, classes other than clinical programs can continue to include examination of the therapeutic jurisprudence perspective (Wexler 2010a [From Theory to Practice]). As noted earlier, a bibliography currently exists that lists readings on therapeutic jurisprudence for classes across the broad law school curriculum. To maintain and enhance the momentum to include therapeutic jurisprudence within the law school context, legal academics must continue to produce therapeutic jurisprudence scholarship and to speak about therapeutic jurisprudence at professional conferences.

In fact, one therapeutic jurisprudence scholar has suggested that legal scholarship around-therapeutic jurisprudence ought to differ from traditional legal scholarship. He calls for this new scholarship to be shorter, more direct, and more readable, including discussions of law reform issues (Wexler 2010a [From Theory to Practice]).

Michael King suggests that there is a dearth of research about judging in problem-solving courts (King 2011). He believes that there is an urgent need for this research and that the research should focus on the nature and process of behavioral change in individuals. According to King, problem-solving courts are too focused on the practice of lawyering and judging. Instead, King argues that these courts ought to be designed based upon a more comprehensive understanding about how change occurs within individuals (King 2011).

With a similar focus on judging, Wexler suggests that judges who are aware of therapeutic jurisprudence should begin to document appropriate situations or circumstances for its application (Wexler 1999). This documentation then can be shared with other judges. Since judges create the legal culture in their courtrooms, it stands to reason that if judges begin to care about therapeutic approaches to the law, lawyers appearing before them also are likely to attune to this perspective (Wexler 1999). Both judges and lawyers should be aware of what Professor Winick has called the "therapeutic moment" (Wexler 1999).

Wexler also suggests incorporating practices from drug treatment courts, such as graduation ceremonies, judicial praise, and family and friend participation, into ordinary juvenile and criminal cases (Wexler 2001). While these activities acknowledge a participant's progress, they also may contribute to maintaining the participant on a path of positive behavior change (Wexler 2001). The judge has the potential to be a tremendous influence on participants due to her stature and authority, and these activities offer a means for the court to offer true support to participants.

Therapeutic jurisprudence is now a well-established field of inquiry with a large international following and an extremely broad scholarship component. In addition, judges, lawyers, court personnel, and services providers all are adopting and applying therapeutic approaches to their roles and behavior. The most noteworthy example is the effusive and continuing proliferation of problem-solving courts. The potential for therapeutic jurisprudence to continue to enhance and improve justice systems internationally is unlimited.

Overview

Third-party policing is an approach to crime prevention and control involving the police partnering with organizations or individuals to prevent or reduce crime problems. It relies on available civil, criminal, or regulatory rules and laws (legal levers) that enable third parties to take responsibility, at least in part, for control of crime. This entry examines the complexities of the legislative and regulatory framework around the problem of school truancy to illustrate the range of opportunities for using legal levers within a third-party policing context.

Introduction

Third-party policing is a strategy where police collaborate with organizations or nonoffending persons to encourage them to take part responsibility for preventing crime or reducing crime problems (Buerger and Mazerolle 1998). In a third-party policing approach, the police aim to improve crime control, where previous efforts were ineffective, by creating third-party partnerships to enforce the law. These third-party partnerships may be cooperative and involve community members, parents, inspectors, and regulators to convince third parties to take on more crime prevention or control responsibility. Importantly, third-party policing relies on available civil, criminal, and regulatory rules and laws (referred to as legal levers) that enable third parties to take crime-control responsibility.

Third-party policing is an international and growing phenomenon in policing. Mazerolle and Ransley (2005) show that about 50 % of problem-oriented policing (POP) projects utilize at least one third-party policing tactic and occur outside the Scanning, Analysis, Response, Assessment (SARA) policing approach to problem-solving. Problem-oriented policing provides a management infrastructure (see Goldstein 1990) and a stepwise approach to solving a crime problem (Eck and Spelman 1987) within which third-party policing may be one response utilized by police to solve a crime problem (Goldstein (2003). Situational crime prevention provides police with ideas and techniques for reducing crime opportunities (Clarke 1992). In fact, third-party policing can be integrated into any of the 25 techniques of crime prevention proposed by Cornish and Clarke (2003).

When third-party policing is implemented as a crime-control mechanism, the structure of the available legal levers dictates how potential crime-control problems are solved. While third-party policing is merely one of many categories of problem-solving responses or situational techniques, the use of coercive power, from the available legal levers, differentiates the third-party policing approach from other policing strategies (see Buerger and Mazerolle 1998). In third-party policing, the police partnerships with the chosen third parties focus on encouraging or coercing the third party to utilize the legal lever available to them to respond to the relevant crime-control issue (Mazerolle and Ransley 2005).

This entry explores the legal context that underpins third-party policing. Third-party policing occurs within a legal framework that establishes the authority for police to partner with or coerce third parties, the contexts in which they can do this, and the types of interventions this may produce. Arguably, it is this legal basis of third-party policing that both defines it as a unique strategy and distinguishes it from other policing interventions, most notably problem-oriented policing.

The most common legal levers used in third-party policing include local, state, and federal statutes (including municipal ordinances and town bylaws); health and safety codes; uniform building standards; liquor licensing; and a wide variety of statutory programs that use injunctive remedies (e.g., domestic violence restraining orders, gang injunctions, drug nuisance abatement). Importantly, the legal lever may not be aimed at crime control but may instead regulate another form of activity that, if managed, could have a crime-control impact. In fact many legal levers used in third-party policing approaches are not sourced from criminal law. For example, many of the legal levers that can be applied in a third-party policing intervention for truancy come from education law but operate to control crime by improving student attendance and reducing the likelihood that students become either a victim or perpetrator of crime.

This entry examines the complexities of the legislative and regulatory framework around the issue of truancy to illustrate the breadth of opportunities for using legal levers within a third-party policing context. It begins with an overview of the general understanding of the problem of truancy, followed by an overview of a wide range of legal, civil, and informal levers and sources of authority available to support a range of possible interventions in truancy across a range of jurisdictions. Next, the challenges for police in initiating and implementing a third-party policing approach to truancy are discussed, and finally, some conclusions are drawn.

Truancy and Third-Party Policing

Truancy is generally defined as unexplained and persistent absenteeism from school. Research has shown a relationship between truancy and numerous negative developmental outcomes for a young person including school dropout (Alexander et al. 1997), unemployment and social service dependency (Attwood and Croll 2006), and teen pregnancy (Spencer 2009). Research shows truancy is symptomatic and causally related to domestic violence, general family dysfunction (Baker et al. 2001), substance use and abuse (Henry and Huizinga 2007), low socioeconomic status (Baker et al. 2001), and bullying or school violence (Reid 2005). Importantly, truancy is also directly related to, among other antisocial behaviors, antisocial peer influence and drug and alcohol use (Henry 2007). This makes effective intervention for truancy critical for the young person, their family, and the community, as addressing truancy may have a crime-control function. However, the variation in underlying causes of truancy makes systematic intervention for truancy difficult for government agencies.

A third-party policing approach to truancy provides the requisite flexibility for a systematic intervention to effectively address truancy. This flexibility is created by the multitude of differentially focused legal levers available to authorities to use in deterring truancy and encouraging school attendance. While each legal lever offers police an opportunity to use a third-party policing intervention approach in response to truancy, the number of legal levers can make it difficult for police to identify which legal levers will be appropriate and effective for different truancy cases. It can also be difficult for police to select an appropriate third-party partner to work cooperatively in a third-party policing approach to address truancy.

Broadly speaking, legal levers fall within two overarching categories: those that seek to *deter truancy* (taking the “stick” approach) and those that seek to *encourage or normalize attendance* (taking the “carrot” approach). Two kinds of third-party policing interventions for truancy emerge based on this classification of available legal levers. The first is a formal third-party policing approach that aims to deter students from truancy by using coercive or punitive legal levers (deterrence-focused legal levers) in organized partnerships with other agencies as third-party partners. The second is an informal third-party policing approach, with police using legal levers that focus on engagement in school (engagement-focused legal levers) to partner directly with parents as the third-party partners. The next section discusses these two approaches to truancy by exploring the available legal levers in various jurisdictions and explaining their anticipated impact on students’ school attendance behavior.

Deterrence-Focused Legal Levers

Deterrence-focused legal levers, those that aim to stop truanting behavior, generally use punishment or the threat of punishment to induce compliance with a legal mandate. For truancy, the legal mandate is consistent across jurisdictions and requires children attend school on all school days (e.g., Education (General Provisions) Act (Qld) s176(1)). Deterrence-focused legal levers authorize, and thus legitimize, a government agency or department to deal with truancy using some form of punitive sanction. To be properly utilized in a third-party policing intervention, deterrence-focused legal levers generally require police to develop a more formal partnership with the agency authorized by the relevant legal lever to take action in relation to truancy. In this way, the identification of a useful deterrence-focused legal lever will lead police to a natural third party whom they can partner with in order to engage in a third-party policing intervention for truancy. As deterrence-focused legal levers typically involve the third party administering punishment, schools and other government organizations, rather than nongovernment organizations, are authorized to act by deterrence-focused legal levers. Schools and other government agencies have access to less punitive deterrence-focused legal levers, such as notifying parents of their duty to ensure their child attends school, and more punitive legal levers, such as revocation of welfare payments to coerce attendance at school.

School-Initiated Legal Levers

In many jurisdictions schools are deputized by law, principally by legislation and regulations, to administer punitive deterrence-focused legal levers. This makes schools an ideal third party for police to partner with in a third-party policing intervention approach to truancy. Additionally, school staff have regular contact with families and consequently knowledge of the contributing factors to an individual student's truancy. In combination with their legal authority to deal with truancy, by way of deterrence-focused legal levers, this means schools can be a powerful cooperative partner for police in a third-party policing approach to truancy. Some of the commonly available school-initiated legal levers and their deterrent value on truancy behavior will now be discussed.

Mandatory Attendance Recording Most countries, including Australia and the United Kingdom, require schools to keep accurate attendance records (Education (General Provisions) Regulation 2006 (Qld) ss18, 20–21; Education Act 1990 s24; School Education Act 1999 (WA) s28; Education Act 1994 (Tas) s6(3); UK Department for Children, Schools and Families, 2008). Some legislation requires that the school track attendance throughout the day, contact parents promptly in the event of an unexplained absence, and confirm explanations for unauthorized absences that are provided by students (Education (General Provisions) Regulation 2006 (Qld) s20(2)). Schools can also be obliged to report an absence where there is reasonable cause to suspect that nonattendance is associated with a risk of harm to the child (e.g., Education (General Provisions) Regulation 2006 (Qld) s20(6)). In New South Wales, it is an offense for a school principal to fail to keep accurate attendance records (Education Act 1990 (NSW) s24(5)). While record keeping may not appear to have a deterrent impact on children and parents, it has two important deterrent functions. First, regular role calls and following up on absences make families aware that attendance is taken seriously and may trigger voluntary reengagement in school before truancy becomes habitual. Second, accurate records of student nonattendance are an integral component in initiating more punitive legal levers.

Notice of Parental Legal Obligations and Consequences In many jurisdictions, schools are required to inform parents of the obligation for children to attend school regularly if a child begins to truant from school. In Queensland (Australia), schools must notify parents in writing of their duty to ensure that their child attends school and meet with parents to discuss how continued truancy can be resolved (Education (General Provisions) Act 2006 (Qld) s178(2)–(3)). Other Australian States and Territories, New Zealand, and the United Kingdom also require schools to warn parents of the requirement that children attend school. Notice to parents often warns that continued truancy will trigger more punitive sanctions, like prosecution or control orders (e.g., Education Act 1990 (NSW) s22C, Education Act 2011 (NT) s23B). Notification procedures deter truancy by raising awareness of the punitive consequences that may arise if truancy is not resolved. Like attendance recording, notification procedures may trigger a voluntary return to school.

Fines Fines are used to punish and deter individuals who enable or engage in truancy in many jurisdictions, including all Australian States and Territories, parts of Canada and the United States (US), the United Kingdom (UK), New Zealand (NZ), and Hong Kong. Fines are principally administered in response to two kinds of truancy-related offenses: adult employers who employ children during school hours (e.g., Education Act 1990 (Ontario) s30(3), Education Act 1995 (Nova Scotia) s115, Education Act 1997 (New Brunswick) s17) and parents who fail to ensure their child attends school (e.g., Education Act 1990 (Ontario) s30(1), Education (General Provisions) Act (Qld) s176(1), Education Act 1990 (NSW) s23(1)). Generally, fine amounts vary based on the target of the fine. Smaller fines apply for first-time offenses, with larger fines for subsequent or repeat offenses. Fines deter truancy by imposing a punitive financial consequence for enabling truancy and place pressure on adults to enforce mandatory school attendance by ensuring children attend school.

Contracts to Formalize Behavioral Undertakings In some instances, parties who are responsible for improving a child's attendance record are required to formalize undertakings to improve attendance in a written agreement or contract. Some contracts are forged between parents and government agencies to arrange support for a return to school (e.g., Education Act 1990 (NSW) s22B, Anti-social Behaviour Act 2003 (UK) s19). Other contracts are made with any responsible adult in the student's life, including grandparents and community elders (Education Act 2012 (NT) s23B). The different forms of contracts in different jurisdictions implicate different family members in remedying the child's truancy and offer a diverse range of partners for a third-party policing intervention.

Contractual undertakings may require that the parents, or responsible adults, engage in counseling or other intervention for their personal problems that interfere with their supervision of the truanting child (e.g., Youth Justice Act 2011 (NT) s140E). In some jurisdictions, including the Northern Territory (Australia) and the United Kingdom, contracts do not give rise to enforceable legal obligations if breached. These contracts are less coercive, and consequently less of a deterrent, because no punishment arises for failing to adhere to the contract. However, these contracts still have a deterrent function for truancy by consolidating the steps that need to be taken to remedy the truancy in one document. They may also trigger a voluntary compliance with the mandatory attendance requirement by creating a moral obligation on parents and families to comply. Some contracts, like those in New South Wales (Australia) (e.g., Education Act 1990 (NSW) s22B(4)), are admissible as evidence in truancy-related court proceedings. Breach of these contracts may be part of a court's decision to impose a more coercive legal lever. This means admissible contracts have a stronger deterrent impact on truancy because they may initiate harsher penalties for truancy.

Government Agency-Initiated Legal Levers

Less frequently, other government agencies are deputized by legislation or a regulation to use deterrence-focused legal levers to reduce truancy. Other government departments may have access to expertise or services that could assist in the implementation of a third-party policing approach to truancy, positioning them as another powerful third-party partner for police. The legal levers available to these agencies generally focus on removing appealing alternatives to attending school, such as driver's license revocation for truanting minors, or punishment to deter further truancy, such as welfare payment restriction schemes.

Investigation Powers Police officers or appointed "attendance," "truancy," and "liaison" officers are in some instances provided with statutory powers to conduct investigations into suspected instances of truancy to curb nonattendance. These powers may include the ability to question school-aged children seen in public during school hours, to return a school-aged child to school or to the student's home, or take other appropriate action in relation to the child (Education Act 1990 (NSW) s122; Education Act 1972 (SA) ss79, 80A; School Education Act 1999 (WA) s36; Education Act (NT) s23C; Education and Training Reform Act 2006 (Vic) s2.1.10; Education Act 1989 (NZ) s31). Some state police services also conduct "street sweeps" of popular locations for truanting such as train stations, shopping malls, and parks. Investigative powers work in several ways to deter truancy. Investigative actions remind parents and children that attendance is important and that missing school is considered by schools and education departments to be a serious act. Investigations of truancy may also trigger either willing compliance with the school attendance mandate or the application of more punitive legal levers like prosecution.

Welfare Payment Suspensions Currently, the Australian government is trialing suspension of family welfare payments as a truancy response in selected communities in Queensland and the Northern Territory (in the SEAM trial). Social security benefits, pensions, defense force income supplements, and armed forces service pensions can be suspended under the scheme if a child in the care of the payment recipient is not attending school (Australian Social Security (Administration) Act 1999 (Cth) s124D). Payment suspensions can only be initiated after the payment recipient has been issued a warning notice and has been given 28 days to remedy the child's truancy (Australian Social Security (Administration) Act 1999 (Cth) s124K). If truancy is not remedied within the warning period, payments can be suspended for up to 13 weeks. If truancy persists after an initial suspension, payments can be suspended again or ultimately canceled (Australian Social Security (Administration) Act 1999 (Cth) s124M). Welfare payment suspension potentially has a powerful capacity as a deterrence-focused legal lever. The financial consequences of a welfare payment suspension far exceed any fine based in education law in most jurisdictions.

Motor Vehicle License Revocations Some parts of Canada and the United States permit the removal of habitual truants' driver's licenses (Reimer and Dimock 2005). For example, the driver's license suspension regimes in California enable suspension for up to a year (Vehicle Code (California) s13202.7). This type of legal lever can only be used on older students who have a driver's license, making it an ineffective legal lever for younger students. However, license revocation has a strong deterrent capacity as it limits students' ability to engage in an alternative activity that is more desirable than attending school. As the decision to revoke a license is administrative rather than judicial, it can be made more quickly and responsively to habitual truancy than those legal levers that rely on a judicial decision from the courts.

Parent-Targeted Control Orders Some jurisdictions have legislative regimes that permit courts to make control orders that force parents to ensure their child attends school. In New South Wales (Australia), the Children's Court can make a compulsory schooling order over the parent to force the truanting child's attendance at school. These orders can include directives to agencies to provide support to the family so that the order is upheld (Education Act 1990 (NSW) s22D(7)(b)). Parenting orders are also used in the UK and can be issued by the court when a parent refuses to be a party to a parenting contract in relation to persistent truancy on the part of their child (UK Department for Children, Schools and Families, 2008). In New South Wales, the penalty for breaching a control order, by failing to ensure that the truanting child attends school, is four times the penalty for breaching the general parental duty to ensure that children attend school (Education Act 1990 (NSW) s22D(9)(a)). This strengthens the deterrent impact of control orders and makes control orders an excellent legal lever for a third-party policing intervention.

Truanting students can also be prosecuted for nonattendance at school in some jurisdictions, including New South Wales and the Northern Territory (Australia) (Education Act 1990 (NSW) s22D(9)(b), Education Act 2012 (NT) s23B(12)). Control orders may have a large deterrent impact on truancy because unlike other deterrence-focused legal levers, the child can be directly punished for nonattendance.

Engagement-Focused Legal Levers

Engagement-focused legal levers, those that seek to reengage the student in school, typically provide resources and support to encourage attendance. These engagement-focused legal levers, which are chiefly sourced in policy, are comparatively "soft" to deterrence-focused legal levers. Unlike deterrence-focused legal levers, which generally require a legally legitimate third-party agency to operate the lever, by using engagement-focused legal levers, police can partner directly with parents. As parental condemnation of truancy may have a significant influence on a student's behavior (Reimer and Dimock 2005), parents can be an influential third party for police to partner with in a third-party policing approach to truancy. While this kind of third-party policing intervention may appear simple to implement, one challenge of using engagement-focused legal levers is finding a nonthreatening way for police to contact and develop a dialogue with parents. The use of a family group conference to implement a deterrent and engagement third-party policing approach between police, parents, and support agencies is currently being trialed in Australia (Mazerolle et al. 2012).

Awareness Campaigns

The broadest of the engagement-focused legal levers explored in this entry are attendance awareness campaigns initiated by governments. In Australia these campaigns include "Every Day Counts" (Queensland), "It's Not OK to be Away" (Victoria), "Every Child Every Day" (Northern Territory), and "All Starts At School" (Western Australia). Typically these campaigns employ sports stars, celebrities, and local or past student mentors as the face of the campaign to promote the importance of regular and consistent school attendance (e.g., Phillips 2011). They aim to change existing normative attitudes toward school attendance (Queensland Department of Education and Training 2010). Awareness campaigns, by informing parents of the problems associated with truancy, may make parents willing to partner with police in a third-party policing intervention for their child's truancy. This makes awareness campaigns clearly engagement focused.

Early Parental Notification of Unexplained Absences

Another simple engagement-focused legal lever is prompt notification to parents of unexplained absences at school. Notification legal levers facilitate a strong relationship between schools and parents by encouraging schools to engage with parents on a regular basis (Kronholz 2011). Legal levers include immediately text-messaging parents if a child is not at school, liaison officers completing regular home checkups with parents of truanting students (Queensland Department of Education and Training 2010), reporting school and statewide attendance levels in the school newsletter to promote awareness of comparative attendance discrepancies (Victorian Government 2006), and conducting family counseling sessions for at-risk students (Reimer and Dimock 2005). Prompt notification of absences may initiate voluntary reengagement with school before truancy becomes habitual.

Programs for Improving Attendance

Some jurisdictions have programs that offer students incentives for regular attendance. Incentive initiatives include mentoring programs, such as the "Big Brother" program in the United States (Reimer and Dimock 2005), and gifts including money, vouchers, special meals, and excursions. Some programs randomize the award of any incentives to avoid strategic school attendance by habitual truants.

A number of schools use incentives and support to ensure students arrive on time. Breakfast clubs have been used to encourage early arrival at school (Chilcott 2009). Daily pickup services (Queensland Department of Education and Training 2010), free bus passes, and wake-up calls (Kronholz 2011) have also been used to facilitate a timely arrival at school. Difficulty with transportation to school has been identified as a cause of truancy (Reid 2005) so these legal levers engage students in school by resolving an underlying cause of truancy.

To make reintegration into the classroom after truancy easier, some programs seek to engage students in school by providing academic support for classes missed. These programs include homework clubs, tutoring, or makeup classes (Victorian Government 2006). These engagement-focused legal levers should assist return to school where academic problems contributed to the student's decision to truant.

Flexible Schooling Arrangements

Flexible arrangements authorize schools to develop alternative methods of attending for students who face difficulties attending standard school hours (e.g., School Education Act 1999 (WA) s24). Flexible arrangements can be used, for example, for older students who have caring responsibilities or young children at home. Under the legislation in Queensland (Australia), arrangements are developed by the parent and can be authorized by the relevant teacher (Education (General Provisions) Act (Qld) ss182, 183). Flexible arrangements encourage engagement with school by removing pragmatic barriers to regular school attendance experienced by some students.

Community Partners and Group Action

Although group action by community partners generally is intended to deter students from truanting, frequently this kind of third-party policing intervention also engages the community to proactively mobilize against truancy. Group action in response to truancy generally involves community members taking action to reduce the availability of activities that students may engage in instead of attending school. An excellent example of group action is the “No School, No Service” program in the Northern Territory, in which business owners agree to refuse to serve school-aged children during school hours, providing a strong disincentive to truant. In these group interventions, the community, unlike a parent, is not legally obligated to play a role in the enforcement of the legal mandate that children attend school. Group action stems from a decision to stop enabling truancy, even though the community is not legally obligated to be part of the enforcement of the mandatory school attendance requirement.

Initiation and Implementation of a Third-Party Policing Intervention

The relative effectiveness of a third-party policing approach to truancy is shaped by how the approach is initiated and implemented. Specifically, the choice of the focus of the third-party policing approach in initiating third-party policing partnerships and the role of the police within an established third-party policing partnership can have significant impact on whether the third-party policing approach to truancy is effective. These initiation and implementation issues are discussed in this section.

Initiating Third-Party Partnerships

In a sense, the success of a third-party policing approach to truancy is dependent on the willingness of police, the third party, and the target to comply with the legal lever used in the intervention. The burden is on police to initiate the partnership process and make the decision about the focus of the third-party policing intervention. These choices can, at first glance, appear difficult in the face of the multitude of legal levers available to address truancy. For each truancy case, the police will be faced with numerous engagement- and deterrence-focused legal levers that they could use in a third-party policing intervention. In a way, the core decision to be made for a successful third-party policing approach is whether to use deterrence- or engagement-focused legal levers. By virtue of the way the law functions in many jurisdictions, the legal lever identifies to the police the target of a third-party policing approach. Third-party policing interventions for truancy, based on the available legal levers discussed in this entry, are mostly targeted at either parent or child.

If a deterrence-focused third-party policing approach is chosen, in most cases the decisions about third-party partners and intervention targets will flow naturally from the choice of legal lever. As discussed, deterrence-focused legal levers, sourced most frequently from legislation and regulations, will typically legitimize a third-party agency, who naturally becomes the third-party partner in a third-party policing approach that uses that legal lever. Deterrence-focused legal levers of a punitive nature will also always identify a target for the third-party policing intervention, which in the case of truancy may not always be the child. This significantly reduces the complexity of implementing a third-party policing approach for police. For example, if the police elect to use a deterrent approach in response to truancy, they may use a parental prosecution legal lever. In most jurisdictions, the legal lever for parental prosecution for the nonattendance of a child will authorize the school or education department in that jurisdiction to engage in the prosecution decision-making process. In making the decision to use a deterrent approach and use the parental prosecution legal lever, the police have already identified a target for the third-party policing intervention, the parent of the truanting child, and a third-party partner, the school or education department.

A similar relationship between legal levers, third-party partners, and targets exists in relation to engagement-focused legal levers. Although engagement-focused legal levers tend to be sourced in policy and thus do not identify a natural third party for police to partner with, most engagement-focused levers have a clear target. In most cases, the target of an engagement-focused legal lever is the child. This is the case with truancy awareness campaigns, incentives, and programs that support attendance, flexible schooling arrangements, and typically community action. In focusing on the child, the parent or caregiver can become a natural choice of third-party partner for police to use a proactive engagement-focused lever to facilitate their child's regular attendance at school.

Once the partnership has been established, police play a critical role in implementing the third-party policing approach to truancy. Importantly, police will often need to provide the third-party collaborator with encouragement and support, to ensure that the third party initiates the chosen legal lever to cause change in the behavior of the intervention target. This is especially true when a third-party policing approach to truancy is used, as legal levers that respond to truancy are often infrequently used. For this reason, it is important that the police remain an active party to the third-party policing partnership to implement the third-party policing approach to impact truancy.

Maintaining Third-Party Partnerships

Timely and consistent activation of the chosen legal lever is critical to the success of a third-party policing approach to truancy. Many engagement- and deterrence-focused legal levers are infrequently used to respond to truancy. Within a third-party policing approach, activation of the chosen legal lever is the focus of the intervention. Ultimately, an infrequently, or unapplied, legal lever will not change truancy behavior. Thus police need to address any third-party reticence to utilize the chosen legal lever within the third-party policing partnership if the intervention is to be effective.

Deterrence-focused legal levers, and in particular prosecution-based legal levers, seem to be particularly infrequently used in relation to truancy. Determining the number of parent- and child-focused prosecutions that take place is difficult because in many jurisdictions the prosecutions occur in lower courts, many of which do not keep record databases of their decisions. Australian states seem reluctant to address truancy by parental prosecution. News reports indicate in April 2009 seven parents were "facing" prosecution in Queensland, with an eighth being referred to the police for action (Chilcott 2009). In South Australia, 24 cases were brought between 1984 and November 2010, only six of which were successful (Keller 2011). Just six parents were prosecuted in Tasmania between 2005 and 2009 (Dickson and Hutchinson 2010). In Western Australia and the ACT, truancy prosecutions were commenced for the first time in February 2010 and 2009 respectively (Dickson and Hutchinson 2010). It is reported that Northern Territory and Victorian truancy laws have never been enforced (Dickson and Hutchinson 2010). In contrast, New South Wales initiated 310 prosecutions in 2010 against parents or children for persistent school nonattendance (McDougall 2011).

The United Kingdom regularly prosecutes parents for failing to ensure their children attend school (Morris 2009). In contrast, enforcement is anecdotally lax in the United States (Kronholz 2011), and in New Zealand there were two prosecutions recorded in 2011 (Fisher 2011) and only 17 between 2004 and 2007 (Rich 2007).

Another related and important issue is how prosecution is initiated. The number of notification steps that must be taken prior to a prosecution, fine, welfare payment suspension, or control order in most jurisdictions precludes immediate use of a deterrence-focused legal lever in response to truancy. In fact, the policy guidelines of some jurisdictions, including Queensland, Tasmania, and New Zealand, specifically identify prosecution as a last resort measure (Chilcott 2009; Dickson and Hutchinson 2010; New Zealand Ministry of Education 2010). Although appropriate consideration before using deterrence-focused legal levers afforded by longer escalation processes is important, delays in the application of a legal lever after truancy occurs may weaken the deterrent power of the legal lever. This is recognized in some jurisdictions, like the United Kingdom, where local authorities are able to override escalation prerequisites to fast track prosecutions in cases where this is considered appropriate (UK Department for Children, Schools and Families, 2008).

The negative institutional attitude toward prosecution and other punitive deterrent legal levers reflects uncertainty in the assumptions that underpin the use of punishment in response to truancy. More specifically, there seems to be a belief that punishing parents for truancy unfairly assumes parental failure causes truancy. Some also object to truancy relevant fines because they disadvantage families with the smallest disposable income.

In a third-party policing approach, possible negative attitudes toward using legal levers, particularly those legal levers that are deterrence focused, can be counteracted by police encouraging and supporting the third party to use the legal levers to address the truancy problems. In this way, a third-party policing approach could make the most effective use of preexisting legal levers to reduce truancy and consequently the prevalence of antisocial behavior.

Concluding Comments

The legal context within each jurisdiction informs the way a third-party policing intervention for truancy is initiated and implemented. The differentially focused legal levers across jurisdictions provide flexibility to address the root causes of truancy, streamline the decision-making process for police determining how to implement a third-party policing approach, and assist police in defining their role within a third-party policing partnership to achieve effective intervention for truancy. Importantly, the various legal levers available offer police a plethora of opportunities to engage in a third-party policing intervention for truancy, which may have a crime prevention impact for the community. Third-party policing offers police the opportunity to address crime prevention effectively by utilizing preexisting legal levers and third-party partnerships in a resource responsible manner.

Third-Party Policing

Michael E. Buerger
Bowling Green State University, Bowling Green, OH, USA

Overview

The original articulation of third-party policing (Buerger and Mazerolle 1998) focused on coercive tactics police use against nominally respectable citizens to impel them to join anticrime efforts. The underlying premise was that the semiformal and informal social control exercised by "place guardians" (Spelman and Eck 1989; Eck 1997; Buerger 1993) was greater overall than that of police intervention. More personal and more consistent over time, it could be more immediate in its consequences (such as denial of entry or eviction for cause). If tapped and coordinated with an overt police effort, it had greater potential for stabilizing place-related behaviors.

Mazerolle and Ransley (2005) extended the concept further, outlining the benefits of formal coordination between police and governmental agencies with specific mandates (oversight over pharmacy sales or alcohol beverage control). Joint endeavors to prevent abuse of prescription drugs (and over-the-counter medicines containing precursor chemicals) were differentiated by specific legislative charges in three Australian states, creating a natural experiment highlighting different levels of authority, commitment, and engagement with the goals of the supposedly joint project. Those considerations also attend local efforts and can be even more pronounced when third-party policing is attempted in nonregulatory environments.

The most salient limit of third-party policing is that it constitutes a *coerced volunteerism*, a response attained by implied threats when appeals for truly voluntary actions fail. The police power to overcome resistance through physical force in criminal matters (Bittner 1970) does not extend to third-party policing, which occurs almost exclusively in the realm of civil law. The proscribed actions police seek to prevent are not those of the recruited citizen but the conduct of their customers, neighbors, or even passersby. Coerced volunteerism imposes an enforcement-like role with no perceptible foundation in law or capacity. Initial resistance should be anticipated in such cases: indeed, one of the fundamental demands of third-party policing is that of finding ways to overcome such resistance.

Coercion is most effective against those who are already vulnerable by dint of playing fast and loose with regulations that define their basic responsibilities, overseen and enforced by nominal allies of the police. Implied coercion is less able to compel individuals in compliance with standard regulations, and those who are accustomed to gaming the existing system. It is most tenuous when the targets are themselves sovereign entities or parties who have already forged alliances with nominal regulators, politicians, and other sovereigns who can intercede on their behalf.

Coerced volunteerism invariably requires actions and expenses outside the normal scope of the third party's life or business. Whether a one-time expense such as the construction of a barrier or a continuing commitment to regulate the conduct of patrons, an obligation is imposed that disrupts the routine activities of the enlisted individual or organization. Some requested efforts may be perceived as injurious to business interests, even dangerous to the participants. Unlike volunteer efforts like Neighborhood Watch, third-party policing does not mobilize any inherent desire or willingness to "do something" about a mutually agreed-upon noxious condition; it is far more likely to be a second-tier enlistment for a police-defined operation, after the softer approaches have been exhausted. Unless the benefits of the requested actions are recognized, resentment and resistance must be anticipated.

Moreover, "recognition of benefits" is not unidimensional. In the best case, the third party either understands intuitively the link between the police request and an improved quality of life or experiences the benefits soon after implementing the requested actions. Much more likely is the probability that the only "benefit" perceived is to be relieved of the annoying presence of the police officers repeating their requests. At the lower end of the scale, the third party may interpret the "benefit" of cooperation to a *quid pro quo* for later favors or leniency from the police.

The limits and boundaries for third-party policing initiatives lie in two distinct domains: among the potential third-party partners of the police and within the police organization itself. Both domains are also vulnerable to environmental influences affecting one or both. Periods of economic constriction not only place severe financial constraints on landowners and businesses but also can redirect police resources personnel from efforts viewed as peripheral. Unless clear benefits can be shown, both agency and political overseers will demand that resources be directed back into "meat and potatoes" channels: traditionally, that has meant staffing patrol to answer calls in the old reactive policing mode.

Several impediments – notably “innovation fatigue” and “limited subscription” – are found in different manifestations in both camps. Though linked in some arenas, they are conceptually distinct in important ways. Nevertheless, the different aspects of individual third parties and organizational third parties are presented together here. Greater differences exist between external organizational resistance and internal police agency resistance, and those are treated separately. Regardless of the class, resistance tends to manifest itself in the distinct forms outlined below.

Innovation Fatigue. Institutional history in police departments (and others) often includes a compilation of highly touted but short-term efforts to “do things better.” Even successful innovations often fail to achieve the critical level of acceptance needed for adoption as a regular practice. While not unique to police organizations, the kiss-of-death pronouncement that “We tried that once; it didn’t work” is recognized by police researchers as the most visible legacy of promoting innovation in policing. (The police see this differently: researchers “arrive with a great idea they’ve dreamed up in the ivory tower, make a mess for a year, and then disappear for 3 years before they come back to tell us what we did wrong.” That pronouncement embodies the perception that externally imposed innovation almost always fails to capture important realities of the practical level.)

A comparable condition may affect community members and partner organizations. Considerable publicity accompanies the onset of any new program, conveying to multiple constituencies both the dimensions of the project and its needs. People invest in the new idea, make the necessary arrangements to participate (disrupting or sacrificing other parts of their routine to do so), and expect to see results. Often those results do not materialize, and those who are most affected by such failure are the community members who stood to benefit from a successful project.

Some programs simply do not achieve the anticipated results, either because of theory failure or because of implementation failure. Some cannot garner the critical threshold of resources to be effective. Others simply fail to materialize for reasons that are never made clear. The cumulative effect is the modern-day equivalent of Aesop’s fable of the boy who cried “Wolf!” Each new iteration of change becomes less and less compelling, until finally people are unwilling to budge. History tells them that nothing good will emerge, no matter what they do.

Uneven Subscription: Whether in organizations or by individual citizens, uneven subscription can occur in one or more distinct manifestations: overt resistance, covert disruption (“monkey-wrenching”) and lip service masking “this too shall pass” passivity, token compliance, and good-faith but witless attempts to participate. Innovation fatigue certainly lends itself to “this too shall pass” passivity, but native skepticism can produce the same condition even when there is no prior history. If there is a perceived gap between the known resources and the stated goals, or distrust of the promoters, *inter alia*, a “wait-and-see” attitude may be prominent even if there is no history of prior innovation collapse.

Wide variation of participation across third-party efforts highlights one of the most prominent limits of the approach: it is inherently time-intensive for police officers. High-end efforts like Oakland’s SMART team, with focused political support and sufficient resources at all levels, are relatively rare. When resistance and reluctance are the norm, officers working with third parties must recontact them frequently to insure that plans or instructions are understood and promised actions taken. Periodic contacts are equally important to learn of legitimate new complications and to debunk new illegitimate excuses for noncompliance.

Overt Resistance. Managers and others in position of authority in agencies approached to become “partners” in a police initiative can say no. This is the most visible hurdle facing officers seeking a third-party solution to problems. Outright refusal is usually couched civilly in terms of one or more of four major objections: (1) lack of centrality of the police request to the business’s or individual’s primary mandate, (2) lack of legal authority, (3) lack of resources, and (4) competing demands from external sovereigns with greater call on the organization's resources.

"Overt resistance" does not necessarily involve confrontation with the police: a common form of resistance is simply to ignore police requests to meet about a problem, and patterns of ownership insulate some place managers by distance. Several RECAP properties were owned by corporations with headquarters on the east coast: leasing was handled by agents in Minneapolis and rent checks mailed to addresses out-of-state. One landlord ignored RECAP attempts to speak with him until the case officer drove to the landlord's residence (in a third-tier suburb outside the Twin Cities) to leave a handwritten note. The landlord's comment that "if he came all the way out here, I figured he must be serious" demonstrated the "ignore them and they will go away" legacy of innovation fatigue. There are other forms of resistance to be aware of, however, hidden under various guises of compliance.

Lip Service. In the face of continued police pressure, the easiest form of noncompliance is verbal acquiescence without substantive action. If the police can be stalled for long enough, they will either give up or be redirected to other pursuits. Follow-up contacts are vital and tangible intermediate actions and goals desirable wherever they can be articulated. Lip service is difficult to maintain in the face of continued reminders that promised work has not been done.

Token Compliance. A step above lip service is token compliance: "face time" attendance at meetings without commitment to action or designation of liaison personnel without real powers or even direction; in short, providing the most minimal level of participation or resources to make a marginally credible claim of cooperation. Token compliance is another stalling technique, but it also constitutes a visible demonstration of good faith: that demonstration is often more for political sovereigns than for the police, though it serves both in the initial stages. Where lip service "says something," token compliance "does something." To overcome ineffective results, police must make a case both for the ineffectiveness of the token effort and the actual capacity of the organization or individual to do more.

Lip service and token compliance illustrate one of the most stringent limits to coerced volunteerism: the "coercion" often is not and cannot be real. The "inherent coercion" of police presence is anchored in the criminal law and has little purchase in the civil arena without a specific regulatory mandate.

Covert Disruption. Third parties may take actions to undermine the entire thrust of the police initiatives. Asked to appoint a manager for an apartment building, one landlord designated a low-functioning tenant as a manager: the individual was incapable of controlling the behaviors of the other residents and limited himself to doing minor physical repairs. A problematic landlord was at first thought to be cooperative: he quickly made the physical alterations suggested and directed his on-site manager to implement the other provisions of the officers' plan for reducing calls to the property. Several months later, the police learned that he had countermanded those orders as soon as the meeting had ended and fired the manager for actually attempting to implement changes.

One of the more notorious landlords reacted to the news that one tenant in his RECAP building was a medium-level drug dealer by evicting the individual. Several weeks later, a precinct raid at another address owned by the same landlord revealed that he had "evicted" the tenant by moving him into another building, in effect transferring the associated problems to a new neighborhood.

Drug dealers were a point of contention that became emblematic of the cognitive gaps in problem definition that sometimes affect third-party policing efforts. To the police and the surrounding neighborhood, problems caused by a resident drug dealer are all too obvious: the influx of unsavory characters and associated rise of property crimes; unpleasant confrontations with marginal individuals and those under the influence of drugs; detritus including feces and urine, needles, and used condoms; constant noisy traffic; and related incivilities.

To absentee landlords, however, drug dealers were almost ideal tenants: they paid the rent on time, in cash; they made no demands on the landlord; and they did not complain about minor deficiencies in the physical plant. Insulated by distance from the toxic by-products of the illicit activity, absentee landlords were ignorant of the problems, and not disposed to oust a cash-paying tenant who had caused the landlord no problems. The problem at the time was accentuated by a surplus of available rental units in Minneapolis. The natural response of the landlords was to categorize the ancillary problems as "police responsibilities" because the police requests flew in the face of the basic purpose of renting property (making money with minimal expenditure of capital and effort).

Good-Faith Incompetence. At a large residential complex, a suggestion that security be employed led to the hiring of a local private service whose employees were gang-connected and essentially used their legitimate employment as a cover for increasing drug sales. It was never certain that they had been hired to suborn the police request in that fashion; they were lowest bidders for the job, and the situation was chalked up to a form of good-faith incompetence.

Similar results were encountered in a variety of settings, including a large homeless shelter that hired a security guard to control behaviors within the facility. One night, several male shelter residents overwhelmed the guard, pinned him to the floor, and ostentatiously cut the buttons off his shirt, one by one, before releasing him unharmed. The security guard quit that night.

A number of caretakers encountered similar problems at multifamily dwellings on the RECAP list. The common link was that they – like the security guard at the shelter – were unprepared to deal with the troublemakers in their facility. The place managers were capable enough for the routine duties of the position but were vastly overmatched by the residents who were hardened by street life and their criminal associates.

Client and Partner-Centered Limits

"Ask, and ye shall receive" is a religious precept. In the secular and often profane world of policing, "to ask" often means to be told to "[bleep] off." Compliance is not the first resort of persons who are asked to take on additional obligations, in order to insure a return that perhaps is perceived as dubious, and in any case is defined in terms of benefit to persons other than the individual so entreated. As a result, forays into third-party policing are constrained by a number of factors centered in the perceptions of the would-be partners (such as the differing perspectives on the drug-dealing tenants, above), many of which are operational counterparts of the techniques of negation articulated by Sykes and Matza (1957).

Corporate and Agency Resistance

Resistance from external organizations can be anticipated in four different guises: (1) the request lies outside the organizational mandate as interpreted by the organizational hierarchy, (2) the lack of legal authority to take on the actions requested, (3) the request cannot be fulfilled because of budgetary restrictions, and (4) the organization is already overloaded with the demands of their own mandate. The rationales sometimes overlap, and they often are legitimate: shrinking budgets are a primary reason that fulfilling organizations' own mandates is difficult, as American police departments are discovering in the "new normal" of the economy.

Organizations: Outside the Ordinary Mandate. While there may be occasions when this is a proper remonstrance, in many cases the argument is really that the request lies outside the routine *practices* of the organization. The analog is to Sykes and Matza's concept of "denial of responsibility." There is a deeper issue, however: the police are seeking an intervention by an agency that possesses defined statutory powers, in order to coerce compliance with police requests in areas that are outside the partners' specific mandates, and for which no coercive authority exists to enable direct police action. While the regulatory authorities do have a mandate to intervene in one or more of the intermediate conditions, there is no corresponding requirement that they do so to enable other actions for other agencies: in most western countries, regulatory functions exist in their own silos.

The challenge of third-party policing is to forge credible links between the separate enforcement rationales. While that might imply a veiled threat that exposure of the conditions will make the regulatory agency look bad in the public eye, such a premise should not be overstated, and certainly cannot be overused. Agencies (including the police) have well-developed defense mechanisms to defend their standard practices against complaints that come from all quarters. The most powerful is that of competing or superseding mandates.

In Jersey City, a grant-funded program to forge a joint Police Department-School Department venture to address absenteeism and in-school misbehavior foundered on issues related to specific legal mandates. It was the position of the School Board that privacy concerns did not permit the sharing of student information with the police, and repeated entreaties to bridge the gap failed. When RECAP tried to persuade the Minneapolis Housing Authority not to house young alcoholics and addicts in senior citizen high rises, the authority invoked the provisions of their charter, comparable to the soon-to-be-enacted Americans with Disabilities Act (ADA).

In Minneapolis, a powerful nominal ally – the City Prosecutor's office – refused to cooperate with RECAP's attempts to curb high-volume shoplifting. Standard practice was to *nolle prosse* misdemeanor shoplifting cases because the volume alone would overwhelm the office's capacity to prosecute cases (a legitimate "lack of adequate resources" refusal). Analysis suggested that most shoplifters were one- or two-time offenders who desisted after they were caught the first time; real damages were inflicted by the serial shoplifters and organized shoplifting gangs. The organized groups were more likely to be from outside the area; when apprehended, they had enough stolen goods to support felony theft charges. RECAP targeted local prolific shoplifters, proposing a plan to monitor all shoplifting arrests (and releases) to aggregate serial offenders' thefts from a series of low, no-prosecution levels to a total amount that constituted a felony, whereupon they would be presented for prosecution.

Though the city attorney's office still balked, invoking its sovereign status vis-à-vis the police, the unit took the issue into the political arena. Their proposal had the backing of the chief, raising the specter of a public spat with adverse political consequences, and so overt resistance gave way: prosecutors grudgingly accepted the RECAP compromise plan. What followed, however, was an institutional process of covert disruption: without notifying RECAP, the city attorney's office moved the monetary bar for prosecution higher and higher, to *nolle prosse* the lower-threshold aggregations that RECAP forwarded. In token compliance with the request, the office had other means to insure that normal practice was not disrupted by RECAP's third-party gambit.

RECAP also attempted to enlist a comparable effort on the part of major retailers whose stores were frequent targets of thieves. Retailers readily agreed to participate in the plan: from their perspective, it was little different than the existing state of affairs, with some promise of a better curb on a small group of local offenders. In the process of the discussion, however, it became evident that the corporate security apparatus – individually and collectively – had a considerably more sophisticated grasp on the situation than did the police. A logical extension of their efforts to track the shoplifting gangs across multiple jurisdictions created an extensive database of apprehended shoplifters. It could have saved the Minneapolis police a considerable amount of effort that ultimately went into recreating the local version. Naturally, the corporations were reluctant to share it with the police.

The polite distance of the corporate entities from anything beyond token compliance with RECAP's plan illustrated another set of limitations when working with private sector entities: overlapping layers of constraint under which the private sector operates. The need to curtail losses to theft certainly fell within the corporate security mandate, but so did protecting company assets from other threats: corporate liability extended well beyond shoplifting. National and regional corporations certainly possessed adequate resources, but a much broader set of threats quelled more extensive cooperation. Logical negative consequences (never confirmed) included exposure to individual or class-action lawsuits for sharing information with the police, possible negative publicity related to accusations of behavior that we now term "racial profiling" (see, e.g., Meeks 2000), and a potential for loss of market share based on rumors. Negative returns on investment conceivably could include the neutralization of security techniques (if revealed publicly, as part of a lawsuit or because of "loose talk" by police officials) and an influx of even more serious shoplifting.

Organizations: Budget Constraints. Organizational budgets are fixed, particularly in the regulatory and social services. Like the police, the budgets tend to be devoted in large part to personnel. The police request often is for a temporary reassignment of employee time, malleable, and already covered by the budget. However, some community policing initiatives involving large-scale activities go beyond a simple redirection of time, and third-party requests may be comparable in their scope.

Overcoming the budget defense often involves building political coalitions that alter, if only temporarily, the priorities of agencies sought as partners. One-time interventions or projects (such as the cleanup of an abandoned lot to establish a neighborhood playground) are easier to mount than long-term, resource-intensive systematic projects to rehabilitate neighborhoods. One-time projects tend to be quick political capital, with *Before* and *After* photos; bringing about long-term changes (improving slipshod management at problem bars, shutting down thinly veiled storefront facades for the drug trade) are fundamentally different problems, inherently more difficult, with fewer opportunities for participants and political sovereigns to claim victory publicly.

On the rare occasion when nonprofit organizations are the focus of third-party efforts, budget will be both a defense and a potential lever. A privately held residential facility serving clients in rehabilitation or under duress was identified as an attractive nuisance: a number of its clients committed crimes both inside the facility and in the neighborhood and contributed substantially to neighborhood incivilities. The proprietor pled a lack of resources, attempting to turn the RECAP officer into an advocate in the proprietor's quest to obtain a higher level of certification that would bring in more money. After a protracted effort against the stalling tactics above, the tables were turned: revocation of existing certifications became the lever for establishing substantive changes. That decision was complicated by the fact that the facility served a large number of needy clientele who were not causing problems and were in need of shelter and other assistance provided there. Such moral dilemmas will attend third-party efforts as well as traditional policing.

Budget decisions made at remote corporate levels are less amenable to police intercession. Many corner gas-and-grocery convenience were beset by large numbers of shoplifting calls. Corporate policy forbade employees from detaining shoplifters, on the theory that the costs of a single successful lawsuit or worker's compensation claim would far outweigh the losses to shoplifting. One franchise owner revealed that while shoplifting losses could run about a thousand dollars in a bad month, the store turned a monthly profit between 50 and 60,000 dollars a month even after shoplifting losses were factored in. Police assertions that shoplifting (free beer, cigarettes, and munchies) was an attractive nuisance with a negative impact on the areas simply had no traction against this economic reality. RECAP officers went so far as to travel to the out-of-state headquarters of one of the chain companies to plead their case, but to no avail.

Leverage: Mobilizing City Organizations

In Minneapolis, building inspections were conducted in routine manner by multiple agencies: building codes, health and sanitation, and others. Advance notices mere mailed to property owners before inspections were to be conducted, allowing owners to make any needed repairs or cosmetic changes, masking deeper structural problems that would resurface eventually. Nominal compliance served an important goal of inspectorial agencies by maximizing their effectiveness to superficial review and minimizing the resources needed for follow-up and enforcement. It also helped to minimize pressure from political sovereigns, who were third-party defense mechanisms for property owners seeking to divert police attention from their own lack of responsibility.

RECAP needed a series of spot inspections outside the normal two-step of nominal compliance. To break the accepted routine of scheduled inspections, the inspection agency needed substantial evidence that such a change was needed. A high volume of calls to the police (the defining condition for selection as a RECAP address) was a behavioral problem, not a structural one. In some cases, the deadlock was broken by documentation: RECAP officers became informal inspectors, documenting the visible conditions of the building during the period when inspections were not anticipated. In others, the time-honored tradition of trading favors – standing by when a district inspector examined a particularly problematic address where physical harm was possible, for instance – would bring an inspector to a property unannounced. In a handful of cases, the documentation of problems at the property would go directly to the ward's Council Member, a preemptive move giving the police version primacy over the subsequent self-serving description by the property owner. It also undercut any agency invocation of past "successful" routine inspections as evidence that no intervention was necessary.

There are definite limits to police officers' ability to tap other city agencies (or employees) for favors outside the normal course of business, but the ramifications of doing so can be enormous. The sudden appearance of a formerly predictable regulatory agent, and the penalties she or he levies subsequent to the surprise inspection, is the civil equivalent of "a public hanging." Both specific and general deterrence (compliance with requests the first time the police ask, in this case) are desired results.

The various workarounds to routine must be used sparingly and cannot be squandered on trivial cases. The best initial case to go forward with will have extensive documentation, including support from neighbors, police records, and photographs where appropriate (RECAP used video surveillance on one particularly nettlesome property with a huge criminogenic impact on the surrounding neighborhood). High-profile targets also improve the media impact of the police efforts, though they can also be a liability if things go sour.

Once it is known that the police have that "power," the word will spread quickly among those accustomed to gaming the system: there is a new set of rules we have to deal with. In Minneapolis, there was a two-tiered division of landlords: individuals who owned one or two properties in an attempt to improve their financial standards, and well-financed owners of multiple properties. The majority in both categories were entrepreneurs who toed the line and maintained good properties; the handful of multiple-site owners who were gaming the system owned a surprising number of RECAP problem properties, and it was to that group that the "public hanging" efforts were directed. Smaller independent owners were more likely to be overwhelmed by unanticipated problems and welcomed police attention and the assistance it brought.

Individual Resistance

Denial of responsibility, denial of injury, and condemnation of the condemners (Sykes and Matza 1957) are the most commonly proffered justifications for refusal by individual citizens. Financial concerns analogous to organizational budgets are frequently offered, sometimes combined with spurious appeals to "higher loyalty" (usually the well-being of the individual's family): like organizational budgets, some of the claims are real, while others are spurious and self-serving.

Individuals: Denial of Responsibility. Unlike the criminals who were the focus of Sykes and Matza's original thesis, third-party individuals who rebuff police attempts to enlist them are not rationalizing any criminal behavior on their part. They are rationalizing a refusal to take on additional burdens, the compelled volunteerism articulated above. This variation of "denial of responsibility" exists upon a continuum, however: at one end are individuals who find themselves caught in the changing social conditions that produce the problems besetting the neighborhood. They are not a part of "the problem" through any actions of their own, and attempts to cast them as part of the problem purely on the basis of not being "part of the solution" (a bumper-sticker platitude at the ground level) will leave a sour taste.

At the other end are slumlords and do-nothing place managers whose *de minimus* discharge of ordinary responsibilities constitutes a complex set of visual and behavioral cues that allow, abet, or even encourage the criminal or disruptive acts that were reported to the police. Sometimes these conditions were due to sloth on the place managers' part, but sometimes they were deliberate: a number of bartenders in Minneapolis were found to have profited from allowing illegal drug sales and prostitution to occur in their premises. Instinctively, police understand that such individuals *are* part of the problem.

That assertion carries the onus of proof, however, so police must document their claim in several ways. The first is to provide evidence to the individual, in hopes that the person will acquiesce to avoid further consequences. Failing that, the case must be made to partner agencies that the individual is thumbing a nose at the regulatory agencies by superficial compliance with routine inspections. Additionally, officers seeking to employ third-party policing solutions may have to justify the effort to their superiors. Often, those justifications must take a form that allows the command staff to justify the efforts to political sovereigns, to whom the proximate targets of the third-party efforts have appealed to "get the cops off my back."

In this context, a variant form of *denial of injury* comes into play, sometimes abetted by a variant of *denial of victim*. Several Minneapolis landlords, and several bar owners, portrayed the police problems at their properties as an inevitable spillover effect of neighborhood demographics: "those people." In some cases, the third-party targets attempted to portray themselves as advocates for the troublemakers: "where else are they going to go?" It was a thin rationale and easily countered by the rejoinder that "help" does not mean allowing the same destructive habits that brought the troublemakers to their present state. Nevertheless, it is a rationale that might find sympathy elsewhere, a triangulation of support that might make the third-party efforts more difficult: police are not the only agents capable of developing coalitions. Because it consists of "soft" coercion applied to nominal respectables, third-party policing carries the onus of anticipating challenges and countermeasures, and taking steps to neutralize them before they are invoked.

Individuals: Budget Limitations. Budget limitations may be very real for the individual landlord or owner of a business establishment; the counterargument that investments made in the police efforts will work to improve the property's bottom line is always speculative at first. Small-time owners (with one or two properties) have fewer resources, and often lesser skill sets for managing, than do the more established and well-capitalized owners of multiple properties.

RECAP's exemplar of this condition was an individual who had just taken back a property when a contracted buyer defaulted, only to find that the well-managed property had been run into the ground: the physical plant had been allowed to deteriorate, and the middle-class tenants had left when more problematic individuals were let into the property by fly-by-night speculators. When the RECAP officer contacted him and laid out the list of police calls to the property, the owner responded with "I'll work on that if you'll work on these" and presented a stack of repair orders from various inspectors' offices that amounted to a huge amount of money. In that case, third-party policing took on a different form, with the RECAP officer interceding with the other regulatory bodies, buying time for physical repairs in exchange for the owner's reestablishing the former rules of conduct. Both sides of the effort were successful.

Another variation of the budget defense – sometimes a bluff in Minneapolis's renters' market, but also exercised – was to threaten to "walk away from" a property. . . essentially abandoning it and allowing it to become derelict. Few landlords actually walked away, but several did sell the property to another landlord, often buying a new property from a third owner in turn. A retrospective analysis of real estate transactions revealed a well-established pattern of such "trading sales." One of most prolific problem-causing properties changed hands five times in the course of the year-long RECAP experiment: each time a new owner took over a property, previous gains and concessions were lost, and the RECAP officer had to begin anew.

Police Organization Limits

Nominally, police agencies are hierarchical organizations that rest heavily on principles of command and control. In reality, those principles are loosely observed, and in some agencies are more honored in the breach than the observance. Leadership in subsidiary parts of agencies may cleave to a nominal subscription to agency values, but add beliefs and inclinations that are independent of it. Individuals' skill sets may or may not be amenable to new duties or approaches. As a result, attempts to gain leverage from third-party policing may falter on one or more of the same deficiencies that are found in nominal partners.

Overt resistance can be particularly sharp in police agencies. When problem-solving officers attempt to enlist the help of others in the organization, it is usually because their particular skills are needed: the work of undercover drug officers, gang unit members with special expertise, and the like. As such, the "lack of centrality" and "lack of authority" defenses available to outside agencies are not viable. Lack of resources and competing demands from sovereigns (within or outside the agency) are generally the first reason given for refusal: "I'd like to help you, but…" Given that the demands for specialized units usually outstrip their ability to meet them, these initial refusals are not unreasonable.

Another form of overt resistance is the darker side of autonomy: police officers take pride in their ability to work through their own problems and to do so on their own terms. Backup requests are routinely honored, especially at the peer level, but when line officers must ask for help from superior officers in other units, that equation changes. Jersey City attempted to evoke a problem-oriented response to street prostitution in two areas but was rebuffed by the precinct command staff. Treating the grant funds as an overtime windfall, the patrol units chose to ignore the problem-oriented plan in favor of traditional suppressive approaches that displaced the street trade into neighborhoods previously free of it. (A simultaneous gambit asked the Jersey City courts to levy jail time instead of fines and credit for "time served" while awaiting arraignment, escalating sentences after multiple convictions; the idea was to deprive pimps of the income from the prostitutes. Like RECAP's shoplifting initiative, the effort was dismissed out of hand: the judiciary claimed a greater need for bed space to house violent offenders.)

Police agencies generally have a silo approach to specialty work: if a special unit has been created, then that work is somebody else's responsibility. That ethos is slowly changing in many places but is real enough to be considered a limitation on third-party policing initiatives, whatever their origin. Overcoming silo mentality requires a skill set and an approach similar to dealing with external agencies: some plausible benefit, or a win-win overlap of separate responsibilities, must create a foundation rationale for internal cooperation.

Going up the chain of command to realign the priorities of nominally equal peer units is risky, though if it is done skillfully enough, the tit-for-tat repercussions that come from "stepping on toes" may be avoided. If persistent requests come from resident groups or other civilian partners, some of the onus might be lifted from the requesting officers. Deferring the decision upward to higher command levels, by presenting various strategies with and without the available units, might be a workaround. In many cases, however, the processes are so heavily linked to personalities at all levels that it is impossible to prescribe a successful path to enlisting organizational assistance.

Covert disruption is less likely within the agency context than elsewhere, because the consequences of disruption attach to the agency and because memories are long. While there are some documented episodes of disruption in the history of policing experiments (beginning with the Kansas City Preventive Patrol Experiment), they tend to be expressions of disdain at interference by outsiders, not internal tampering. More serious disruptions tend to work in the opposite direction: "cooking the books" to make ineffective anticrime initiatives look better for political reasons.

Lip Service requires much less effort than covert disruption and is a more likely result in police agencies. The demands of external sovereigns, the changing priorities within the agency (or the precinct, or other unit), and the demands of the 9-1-1 system all become plausible reasons why promised assistance does not materialize. One RECAP officer attempted to enlist the assistance of peers he had worked with in patrol, asking them to make arrests when called to domestic violence incidents at a pair of properties where domestics were the primary driver of police numbers. Though they readily agreed, no arrests were forthcoming, even though an analysis of the active call information indicated a sound foundation of probable cause in multiple interests.

Token compliance is a close cousin to lip service within agencies, but as with outside partners, it involves a "did something" component that falls well short of the assistance needed. A day of directed patrol in a problematic neighborhood where 2 weeks or more are needed is one such manifestation. A couple of undercover drug buys where a sustained effort is needed is another. In all cases, a resort to competing demands for short resources is the explanatory rationale for levels of participation that are less than desired.

Good-Faith Incompetence. All departments of any size have individuals who meet minimal levels of competence but are unable or unwilling to reach more desirable levels of performance (the subtle Minneapolis appellation was "the sick, the lame, and the lazy"). Seconding an underperforming or "problem" member to the third-party request is a way of answering two distinct needs: the home unit is no longer responsible for the individual, and the unit can claim to have responded positively to the request. (While "good faith" may be a stretch in such cases, the response can be distinguished from covert disruption because no particular ill effects are intended.)

Like many policing initiatives, third-party policing is also vulnerable to a systemic problem in policing: lack of stability and continuity. Though no employee is irreplaceable, some are more attuned than others to the nuances of third-party work (like any other specialty). Local knowledge and trust are important to patrol officers, who tend to be regarded as interchangeable cogs in the machine. The "here today, gone tomorrow" transfers that are the norm for patrol can be fatal to third-party efforts. Knowledge and trust are vital to being able to sustain third-party policing, but when police agencies fall short, it inadvertently adds to innovation fatigue. Because building coalitions factors into many third-party and community-based initiatives, it is important to sustain third-party effort with long-term planning for promotions, transfers, or retirements.

Summary

The basic premises of third-party policing are simple: the police can be more effective by enlisting the efforts of partners with effective, consistent influence over the lives of the offenders who are the ultimate targets of police efforts ("policing *by* third parties"). Those potential partners who are reluctant to participate can be brought into conformity by civil pressures unrelated to the criminal law, if necessary ("the policing *of* third parties"). Excuses are illegitimate, and effective third-party policing is simply a matter of finding the right tool and establishing leverage.

In reality, those premises sometimes founder upon harder realities. Some reasons for nonparticipation are legitimate, most often those related to available resources: attempting to push past them will create ill will at least and quite possibly may create active resistance sufficient to undermine an otherwise legitimate effort. One of the greatest unknowns of third-party policing efforts is whether or not the narrow interest of a particular initiative will run afoul of competing priorities of more sovereign entities, as was the case with the RECAP shoplifting initiative and the Jersey City prostitution abatement project.

The right tools are not always available, particularly when political relationships lie behind the problem definition. Some political decisions will be legitimate choices to forego one opportunity (the third-party initiative) for another, larger political goal. Others may be the result of hard or soft corruption, but in any case will not yield to police insistence. "The wisdom to know the difference" is one of the mantras applicable to third-party policing efforts.

The "we tried that once; it didn't work" pathology of organizational thinking can be deadly. Overcoming it requires a nonconfrontational investment in analyzing both prior and current efforts. Special operations teams routinely conduct after-action critiques to identify areas needing improvement, but SWAT and SRT units have a cachet within police culture that community policing still strives to achieve. The concept of meaningful review of other efforts has made only modest inroads in other areas of policing and needs to expand to improve third-party policing.

Against those limits, third-party policing requires a continuity and a sense of long-term strategy quite distinct from the call-driven siloing of patrol work. In some instances, success requires the building of coalitions to overcome obstacles, and there is much to be learned in that respect from the community organizing movement. The existence of coalitions of affected parties lifts the onus of "being the bad guy" from the police, and both legitimizes and broadens the pressure on third-party targets. A clear understanding that "coerced volunteerism" works best when the coercion is minimal, and the benefits of cooperation are perceived early in the process, should be a fundamental tenet of third-party policing.

Tobacco Abuse in Correctional Settings

Overview

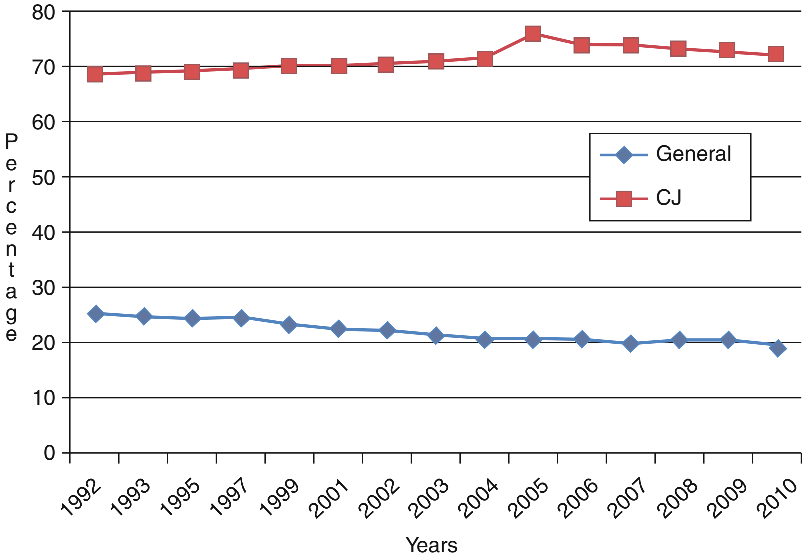
The United States incarcerates the largest percentage of its population of any country in the world, with over eight million adults and 650,000 youth under some form of local, state, or federal supervision, including prisons, probation, or parole (Taxman et al. 2007). The number of individuals under criminal justice supervision in the community has quadrupled over the past 25 years from 1.12 million in 1980 to 4.9 million in 2010 and comprises the largest segment of the criminal justice population (Glaze and Bonczar 2011). The increase in the criminal justice population has been attributed in part to the war on drugs and a political climate that favors increasingly punitive sentencing. Although a common misconception is that incarcerated people are removed from the community indefinitely, as many as nine million individuals are released from prisons and jails and return to their communities each year (Beck 2006). Consequently, policies surrounding the availability and use of tobacco products and the availability of resources for tobacco cessation in correctional settings have a profound impact on efforts to reduce the morbidity and mortality associated with tobacco use in the United States.

This entry discusses the prevalence of smoking and trends in tobacco use in correctional settings, common comorbidities such as substance abuse and dependence and psychiatric illness associated with tobacco use among incarcerated people, the health consequences of tobacco use among people in the criminal justice system, policies surrounding tobacco use in correctional settings, interventions for smoking cessations with criminal justice populations, and implications for the public health impact of tobacco use in the United States.

Fundamentals

Prevalence and Trends in Smoking

Despite over 40 years of public health messaging as well as population- and individual-based interventions, smoking remains the leading cause of death and disability in the United States. While smoking rates have declined to about 19 % among the general population, smoking remains disproportionately high for individuals in the criminal justice system (Cropsey et al. 2010).



Tobacco Abuse in Correctional Settings, Fig. 1 Prevalence of smoking for criminal justice (*CJ*) and general population (1992–2010). Note: CJ data was available for the following years in the United States: 1992, 2004, 2005, 2006, and 2010; missing points were estimated. General population smoking estimates were taken from CDC, 2011, "Trends in Current Cigarette Smoking Among High School Students and Adults, United States, 1965–2010"

Figure 1 illustrates the prevalence of smoking from 1990 to 2011 for the general population and correctional populations. While individuals under criminal justice supervision represent approximately 3.6 % of the general population, they represent over 12 % of current smokers (Centers for Disease Control 2011). The high rates of continued smoking among individuals in the criminal justice system suggest that public health messages and interventions have been largely ineffective or have not penetrated to this population.

Smoking prevalence among adults in the general population is about 19.3 % (Centers for Disease Control 2011). Among incarcerated men, smoking prevalence is 70–80 % and has remained steady over the past 20 years (Cropsey et al. 2010). Similarly, a recent survey of individuals under community corrections supervision indicated that 72.3 % were current smokers (Cropsey et al. 2010). Smoking rates among female arrestees range from 42 % to 91 % – two to four times greater than among women in the general population (Nijhawan et al. 2010). Finally, approximately 70 % of adolescents in the juvenile justice system have tried smoking and half are daily smokers (Cropsey et al. 2008b). This compares to about 44.7 % of adolescents not in the juvenile justice system who have tried smoking and 6.4 % who reported smoking on 20 or more days of the month (Centers for Disease Control 2012).

Smoking is entrenched in the culture of prisons and jails and has a place in prison life that differs from that in the "free world." With smoking rates three to four times higher among criminal justice populations than among individuals in the general population, smoking is normative in correctional settings and lacks the stigma attached to smoking in the "free world" (Cropsey et al. 2008a). In correctional settings, smoking connotes peer acceptance and creates a shared social and emotional connection. In addition, tobacco products are an important part of the informal economy in correctional settings and are traded and bartered for other commodities or services.

Smoking Comorbidities

Mental Illness

In the general population, individuals with histories of psychiatric disorders have higher rates of lifetime and current smoking and are less likely to quit smoking. Rates of smoking are substantially higher among individuals diagnosed with depression, schizophrenia, and anxiety disorders. Active psychiatric disorders are risk factors for onset of daily smoking and progression to nicotine dependence. Nicotine-dependent individuals with comorbid psychiatric disorders make up less than 10 % of the US population but consume over a third of cigarettes smoked in the United States (Grant et al. 2004). In addition, the burden of smoking-related disease is significant in smokers with chronic mental illness. For example, among individuals with chronic mental illness, the prevalence of chronic obstructive pulmonary disease (COPD) is over four times greater than the estimated COPD prevalence for individuals of a similar age in the general population.

Psychiatric disorders are prevalent in correctional populations, which may contribute to the high prevalence of smoking in criminal justice population. The prevalence of psychiatric disorders in correctional populations ranges from 7.6 % to 36.5 %, with 14.7 % of incarcerated individuals diagnosed with a psychiatric disorder in the past year (Glaze and James 2006). Additionally, one in four incarcerated people reports a learning impairment, which may compound the morbidity from other psychiatric diagnoses. The high prevalence of psychiatric disorders in correctional populations has been linked to the deinstitutionalization of mentally ill persons in the United States and the lack of access to mental health services in the community. Suicide was once the leading cause of death among jail inmates. Over the past 20 years, suicide has decreased drastically in the incarcerated population; however, the suicide rate in jails remains at 47 per 100,000 (Mumola 2005) compared to 12 per 100,000 in the general population (Heron 2012). Outside the correctional setting, incarcerated individuals are exposed to factors that contribute to the development of, and relapse to, mental illness, including sexual assault, childhood abuse and neglect, and abusive relationships. In addition, incarceration may exacerbate mental health problems, with violence, isolation from family and friends, and overcrowding being likely contributors to the high rates of mental illness in correctional populations. Thus, the rates of smoking and the high prevalence of psychiatric disorders in correctional populations suggest that a large proportion of incarcerated individuals may have difficulty quitting smoking without intensive interventions and may suffer long-term and serious health consequences from smoking.

Substance Abuse

In the general population as well as the incarcerated population, smoking is closely linked to the use of alcohol and other substances. In the general population, individuals with histories of dependence on alcohol and other substances smoke more heavily, are more nicotine dependent, and are less likely to quit successfully without intensive interventions. For example, 70–90 % of individuals who abuse alcohol and other drugs are cigarette smokers (Bowman and Walsh 2003), and tobacco use is associated with initiation and increasing levels of consumption of alcohol and other drugs.

Population studies show a clear, bidirectional relationship between nicotine dependence and dependence on alcohol and other drugs. Nicotine dependence is most prevalent among individuals with a current substance use disorder. Alcohol-dependent smokers are more physically dependent on nicotine, and heavy drinkers smoke more cigarettes, smoke sooner after awakening (an indicator of nicotine dependence), and inhale more smoke from each cigarette. In addition, individuals who are dependent on other substances smoke higher nicotine content cigarettes. Smokers with comorbid abuse of other substances are less likely to maintain long-term tobacco cessation and require more intensive behavioral and pharmacological interventions. Finally, alcohol and tobacco have a synergistic impact on health; health risks for individuals who abuse alcohol *and* smoke are greater than health risks for individuals who abuse either substance alone. In fact, among treated alcoholics, more deaths are attributable to smoking than to alcohol.

The “war on drugs” has been credited with the sharp increase in drug-related offenses among individuals in the correctional population. Most incarcerated people enter prison or jail with a history of abuse and dependence on alcohol and other substances. For example, about 56 % of inmates reported using drugs in the month prior to their offense, while about a third reported using drugs during the time of their crime (Karberg and Mumola 2006). Overall, about half of individuals in prison meet DSM-IV criteria for a substance use disorder. Given the overwhelming use of criminal sanctions for drug use behavior in the United States, as well as the association between drug use and smoking, it is not surprising that so many prisoners have high rates of smoking.

Medical Problems

The increase in incarceration over the past 30 years has resulted in increased correctional costs, from $20 billion in 1982 to over $74 billion in 2007, more than a threefold increase in annual expenditures (Bureau of Justice Statistics 2012). Healthcare costs have contributed substantially to this increase and are expected to double over the next 10 years, adding further financial burden to correctional systems already facing economic hardships (Lamb-Mechanik and Nelson 2000). Smoking-related diseases contribute substantially to this increase in correctional medical costs. Even though 88 % of individuals in the correctional system are younger than 50, 43 % of incarcerated males and 57 % of incarcerated females report at least one medical problem (Maruschak 2008). The most common medical problems are directly related to or exacerbated by smoking, including diabetes and heart, circulatory, respiratory, kidney, and liver problems.

Correctional populations are especially vulnerable to the negative health consequences of smoking. Many smokers increase smoking during incarceration, and many incarcerated people report a greater need to smoke due to the stress, boredom, and deprivation of prison life. Because of restricted availability and the expense of purchasing tobacco products from prison or jail commissaries or on the black market, many smokers switch to unfiltered hand-rolled cigarettes, which are higher in tar and nicotine. Recent studies have demonstrated that smoking roll-your-own cigarettes was associated with greater smoke exposure compared to factory-manufactured cigarettes. Thus, smoking in prison may present a greater health risk than smoking outside prison.

Racial Disparities

Over the past decade, smoking prevalence rates for African-Americans have come to equal those of Caucasians (21.3 % vs. 22.1 %; Centers for Disease Control 2011). This increase in smoking for African-Americans is further complicated by the fact that they tend to have higher rates of smoking-related diseases and mortality from smoking and more difficulty with smoking cessation. The differences in cessation rates have been documented even when controlling for potential moderators in both incarcerated (Cropsey et al. 2009) and nonincarcerated populations. This increase in smoking-related consequences and difficulties with cessation may be due to African-American's preference for smoking mentholated cigarettes which results in higher CO concentrations. African-Americans are overrepresented in the criminal justice system such that while they comprise only about 30 % of the general population, approximately 60 % of African-American men are incarcerated for at least 1 year before age 35 (Pettit and Western 2004). The overrepresentation of African-Americans in the criminal justice system in conjunction with their increased difficulty with cessation and greater health risks highlights both the importance and difficulty of cessation in this population.

Prison Policies

Tobacco policies have changed profoundly in US correctional facilities in the past several decades, with a consistent trend toward increasingly restrictive policies toward tobacco availability and use (Kauffman et al. 2008). Historically, tobacco use was an accepted part of life in US penal institutions, and state and federal correctional institutions routinely provided free tobacco. Although some correctional systems provided tobacco products to make incarceration more humane, cigarettes also played a role in maintaining order within facilities.

In the mid-1980s, about half of state correctional facilities provided free tobacco. By the early 1990s, tobacco products were sold in about 88 % of prison commissaries, 26 % of prison systems provided tobacco at no cost for indigent inmates, and 8 % of prison systems provided no cost tobacco products to all inmates (Vaughn and del Carmen 1993). Some correctional systems phased out distribution of free tobacco as incarcerated people gained the opportunity for paid employment and had money to purchase tobacco products from prison commissaries.

The initial impetus for changing tobacco policies was cost containment, including the cost of providing tobacco products, maintaining buildings and facilities, and treating smoking-related medical conditions. The trend toward restricting tobacco gained momentum because of concerns about exposure to environmental tobacco smoke (ETS). ETS is a particular health risk in correctional facilities because of the high prevalence of smoking, overcrowding and poor ventilation, inadequate facilities, and unrestricted indoor smoking or poor enforcement of indoor smoking policies. Smoke concentrations in correctional facilities are greater than in the homes of smokers. Finally, the desire to limit amenities for incarcerated people provided additional impetus for changes in tobacco policies. In 1986, only 5 % of US prisons had smoke-free living areas; by 2007, 96 % had smoke-free living areas, 27 % banned indoor smoking, and 60 % banned smoking completely (Kauffman et al. 2008).

Tobacco policies in correctional settings range from policies restricting smoking to policies prohibiting possession of tobacco products or tobacco use anywhere on facility grounds. A complicating factor in correctional tobacco policies is that the correctional facility is the incarcerated individual's home and there is some debate whether incarcerated people have the right to smoke as long as nonsmokers, other inmates, and staff members are protected from exposure to ETS. Complete tobacco bans force incarcerated people to quit tobacco use involuntarily or continue to use tobacco products illicitly (Eldridge and Cropsey 2009).

Although there is relatively little research on the impact of tobacco bans and restrictions in correctional settings, the research that is available indicates that the majority of people continue to smoke after the imposition of tobacco restrictions. Partial tobacco bans (i.e., incarcerated individuals are allowed to possess tobacco products but smoking is restricted in indoor areas) may be more difficult to enforce than complete tobacco bans. Organizational and environmental factors in correctional settings often mitigate against consistent enforcement of tobacco bans and the imposition of disciplinary sanctions for tobacco possession or use. Although administrators and others are often concerned about the possibility of violence and disciplinary infractions during the transition to smoking restrictions, there is little evidence that this occurs.

Despite the fact that tobacco use tends to persist after the imposition of smoking bans and restrictions, there is evidence of a reduction in the amount of tobacco consumed, which has implications for health and air quality in correctional settings. There is evidence of an improvement in air quality and a reduction in ETS and suspended particulates after the imposition of tobacco restrictions.

Despite these positive changes as a consequence of tobacco bans and restrictions, one negative change is a gradual reduction in the availability of tobacco cessation programs and materials. For example, tobacco cessation programs were offered in 86 % of correctional facilities with indoor tobacco restrictions compared to 39 % of facilities with total tobacco bans. Similarly, tobacco cessation aids (e.g., nicotine replacement) were available in 65 % of facilities with tobacco restrictions but only 35 % of facilities with total bans. This raises the question about whether the goal of tobacco restrictions in correctional settings is to suppress tobacco use during incarceration or to accomplish lifelong tobacco cessation. The trend toward restricting tobacco use while decreasing availability of tobacco cessation programs and materials is likely to result in temporary suppression of tobacco use during incarceration rather than long-term tobacco cessation during incarceration and after release (Kauffman et al. 2008). Although data are sparse, almost all individuals released from smoke-free correctional facilities resume smoking within 6 months of release (>98 %), with only 37.3 % remaining abstinent from smoking at the end of the first day post-release (Lincoln et al. 2009).

Interventions

Very few smoking cessation studies have been conducted with correctional populations, and none have been conducted with individuals in community corrections. Initially, two pilot studies examined smoking interventions with prisoners, and both used small samples and focused exclusively on male inmates. More recently, a large randomized controlled trial of smoking cessation with female prisoners who were provided NRT and 10 weeks of group smoking cessation counseling showed cessation rates comparable to community smoking cessation interventions. The literature suggests that spontaneous quit attempts among female prisoners are rare. However, this study demonstrates that female prisoners are interested in smoking cessation that it is feasible to provide smoking cessation in correctional environments, and that incarcerated smokers quit smoking successfully when provided with community standard smoking cessation interventions. However, no studies have examined providing integrated smoking cessation treatment to community corrections populations, despite the high need for such interventions and the public health relevance of reaching this low-income population. Given that smoking is now concentrated in individuals with low incomes who may have substance use and mental illness problems, smoking cessation interventions must be able to reach these individuals who are at risk and who do not have access to standard smoking cessation interventions in the community. Individuals in community corrections represent such a population of high-risk smokers who are poor and do not have access to community-level smoking cessation interventions.

Recommendations for the Field

Correctional settings house individuals with high rates of smoking, smoking-related medical conditions, histories of drug and alcohol abuse and dependence, and psychiatric illnesses that present challenges to long-term smoking cessation. Incarceration (and criminal justice supervision in the community) provides an opportunity to address tobacco use in a population that may otherwise have less access to tobacco cessation programs and materials. In 2002, the National Commission on Correctional Health Care in its report on the health status of soon-to-be-released inmates recommended that incarcerated people have access to smoke-free environments and smoking cessation materials and programs. However, smoking among criminal justice populations, particularly individuals under community corrections supervision, is virtually ignored in the research literature, despite the enormous human, health, and economic costs to correctional settings and to the community after release (Cropsey et al. 2004).

The current state of tobacco policies (i.e., tobacco bans and restrictions and availability of tobacco cessation programs and materials) in correctional settings highlights the gap between temporary suppression of smoking during incarceration and long-term smoking cessation. Although data are sparse, most individuals released from correctional facilities relapse to smoking soon after release. Prisons and jails provide an opportunity for achieving lifelong smoking cessation for disadvantaged men and women, with the potential for an enduring positive impact on health and economic security. However, as correctional settings impose tobacco bans and restrictions while diverting resources away from smoking cessation programs and materials, that opportunity is being lost.

Traditional Retributivism

Alfonso Donoso

Universidad Católica de Chile, Santiago
Metropolitan Region, Chile

Overview

This entry offers an account of some of the canonical ideas and authors of traditional retributivism. For present purposes, retributivism is understood as a type of justification of criminal punishment. One of the most salient characteristics of this justification is that it focuses on a past event, prior to the infliction of hard treatment upon the offender. Retributivism is thus defined as a backward-looking justification of punishment. Rather than emphasizing the likely consequences that the imposition of penal sanctions may bring about, traditional retributivism insists that the core of justified punishment is the intrinsic wrongness of the act committed by the agent, which makes the offender deserve the hard treatment entailed by this practice. This entry unpacks and explains these different retributivist claims by offering an overview of the *lex talionis*, Kant's retributivism, and Hegel's retributivism, three of the most fundamental sources of retributivism (for an account of contemporary retributivism, see Christopher Bennett's entry in this volume).

Introduction

Punishment is a perplexing practice. On the one hand, it imposes burdens upon individuals that under most circumstances we would consider inadmissible. The punished may see her freedom of movement radically hindered, her property expropriated, and even her life terminated. On the other hand, punishment is a pervasive practice the state undertakes on a daily basis. Indeed, the state claims punishment is part of its legitimate functions and, therefore, a practice to which it is entitled.

How can a practice like that be justified? Or, more fundamentally, is there anything that could possibly justify it? Abolitionists argue that punishment cannot be justified and, thus, should be abolished. However, *pace* abolitionists, there is a long tradition that has devoted time and effort to develop an argument for the justification of punishment. One such type of justification is consequentialism. Another is retributivism. Consequentialists hold that punishment is a justified practice if and only if it brings about consequences whose benefits outweigh the costs it causes and these benefits are greater than (or as good as) those obtainable by nonpunitive means. By contrast, retributivists hold that offenders deserve to be punished for their wrongdoings. Thus, for retributivism it is not the case that punishment is a justified practice only if it produces a benefit such as deterrence or rehabilitation and produces such a benefit better than alternatives. The retributivist insists that those ends cannot justify the infliction of hard-treatment. Instead, rather than focusing on future consequences, retributivists focus on a past act – the criminal offense – thereby offering a backward-looking justification of punishment. For the retributivist, those who committed a wrong are guilty of that wrong, and the guilty deserve to be punished. Punishment is, the retributivist claims, the intrinsically adequate response to wrongdoers.

Keeping these features of retributivism in mind, let us now consider three traditional sources of retributivist principles and ideas. In the course of presenting these different sources, emphasis is put on the questions of how to determine adequate types and amounts of punishments, the justificatory connection between punishment and crime, and the place of punishment in the broader context of moral and political theory.

Lex Talionis

Some of the oldest expressions of retributivism can be found in various passages in the Hebrew Bible. In "Leviticus," for example, it is said that "if a man cause a blemish in his neighbour; as he hath done, so shall it be done to him; breach for breach, eye for eye, tooth for tooth: as he hath caused a blemish in a man, so shall it be done to him again. And he that killeth a beast, he shall restore it: and he that killeth a man, he shall be put to death (24:19–21). And Exodus states: "if *any* mischief follow, then thou shalt give life for life, eye for eye, tooth for tooth, hand for hand, foot for foot, burning for burning, wound for wound, stripe for stripe" (21: 23–25). In ordinary parlance, this is what has come to be known as the "eye for an eye" principle or, in its Latin formulation, the *lex talionis*, which is aptly translated as the law that imposes a punishment that resembles in kind and degree the wrong committed (for another, older source of the *lex talionis* see the Hammurabi's Code of Laws (c. 1780 BCE)). For the purposes of this section, this principle's most relevant feature is the idea of "likeness" between present punishment and past wrongdoing. This feature shall lead us to consider in some detail both the plausibility and nature of the *lex talionis*.

To contemporary eyes, the *lex talionis* seems to be a very unlikely source for justified criminal punishment. The most obvious objection against this principle emerges when we think of the type of punishment that should be inflicted upon offenders for very serious wrongdoings. For example, should we rape the rapist? Or, should we torture the torturer? For some people, this makes a conclusive point against the revival of the *lex talionis* in current criminal practices (see Bedau 1978; Lacey 1988). However, this response is too quick. First of all, defenders of the "eye for an eye" principle may argue that although the *lex talionis* may not work for any type of crime, it does help us to explain the type of punishment that should be inflicted on some offenders for some crimes in certain circumstances. An offense at point is murder. In cases of intentionally killing of a person without justification or excuse, the *lex talionis* shows straightforwardly the punishment that is to be meted out to the murderer. Furthermore, proponents of the *lex talionis* may argue that this law has a much more sophisticated form than may first appear and that this qualified understanding of the principle should make us see the *lex talionis* as an adequate principle for a theory of punishment. The rest of this section shall consider in some further detail this more nuanced depiction of the *lex talionis*.

We should begin by asking what kind of principle is the *lex talionis* and in what sense it is connected to retributivism. This is a relevant question because it would be a mistake to understand the *lex talionis* as a version of a retributivist justification of punishment. The *lex talionis* does not tell us why someone may be morally justified in inflicting punishment upon an individual for her offense. Instead, it advances an answer to the question of what ought to count as the adequate punishment to be imposed upon an offender. This means that the *lex talionis* is logically posterior to the justification of punishment. In turn, this opens the possibility that the *lex talionis* is a principle that is compatible with different types of justification of punishment, including consequentialist justifications (see Waldron 1992).

The possibility that the *lex talionis* may be part of a consequentialist justification of punishment forces us to specify the sense in which this principle is connected with retributivism. The clearest sense in which both are linked is that both focus on a past event. We have already seen that retributivism offers a backward-looking justification of punishment. Similarly, the *lex talionis* answers the question of the type of punishment that is to be visited on an offender in the present by looking at the act performed by the offender in the past. This gesture to a foregoing act provides us with an answer (at least part of it) to the question of how we should punish an offender. In short, both retributivism and the *lex talionis* contemplate a time prior to the present to unravel relevant questions about punishment. This is what connects the "eye for an eye" principle with retributivism.

This connection to the past brings us to the core of the possibility of a more nuanced, sophisticated, and thus plausible account of the *lex talionis*. Such an account depends largely on how we interpret the equivalence that ought to exist between a past offense and present punishment. The bad name that the *lex talionis* may have derives from interpreting this equivalence strictly (i.e., raping the rapist and torturing the torturer). Indeed, strict equivalence makes punishment look more like sheer cruelty than like a justifiable practice grounded in a sound moral theory. Thus, the moral plausibility of the *lex talionis* depends on the existence of a more charitable interpretation of the connection between a past offense and its present punishment. The kernel of this more nuanced account of the *lex talionis* is to deny that we should punish offenders with an action identical to the offense committed. Instead, an adequate account of this principle is that an offender should be visited with the same relevant type of act as the one that constituted the offense. There are different and independent reasons for dismissing a strict interpretation of the *lex talionis*, but perhaps the two most evident are, first, that it is not possible (perhaps, not even logically possible) to inflict upon an offender at a present time an action identical to the past offense and, second, that a practice like that is vengeful, cruel, and inhumane.

If the strict interpretation is successfully dismissed, what can be offered as a plausible account of the *lex talionis*? Rather than asserting the *identity* between a past offense and the punishment that ought to be visited upon the offender, a plausible interpretation of this principle should affirm the *similarity* between these two events. But this is insufficient: what are the features of a past offense that are to be matched in present punishment? Should punishment bring about a physical and/or psychological harm similar to the one the past offense caused the victim? Should it be performed with a violence similar to that used by the offender? Should punishment be inflicted the same day of the week in which the offense was committed? All these are features that would make present punishment similar to a past offense but, surely, they are not what a defender of a morally grounded account of the *lex talionis* will advance in support of the principle. Instead, the *lex talionis* is considered in its best light when it is understood as a principle that, first, makes us focus on what constitutes the wrong of a past offense and, second, makes us choose the adequate type of punishment in light of that wrong. Thereby, the *lex talionis* tells us that only by establishing the wrongness entailed by the past offense can we have an answer to the question of the punishment that must be inflicted on the offender. Of course, which is that wrong and what are the relevant features that must constitute present punishment for a past wrong are things on which we will disagree. That is inescapable. However, inescapable disagreement does not imply that no arguments can be advanced in this matter.

Kant's Retributivism

Immanuel Kant's views on punishment and its justification are generally considered as paradigmatic of retributivist reasoning. Although some commentators have challenged this interpretation, or, at least, challenged that Kant's account is *purely* retributivist, this entry will be mainly concerned with the most widespread view on Kant's account of punishment. Thus, irrespective of the plausibility of a non-retributivist account of Kant's philosophy of punishment, Kant is here interpreted as an exemplar theorist of traditional retributivism (for non-retributivist interpretations of Kant, see Byrd 1989; Cummiskey 1990; Tunick 1996; Brooks 2003. For an account that challenges the consistency and coherence of Kant's views on punishment on grounds that they advance both a deterrence and retributivist system of punishment, see Murphy 1987.

The most developed account of Kant's retributivism is found in "The Doctrine of Right," the first part of his late work *The Metaphysics of Morals* (Henceforth, Kant 1991 followed by the pagination of the Prussian Academy of Sciences edition of Kant's writings and the page number of the English edition. For Kant's views on punishment, see also *Lectures on Ethics* [27: 286, 547, 552f]; *Critique of Pure Reason* [A317/B373]; and *Critique of Practical Reason* [A65-A67]). In "The Doctrine of Right," Kant emphatically tells us that criminal punishment.

> can never be inflicted merely as a means to promote some other good for the criminal himself or for the civil society. It must always be inflicted upon him only *because he has committed a crime*. For a man can never be treated merely as a means to the purposes of another or be put among the objects of rights to things [. . .]. He must previously have been found *punishable* before any thought can be given to drawing from his punishment something of use for himself or his fellow citizens. The principle of punishment is a categorical imperative, and woe to him who crawls through the windings of eudaemonism in order to discover something to release the criminal from punishment or even reduces its amount by the advantages it promises [. . .]. (Kant 1991, 6:331–332, pp. 140–141)

Kant is clear in insisting that an offender must be punished *only because* he has performed an action deemed criminal by the civil society. It is only because the offender has made himself worthy of punishment that punishment must be visited upon him. To do otherwise is to act impermissibly. To punish an offender O for action A because under the circumstances this would increase or maximize society's feeling of security by deterring O or other potential offenders from A-ing (or from performing other actions deemed criminal) is illegitimate and wrong. Similarly, to punish O because punishment would reform O, so after punishment O would be less likely to A again, is also an expression of illegitimate punishment. For Kant, only the guilty must be punished, and the guilty must be punished *because* it is deserved. To do otherwise is to use the offender as a mere means to an end, a violation of the Kantian moral law.

However, despite this strong retributivist approach, Kant notes that consequentialist considerations can also enter into the justificatory scheme. The point is that they cannot figure as having a primary or exclusive role in the justification of punishment. Indeed, by opening the door to consequentialist features in the justification of punishment, Kant advances an attractive and plausible account of retributivism that may well anticipate contemporary mixed theories of punishment (for Kant as a mixed-theorist see Byrd 1989. For mixed theories in general, see Hart 1959; von Hirsch 1976, 1993). Thus, Kant's account presents a version of retributivism that is more complex than some critics have been willing to recognize (e.g., Dolinko 1992). However, and to be sure, independently of the good and desirable consequences that may follow the imposition of punishment upon an offender, for Kant it is the intrinsic evil of the act performed by the offender that makes her deserve punishment.

This conclusion, however, can only be a part of a complete answer to the question of the justification of punishment. As Kant himself realizes, we also need to know "what kind and what amount of punishment is it that public justice makes its principle and measure?" (Kant 1991, 6:332, p. 141). To answer this question, Kant appeals to something close to the *lex talionis* conceived in terms of a "principle of equality." According to this principle, "whatever undeserved evil you inflict upon another within the people, that you inflict upon yourself. If you insult him, you insult yourself; if you steal from him, you steal from yourself; if you strike him, you strike yourself; if you kill him, you kill yourself" (ibid.). In Kant's own words, "the law of retribution (*ius talionis*) [. . .] can specify definitely the quality of and the quantity of punishment" (ibid).

How would Kant reply to the difficulties posed in the previous section of this entry in relation to the "eye for an eye" principle? Kant recognizes that although there are times in which the *lex talionis* principle cannot be strictly followed, it remains as a valid way to specify what the wrongdoer deserves: the spirit of the principle is upheld insofar as the punishment inflicted "is quite similar" to the offense performed (Kant 1991, 6:332, p. 141. See also 6:363, pp. 168f). It is worth noting that Kant's proposal on this issue seems to expand the types of punishment that may be rightly imposed upon an offender. He does not reduce the practice of state punishment to widespread types of penal retribution such as expropriation, restrictions of freedom of movement, or the termination of life. Indeed, he goes as far as to consider a variety of punishments, such as public apology or hand kissing (presumably to demonstrate the equal status as citizens of individuals from different social classes). Moreover, for cases in which the strict exercise of the *lex talionis* may seem offensive, cruel, or inhumane, Kant authorizes alternative forms of punishment (although to our eyes these alternatives may still be offensive, cruel, or inhumane). Thus, for rape and pederasty he proposes castration, while for bestiality he suggests "expulsion from civil society, since the criminal has made himself unworthy of human society" (Kant 1991, 6:363, p. 169). There is, however, one class of offense that cannot be responded to by proxy, namely, murder. "Here there is no substitute that will satisfy justice" (Kant 1991, 6:333, p. 142). In this case, death is the only legitimate response to be visited upon the offender since this sentence is proportional to the criminal's "inner viciousness" (ibid.).

Beyond the reasonable and serious doubts these types of punishments may bring about, Kant's conception of the *lex talionis* is successful in advancing an important consideration not to be overlooked when establishing both types and quantum of legitimate punishment. Kant's nuanced account of the principle of retribution brings to the fore the duty we have to uphold a principle of humanity in retribution, the violation of which contravenes not only human dignity but also the very concept of punitive justice (see Kant 1991, 6:363, p. 168f). Thus, Kant sees the *lex talionis* as the adequate principle of retribution, the appropriate way to determine how to punish offenders in a way required by the respect owed to all human agents. The satisfaction of this principle of respect is a core aspect of Kant's retributivism.

Besides this and other virtues, Kant's theory of punishment faces a series of difficulties that have been largely noticed by commentators (e.g., Murphy 1987; Merle 2000; Hill 2003). These problems are either inherent to retributivism, and thus, shared by all or most versions of it, or characteristic of Kant's moral and political theory from which his retributivist theory is built. Because many of the former difficulties are discussed in different places of this and Bennett's entry on retributivism, this section concludes with some brief comments on the latter type of difficulties.

By now it should be clear that desert has a central role in Kant's retributivism: it strongly denies the legitimacy of punishment inflicted, primarily, for reasons other than desert. However, given Kant's emphatic distinction between actions – external and the proper subject of justice – and motives – internal and the proper subject of virtue – it is difficult to provide desert with a coherent place within the theory, at least in the way it is presented in the "Doctrine of Right." To some extent, the difficulty derives from the lack of a sufficient account of intentional actions that make sense of the relevant internal factors of agents that Kant's retributivism must take into account to justify punishment.

This gap in the theory is closely linked to another feature missing in Kant's account. Kant affirms that offenders ought to be punished because their wrongdoings show inner wickedness. At the same time, Kant makes clear that the law is there to deal only with external actions – that is, it "does not include the incentive of duty in the law and so admits an incentive other than the Idea of a duty itself" (Kant 1991, 6:219, p. 46). From a liberal point of view, precluding the state and its coercive apparatus from meddling in the inner sphere of individuals is something to welcome. However, this insight is difficult to reconcile with Kant's concern with the internal wickedness of offenders that may make punishment justifiable. These are not irremediable difficulties, but they do cast some doubts about the internal coherence of Kant's theory of punishment.

Hegel's Retributivism

In the Anglo-American tradition of legal and political philosophy, G.W.F. Hegel's retributivism has received much less attention than Kant's (for exceptions, see Wood 1990, Chap. 6; Tunick 1992; Brooks 2012). This is regrettable, as Hegel's account of crime and punishment – mainly developed in his *Elements of Philosophy of Right* – provides enlightening insights into the nature of retributivism in particular and the institutions of criminal justice in general. It is worth noticing that, despite this dearth of attention, Hegel's theory of punishment has still managed to influence contemporary accounts of criminal punishment and penal justice (e.g., Hampton 1984; Morris 1968; Brudner 2009).

As happens with Kant's theory, there is room for debate on the extent to which Hegel does advance a pure retributivist account. However, whether he coherently introduces non-retributivist elements in his theory is something that this entry will not consider in further detail. Rather, our concern is confined to the retributivist aspects of Hegel's views in relation to punishment. For a recent treatment of Hegel as a mixed-theorist, see Brooks 2012.

Before considering the sense in which Hegel is a retributivist, a general contextual preliminary is in order. In the *Elements of the Philosophy of Right* (henceforth Hegel 1991, followed by the paragraph and page number in the English edition), Hegel is concerned "with the concept of right and its actualization" (Hegel 1991, §1, p. 25). Hegel's project is thus devoted to the manifestation in the social world of the concept of right, which manifests itself from different but interrelated positions that Hegel calls the "Abstract Right," "Morality," and "Ethical Life." The *Elements*, in short, aim to account for the dynamic and connection of these different appearances of right. Hegel's discussion on punishment appears mainly in "Abstract Right" where persons are seen as abstract agents, stripped from their particularities, and capable of manifesting their freedom and self-determination in external things. A consequence of this conception of the individual is that, to treat someone as a person, we are obliged to act in ways that recognize her ability to conduct her life as a free agent in the world. As we will see shortly, this has important consequences for Hegel's retributivism. For a useful synthetic exposition of these general preliminaries, see Dubber 1994.

The essence of Hegel's retributivism emerges with some clarity when he articulates the relationship that exists between crime and punishment. Hegel states in his characteristic style that the "determination of the concept [of punishment], however, is precisely that necessary connection [which dictates] that crime, as the will which is null and void in itself, accordingly contains within itself its own nullification, and this appears in the form of punishment" (Hegel 1991, §101, p. 128). In this passage, Hegel is drawing our attention to the structure of punishment and how it is essentially linked to the criminal act. For Hegel, crime implies punishment and punishment implies crime. This is not to suggest the obviously mistaken point that any time a crime is committed a punishment is meted out. Neither does it advance the view (consistent with Hegel's position) that who is to be punished and to what extent depends on the nature of the criminal act. Hegel is rather pointing to a logical, and thus necessary, connection between these two parts of a single totality: "punishment is merely the manifestation of the crime, i.e., it is one half which is necessarily presupposed by the other" (Hegel 1991, §101 addition (H), p. 129).

Given this argument, it seems natural to elaborate further on the notion of crimes in order to ground the justification of punishment. Indeed, Hegel dedicates various paragraphs of "Abstract Right" to elucidate the nature of crimes. He distinguishes three varieties of wrongdoing: (1) civil wrongs, in which a particular will judges by itself, mistakenly, what is right about a particular case. These judgments are wrongs because they are mistaken judgments, but they do not thereby negate or intentionally disrespect the system of right as such (Hegel 1991, §§84–6, pp. 117–118). (2) Deception, by contrast to civil wrongs, involves the intentional violation of the law. However, in committing this wrong, I am simultaneously recognizing the system of right: I deceive someone by pretending to be acting according to the law (Hegel 1991, §§87–9, pp. 118–119). (3) Crimes are wrongs that negate right. They are neither unintentional, like civil wrongs, nor do they try to deceive others, like deception. Rather, crimes are an attempt to debunk right. But crimes go even further in their negative judgment. When a criminal act is committed, it is not only right as such that is negated (the offender has acted according to a maxim that contradicts right itself), but also the victim's status as a person (her external freedom has been violated), and the offender's right (he can then be treated according to the maxim generated by his action, namely, that one should violate other people's external freedom).

With this account of crimes in place, the logical connection between punishment and crime should become clearer. For Hegel, "Punishment is the negation of the negation" (Hegel 1991, §97 addition (H), p. 123), which is to say that punishment cancels the negations of right involved in the criminal act. To make further sense of this idea we must notice that for Hegel right is absolute, that is, right is something that cannot possibly be canceled. Crimes are thus "null and void," because offenders could never *really* negate right by means of their criminal actions. Punishment simply exposes such a vacuity and reaffirms right as right. Understood in this manner, punishment "is the reconciliation of right with itself"; "this reconciliation applies to the *law*, which restores and thereby *actualizes itself as valid* through the cancellation of the crime" (Hegel 1991, §220, p. 252). Punishment is just "in and for itself" (Hegel 1991, §99, p. 125). (For clarification on Hegel's use of cancelation (*Aufheben*), see Hegel 1969, p. 107. For a critique, see Honderich 2006, pp. 41–45).

The previous analysis allows us to see how punishment reaffirms right as right (punishment reaffirms the validity of the system of law) as well as the right of the victim of crime (punishment denies the universal validity of the right violations entailed in the criminal act). But Hegel also contends that the reaffirmation of right via punishment does justice to the offender. This is the case because punishment is "a right for the criminal himself" (Hegel 1991, §100, p. 126). This is surprising since, as we have seen, punishment involves treating the offender in ways that we normally consider inadmissible. How then could punishment be an offender's right? A characteristic aspect of Hegel's theory becomes salient at this point. In "Abstract Right," persons are defined in terms of their capacity for freedom and rationality, and by punishing offenders – who also happen to be persons (!) – we honor them as rational beings and recognize them as subjects of right. Justice is done, and the right as right is asserted, first, when punishment is imposed, and second, when it is imposed not as the result of a private but of a universal will (Hegel 1991, §104, p. 131). To consider punishment otherwise, as a mere threat or an act of revenge imposed by a private will, would mean to treat "a human being like a dog instead of respecting his honour and freedom" (Hegel 1991, §99, pp. 125–126. See also §102). The criminal "is denied this honour if the concept and criterion of his punishment are not derived from his own act; and he is also denied it if he is regarded simply as a harmful animal which must be rendered harmless, or punished with a view to deterring or reforming him" (Hegel 1991, §100, p. 126). This shows Hegel's retributivist credentials in full light. By being punished, the wrongdoer is treated as he deserves, a rational human being capable of acting on universalizable maxims – in the case of crimes, the maxim of permitting the violation of another person's external freedom. Punishment simply applies the universalized maxim of his offense to the wrongdoer himself.

If all this is sound – namely, that punishment is an integral part of the rational manifestation of right and, thus, it is in itself an act of justice that reaffirms the right that the offender attempted to cancel – then, how and how much should we punish the offender? This is a particularly pertinent question in this context. If punishment is also a right of the offender, as Hegel believes, he must surely have something to say about the amount and types of punishment that the state may legitimately inflict upon the offender. Unfortunately, Hegel says very little about this. Hegel seems aware of the difficulties involved in many interpretations of the *lex talionis*, and thus he proposes what he calls an "equality of value" principle between the past offense and present punishment (Hegel 1991, §101, pp. 127ff). However, this looks like a very unspecified, if not obscure, way to establish how and how much we ought to punish offenders. In addition to some form of ordinal equality, according to which the more serious the offense the harsher the punishment, it is unclear how Hegel means the principle of "equality of value" to be understood. It is not until "Ethical Life," the third part of the *Elements*, that Hegel elaborates a bit further on these matters. In this later stage of the *Elements*, the individual is not depicted as a formal agent, as in "Abstract Right," but as a particular person (Hegel 1991, §182, p. 220). Since for Hegel philosophy is concerned only with general and abstract principles, whereas the precise determination of these principles – one of which concerns the quantum of punishment – is a matter that depends on history and other contingencies (Hegel 1991, §3, pp. 28ff), it is no surprise that he left considerations about the distribution and proportionality of punishment to this later, less abstract, stage of the *Elements*. In short, Hegel believes that how and how much we should punish offenders is a matter to be resolved within the specific society in which punishment is performed. "A penal code [and with it, the definition of crimes and the harshness of punishments] is therefore primarily a product of its time and of the current condition of civil society" (Hegel 1991, §218, p. 251).

Hegel seems to be right. A universal code that establishes, irrespective of the circumstances of societies, conclusive measures and types of punishments for specific offenses is far-fetched. Hence, it seems sensible to adopt something like Hegel's contextual proposal. However, his reflections on the importance of history and circumstances regarding proportionality and types of punishment can only work as the beginning of an adequate answer. Indeed, as it stands, there is nothing in his proposal that may impede it from being hijacked by undesirable consequentialist considerations on the question of proportionality. For example, in a time different from ours, a rational and decent consequentialist judge could conclude, in consistency with Hegel's view, that given his society's current circumstances, not only the stability but also the very survival of society demands torturing terrorists in the public square. He could defend this conclusion by expressing that this is what "equality of value" requires in a time like his. To be sure, Hegel's account may have the conceptual tools to advance an answer that would avoid undesirable outcomes such as this, however, as it stands, it is unclear how this solution would proceed.

Concluding Remarks

In 1939, J.D. Mabbot stated: "the retributive view is the only moral theory except perhaps psychological hedonism which has been definitely destroyed by criticism" (Mabbot 1939, p. 152). Indeed, up to the mid-twentieth century, the established view on punishment was some version of consequentialism, whereas retributivism was dismissed as something akin to superstition. The panorama is now very different. Since the last years of the 1960s, retributivism has come to life again and became an influential form of justification of punishment.

In essence, current retributivism maintains many of the main claims found in traditional retributivist ideas. Some of those claims have been explored here, namely, present punishment can be inflicted on an offender only because he deserves it due to his past offense; wrongdoers must not be used as mere means for achieving a social end; the amount of punishment that can legitimately be inflicted upon an offender depends on some feature of the wrong committed. These are retributivist considerations that, it is fair to say, are well-established principles in most plausible theories of punishment, and rightly so. They adequately capture widespread intuitions about punishment and the criminal justice system in general.

However, the virtues of traditional retributivism should not make us forget the difficulties and gaps we have encountered in the process of exposing this theory. Before finishing, it is worth recapping some of them.

We have seen that traditional retributivism works well as a type of justification of punishment. However, as Hegel himself realizes, this justification cannot be considered, nor successfully grounded, in isolation from wider state institutions and social circumstances. In particular, a comprehensive account of punishment and criminal justice must provide a sufficiently well-defined account of moral and political theory. This is, *pace* Hegel's suggestions, something that traditional retributivism does not advance in an adequate detail or with precision. (For a contemporary attempt to integrate the justification of punishment with broader political and moral theory, see Matravers 2000).

Retributivism in general should also make additional efforts to avoid the charge of advancing an account of punishment that is utterly insensitive to consequences. Critics have asked, with reason, what is the point of punishment – an expensive and morally problematic practice – if it does not bring about any further good. When detached from any positive consequences, is not punishment a mere expression of revenge or uncivilized practices? Without having to deny the core premise of this objection, traditional retributivism may respond that this criticism is ill grounded for two different reasons. First, in the course of this entry it has been mentioned that retributivism is capable of including non-retributivist considerations as part of the justification of punishment. Thus understood, it is not true that traditional retributivism disregards consequences all the way, but rather that it does not locate them as the first and main element in the justification of punishment. Second, traditional retributivists seem to believe that punishment does produce a good, indeed, a significant one. This is especially clear in the case of Hegel: punishment reaffirms right, which in turn is at the basis of the existence of the civil society. Thus understood, punishment is necessary for the maintenance of the polity. Such is the good, not a trivial one, to which punishment contributes (notice that although in this sense Hegel's account is teleological, his justification of punishment is still strongly non-consequentialist). Be that as it may, it is far from clear how these considerations would suffice or be convincing enough. A plausible justification of punishment must not only take consequences into account, but it also needs to emphasize the relevant type of consequences and locate them in the right place within the theory.

Finally, although part of the appeal of traditional retributivism derives from its insistence on the connection that must exist between the present punishment and the past offense, the details of this aspect of retributivism are left very much underdeveloped. The *lex talionis*, in its most plausible formulation, only indicates the need of preserving the relevant connection between punishment and crimes, but it does not tell us much about how to establish this connection. In turn, although affirming the obligation we have to respect the dignity of the offender in sentencing, Kant offers little insight into this issue. In the case of Hegel, things are not very different. He only tells us that this is a matter of detail to be considered in the social and political circumstances in which punishment is effectuated. As they stand, none of these sensible suggestions are very helpful. They work as general guidelines, but do not provide sufficient grounds to direct our practices.

Nothing of this is to say that we should dismiss traditional retributivism. Indeed, it is unclear whether any alternative justification of punishment would do much better than retributivism in these and other issues. Moreover, the difficulties noticed here are not necessarily insurmountable, and retributivism may well develop (and indeed has developed) answers to many of these difficult and problematic issues.

Traffic Enforcement and Control

Joseph A. Schafer
Department of Criminology and Criminal Justice, Southern Illinois University, Carbondale, IL, USA

Overview

Police agencies engage in a variety of traffic services. These efforts are designed to encourage motorists to obey traffic laws and regulations through a variety of methods. It is hoped that such compliance will maximize traffic efficiency and obedience of the law while minimizing traffic disruptions and accidents. The traffic services provided by state, county, municipal, and special jurisdiction law enforcement agencies are frequently associated with a range of organizational objectives. Though enforcement of traffic laws is a major objective, traffic services are also provided with the intention of minimizing injuries and property damage due to traffic accidents, determining facts when accidents and collisions have occurred (both to determine fault and to provide data for accident prevention efforts), assisting accident victims, obtaining compliance with traffic laws, and maximizing efficient use of congested roadways (Sheehe 1971). Traffic services include efforts to enforce traffic laws, regulate and direct the flow of traffic, minimize traffic accidents (both volume and severity), and efficiently respond to accidents when they do occur.

After providing generalized patrol services, traffic enforcement is one of the major ancillary tasks undertaken by local police agencies (Walker 1992). Citizens report that traffic stops are the most common situation in which they have contact with the police (Durose et al. 2007). Data suggest that nearly 10 % of citizen calls to the police relate with a traffic problem of some sort (most typically reporting traffic accidents but also to complain about traffic violations or traffic flow problems) (Scott 1981). Other studies have found that nearly one-quarter of patrol officer time is spent on traffic enforcement activities (Greene and Klockars 1991). Traffic services and enforcement serve a crucial secondary purpose for police officers and organizations. For officers, traffic enforcement may have less to do with the enforcement of traffic laws and more to do with providing an officer legal grounds to look for more serious violations (Schafer and Mastrofski 2005). Though traffic services may not seem glamorous and are often downplayed in media portrayals of policing, they represent a range of tasks that are central to policing, both in terms of their frequency and importance.

Fundamentals

Agencies vary considerably in the extent to which traffic services are a specialized or generalized function (Walker 1992). Specialized traffic services assign traffic enforcement, traffic regulation, and/or traffic accident investigation to specific officers who are usually freed from other policing duties, such as responding to emergency calls for service. This situation is increasingly common as the size of an agency increases and specialization of all types begins to be more evident within the organization's structure.

Specialization of any policing task is presumed to increase the efficient use of personnel resources and to free general patrol officers from time-consuming tasks not directly related with crime control. The presence of a specialized traffic service function does not mean general patrol officers will not engage in any traffic-related activities; rather, having a specialized function would be expected to reduce the amount of time general patrol officers spend on these activities, at least during the times when specialized officers are working.

Generalized traffic services responsibilities occur when all officers are expected to routinely engage in traffic enforcement, traffic regulation, and accident investigation. This is more likely to be noted in medium and small agencies, where specialization is less common or the extent of specialization is modest. For example, in a 30-officer department, 1 or 2 officers working the day shift might be given responsibility for traffic services. During other times of the day, general patrol officers would be expected to provide those services. There may be additional variation in how agencies assign traffic service duties, even where a specialized unit is present (i.e., a traffic unit might handle traffic control and traffic accident investigation, while all officers are expected to engage in routine traffic enforcement). In agencies that place a heavy emphasis on traffic enforcement, such as state police and highway patrol, traffic services may be a generalized responsibility even when the agency is quite large.

Though contemporary evidence is sparse, some research suggests agencies produce a higher volume of traffic enforcement activity when traffic is a specialized function (Gardiner 1969). A variety of reasons could explain this situation. In larger agencies, general patrol officers may not have the time to engage in traffic services because of a high volume of calls for service. General patrol officers may also lack some resources in support of traffic enforcement; for example, radar units might not be installed in vehicles used by general patrol officers and/or not all officers may be certified (if required by the state) in the use of radar equipment. There might also be an absence of a culture of traffic services in a given jurisdiction; traffic services might be viewed as a "soft" assignment, something an officer does when she/he wants to work the day shift or escape the "grind" of routine patrol.

Traffic Enforcement

When most citizens think about police efforts centering on traffic services, it is likely that traffic enforcement is the first activity that comes to mind. Traffic enforcement and regulation efforts represent a curious convergence of circumstances in the understanding of police organizations and discretionary choices of police officers (Lundman 1979). Organizations have various incentives to regulating the volume of enforcement efforts by personnel, including the desire to ensure public safety, to control crime, and to respond to public demands for action on select offenses (i.e., drunk driving) (Mastrofski et al. 1987). Within those circumstances, however, traffic services remain a highly discretionary activity for officers and, at times, a low visibility activity (Brown 1981). Though officers may have to meet certain overall expectations for their production and provision of various traffic services, they often enjoy considerable latitude (sometimes granted by state law) to decide when to invoke the law. Situations where officers show such leniency are rarely captured in existing police data systems and are rarely known to anyone aside from the officer and the motorist.

Traffic enforcement activities can be the source of tension, danger, and inconsistencies for the police and the public. Citizens may resent being stopped and subject to extra attention by the police, even if a citation is not issued. It should be noted, however, that the overwhelming majority of citizens stopped by the police report that they believe the police had legitimate reason for initiating that contact (Durose et al. 2007). Officers killed or injured on the job are often involved in traffic service activities. Around 13 % of police fatalities and nearly 10 % of assaults on the police occur while officers are engaged in traffic stops (Lichtenberg and Smith 2001). For decades researchers have noted inconsistencies in the traffic enforcement actions of agencies. James Q. Wilson first noted this variation in his classic text *Varieties of Police Behavior* (1968), observing that agencies of similar size and jurisdiction often vary considerably in the rates with which they engage in traffic stops and, when stops are made, take formal enforcement action by issuing a citation. Some agencies demonstrate low levels of enforcement and/or respond to traffic violations with verbal warnings, while other agencies are quite actively involved in traffic enforcement, including the issuance of a high rate of citations (Gardiner 1969; Mastrofski et al. 1987; Wilson 1968). This may contribute to citizen frustration, as it is not always clear when and where a traffic offense will invoke a formal police response.

Explaining Variation in Traffic Enforcement

Variation in the frequency of engaging in traffic stops and issuing traffic citations can be explained by a number of potential factors. In large part, such variation is likely a reflection of differing department objectives and community expectations. Though rarely discussed, in many communities traffic enforcement often contributes appreciably to city and county coffers (Radelet and Carter 1994). When a traffic citation is issued and the motorist is subsequently ordered to pay a fine, the issuing agency is not the direct recipient of those funds. However, the overriding governmental unit (the city or county) often does receive a proportion of the fine paid by the motorist. Particularly in difficult economic times, governmental units can become dependent on a certain level of resources. This might not pressure an officer to issue a citation on any given traffic stop, but it might result in implicit pressure on an agency to maintain or even increase the volume of citations issued over time. Some agencies might try to limit local opposition to heavy traffic enforcement by targeting efforts in areas where out-of-town drivers are more likely to be caught committing a violation (i.e., encouraging officers to "run radar" on a state highway).

High levels of traffic stops and/or traffic citations can also be a reflection of myriad noneconomic pressures. For example, a community may be calling upon the police to increase traffic enforcement, particularly for select offenses (i.e., speeding) or in specific areas (i.e., near schools or commercial area). Top agency administrators may request officers to modify their behavior in specific ways, such as requesting that officers increase the number of traffic stops or show more restraint in issuing traffic citations. Calls for increased traffic stops or enforcement may reflect a belief that such actions will enhance public safety, though evidence demonstrating a clear ability of the police to achieve that outcome is mixed (see below). Leaders may also formally or informally ask officers to increase traffic enforcement because traffic stops are one way agencies can document that officers are working. Agencies will be reluctant to refer to these expectations as "quotas," but it is not uncommon for agencies to establish "productivity standards" (or similar expectations) based in part on the frequency of traffic stops and/or citations for each officer. Given the limit direct supervision most officers receive, a traffic-related productivity standard is one way supervisors and agency leaders can ensure that officers are being vigilant in engaging in work-related activities while on routine patrol (Walker 1992). Agencies cannot easily assign officers to make a given traffic stop (as an agency might assign an officer to handle a specific complaint or take a specific report), but expecting officers to document a select number of traffic stops per shift or issue a certain number of citations or warnings per month is thought to demonstrate a minimal level of vigilance on the part of each officer. Such expectations are predicated on the assumption that officers can routinely identify legal cause to stop motorists for violations or other pretense.

The volume and nature of traffic enforcement behavior by officers has been noted to vary not only across agencies, as discussed earlier, but also across officers. Within the cultural and organizational expectations regarding traffic enforcement, officers may opt to merely meet standards or choose to exceed organizational expectations (Schafer and Mastrofski 2005). This reflects an established reality in policing research that demonstrates that officers vary in when, where, and how they use discretion in performing their work-related duties (Brown 1981). In the context of traffic enforcement, some officers will have a strong inclination to engage in a high rate of traffic stops and issue a large number of citations. This vigor may be due to the belief that such activities will either ensure greater control in the community or because of a desire to remain active during unassigned duty time. Other officers will engage in these activities with enough frequency and vigor to satisfy the expectations of their supervisors and organization, but will not go substantially beyond that threshold. Still other officers may engage in a high rate of traffic stops while issuing few citations. For these officers, traffic stops have instrumental value; they allow officers to initiate contact with citizens to investigate suspicious or unusual circumstances with the ultimate objective of detecting criminal conduct. Though organizations and communities can exert some influence, individual officers maintain some latitude to decide how they prioritize traffic enforcement efforts in the performance of their duties.

Nonenforcement Traffic Services

In addition to enforcing the law, police officers and organizations engage in other traffic services aimed at regulating the flow of traffic and responding to traffic accidents. Nonenforcement traffic services can also generate tension and dangers for the police. Directing traffic is a common policing activity, both in special circumstances (i.e., at a special event or during the aftermath of a traffic accident) and as a routine assignment (i.e., directing traffic near a school or at busy urban intersections). Motorists may be frustrated with the perceived inflexibility of officers or delayed movement of traffic. A driver may feel ill will toward the police because they are not allowed to take their preferred route. Officers may become frustrated while working long assignments in full uniform, with full exposure to the elements. Citizens may perceive the police are exacerbating traffic problems, and officers may perceive shortcomings in the cognitive and driving abilities of the driving public, though neither of these outcomes will be universally present.

In addition to enforcing motor vehicle laws and regulating the flow of traffic, an important traffic service function performed by the police is the investigation of accidents. Traffic crashes are a leading cause of death (causing more annual deaths than crime) and generate a tremendous economic impact. As a matter of public safety, officers are tasked with responding to traffic accidents in order to facilitate medical care, regulate the flow of traffic while a matter is resolved (to minimize the likelihood of a secondary accident occurring), coordinate the removal of disabled vehicles, and assist the involved parties. Officers will generally question the motorists and any witnesses, examine the vehicles involved, note the position of vehicles on the roadway, and in some cases take photographs, collect physical evidence, or otherwise examine and record the existing evidence (i.e., skid marks). These investigative efforts are intended to support officers in determining how an accident occurred, what took place, and, where relevant, how to assign blame for the accident. The latter point becomes relevant if it is determined that enforcement actions are needed but also to support decisions of responsibility relevant to insurance and other financial and legal claims that may arise as a result of an accident.

Data generated by police accident investigations and reports can also be used to support traffic safety enhancement efforts. On a local level, agencies use data to identify high-risk intersections. This information might shape traffic regulation decisions within a jurisdiction, such as changing the pattern of a traffic light or installing some form of traffic regulation technology. Local data might further be used as a rationale for increasing enforcement efforts in a particular area. On a large scale, traffic data might be used to inform traffic laws or policies. Knowing who is often involved in accidents, when those accidents occur, and the nature of those accidents can all provide support for changes. For example, a state might opt to lower speed limits on certain road, restrict select driver behavior (i.e., texting while driving), or modify who is allowed to operate certain types of vehicles (i.e., allowing additional testing to authorize someone to operate a motorcycle). Though large volumes of data amassed by street-level officers often are used to justify these policy changes, it is not always clear those changes achieve the intended outcomes (typically a reduction in the frequency and severity of traffic accidents).

The Effectiveness of Traffic Services

The efficacy of traffic services and enforcement is subject to some debate. The relationship between police enforcement behaviors and actual reductions in crime, traffic violations, and traffic accidents has not been conclusively established. Steven Rock (1989) evaluated a traffic enforcement program that was implemented to reduce traffic accidents in Batavia, Illinois. Rock's analysis suggested that accident rates did decline in Batavia, though perhaps not for the expected reason. He attributed at least some of the decline to improved accident investigations conducted by Batavia officers, which in turn helped generate data that allowed the city to redesign intersections where a high rate of traffic accidents occurred. Thus, the efforts of the Batavia police did not directly influence the behavior and actions of motorists. Instead, the effect was indirect; the police influenced traffic engineering and roadway design, which influenced driver behavior and resulted in fewer accidents.

It remains unclear how police should direct efforts to reduce traffic violations and associated problems (i.e., the volume and severity of accidents) (Scott 2001). Though the limited available research has tended to focus on reducing traffic issues through the use of enforcement, other mechanisms might be presumed to achieve the same outcome. Citizens can be educated using signage, media alerts, and the distribution of literature. Potential violators might be deterred through visible police presence and/or a heightened volume of traffic stops, even if enforcement (i.e., traffic citations) is not an outcome of those efforts. Roadways might also be engineered to improve the flow of traffic through high-accident areas and/or by building design elements (i.e., "traffic calming" features such as narrowing roadways, intentionally creating curving roadways, or creating speed humps) into roadways to make violations less likely. Tactics deemed to be less effective in reducing traffic violations and accidents include decreasing speed limits, increasing fines and penalties, and reengineering vehicles (i.e., the use of speed governors) (Scott 2001).

Traffic enforcement is a common element in police efforts to reduce crime and violence (McGarrell et al. 2002). In such instances, traffic stops are not used with the explicit intension of reducing traffic violations. Instead, traffic stops are used to provide lawful pretext for officers to stop vehicles, either in general or when the vehicle is deemed to be "suspicious." Officers are likely focused more on identifying motorists, running want/warrant checks on vehicles and their occupants, and obtaining lawful authority to search vehicles and their occupants. Such authority might be obtained by a citizen granting consent, when officers determine they have lawful authority to conduct a *Terry* search, or when other legal circumstances are present (i.e., contraband observed in plain view, incident to an arrest, or incident to a vehicle being towed). When the police engage in this type of traffic enforcement, the objective is usually to reduce crime and disorder, not to influence or regulate driving behavior. The traffic stop becomes the legal means to achieve some other end objective.

Only a few quality studies have attempted to assess whether aggressive police enforcement of traffic laws can achieve a meaningful reduction in crime rates. Early studies of this phenomenon supported that areas with higher levels of traffic enforcement had lower rates of robberies (Sampson and Cohen 1988; Wilson and Boland 1978). In contrast, Weiss and Freels (1996) found that increasing traffic enforcement in high-crime areas did not influence robberies or auto thefts nor did it increase the frequency of felony arrests, in Dayton, Ohio. Their analysis also could not support that higher enforcement resulted in more arrests for drug crimes, weapons crimes, or DUI.

Despite the common presumption that increasing the vigor of traffic enforcement will engender ill will toward the police, some studies have found the opposite to be true. This situation may be a function of the traffic enforcement methods used by the police. If the police seek to influence the behavior of the driving public, they might do so by increasing the issuance of traffic citations. If the police seek to influence crime and disorder, they might increase the frequency and investigative rigor of traffic stops, without actually issuing more citations. In such circumstances, traffic stops are not the end objective but rather a means to that objective. Research has found citizen support for more aggressive traffic enforcement actions by the police when those actions are undertaken in the name of community safety and order. This finding is tempered to some extent by the reaffirmation that while aggressive strategies might enhance citizen perceptions of the police, they might achieve that outcome without actually influencing crime (Chermak et al. 2001; Weiss and Freels 1996). In other words, while citizens might support aggressive traffic enforcement efforts initiated in the name of reducing crime, those efforts have not conclusively been shown to influence crime rates.

Key Controversies

Traffic services have been a contentious aspect of police-community relations, since police agencies first assumed responsibility for investigating accidents, enforcing motor vehicle laws, and regulating the flow and movement of traffic. Citizens presumably recognize the need for, and value of, traffic enforcement and regulation by the police. Citizens may not, however, appreciate being the specific recipient of such police attention and intervention (Lundman 1979). A motorist might question why an officer is “hassling” them for failing to completely stop at a stop sign, instead of addressing “real crime” within the community. Despite the presumption that aggressive traffic enforcement efforts will engender citizen ill will toward the police, studies have not always found that to be the case. An aggressive enforcement strategy used by the Indianapolis Police Department was implemented as a means of targeting select high-crime neighborhoods. Citizens in these neighborhoods were found to be supportive of the police department’s efforts (Chermak et al. 2001), though it is worth noting that officers were instructed not to simply conduct more traffic stops but to engage in more targeted enforcement efforts and to conduct more thorough contacts with motorists they stopped.

Corruption

A number of investigations into police corruption have involved issues related with traffic services (see The Knapp Commission Report on Police Corruption 1972). This problem has included officers accepting bribes to not issue citations, police personnel being paid to “fix” traffic citations and parking tickets, police soliciting payment for providing favorable traffic-related services, and companies paying police officials for favorable consideration (i.e., tow truck companies paying to be called more often when citizens needed motor vehicle assistance). Across the country, agencies of all sizes and types have allegedly been involved in such scandals. The problem appears isolated to very small numbers of officers and non-sworn personnel but demonstrates the financial motivations citizens may have to avoid legal sanctions or secure more favorable treatment with traffic-related matters.

Racial Profiling

Traffic enforcement behavior reached a new level of scrutiny in the mid-1990s with the emergence of concerns over racial profiling (also referred to as “Driving While Black” and “Driving While Brown,” among other labels). Though the practice of racial profiling is often seen to have deep roots in the dynamics of American criminal justice, this behavior achieved a more tacit level in the 1980s when the Drug Enforcement Administration (DEA) began to train local law enforcement personnel under the Operation Pipeline program (Buerger and Farrell 2002). Operation Pipeline was predicated on the belief that drug traffickers brought their goods into major port cities using various methods of bulk transportation. From these ports, drugs were distributed throughout the country using couriers who normally used cars to transport their deliveries. The DEA developed a “profile” of the behaviors and other characteristics of drug couriers, including that drivers were often members of minority groups. Though not an explicit endorsement of using race as a factor in deciding whom to stop, Operation Pipeline is often considered to have legitimized what some view as a long-standing practice of incorporating race into police enforcement decisions and practices.

Racial profiling received considerable attention beginning in the 1990s as a number of court cases and media exposés highlighted disparities in the characteristics of citizens stopped and searched by various departments (Weitzer and Tuch 2006). Prominent among these anecdotes was *State of New Jersey v. Pedro Soto*, et al. (1996), a court decision that incorporated statistical analysis of behavior exhibited by officers patrolling the New Jersey Turnpike. In particular, a rolling survey of turnpike users and violators found that African American motorists accounted for approximately 15 % of drivers on the turnpike, but accounted for 46 % of violators stopped by police on that roadway. In the first decade of the new millennium, dozens of states created laws regarding racial profiling, and thousands of agencies began collecting data regarding traffic stops in their jurisdictions. Some of the latter efforts were voluntary, while many others were compulsory under state law.

The net result of these laws and data collection efforts remains largely unclear. A wide variety of reports and studies were published in the 2000s seeking to examine whether and how driver characteristics influenced police discretion in traffic stops. Many of these studies were based on data that suffered from a range of limitations and often data were from a single agency and/or a relatively short period of time, making conclusions tenuous. The majority of studies lacked data of sufficient validity to help determine whether minority motorists were more likely to be stopped when compared with nonminority motorists. A few studies suggested that young, male, and minority drivers were more likely to commit more serious traffic violations, which could explain at least some disparities in patterns of who the police stop for traffic offenses (Lundman and Kowalski 2009). The studies generally did suggest minority drivers (especially those who were young and male) were more likely to be searched when stopped by the police, though many datasets did not allow researchers to clearly control for the reason a search was conducted. It was often noted that minority drivers were less likely to be found in possession of contraband when searched, though many studies did not include data on the specific type and quantity of illicit materials and goods. The net result is that racial profiling clearly remains a matter of concern to the public, politicians, and police officials, but the available data provide a very incomplete picture of the extent to which this problem exists and, if so, how profiling actually manifests itself across the range of choices officers make during traffic stops.

Technology-Assisted Traffic Enforcement

The introduction of technology-assisted traffic enforcement efforts has also become a controversial practice. Communities have used video-capture technology and other applications to detect violations and automate the issuance of citations for offenses such as running red lights and stop signs, as well as speeding. Often these systems operate in a "passive" manner without the real-time presence of an officer and the use of a traffic stop. The camera/radar system detects and records the violation, along with the identity of the offending vehicle. The registered owner(s) of the vehicle often receives a citation by mail with some documentation of the offenses in question. In many communities, the expense of installing, maintaining, and operating these systems has been assumed by a private entity. A jurisdiction allows a private corporation to place enforcement devices in the community; that corporation receives a portion of the revenue generated by operating the device. The privatized nature of enforcement and the high revenues automated systems can generate have made the use of technology-assisted devices quite controversial. At times these systems are seen being more focused on generating revenue and profits than actually improving public safety.

Future Directions

Traffic services remain an integral part of modern policing. Traffic regulation and enforcement consume a large proportion of uniformed policing resources and attention. Traffic stops are the most common venue in which the police and public interact; they also provide important pretext to justify police-citizen contacts when authorities are primarily interested in identifying and intervening in more serious criminal matters. These situations are not likely to change in the immediate future.

Sorbonne Paris Cité, CRESC/Pleiade,
Paris, France

Overview

Despite its seemingly obvious denotation, the phrase "traffic police" is far from self-evident. One may see it in the charts describing the structure of national, local or municipal police forces, but the term may as well be never written in the records of organizations where, functionally, a traffic police does exist. In its broadest extension, the phrase denotes the group responsible, within the police organization of a state, for the management of traffic and the safety of individuals – be they drivers, passengers or pedestrians – during their travel and transportation. In turn, "traffic policing" refers to the activity associated with this body of officers. It includes the definition of problems by higher ranking officials or experts, the implementation of technical solutions and the enforcement of the law, up to the procedures for actions taken on the field. The importance of traffic police and traffic policing is evident, given the place of mobility as a major element in contemporary societies: traffic, the structural environment facilitating it, and the formal and informal rules regulating it have a profound impact upon our understanding, use and organization of space. These modes of action thus have become routine aspects of any space, so much so that they are the first phenomena identified by a foreign traveler.

It is then a paradox that the body of scholarly work focusing on this branch of policing as such is very thin. Studies on the matter are diverse in perspective and discipline (history, sociology, political science, criminology, law, psychology), which renders all efforts toward a synthetic work less easy, but also makes it all the more needed and interesting.

A Constructivist History of Traffic Police

It is commonly claimed that the problem of traffic regulation is as old as traffic itself. The existence of a body of officials specifically appointed to the control of this activity, however, is not that old. For historians studying the matter, a number of assumptions must be questioned. "traffic police," as defined above, emerged during the seventeenth and eighteenth centuries in western capital cities. In Paris, for instance, it was linked to two phenomena: on one hand, an increase in trade and exchanges, the idea that a city can be seen as an organism with a healthy circulatory system, and the speeding of the urban pace (going from walk to full gallop); on the other hand, the development of "police" forces in the modern acception of the term, leading to more officers paid by the state, and the cultivation of autonomous knowledge and practices. *Commissaires* were initially responsible for the enforcement of traffic regulations and the protection of freedom of movement, then a brigade of the newly visible police created in 1829 was appointed to this duty. The same effort is also at play when London's Metropolitan Police was created that same year. The role of this police and its officers became increasingly important throughout the following century, as traffic became more and more significant, and the road and railroad systems were being developed. The police force took various forms throughout the country, and local regulations vary, leading to a "patchwork of recommendations" (Roche 2008), both precise and varied.

The situation changed in the late nineteenth century, for several reasons: the (slow) establishment of automobile as the dominant form of transportation, leading to changes in the perception of speed; the fear of accidents (numerous early on, and rapidly becoming more frequent); the rising intolerance for traffic congestion, earlier seen as a necessary evil. Changes in political and police response were also numerous: the number and visibility of traffic agents rose, more ambitions laws were drafted (*Code de la route* in France in 1921–1922, Road Traffic act in the United-Kingdom in the 1930s). Urban landscape and road network underwent transformations that reflected the growing use of both personal and collective motor vehicles. To the ongoing rationalization of streets and roadways (sidewalks, definition of street width and pavement material) were then added roundabouts, one-way streets, and traffic lights – the very first of which was installed in Cleveland, Ohio, in 1914, the first Parisian light coming in 1923. In a sense, a new traffic regime was substituted to the old one, with agents of traffic policing taking part to the change. Other transformations took place after 1945, as automobiles became available to the masses, urban population increased, land use planning gained importance, technical innovations appeared, and "traffic safety" is redefined.

This brief historical overview could be written for other locations, following the particulars of each. Three conclusions can be drawn from these works: first, traffic police is not, as it is often noted, a simple adaptation of the police to a linear development of modes of transportation. Rather, one can observe configurations of social, political, technical, legal or cultural issues, within which arise specific problems and solutions. Secondly, each configuration leaves, when being replaced, its imprint on the next – especially visible in the development of roadways, or in the institutional structures owing to police structure. Such layering can explain the complexity of current situations. Lastly, the definition of traffic police is far from self-evident, and is inseparable from a group of phenomena and external influences playing decisive roles in issues of roadworks and transportation: elected officials, decision-makers, road-users, engineers... Traffic police is but one element in a larger network, and from it draws its specificity.

Within Police Organization: Between Specialization and Globalization

The place of traffic police within police organizations gained importance in the 1960s and 1970s, when road transportation increased drastically, and developing countries started to catch up. In several industrialized countries, traffic police personnel make up about 10–15% of the police force (Carnis et al. 2004), overall a non negligeable branch of the force.

As can be seen in the rare studies of the organizational aspect of traffic police, it still remains difficult to propose a fixed definition of it. This is chiefly because of the broad spectrum of tasks it is expected to perform, and prevents one single specialization from being pointed out. Those tasks include the safety of individuals on streets and highways, control of vehicle speed, radar surveillance, accident investigations, schoolchildren education, prevention of traffic congestion, direction of traffic, verification of proof of insurance, help to distressed road-users, investigation of auto theft, policing of individuals, surveillance of national security and drug trafficking.

A recurring question, linked to this aspect, is that of the relation of traffic police to other, sometimes more visible or legitimate branches of the police force (such as criminal police). Furthermore, the particulars vary from one corps to another. The very concept of “traffic policing” has its own history, connected to American police officer turned researcher Franklin Kreml (1907–1998). Among the first scholar to identify as a Traffic Safety researcher, Kreml created in 1936 the Northwestern University Traffic Institute (NUTI) and the Traffic Safety Division of the International Association of Chiefs of Police (IACP). NUTI defines, and circulates throughout the country, knowledge and training adapted to traffic issues. This could explain the stricter definition of the term in the English-speaking world.

Traffic branches are also diversely integrated within their institutional environment. They may take the form of an autonomous corps devoted to road policing (like the California Highway Patrol, one of the most accomplished forms of traffic police), be a branch only of the whole organization (like in New Zealand), or be an important activity without a specific service (like in France, where the *gendarmerie* plays a major part). Along the same lines, this police raises with particular sharpness the issue of its relation with other actors of civil society (victims associations, coalitions of contractors or insurers) who participate to some degree in the production of order of the road. Obvious in the United States, this phenomenon can also be observed in Ghana where the private sector is organized into a Transport Union defining the conduct codes and paying wages to guards overseeing drivers. Lastly, this police also bring up with intensity the old debate on the relationship between local and national levels of action, on allocation of road networks, modes of police administration, or inside the kind of State’s organization (federal, centralized, strong or weak). These forms of policing thus appear as an indicator of the complex and layered administrative and political structures marking the action of policing organizations. This raises the issue of the forms of specialization and definition of the traffic policemen’s professional identity. Research on this domain is only in draft form, but suggest that this identity would depend on the existence of a well identified service, the need for training, the wearing of a specific uniform, or the institutional recognition of the specificity of road surveillance.

Paradoxically, while deeply impacted by local and national contexts, this sector is singularly open to the international standardization of methods and techniques. It is far from a new turn of event, as can be exemplified by the internationalization of road signage (McShane 1999): inaugurated in the United States in the mid 1910s and the 1920s, then standardized within various organizations (League of Nations, Institute of Traffic Engineers), traffic lights and street signs are adopted by most industrialized countries after 1945. The exchange and large scale adaptation of signage is organized by more or less formal political, industrial or police networks, with global activities (such as tourism) as an incentive. This also concerns developing countries and former colonies who were confronted to a rise in traffic accidents following the rise, after World War II, of the automobile, and who sought outside help. The Egyptian ministry of interior, for instance, followed in the 1970s the advice of the Overseas Unit of the Transport and Road Research Laboratory (TRRL) to set up the best adapted tools for road policing. The works on this transnational dimension still remain limited in number, and connected to a diffusionist model or to the mere acknowledgment of socio-economic inequalities: matters of adaptation, potential drawbacks, or issues of sovereignty are rarely studied.

The best example of the phenomenon is probably the standardization of training, and the ubiquity of traffic radars and traffic lights, which are systematically integrated even in the less developed countries and those where traffic policing is nearly non-existent. This technical aspect of traffic policing is probably the most globalized. Far from excluding each other, globalization and integration into social and administrative layers specific to a nation rather go hand in hand. As these researches point out, the study of traffic police then seem all the more interesting, for both the field of police studies and that of the sociology of organizations.

Managing the “Public Problem” of Road Safety

The importance of traffic police also comes from its role in now very sensitive issues, that are all at the same time human, economic and symbolical issues. Road accidents are one of the chief causes of mortality in a number of countries, especially among the younger population – any given year, they are the cause for 1.3 million death and between 20 and 50 million injuries. Traffic accidents also reflect inequalities in development: in 1978, the number of death per 100,000 inhabitants was 238 in Nigeria, 60 in Pakistan, and below 40 in Korea, and below 10 in Western Europe, North America and Japan. This pattern is still current, judging from the figures of death per billion of vehicle kilometer – in 2011, it was 8.5 in the United States and Canada, 39.8 in Romania, 310 in the United Arab Emirates, and 106,6 in Yemen.

Yet these data have to be in relation to the context of the social representations that give them meaning in each country, and that organize the public issue of road safety, as was noted by a well-known study on driving and alcohol intoxication (Gusfield 1981). The emergence of the problem of deadly accidents in late twentieth-century Europe is at first tied to the arrival of motor vehicles than to a real hike in the number of killed – which comes at a later date. Studies of the social representations of automobile traffic and its regulations show the evolution in the points of concern, made obvious in the type of figures chosen, or by the shifting focus of the press: to the insistence on human losses is added the economic toll and the lamentation over the time lost in traffic, before the recurring theme of “road violence” come back with strength. The media coverage also tends to criminalize irresponsible road behavior. It is significant that most industrialized countries have recently substituted the notion of “traffic lawlessness” to that of “road safety.” These two aspects – number of victims and perception of the issue – go hand in hand: the problems caused by the increased number of motor vehicles after 1945 also reflect mutations within the society, and the transformation of the questions the society adresses to itself. Automotive traffic, as noted by Joseph Gusfield, is thus marked by the social and cultural contexts of the spaces it modifies.

This aspect is in direct relation to the activity and structure of the traffic police: first, it presses for a response to traffic problems, and requires solutions adapted to the type of concerns it raises. Second, traffic policing institutions are also responsible for the production of symbols and discourse. Those may concern legitimation – the choice of insignia, symbols, uniforms, promotion campaigns for the force, for modes of intervention or modes of transportation – but may also be the very instruments of police actions, as can be seen in road traffic safety campaigns striving to leave its mark on the public and target at-risk road users. This symbolic aspect concerns all visible police branches, but the social and global magnitude of these issues give it a particular importance in traffic policing. These efforts draw attention to the relation between traffic policing and its social environment, which takes nothing away from the reality of the issues.

Man or Machine? Questioning Police Technology

The weight given to solutions to traffic issues, for the sake of economic continuity and the safeguarding of human lives, is easily understood. This aspect of police activity has been the primary focus of several research studies, which have evaluated the efficiency of policing, and tried to provide police intervention with more better performing tools.

The means of public action are varied: the first is the legal aspect – voting of bills, definition of violations and crimes, choice of penalties. The second mean is enforcement, and as such is directly tied to policing: increase in the number of agents, compilation and teaching of adapted policing knowledge, choice of modes and location of intervention (possible mobility, on foot, motorbikes or in cars). Intervention can be of punitive or preventative nature: one important aspect of police action resides in education, as can be seen in the constant work of police officers within the school system. Such educational focus proved a major aspect of the effort to establish the sharing of the road system and the statute of the pedestrian, in the early twentieth century, and is still ongoing.

The fundamental principles of road traffic safety, expressed as early as 1923 by Director of the Kansas City Safety Council Julian Harvey, and never contradicted since then, can be summed up in what is called the 3 "E" rule: Education, Enforcement, Engineering. The latter is important too, and takes on various forms. A number of psychology studies, for example, through the factorial analysis of answers to questionnaires, focus on the identification of social groups that are the most likely to commit infractions, on determining external, involuntary causes (state of the vehicles and roads, presence of driving schools) and the emotional motivations (aggressiveness in young males, irritability caused by the daily experience of traffic congestion). The goal of these studies is to better target police response. Research conducted in two Chinese cities (Beijing and Chengde) concludes for example that potential countermeasures should be sought among young women and thirty-somethings (Xie and Parker 2002). Cognitive psychology, for its part, is more focused on the determination of causes to loss of attentiveness, and on the stimulation of the ability to focus on the road. Lastly, engineers – administrative or urban engineering, transport or computer systems specialists – propose innovations aiming to facilitate vehicle flows and reduce the number of accidents through changes to the external environment – car structure, pavement material, traffic information displays, computerization of data. Undoubtedly one of the most dynamic field today, traffic telematics and the automation of the control/penalty chain lessen the need for police presence. Where police agents stand in this vast social, political and technical arena is a delicate matter. Police often appears as a liaison within a very varied group of modes of intervention, which is understood as typical of new forms of management and governing, raising issues of negotiation, acceptation and reject.

Parallel to these studies concerned with public action, others develop a more critical reflection on the means themselves, and their evolution.

A number of them consider the ever-progressing behavior regulation technologies as what Michel Foucault called “biopower”: they reveal the insertion of always more subtle power relations within bodies and behaviors. This police activity and its extensions are described as the milieu *par excellence* where these standardizations become accepted, as they are performed on a daily basis and justified by the goal of reducing the loss of human human lives. Other researchers show that an organizational study of police systems raises the question of the efficiency of such programs. Technological and administrative tools are in fact incorporated to the “music” of the organization (Manning 2008) and act according to its criteria and definitions of issues, which are sociological constructs. Following a reasoning at times more philosophical, several authors question the relation between man and machine as it is in place in this form of policing, and the dehumanization of the road simultaneously in process. Cars and roadways are seen as the space for a specific social experience, an experimental field for future evolutions, which in this respect must be studied. The major question is that of the acceptability of these technical and automatized artifacts. While it is an effect of public policies, it is also dependent on habits developed with broader social mutations. Rather than offering an opportunity for the denunciation of the control of the body, the disappearance of the police body and physical interactions, replaced by remote, computerized surveillance, would then invite the questioning of the creation of new forms of social relations, navigating between internalization, adjustments, and resistance.

What Efficiency? Reducing Accidents, Normative Incorporation, Social and Cultural Variations

The last question can be worded as follows: what is the efficiency of this multiform action? Answers are contradictory, and are open to a debate that is not defined as of yet. Criminologists and sociologists have long shown that police action is generally of little influence on the evolution of criminality. Yet, traffic police may be the exception to the rule: it is one of the only field where this impact is established and measurable. It can be seen in the evolution of the figures: the number of death per 100,000 inhabitants within the OECD went from 23.4 in 1970 to 11.4 in 1999, while in some countries such as Israel, the rate of deadly accidents has been divided by ten in the same period. This trend has been confirmed in recent years, as can be seen in the United States, Hungary or Ireland, where the number of death has followed a stronger declined between 2008 and 2011 than it had during the 15 preceding years. Overall, when a variety of road safety measures are massively implemented in coordination, a rise in the number of drivers can be observed, as well as a decline in the number of accidents. This observation, however, is disputed: some researchers think that the decline is not due to police action or law enforcement, but rather to technical progress in vehicles and road environments, as well as the social acceptance of the norms, the real condition to the efficiency of these measures. Other studies focus more on some countries, some but not all of them developing countries, or on a selection of regions within countries, where the trend cannot be observed.

In any case, traffic police action is often considered a field of choice for observation, because of the intense impact of normative pressure, of the repetition of contacts, of the will to make mobility easier, and of the internalization of driving laws and norms. The analysis of the action of traffic police agents (most often at an intersection) is a staple of sociological studies: on the changes in behavior when drivers are faced with an officer (E. Goffman), on the internalization of social order into non-conscious habitus, through the “natural” respect for driving rules (P. Bourdieu), or on the revealed cognitive styles, through a relation to the rule that would be specific to differentiated societies (H. Garfinkel).

This shared observation of an interaction that is continuous or temporary, physical or technical, and that isn’t without its effect son behaviors, is challenged by other forms of studies. Some of them focus on the persistence of inequalities, based on rank, race or gender, and are visible even in traffic policing. Officers in some US states may, consciously or not, tend to be more zealous with younger drivers, as well as females, and Black and Hispanic drivers. The study of "Driving while Black" has led to a number of scholarly works and to a debate on how to observe and analyze the phenomenon. Other researchers, on the contrary, highlight the varying cultural interpretations of these forms of social control. In Indonesia, the law on the compulsory helmet for motorbike users, for example, seems to have little effect on the seriousness of injuries. The frequency and gravity of accidents is not linked to the use of alcohol, as is the case in numerous other countries (religious rules are strictly observed and alcohol plays a very minor part in traffic accidents); rather, accidents are in part due to the very formal interpretation of the law, on the part of drivers and agents. They wear a helmet, and control that a helmet is worn, but pay no attention to how it may prevent injury, as no protection in case of accident is attached to the wearing of helmets. So helmets are worn, but without efficiency. In another area, on the Polynesian island of Niue, 20 % of non-intentional deaths are caused by road accidents, amounting to a cost of 1–2 % of the GDP. An anthropological study shows that this rate is tied to the nature of vehicles, the nature of the road environment, and forms traffic policing, but also to cultural factors such as low sensitivity to risks and a culture of road warriors among the youth, reflecting older Polynesian representations. Social, institutional and cultural imperatives thus constantly intervene in the possible imposition of a norm by the authorities, posing them dreadful problems. Traffic police may at times be in opposition to these imperatives, and sometimes heavily influenced by them: traffic police seems to be at the crossroad of diverging normative domains, making its action and the usual interpretation of its efficiency less mechanical. Future research could study this further.

Traffic police appears as an important, fragmented and stimulating research subject. The state of the research on the topic is tied to the diversity of the forms and the names it takes, and to the relative invisibility of its action, integrated to daily life or gradually disappearing as new forms of control take over. However, it may also be due to the fact that the various academic fields involved are separated by debates over their epistemological foundations, their methods and their conclusions (transport engineering, cognitive psychology, macro-economy, urban history, sociology of organizations. . .) Above all, studies are separated by their intended destinations: there is a rift between research targeting public action and aiming to improve policing, and more reflexive or critical studies aiming to define the stakes and issues of traffic police and policing. The bridging of that rift, while often claimed to be accomplished, is still fragile (Monjardet 1996). Yet, the study of this somewhat neglected branch of policing is of great importance, when mobility in all its forms takes a major place in the experience of daily life as well as in social organization. A lot can be gained through well regulated interdisciplinary research focusing more directly on the aspects mentioned here. In this human and organizational work on mobilities and individuals, are at stake the major challenges to the modes of functioning of law keeping and enforcing institutions, and more broadly the changes in the relation to the law, to the norm, to the freedom move, and to safety within contemporary societies.

Human trafficking; THB; TIP; Trafficking in persons

Overview

Trafficking in human beings (THB) concerns the exploitation of vulnerable individuals for the purpose of financial profit. Victims of trafficking, women but also men and children, fall prey to different forms of exploitation, such as forced labor or services, slavery, servitude, or the removal of organs. However, the most frequently reported type of trafficking is the one that results in the exploitation of women in the sex industry.

This contribution focuses particularly on this type of trafficking.

The concept of THB came into use in the early twentieth century in connection with white slavery, a term then referring to forced or fraudulent recruitment of women and girls for prostitution. Currently THB refers to a broader phenomenon that can be approached from different perspectives, for example, as a public order problem, a migration issue, a criminal justice issue, a violation of human rights, or a combination thereof.

Usually the trafficking process is distinguished in three phases: the recruitment of victims, their transportation, and the eventual exploitation. These phases are reflected in the most widely shared definition of THB, the definition in article 3 of the United Nations Protocol to prevent, suppress, and punish trafficking in persons, especially women and children:

> Trafficking in persons shall mean the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labor or services, slavery or practices similar to slavery, servitude or the removal of organs.

This definition, although widely shared, has also been heavily criticized. It answered some of the difficult questions that were raised. It became, for example, clear that not only women and girls but also boys and even men can be trafficked and that THB is not restricted to the purpose of forced prostitution. However, because the definition in the protocol describes a process involving several actions and outcomes which themselves are not clearly defined, there is still dispute about what falls under its umbrella.

Furthermore, in practice, it is difficult to distinguish THB from the smuggling of persons. In fact, assisted illegal immigration may precede exploitation, as some smuggled illegal immigrants end up as victims of trafficking later on. Lured with bogus offers of employment, these migrants fate only becomes clear when they are gradually forced to do other work than they had agreed upon or under very different circumstances than expected. The most obvious difference between the two phenomena is that human *smuggling* primarily relates to illegal immigration and the violation of immigration laws, whereas human *trafficking*, which often but not necessarily involves border crossing, implies exploitation, and the violation of an individuals' human rights.

Until the endorsement of the UN Trafficking Protocol, the response to THB was exclusively human rights based. Human rights law nowadays remains important to ensure the protection of the rights of victims of trafficking, but a different perspective was necessary in order to realize the current level of global attention and resources to combat contemporary exploitation (Gallagher 2010). Since the shift in perspective and the protocol, several regional treaties and treaty-like instruments on trafficking have been developed, dealing with issues like criminalization, international cooperation, and the protection of victims. In addition, 80 countries have implemented a comprehensive anti-trafficking act, 64 countries have provisions in their penal codes criminalizing all forms of trafficking, 22 have provisions criminalizing some forms of THB, and only 2 countries have no such laws. Furthermore, 58 countries have a National Plan of Action (NPA) to deal with THB, and 12 have NPAs that target human right violations related to THB (Protection Project 2012). Attention to the phenomenon of THB has grown significantly, and numerous activities to combat THB and deal with its victims have been implemented but little is known about which interventions are the most effective in preventing human trafficking, protecting victims, and prosecuting traffickers.

This contribution presents information about traffickers and their modus operandi, a description of some of the many policies and interventions dealing with THB. Furthermore, limitations of the amply available research on this topic are discussed, followed by the findings of a systematic review that underline these limitations, and a conclusion.

Traffickers and Their Modus Operandi

Individual Characteristics of Perpetrators

Information about the background of individual traffickers is mainly based on national statistics concerning those who have been prosecuted and convicted. Most are males in their mid-20s or mid-30s, but women, who are traditionally regarded as victims, are also involved in recruitment, organizing the trafficking process, and controlling victims. The percentage of women involved differs per nationality of convicted perpetrators. Some perpetrators recruit or exploit fellow countrymen. Already present migrant networks can help newcomers with their start in the new country, by assisting in finding shelter or work, but newcomers also are an easy prey for malicious fellow countrymen.

Trafficking and Organized Crime

Trafficking is often described as a crime perpetrated by ruthless criminal networks, and the above-mentioned "trafficking protocol" supplements the UN Convention against Transnational Organized Crime (2000). Article 2a of this Convention defines an organized crime group as *a structured group of three or more persons existing for a period of time and acting in concert with the aim of committing one or more serious crimes or offences established in accordance with this Covention, in order to obtain, directly or indirectly, a financial or other material benefit*. A "structured group" is *a group that is not randomly formed for the immediate commission of an offense and that does not need to have formally defined roles for its members, continuity of its membership or a developed structure* (article 2c).

According to the US trafficking in persons (TIP) report 2012, organized crime and complex networks indeed contribute significantly to the trafficking of persons. The TIP report is a yearly comprehensive report by the US Department of State on efforts made by governments worldwide to combat THB.

Human trafficking networks are likely to be organized in small groups, which operate both independently and in cooperation with other crime groups. The interaction between groups is often connected to the provision of specific services such as the recruitment of victims in particular countries or areas or their transport to locations where (forced) prostitution takes place. Among other roles individuals take on are those of investors, debt collectors, and money launderers.

However, not only organized crime groups commit THB. It is known, for example, that within the European Union, the removal and relaxation of internal border controls provided opportunities for individual criminals and less sophisticated, smaller, or mid-level groups to operate across borders, and there are also individual perpetrators enriching themselves by exploiting other humans. The actual share of organized crime in THB worldwide is unknown.

In her study on THB in the Netherlands, Van Dijk (2002) distinguished three main forms of criminal cooperation: solo-offenders, self-supporting criminal groups, and criminal macro-networks. Solo-offenders force one or more individuals into prostitution. Self-supporting criminal groups control all phases in the trafficking process, from recruitment to prostitution. They do not have established contacts with other offenders or criminal groups involved in human trafficking. The main suspects are often in charge of brothels or sex clubs, relying on personal contacts to recruit and transport victims. Criminal macro-networks include solo-offenders as well as criminal groups, clustered by geographical proximity, family ties, friendships, commercial circuits, or similarity in criminal activities. The characteristics of organized trafficking groups are related to the perpetrators' nationality/ethnicity and the region in which they operate.

Shelley characterized organized trafficking groups in five different ideal typical "business models," linked to specific geographical areas and modus operandi. These are (1) the post-Soviet *national resource model* (women recruited in source countries are trafficked for prostitution), (2) the Chinese and Chinese-Tai *trade and development model* (smuggling and trafficking men for labor exploitation and to a lesser extent women for prostitution), (3) the US-Mexican trade *supermarket model* (smuggling large numbers of men and women, the women trafficked for forced prostitution), (4) the Balkanese violent *entrepreneur model* (women trafficked for prostitution by middlemen are controlled from bases in the Balkan), and (5) the *traditional slavery with modern technology model* (trafficking young women out of Nigeria and West Africa for prostitution, forcing compliance by using contracts and voodoo practices) (Aronowitz 2009).

Even THB cases in which organized crime and foreign criminal groups are involved often have a local component, sometimes referred to as "glocalization." Criminals have to trust each other in order to be able to do business. Friends, relatives, or others with whom they have had good experiences are eligible as "partners in crime."

The Recruitment of Victims

Traffickers recruit their victims mostly in deprived, disadvantaged, or poorly integrated sectors of society, offering them employment abroad. Unemployment and low earnings are among the strongest push factors for victims. The Internet provides anonymous opportunities to recruit victims. Most migrate willingly, and many are aware of the fact that they will work in prostitution. Other victims have been promised jobs in the entertainment industry or as, for example, nannies or domestic servants. Outright abduction or selling into prostitution is rather the exception than the rule (Andrees 2008). This can also be concluded from data in the International Organization for Migration (IOM) Counter Trafficking Database. In 9.646 cases (who received assistance from 1999 to 2006), 60 % had been recruited via personal contacts (in 25 % of these cases by friends, relatives, or partners), and only nine victims had been kidnapped.

An often used recruitment strategy is the so-called loverboy method: after manipulating victims by faking love, they are gradually coerced or threatened into prostitution. Not all recruitments of foreign victims take place in countries of origin. Some victims are recruited in the country of destination, after having arrived there as undocumented migrants. They are vulnerable to exploitation, as they risk alien detention and expulsion.

Means of Control

Once the exploitation has started, and victims are working in street prostitution, behind windows, in clubs, private homes, massage parlors, or as escorts, they have to be persuaded to keep "delivering." The principle means of control are debt bondage, dislocation, and mobility (rotation of victims between different locations, sometimes across borders), as well as close monitoring, intimidation, and violence. Recently, however, perpetrators have started to use more subtle methods of control and share a small part of the profits with the victims, thus discouraging them from complaining to the authorities and making it more difficult to prove coercion. In cross-border trafficking, fuelling the victims' fear of local authorities and the prospect of expulsion is a common control method.

Some Policies and Interventions in the Fight Against THB

Many different policies and interventions have been implemented to deal with THB. These partly depend on the perspectives with which THB is approached. Most are not specifically or not exclusively aimed at trafficking by organized crime groups.

Policies Dealing with Prostitution and the Sex Industry

Policies against human trafficking for sexual exploitation are often directly linked to policies dealing with prostitution and the sex industry. Among these are interventions to address the demand for commercial sexual services, including a variety of campaigns and educational programs to change men's attitude and behavior towards buying sexual services, and so-called John Schools to educate buyers in order to prevent them from soliciting again. Shaming tactics, such as making the names of the males involved public, are also mentioned. According to this report, most men believe that criminal penalties would have a deterrent effect only if they believed they were at risk of being caught. However, in most countries this risk is rather minimal.

In many countries, prostitution is tolerated to some extent, though different forms of prostitution and exploitation are regulated or combated in different ways. In Sweden, however, prostitution is regarded as a form of violence, committed by men against women. In 1999, the purchase of sexual services became punishable by law, while the sale of such services was decriminalized. Since then street prostitution has been halved, while at the same time, it increased in Denmark and Norway. Internet prostitution increased in all three Scandinavian countries but on a larger scale in the neighboring countries, while the proportion of Swedish men reporting that they have purchased sexual services has decreased. However, some of these conclusions are based on estimates, and the effects of the law on *trafficking*, which is not the same as prostitution, remain unclear.

The Dutch authorities took a different approach. In 2000, after a policy of tolerance for many years, the general ban on brothels was lifted. Under certain conditions, making money out of voluntary prostitution by adult prostitutes was no longer prohibited, and brothels were legal if they complied with certain licensing conditions. The intention was to simultaneously act forcefully on prostitution of minors and illegal aliens, as well as involuntary prostitution. An extensive evaluation showed that this approach of location-bound prostitution produced some positive effects: business owners tend to comply with licensing conditions and the number of prostitutes without legal documents decreased. However, the position of prostitutes did not improve much, and pimps are still a common phenomenon. Furthermore, law enforcement investigations show that human trafficking still thrived behind the legal façade of regularization. The main reason is that the policy focused on business owners, whereas the exploitation of women is more often carried out by pimps.

In Finland, yet another position was taken: the law prohibits the buying of sex from a trafficking victim or from a subject of procurement. But will a client be able to know who is a victim, or who is being procured? And if so, will he act upon it? Some clients are willing to report on involuntary prostitution but most men who buy sex are aware of trafficking and exploitation, but this does not affect their behavior. A quarter of 103 London men who buy sex in the UK report having encountered a woman in the sex industry whom they believe was forced, but only five reported this to the police (Farley et al. 2009).

Policies Against Illegal Migration

Another way to combat human trafficking is to treat it as a form of illegal migration and increase border controls in destination and transit countries. Examples are exercising due diligence in regulating entry of foreigners, in order to identify individuals at risk, checking transit documents, and providing protection to suspected victims of trafficking in transit. However, this is easier said than done as much THB for sexual exploitation takes place over short distances within countries, and if borders are crossed, this frequently involves future victims who bear legal travel documents.

Cooperation in the Investigation and Prosecution of Traffickers

Next to national policies regarding the attitude towards the sex industry and border protection, there are policies directed at the investigation of trafficking cases and the conviction of perpetrators. Cooperation is an important characteristic of this type of policies. It concerns cooperation between different actors within regions and municipalities as well as cross borders. In the Netherlands, for example, several investigative bodies cooperate with local authorities, victim assistance, and health care in a combined criminal and administrative approach, which also contains preventive measures. In order to gather enough evidence in cases in which victims do not cooperate in the investigation and in which it is difficult to conclude a case because it is one's word (the victim's) against another's (the suspect's), the Dutch police developed a proactive investigation technique. The method implies the piling of all established facts, from testimonies and telephone tapping to observed injuries in order to establish a body of evidence without using victim statements.

The fight against cross-border trafficking cases that involve foreign suspects requires cooperation with criminal investigators in other countries. Such cooperation takes place ad hoc as well as in the form of well-planned actions, in Europe called Joint Investigation Teams (JITs). The work in such teams is not always easy because of differences among countries in laws, jurisdiction, and priorities. Eurojust can help in solving jurisdiction problems that occur in the cooperation in the fight against cross-border criminality, among which trafficking cases.

Awareness Raising Campaigns, Training Material, Manuals, and Toolkits

Finally, the many campaigns and materials that have been developed for the various target groups who may fall prey to traffickers as well as for those who may come across victims of trafficking are worth mentioning. Among these are awareness raising campaigns to warn potential victims and manuals for professionals. Awareness raising campaigns include radio and television advertisements, educational school programs, and posters at airports informing incoming passengers of hotline numbers they could call should they become victims of THB. To strengthen the law enforcement response to THB, training materials or modules have been developed. The UN, for example, developed an “anti-human-trafficking manual for criminal justice practitioners,” and organizations like the International Labour Organization (ILO) and the International Trade Unions Confederation have developed training material about the way to handle indications of trafficking for Labor Inspectorates, unions, and employees (see, e.g., the manuals on the ILO site www.ilo.org and the UNODC online “Toolkit to combat trafficking in persons”). Whenever a victim has been identified, protection and assistance have to be offered. Several of the above-mentioned manuals and toolkits offer handles in this matter.

Limitations in Research on THB

Scarcity of Data

Because of the definition problems mentioned in the introduction, the criminal nature of THB, and the fact that victims rarely come forward with what has happened to them, accurate data on THB are scarce. Most often victims are discovered during police investigations of some sort of criminal activity, for example, during raids on locations where prostitution takes place.

Victims refrain from reporting to the police, some even after having been discovered, because they do not consider themselves victims but migrants whose journey went wrong, because they are embarrassed, they fear expulsion, or because they either fear their perpetrator or are emotionally attached to him. Notwithstanding the lack of accurate data, many figures are presented to map the scale of the phenomenon. Goodey (2008) describes how “guesstimates” are used for that purpose. Between the estimates, for which the computing methodology is rarely provided, and the number of identified victims exist huge differences.

Much has been written about initiatives to deal with trafficking for the purpose of sexual exploitation, but knowledge on “what works” is particularly limited. Although thorough evaluation is important, as evaluative knowledge on trafficking can be used to develop adequate prevention techniques or policies, this is scarce. The United States Government Accountability Office (GAO), for example, reviewed documents of 23 US government-funded anti-trafficking projects in Indonesia, Thailand, and Mexico. It revealed that 21 of the 23 projects included one or more monitoring elements, but only ten stated how performance was measured. The majority lacked a logic framework of monitoring that linked activities to goals, indicators, and targets (GAO 2007).

Limited Scope of and Methodological Fallacies in Trafficking Research

Most publications on THB are primarily descriptive, for example, describing the hardship of or social assistance to victims. Others mainly aim at collecting numbers to define the scale of the phenomenon. Few, if any, interventions are accompanied by evaluation research to assess their impact and cost-effectiveness and not much systematic data collections exist. There has been relatively little *independent* research – research carried out by others than the ones who developed or delivered the counter trafficking initiative – to evaluate and assess the effectiveness of counter trafficking policies, programs, and interventions. This can be problematic since organizations evaluating their own initiative may have explicit or implicit political or practical agendas that influence their conclusions, for instance, by selecting or disposing of certain information.

Another frequently encountered restriction in the research on THB is the lack of large samples. This is often due to the limited access to victims and perpetrators. Using a variety of methods on small samples can produce illuminating results but often preference is given to a single method such as either interviews or questionnaires. Furthermore, much of what is known comes from just one source, such as governmental statistics, data that reflect the legal framework and enforcement strategies in a country rather than the actual scope of the problem, or victims who have been or are being assisted. As a result, (reliable) knowledge on effectiveness of interventions in this area is scarce. In the meanwhile, anti-THB interventions can cause collateral damage, for example, by putting restrictions on women's migration or travel.

The Need to Know More

Because of the severity of the crime, the impact on its victims – some are severely traumatized by what they went through – and the possible collateral damage of anti-THB measures, it is important to gain more insight into the working and effectiveness of anti-trafficking strategies and interventions. This was the reason to undertake a review to assess the presently available evidence on the effects of interventions that aim to prevent and suppress this type of crime (Van der Laan et al. 2010).

A Systematic Review

Objectives of the Review, Research Questions, and Method

The review aimed at contributing to a more evidence-based approach in the prevention and suppression of cross-border THB for the purpose of sexual exploitation. The questions to be answered were as follows: Which anti-THB strategies were evaluated in a way that is rigorous enough to determine their effect, and what are the outcomes of these (quasi-)experimental studies? Only studies focusing on cross-border trafficking for the purpose of sexual exploitation were reviewed. The focus was on cross-border trafficking because internal trafficking was not (yet) or just recently recognized in many countries. Furthermore, the review was limited to trafficking for prostitution or sexual exploitation, in any form there is. Trafficking for forced labor or services, slavery, servitude, or the removal of organs was kept out of consideration.

All eligible evaluation studies in the abovementioned field were categorized according to the Maryland Scientific Methods Scale (SMS), in order to assess the strength of the evidence (Sherman et al. 2002). The studies dealt with initiatives targeting individual perpetrators and criminal groups as well as vulnerable individuals and professionals in the field of anti-THB. Studies exclusively regarding victim assistance, the reintegration of victims, or arrangements for their legal status were excluded. Eligible studies in nine European languages, either published or unpublished, from the year 2000 up to the end of June 2009 were reviewed. For the broad search strategy, including the databases that have been searched and the key words used, see www.campbellcollaboration.org.

Main Results

The search resulted in 144 potentially eligible studies. These concerned interventions of a primarily preventive nature, suppressive interventions (mostly regarding legislation and prosecution) or were of a combined preventive/suppressive nature. In 48 studies no specific initiative was described. Most studies were in the field of sexual exploitation or concerned more than one type of exploitation. The target group varied and consisted of both adults and children, focusing on women and children, but studies on programs that were especially developed for minors were found as well. After a more extensive examination, not one study was found to be applicable to be included in the review since they could not be qualified as (quasi)-experimental study.

Four studies qualified in most respects (they concerned interventions developed for prevention or suppression of cross-border THB for the purpose of sexual exploitation), except for using pre- and post-measures and a control group (corresponding with level 1 or 2 on the SMS). In the following these studies will be described briefly in order to give an idea of the kind of interventions being evaluated and the limitations in the evaluation designs used.

A Closer Look at Four Studies

The first study (Association for Emancipation, Solidarity and Equality of Women 2006) concerned a qualitative evaluation of the economic and social stabilization program for potential victims of trafficking in the border regions of Former Yugoslavic Republic Macedonia. The main goal of this program was empowering these potential victims – vulnerable groups, especially women – by providing employment opportunities through skills training. Basic business training courses were organized aiming to develop knowledge on how to start and manage a small business and how to generate income. The study assessed the impact of the project on the beneficiaries, their families, and local stakeholders as far as socioeconomic position, quality of life, and vulnerability towards human trafficking are concerned. The study consisted of a posttest measure only (using questionnaires and interviews), there was no control or comparison group involved, and no empirical outcomes were reported.

The second study (Balanon and Barrameda 2007) evaluated the impact of the Young Men's Camp in the Philippines, an intervention addressing the demand for sexual services. Its goal was to change the sexual attitudes and practices of boys and young men. The study contained pre- and posttests to assess changes in their knowledge and perceptions. Next to these assessments, there were follow-up activities, consisting of 1-day fora and workshops. It remained unknown whether the intervention focused only on cross-border trafficking.

The third study (Centre for Research on Environment Health and Population Activities 2004) included an evaluation of an awareness raising program in rural Nepal. The primary target group of the program was adolescent girls, and their peers, parents, and the community were the secondary focus group. This intervention educated the girls and aimed to prevent them from becoming victims of trafficking. The effects of the program were measured using interviews and surveys. The study contained a pre- and posttest measure without a comparison or control group. Outcome measures were the increase of awareness and knowledge on trafficking.

The fourth study (Hashash 2007) evaluated an Israelian prevention program aiming at raising awareness among the wider public and creating attitudinal and institutional change among decision makers and law enforcement personnel. Education on trafficking was achieved by distributing information, providing training, publicizing reports, using media advocacy, and giving lectures. The program intended to influence public policy and opinion. The researchers conducted a pre- and posttest using interviews and questionnaires. No control or comparison group was used.

Even though these studies were better designed compared to most of the studies in this field, they do not allow for firm conclusions regarding the effectiveness of the interventions concerned.

Conclusion and Discussion

Trafficking in human beings is a crime conducted by individuals as well as by smaller and larger organized crime groups. They recruit vulnerable victims – women, men, and children – mostly in deprived regions or sectors of society, in order to exploit them in the sex industry or in other economic areas. The perpetrators use different and more or less violent means of control, ranging from close monitoring and threats to outright violence.

The attention to THB has risen during the last two decades.

Most countries now have laws in place making trafficking punishable and protecting its victims. Many have National Action Plans to combat THB, and numerous policies and interventions to deal with THB have been developed. Depending on the perspective from which THB is approached, these policies and interventions range from addressing the demand for commercial sexual services, border protection, or improving the investigation of trafficking cases and the prosecution of its perpetrators. In addition, there are the awareness raising campaigns and manuals, toolkits, and training materials that have been developed for potential victims and for parties who may come across them.

For various reasons there is not much reliable data about THB. Still, some progress has been made. An increasing number of countries have trafficking data available, also thanks to the pressure to provide national trafficking data, for example, by the US government for its yearly TIP report. In addition, there have been several initiatives to collect data across countries in a uniform way, and guidelines for the collection of data have been published.

Still lacking is evaluation research on anti-trafficking initiatives that is methodologically rigorous enough to be able to reach substantive conclusions about the effectiveness of the present anti-trafficking initiatives. Many go without pre-test measures and/or a control group. Improvements in research design are seriously needed. This does not have to be that difficult since individuals who do not participate in an intervention or who are on a waiting list can, for example, be treated as control group. Researchers, funding institutions, and policy makers should demand higher methodological standards of evaluation studies in order to gain knowledge on outcomes. This would enable them to better succeed in preventing and suppressing trafficking in human beings for the purpose of sexual exploitation. Partnerships can be sought in the area of politics and funding agencies.

Debates about the approach of THB, especially where it concerns THB for sexual exploitation, are currently often heated and clouded by generalizations and myths. Better research might also help to make these debates more evidence-based and more fruitful.

Overview

The exercise of defining criminal deviance entails a complex and mystifying process often fraught with tension and paradox. The locus questions of *who* defines deviation and *how* it is defined remain the key "flash-points" in this debate. The crux of the matter is enmeshed in the dissatisfaction of the current criminal justice system which has maintained a highly positivist (clearly defined, scientific) approach to the notion of deviance. This positivist inclination is deeply rooted in rational choice and/or criminogenic theories (psychopathic explanations) and has adopted certain tenants of social control theory which rotate around three major "pillars" of rationalization for the institutions of criminal justice: deterrence, rehabilitation, and incapacitation (Kaplan 1973).

With the rise of transitional justice applications in post-war contexts (where gross human rights violations, mass atrocities, and genocide have occurred), these tensions around defining deviance and the location of justice have become even more pronounced. An alternative agenda is required in order to reframe the on-going debate around criminal deviance and its implications for the administration of justice.

An alternative agenda is emerging in the transitional justice field through the current revival of restorative, indigenous justice practices that are "filling in the gaps" of what constitutes satisfying human justice. Simply put, numerous forms of ancient indigenous justice that are restorative in nature are providing new lenses for reconfiguring what justice means and how it is implemented (Cobban 2007; Pouligny et al. 2007). There are three critical observations regarding this renewal of indigenous justice systems:

1. The Transitional Justice field has unwittingly provided the scaffolding of language and the platform of dialogue for indigenous justice forms to surface in order to meet the desperate need for justice to be felt as transformative by local communities on-the-ground who otherwise are often left out of the national and international transitional justice discourse and accompanying mechanisms.

2. These ancient forms of indigenous justice are offering coherent frameworks that engage ethical values and processes of facilitation that are necessary in order to critique and create new future hybrid models of justice.
3. There are numerous paradoxes and negative externalities resulting from the attempts to concretely define deviance in the current Western legal system. Indigenous justice applications are showcasing the restorative corrective "DNA" to assist in redefining the meaning of human deviance away from a stagnant code of legislated behaviors toward a nested paradigm of human interaction that is negotiated through relationship ties, and the norms and mores of community networks.

Fundamentals

What Is Transitional Justice?

The survivors of war, mass atrocities, and genocide across the Globe are crying out for justice. The question is: what does justice require? How is justice satisfied? What does justice *feel* like? Many say justice meets violence with violence – a revenge justice characterized by a visceral form of "blood rites" or a need to honor the memory of the dead who have been immortalized in a premature death of injustice (Ignatieff 1998). In its "civilized" expression this punitive justice is meted out in the form of state-sanctioned (legal) revenge in response to individual or communal (illegal) violence. This form of "retributive justice" is the dominant model of the western legal system which is based on the foundational notion that punishment (usually in the form of incapacitation or prison) results in individual change (rehabilitation) and collective restraint (deterrence). Some have relinquished the attainment of justice to a universal power beyond themselves – a Divine command, often requiring a form of "sacred violence" (Girard 1972). This is prevalent today in the political application of ancient legal codes such as the Mosaic or Sharia Law believed to be direct revelations from God and therefore sacred forms of justice. Others see justice as a human construct – a Natural Law. This concept emphasizes the rational law of "cause and effect" and that every action results in a ripple effect of consequential responses. The familiar adage of "you reap what you sow" contains this idea well. Social contract theorists such as Hobbs (1651), Locke (1689), and Rousseau (1762) are some of the best known proponents of this form of justice. Still others understand justice as social equity (freedom of choice), rights-based egalitarianism (fairness), and the search for the maximization of the "common good" – a kind of utilitarian or distributive justice (Rawls 1971; Sen 2009). Elements of all these conceptions of justice permeate the guiding principles of what is now termed *Transitional Justice* – a burgeoning field of systematic justice that aims to reconstruct the human and material capital of societies that have experienced mass atrocities (Hamber 2009).

Transitional justice involves a range of approaches that nation-states employ to address past human rights violations including trials and prosecution, truth commissions, lustration or vetting, reparations, reintegration of ex-combatants and war-affected populations, memorialization, and various institutional measures of reform and accountability (good governance, security sector, human rights, gender equity, and anticorruption structures). The said overarching aim of transitional justice is to end the culture of impunity and establish the rule of law in a context of democratic governance. To this end, the transitional justice field has identified eight broad objectives:

- Truth-telling at both the macro and micro levels
- Giving voice to victims – public platforms that "bears witness" to atrocities
- Ensuring accountability – perpetrator acknowledgement and responsibility
- Providing victim and survivor restitution and reparations
- Promulgating individual and collective healing and reconciliation
- Bolstering good governance structures that are sustainable
- Advocating for institutional reforms for the prevention of future violence
- Reinforcing public participation and dialogical democracy

What Is Restorative Justice?

In its best form, Transitional Justice should be *restorative* in nature. The field of Restorative Justice as an academic discipline and as a global practice movement is relatively young (early 1970s) with its contemporary origins rooted in experiments in alternative criminal diversion in Canada (Peachey 1989) and Indiana (Zehr 1990). However, in many ways it is simply a re-enactment of past practices of justice not too far distant in many ancient cultural traditions, but eclipsed by the current Western justice system (Braithwaite 2002). Restorative Justice is concerned with right relationships and the revitalization of community and collective harmony after a breach of violence. It is a justice that demands *accountability* (recognizing the harm and taking responsibility), making clear that no act that destroys human dignity goes unnoticed. However, along with this accountability it creates an avenue for *reconstruction* (equalizing power and addressing future intentions through restitution, reparations, and reconciliation).

Instead of a justice system that is obsessed with apportioning blame and shame, and administering punishment and isolation, restorative justice seeks to heal the harms of victims, rehabilitate offenders, and reintegrate both of them into community networks of support as a safeguard of justice. It is simple, but never easy. A comprehensive definition of restorative justice is:

> a broad term which encompasses a growing social movement to institutionalize peaceful approaches to harm, problem-solving and violations of legal and human rights. Rather than privileging the law, professionals and the state, restorative resolutions engage those who are harmed, wrongdoers and their affected communities in search of solutions that promote repair, reconciliation and the rebuilding of relationships. Restorative justice seeks to build partnerships to reestablish mutual responsibility for constructive responses to wrongdoing within communities. Restorative approaches seek a balanced approach to the needs of victim, wrongdoer and community through processes that preserve the safety and dignity of all. (Center for Restorative Justice, Suffolk University 2011)

Definitions and Theories of Deviance

In general, deviance is understood to be those actions or behaviors that stand in defiance to legislated legal boundaries (e.g., crimes) and/or culturally enforced social norms and mores (expected societal traditions and customs). Leading sociological thinking has extended the meaning of deviance to include any "*thought*" *or* "*feeling*" not just actions or behaviors (Douglas and Waksler 1982); deviance as contextually based in "*a particular society at a particular time*" (Dinitz et al. 1975); and deviance as having to do with "*a disapproved direction and of sufficient degree to exceed the tolerance limit of the community*" (Clinard and Meier 2008).

By in large, the *rationalist-utilitarian* conception of deviance remains dominant in the current Western legal system. This school of thought promotes a clearly defined set of "objective" legal codes that philosophically and practically delineate between deviant and nondeviant behaviors. Although to a lesser degree than the former, the current legal system has also given ample attention to the *structural-functionalist* approach to deviation which understands deviance as a necessary function in society that need only be managed effectively in order to maintain social equilibrium. The concept of "necessary function" entails the idea that through the existence of social deviance social service institutions and professional employment is created, social identity is formed, and a comparative standard of what is acceptable and unacceptable behavior is shared and reinforced for the "common good" (socialization). *Conflict theorists*, on the other hand, see the clear definition of deviance as an instrument of modern day institutions of domination (including the prison industrial complex) which are primarily concerned with maintaining the status quo in order to solidify power and harness the means for repressive social control – especially as it relates to class struggle, labor rights, and marginalized groups in society (Foucault 1977). Finally, there is a rising postmodernist critique (in the vein of *micro- or symbolic-interactionsim*) of the current Western legal system which would question the essence of the idea of deviance to the point of obscurity claiming that the very conceptualization and language of deviance as an illegal behavior is irrelevant and incomprehensible without a particular context to interpret them in. Thus, the two critical intersecting factors of analysis that lie at the heart of the debate around deviance theory are: Issues of *agency* (does the cause and responsibility of deviant behavior lie at the individual or collective level?) and issues of structural *purpose* (does deviance serve a functional or dysfunctional purpose in society?).

One of the best examples of how theories of deviance impact actual criminal offenders is found in what is termed *labeling theory* (Becker 1963). While there are many forms of labeling theory, when it comes to the present criminal justice system one could argue that the current penal codes serve as an official, state-sanctioned labeling process – often imposed for a lifetime (criminal offender stigmatization), without consideration of the particularities of context, void of the historical and relational complexities surrounding a crime, and bound to a mind-set and a timeframe of the present. This focus on the "present" labeling of a criminal offender does not allow for a process of reinterpretation (renarrating) of the past or for the opportunity to address future intentions such as exploring the possibilities of personal and relational transformation and/or creating new opportunities for healing and reconstruction. Winslade and Monk (2000) in their work on narrative mediation refer to this process of dealing with the past and the future as "deconstructing a conflict saturated story (labeling) and reconstructing a new story." In summary, when the criminal justice system attaches a label to certain codified "deviant" activity it does so in a contextual vacuum, it opens the door for the labeled person to became a societal "scapegoat" and it denies the offender the opportunity to take responsibility, show remorse, and offer some form of redress for the wrong they have committed. In short, transformative change is denied.

Comparative Study of Three African Transitional Justice Processes

Effective transitional justice processes call forth intersectoral and multidimensional interventions; approaches that can coordinate communication and collaborative action across the vertical and horizontal planes of human organization. In this section, a brief comparative study of post-violence justice efforts in South Africa, Rwanda, and Sierra Leone will be highlighted with the intersections of the formal legal system, transitional, restorative, and indigenous justice applications, and their impact on the understandings of deviance in mind. In its broadest sense, transitional justice as a process has the overarching mandate to (re)define the meaning of, and to deal effectively with, deviant violence enacted at a mass systems-level of society.

The Truth and Reconciliation Commission (TRC) in South Africa

The South African Truth and Reconciliation Commission (TRC) represents an example of a state-sanctioned (official) structure set up to legally define and come to terms with deviance as it was expressed through the Apartheid system and the ensuing violent struggle for liberation. For this post-war reconstruction context, the criminal courts were the only other form of institutional justice that South Africans had at their disposal. While the TRC moved away from blanket amnesty (the primary experience of Latin/South America) and embraced *conditional* impunity, it fell short on a number of other critical measures. First, it was perceived to be *perpetrator-biased* as opposed to victim-centered in part because of the amount of time and attention given to the legal aspects (rights and procedural undertakings) of the amnesty applicants. For example, victim-offender interactions were seriously hampered by the legal constraint that restricted perpetrators from discussing the past outside the parameters of the amnesty hearings themselves. The perpetrator was liable in a court of law for any confessions or admissions of guilt expressed outside the amnesty hearings. Hence, in this case, the law actually stood as a barrier to accomplishing the essential outcomes of relationship-building and reconciliation, forms of deviant resolution. Second, the TRC functioned from a *top-down approach* which was successful in opening up a robust debate on reconciliation at a national level, but it failed to translate that reconciliation experience in practical application at the local community-level context. Across South Africa there was no formal interface between the TRC and other traditional, indigenous practices of justice, healing, and reconciliation, and as such many citizens are living with the ambivalence of daily encounters with past, unresolved deviance at a neighborhood level. Third, the TRC ended up making a once-off payment of money to its victims, thereby, failing to engage perpetrators and communities in creative, meaningful efforts at *compensation and reparations* that would restore dignity, build community, and bring some form of vindication to a violent, repressive past.
